Translator Version 2

Upright reason dictates that the recipients of the good, of whatever type and level of beneficence it may be, must show gratitude and blessing to the beneficent person in every way possible, commensurate with the value of the beneficence. And one who has benefited all the people of the world — for example, one who invented a new instrument for the good of the world, or a good book — it is fitting for every discerning person, out of the obligation of love of fellow beings, to at least purchase it, so that the man will profit and his heart will be encouraged thereby to invent yet more good instruments in the world. And similarly, all other wise-hearted people will likewise strive and exert themselves to invent good things and instruments needed for the repair of the world and its perfection.

And therefore, whoever says: "What do I need this new instrument for?" — he does not act well towards the world. For if not for the man who invented it, where would you be? And what would your city do? And more than this, if the man did not exert himself, what would the world do?

— R. Pinchas Eliyahu Hurwitz, *Sefer HaBris HaShalem* (1797)

A note on the work

A vast attempt to explain the whole hidden world beneath our feet. Drawing on a daring descent into the smoking crater of Vesuvius and a lifetime of reading, it describes a planet riddled with fiery channels and underground rivers, ranging across volcanoes, springs, tides, metals, minerals, fossils, poisons, subterranean creatures, and the secrets of alchemy. Famous for its dramatic engravings — above all the cross-section of an Earth burning at its core — it blends bold observation with Hermetic and biblical speculation. First published in 1665, it is the foundational synthesis of early modern earth science.

A note on the translation process

This translation was produced with the [translation-pipeline](#). See the linked repository for details on the process.

This text is the product of a highly refined automated translation process. It has undergone only cursory human review and should not be treated as an authoritative or scholarly rendering. It is offered solely as a reference and reading aid — a way to make an otherwise inaccessible work approachable — and any passage of real consequence should be checked against the original source.

Mundus Subterraneus — Front matter (binding and endleaves)

This opening consists entirely of the volume's binding and pre-textual leaves. No printed title page, dedication, privilege, or engraved plate appears yet; these pages carry only the limp-vellum cover and modern librarian's notes in pencil. The printed text begins in a later opening.

**** — Front cover (limp vellum).** ****** The outer board of the binding: a plain limp-vellum (parchment) cover with raised sewing-bands visible along the spine edge, surface staining and faint offset markings, but no printed or lettered title. No text content.

**** — Front pastedown / endleaf with library cataloguing notes (modern, in pencil).** ****** The leaf carries a modern librarian's hand in pencil. These are not part of Kircher's text; they are a 20th–21st-century cataloguer's collation and shelfmark notes. Transcribed as written:

[Margin: Shelfmark, upper left:]

Q 155 .K58 1865 JESUITANA

[Margin: Collation notes, center:]

I. Engr. title, (28), 346, [6][?] pp. Two portraits II. Engr. title, (10), 487, (9) pp.

19 engr. plates (12 fold. or double-page) 2 smaller plates (vol. II pp. 30, 384) 7 fold. tables slips with engr. volvelles (vol. I) at pp. 133, 154.

(one map at p. 71 (vol. I) a bit shaved)

[Margin: Lower edge:]

OCLC 52043805 RSR 4/1/03

These notes confirm the scan binds **both volumes together**: Tomus I (engraved title, 28 preliminary pages, 346 numbered pages, plus index leaves, with two portraits) and Tomus II (engraved title, 10 preliminary pages, 487 numbered pages, plus 9 leaves). The note "JESUITANA" indicates the copy belonged to a Jesuit collection.

**** — Free endleaf with faint pencil notes.** ****** Mostly blank laid paper. Faint modern pencil jottings at the upper corners only:

[Margin: Right, in pencil:]

4083V[?] aTzr/ex[?] w/TS[?]

No source text.

**** — Blank endleaf.**** Blank laid paper, no text or image. No content.

Diagram. Engraved allegorical title page (frontispiece title) of the work. The composition is dominated by a great radiant terrestrial globe at center, drawn as a sphere of fine engraved lines with landmasses sketched across its face, emitting rays in every direction. From a chain descending out of the clouds at the top hangs a winged emblem (an ouroboros-like serpent with outstretched wings). To the upper left a brilliant Sun blazes with long rays; to the upper right is a darkened, eclipsed orb (an eclipse of the Sun, or the Moon in shadow) also radiating lines. Banks of clouds fill the upper register, peopled by numerous putti (winged child-figures) and several venerable bearded figures (philosophers / personifications of the elements and natural forces) who gesture toward the globe. A hand emerges from the cloud at the very top, holding the chain. In the lower corners are two seated allegorical female figures: at lower left a woman in classical drapery holding an armillary or celestial globe (Astronomy / Urania); at lower right a seated woman holding a long instrument resembling a telescope or a torch, with a sword and other emblems at her feet. Across the center-bottom a large draped cartouche bears the title, and a scrolled banner at the very bottom carries the imprint.

A motto-banner unfurls across the middle register, beneath the winged emblem, in two scrolled halves:

- Left scroll: "Spiritus intus alit, totamque" [the spirit nourishes within, and the whole...]
- Right scroll: "infusa per artus Mens agitat molem" [...mind, infused through its limbs, sets the mass in motion]

(This is Virgil, *Aeneid* VI.726–727: "Spiritus intus alit, totamque infusa per artus / mens agitat molem" — "A spirit within sustains it, and a mind infused through its limbs stirs the whole mass.")

Title cartouche (center):

ATHANASII KIRCHERI E SOC. JESU **MUNDUS SUBTERRANEUS.**

[The *Mundus Subterraneus* of Athanasius Kircher, of the Society of Jesus.]

Imprint banner (bottom):

AMSTERODAMI, Typis Joannis Janssonii à Waesberge et Elizæi
Weyerstraet. 1665.

[At Amsterdam, from the press of Joannes Janssonius van Waesberge and Elizæus Weyerstraet. 1665.]

Engravers' signatures at the very foot, flanking the date:

- Lower left: "Jo. Paul. Schor delin. Romæ." [Johann Paul Schor drew (this) at Rome.]
- Lower right: "Theod. Matham sculpsit." [Theodor Matham engraved (it).]

[This confirms the edition: Amsterdam, Janssonius van Waesberge & Weyerstraet, 1665 — the first edition of *Mundus Subterraneus*.]

Diagram. Engraved portrait of the author. A bust-length oval portrait of Athanasius Kircher, shown half-turned to the viewer's right, wearing a Jesuit's biretta (clerical cap) and black cassock with a white collar. Behind him at right is a curtain drawn back to reveal a bookcase with volumes on shelves and a closed cabinet below; on a shelf rests an open book. The portrait is set within an oval frame bearing a circumferential inscription. Above the sitter's head, at the top of the oval, is the Jesuit emblem "IHS" surmounted by a cross. Below the oval is a scrolled cartouche with a verse legend and the author of the verse.

Oval-frame inscription (reading clockwise from top, around the oval):

P. ATHANASIUS KIRCHERUS FULDENSIS E SOCIETATE IESU ÆTATIS LXII
ANNO CIOICXLIV.

[Father Athanasius Kircher of Fulda, of the Society of Jesus, in the 62nd year of his age, in the year 1664.]

Cartouche verse (below the oval, in engraved italic script):

Frustrà vel Pictor, vel Vates dixerit, HIC EST: Et vultum, et nomen terra
scit Antipodum.

[In vain would either Painter or Poet have said "Here he is": for the land of the Antipodes knows both his face and his name.]

Attribution of the verse (lower right of cartouche):

Jacobus Albanus Ghibbesius, M.D. in Rom. Sapientiâ Eloq. Prof.

[Jacobus Albanus Ghibbesius (James Alban Gibbes), M.D., Professor of Eloquence in the Sapienza at Rome.]

Letterpress Title Page

ATHANASII KIRCHERI of the Society of Jesus

MUNDUS SUBTERRANEUS [*The Subterranean World*]

Arranged in XII Books;

in which

the divine workmanship of the subterranean world, the wondrous distribution of Nature's workshops [*Ergasteria*] within it — in a word, the all-shaping [Greek: *πάνταμορφον* (*pantamorphon*, "all-shaping," "of every form")] Realm of Proteus

and finally the whole Majesty and abundant riches of universal Nature are set forth in the fullest variety of things. The causes of hidden effects are demonstrated by keen investigation; and, once known through the union of Art and Nature, they are applied — by a varied apparatus of experiments, and also in a new manner and method — to the use necessary for human life.

TOMUS I. [Volume I]

To

ALEXANDER VII SUPREME PONTIFF

Diagram. An engraved allegorical vignette set within the title-page letterpress, below the dedication line to Alexander VII. At the center a female personification (Nature/Wisdom) is seated, draped, her right hand raised toward a radiance descending from the upper right; her head is encircled by a halo of stars. A short Latin motto is engraved in a band around her: "Sapientia Domina, sidere afflata sancto" [*Wisdom the Mistress, breathed upon by a holy star*] — the band-text is small and partly worn, read with some uncertainty [?]. To the upper left a radiant sun-face shines through smoke; below and around the seated figure are emblems of subterranean and natural philosophy: an alembic and furnace, glass vessels and flasks at left; a large terrestrial/sectioned globe at lower right; serpents, fish, and small creatures along the ground. In the right background, ships at sea and erupting/smoking volcanic mountains; a bare tree at far right.

- Center: seated female personification (Nature / Wisdom), haloed with stars
- Encircling band: "Sapientia Domina, sidere afflata sancto" [?] (Wisdom the Mistress, breathed upon by a holy star)
- Upper left: radiant sun-face amid smoke
- Left foreground: alembic, furnace, flasks, glass vessels
- Lower right: large sectioned globe / sphere
- Ground: serpents, fish, small creatures
- Right background: ships at sea; smoking volcanoes; bare tree

AMSTELODAMI [Amsterdam], By Joannes Janssonius & Elizeus Weyerstraten, In the year 1665 [cld lcc lxv]. *With privileges* [Cum Privilegiis].

Approbations

JOANNES PAULUS OLIVA [Gian Paolo Oliva] OF THE SOCIETY OF JESUS **VICAR GENERAL**

Since three theologians of our Society have examined the Twelve Books *On the Subterranean World* by Father Athanasius Kircher, a priest of our Society, and have approved that they may be published, we grant permission for them to be committed to print — if it shall so seem fit to those whom it concerns. In testimony of this we issue these letters, signed by our own hand and secured with our seal. Rome, 19 April 1662.

JOAN. PAULUS OLIVA.

Let it be printed, if it shall seem fit to the Most Reverend Father, Master of the Sacred Apostolic Palace. **OTTAVIANO** [Ottavianus], Bishop of Patras [Patracensis], Vicegerent.

Let it be printed, **F. RAYMUNDUS CAPISUCCUS** [Raimondo Capizucchi], Master of the Sacred Apostolic Palace.

Engraved Portrait of Pope Alexander VII

Diagram. A full-page engraved oval portrait of Pope Alexander VII (Fabio Chigi). The pope is shown half-length, facing slightly right, wearing the papal camauro (cap) and mozzetta with a buttoned cassock. The oval is framed by an inscribed border. At upper right, a putto (cherub) holds the papal tiara and crossed keys above clouds; in the right background, through an architectural opening, appears

a domed church with a smaller dome and lantern. At lower center, below the portrait, a cartouche bears the Chigi coat of arms (six mounds surmounted by a star, with an oak/tree element); two winged putti flank it holding garlands of fruit and flowers. A caduceus appears at left.

Inscriptions:

- Around the oval border (top): "IUSTITIA ET VERITATE" [*By Justice and Truth*]
- Border, upper left: "CREATUS APRILIS MDCLV." [*Created [Pope] April 1655*]
- Border, right side: "ALEXANDER VII PONTIFEX MAXIMUS" [*Alexander VII, Supreme Pontiff*]
- Lower cartouche: the Chigi armorial shield

Verse legend (engraved at the foot, in two columns of four lines):

Never did invincible Modesty clothe itself in mortal countenance, nor,
born of heaven, return to earth so [graced]; nor did kindly Wisdom more
fully unfold itself to the human mind, and offer itself to be cultivated; —
and seemly Justice, of its own accord lovely, the True: no beauty, unless
such as this, can please. While Peace, Counsel, and Right are demanded,
the World seeks in ALEXANDER the face of God.

[Reading of the verse legend is partly uncertain owing to the fine engraved script — several words read with low confidence [?]. Closing line abbreviated "PIE." [?].]

Dedicatory Epistle to Pope Alexander VII

**TO ALEXANDER VII, SUPREME PONTIFF, ATHANASIUS KIRCHER of the
Society of Jesus wishes happiness.**

MOST BLESSED FATHER,

While you, before the whole world, devote yourself to the majesty and august holiness of the City of Rome — while, with the most magnificent generosity, you both adorn and raise up from their foundations, at home and abroad, the churches of the most beneficent Mother of God and of your own Saint, Thomas of Villanova [Thomas of Villanova], that great bishop — while you inscribe the names of the pious in the new and happy register of eternity, duly bringing them to the altars with that authority which you alone on earth possess, first and supreme after God, and recording them in the sacred lists — you continue to deserve well of Rome, and best of all of the Heavenly City: that City whose

loftiness and solid wisdom we look up to in you, confirmed as it is by the laws and examples of ecclesiastical discipline. You let no single year slip away without commending it to memory by some heroic work, as though by a deed of living testimony.

I, meanwhile, am preparing a journey into the lower parts of the earth. There too I shall find some portion of your Apostolic kingdom, in that place where blessed souls, as if in exile, await your keys — the keys by which you may open to them the treasures of the Church, and supply them, as a kind of provision for the road, that they may reach their homeland the sooner. But that I may be allowed to set my foot fearlessly into the hidden recesses of that subterranean world, shut off from us and from the more secret Earth, I need your favoring star to bless the introductions I am planning. By its light I may describe those shadows clearly, lest the darkness trample me as I wander and labor in the labyrinth of the lower world — that is, as I turn a greater cask than Diogenes ever entered or turned. For since once the inner sanctuary of the temple, the hidden shrine, lay open to no one but the priest, I take you, the supreme Priest, as my guide. Under your auspices I shall enter that temple which God founded beneath this temple we inhabit, as a kind of shadowy basilica of his own marvelous nature and of his hidden works — and in it God placed the august darkness as his own hiding-place.

As I prepare to penetrate it, be present to me with your most blessed light, so that I may set these shadows of mine within the good light of your countenance. I shall search the bowels of the earth, and behold its dark gates, so that from what I glimpse within I may draw forth treasures of light. You once saw temples beneath temples in Germany, and now you see them in your Vatican. So, beneath the World a world lies hidden (as it were God's temple), and it holds no few mysteries — like the veins, as they call them, of hidden mineral ore and concealed gold. From this I must dig out the slight tribute of my talent, which I offer to that Genius and Wisdom of yours, so richly varied, as a token of the obligation by which you bind me too — since you love the least Society of Jesus as a father. And it will be the consolation of my return, when, brought back from the depths of the earth, I find again the Vatican square of Peter [Saint Peter], girded by your amphitheater; and the Chair of that same apostle, conspicuous at the head of the temple; and many other such things besides.

Deign therefore, MOST BLESSED FATHER, to look with the eye of your star upon this obscure gift; open your hand to receive the Book, and fill the Book's Author with your blessing. You who would not allow the statue decreed to you by the

Senate and People of Rome [S.P.Q.R.] — by this very act most worthy of the honors of the immortal and everlasting Capitol — admit these first shadows, or shades, of the Subterranean World; that in them the image of your most blessed Wisdom, and of your Piety useful for all things, may shine forth the more, and may make my shadows glow with the light of learning.

PRIVILEGE OF HIS IMPERIAL MAJESTY

Leopold, by the grace of divine clemency elected Emperor of the Romans, ever August, and King of Germany, Hungary, Bohemia, Dalmatia, Croatia, Slavonia, etc.; Archduke of Austria, Duke of Burgundy, Styria, Carinthia, Carniola, and Württemberg; Count of Tyrol, etc.

We acknowledge and make known to all by the present letters as follows. Our faithful and beloved Joannes Janssonius and Elizeus Weyerstraet [Janssonius van Waesberge & Weyerstraten], booksellers of Amsterdam, have most humbly represented to us that, for the public good of letters, they have committed to their press and undertaken to publish all the works of Father Athanasius Kircher of the Society of Jesus — both those already published, such as the *Ars Magnetica* [*Magnes, sive de Arte Magnetica*], the *Musurgia* [*Musurgia Universalis*], the *Ars Magna Lucis et Umbrae*, the *Obeliscus Pamphilius*, the *Oedipus Aegyptiacus*, the *Itinerarium Exstaticum Caeleste et Terrestre*, the *Scrutinium Physico-Medicum de Peste*, and other lesser pieces — and those still to be published hereafter, namely the *Mundus Subterraneus*, the *Ars Magna Sciendi* or *Ars Combinatoria*, the *Geographico-Physico-Politica Descriptio* of Etruria and Old Latium, the *China Illustrata*, the *Diatribes de Occultis Numerorum Mysteriis*, and the *Arca Noë et Turris Babel*. Fearing, however, that other printers, intent on their own profit, might by reprinting these same works in whole or in part deprive them — through fraudulent imitation and underhanded practices — of the fruit of their labors and expenses they hope for, they have humbly petitioned that we might graciously deign to provide for their indemnity in this matter by our Imperial privilege.

In keeping with our benevolent affection for assisting the cause of letters, we have been unwilling to refuse their most humble prayers. Accordingly, by the present letters we firmly forbid and prohibit each and every printer, bookseller, and any others who carry on the book trade, that none of them — within the bounds of the Holy Roman Empire and of our hereditary Kingdoms and Provinces, for the space of twenty years to be reckoned from the day of first publication — shall dare or presume to reprint the aforesaid works of Father

Athanasius Kircher, in whole or in part, by a similar or any other type or form or with the titles of the books altered; or to give them to another to reprint; or to bring in, sell, or distribute openly or secretly elsewhere any copy printed against the will of the said Father Kircher, the author, and of the aforesaid booksellers Janssonius and Weyerstraet and their heirs.

Should anyone, acting otherwise, attempt to scorn, violate, or transgress this our prohibition, we decree that he is irremissibly to be punished: not only by the forfeiture of such books — wrongfully reprinted and imported (which indeed the aforesaid booksellers, or with the aid of the local magistrate, may claim for themselves) — but also by a fine of ten marks of pure gold, to be paid in equal portions to our Imperial Treasury and to the use of the party or parties injured. This provided, however, that the said books contain nothing contrary to good morals or to the Constitutions of the Empire, and that they display the text of this our Imperial privilege printed at the front for public notice, and that the said booksellers transmit at least four copies, at their own expense and as soon as possible, to our Imperial Aulic Chancery.

We therefore command each and every one of our subjects and those of the Holy Roman Empire and of our hereditary Kingdoms and Provinces, of whatever station, rank, order, condition, or dignity they may be — ecclesiastical as well as secular, but especially those constituted in a magistracy, whether in their own name or in the name and place of their superiors administering law and justice — that they suffer no one rashly and with impunity to transgress or violate this our Imperial privilege; but rather that they take care to have any defiant persons whom they discover punished with the prescribed penalty and constrained by other suitable means, insofar as they themselves likewise wish to avoid the same fine. In testimony of these letters, which we issued furnished with the subscription of our hand and the impression of our Imperial seal, given in our Royal Castle of Pressburg [Pozsony / Bratislava], on the twenty-eighth day of the month of July, in the year of the Lord one thousand six hundred sixty-two, of our reigns the fifth of the Roman, the eighth of the Hungarian, and the sixth of the Bohemian.

LEOPOLD.

Wildericus, Baron of Walderdorff.

[Place of the seal.]

By the proper command of His Sacred Imperial Majesty,

J. Walderode.

PRIVILEGE OF CHARLES II

Charles II [Charles II of England], by the grace of God King of Great Britain, France, and Ireland, Defender of the Faith, etc. To all and singular who shall inspect these present Letters, greeting. Whereas Joannes Janssonius and Elizeus Weyerstraet, printers and booksellers of Amsterdam, have committed to their press and undertaken to publish a certain work of Athanasius Kircher entitled *Mundus Subterraneus*; and lest such an undertaking — which will be established at no small expense — should turn to their loss and detriment, were others permitted to print or imitate the same Book against their will: they have therefore most humbly petitioned that we might by our Royal privilege provide for their industry, by restraining at least our own subjects from the injurious appropriation of another's labor.

We indeed, in keeping with the affection with which we desire to embrace and promote Letters and the cause of Learning, have deigned to grant their just prayers. Accordingly, we forbid, and will that it be provided, that none of our subjects shall dare to print the aforesaid work of Kircher within our Kingdoms or Dominions, in a similar or other form, in whole or in part, for the term of the next ensuing decade, or to sell it printed elsewhere, without the knowledge and against the will of the aforesaid Joannes Janssonius and Elizeus Weyerstraet or their heirs. Whoever does otherwise shall not otherwise bear with impunity the contempt of our royal authority, but shall be fined with the confiscation of the books printed or imported contrary to the tenor of these presents — the same to be awarded to Janssonius and Weyerstraet or their heirs or agents toward the making good of the loss. Given at our Palace of Westminster on the fifteenth day of the month of August, in the year of the Lord 1664, and of our reign the sixteenth.

By command of His Sacred Royal Majesty,

Guil. Morice [William Morice].

[Privilege — Dutch]

Extract from the Privilege.

The States of Holland and West-Friesland have consented and granted to Joannes Janssonius and Elizee Weyerstraet, booksellers at Amsterdam, that for the term of fifteen successive years next to come, they alone in this country may print, have

printed, and publish all the works of Athanasius Kircher, whether in Latin, French, High German, or Low Dutch; forbidding all inhabitants of these countries to reprint, have reprinted, publish, or sell the aforesaid works in whole or in part, or to bring them, reprinted elsewhere, into the said countries, on penalty of [forfeiture of] the reprinted copies and of such a sum of money as appears from the Letters of Grant issued thereupon.

Done in the Assembly of the High and Mighty Lords the States of Holland, at The Hague, the 19th of January 1665.

Signed, Johan de Witt.

By Ordinance of the High and Mighty Lords the States of Holland.

Herbert van Beaumont.

PREFACE TO THE *MUNDUS SUBTERRANEUS*

Caput I.

On the occasion of this work, and on the author's travels.

The World plays as an organ vocal with its tenfold stops: as many measures sound in it as there are things that are. GOD is the harmost [master of harmony], in whom the Wisdom of the Father — which has ordered all things well — and Love, the πνεῦμα [Greek: pneuma, "breath" or "spirit"], make one. This love is harmony; by this love the World is bound together. Will you deny that this World is the ὄργανον [Greek: organon, "instrument" or "organ"] of the Divine?

So it is, kind Reader. This organ may, with the best right, be called the theme of this work, which we have entitled by the name of the Subterranean World. It is truly a harmonic organ, arranged and fitted by the workmanship of the most provident Triune Godhead in number, weight, and measure. For although it keeps the instruments of its operation hidden away in the innermost recesses and secret retreats of the Earth, yet through the dense subterranean tubes and pipes of an immense multitude it pours forth such modulations of sound, such a variety of the most diverse voices, that nothing within the compass of the sublunary World presents itself which is not steeped in a kind of sympathetic harmony — in its own number, its own weight, and at last its own measure. In twelve Books, then, as though furnished with so many stops, we comprehend this organ; and by them the whole Majesty and riches of Nature, with the greatest variety of things, are set forth.

In undertaking to expound this, I may well seem to commit a bold, indeed presumptuous deed, perhaps beyond a chest even of Hercules. For I am traveling in a far loftier chariot than that in which the mythologists tell of Proserpina once carried off by Pluto, into the hidden and unknown realms of the subterranean World, into the innermost sanctuaries and secret recesses of the Geocosmic Monarchy — by a road which, so far as I know, until now has been (I will not say attempted and trodden by [no one's] footsteps, but) not even penetrated by the conception of a human mind. To set out upon it less advisedly, I attempt. Yet I do not delay: I dare — I dare, I say, to enter upon and undertake the journey, undertaken not so much by my own will as persuaded by some impulse of the Divine Power I know not what, and extorted moreover by the prayers of illustrious men.

I know that, in the course of this enlightened age, there has been no lack of men distinguished by their cultivation of geographical study, who with truly outstanding effort — and with no less praise and the immortality of their name — have toiled tirelessly and at the greatest expense to set forth the external face of the Geocosm. Yet of those who might supply the one thing that seemed to be lacking — who might reach the internal Economy of the Earth and the hidden mysteries of latent Nature (I will not say penetrate them, but even attain them in thought) — no one has been found. Hence it came about that I turned the eyes of my mind, as much as ever I could, to the admirable Organ of the Earth's interior and to its structure — neglected until now, whether on account of the inaccessible hiding-places of Nature, or generally despised because of the insuperable difficulties in penetrating it. I had long since conceived this theme to be as rare, unusual, and excellent as it was most worthy of every effort of human genius to toil over.

Much, I confess, I had read in most writers of Natural History concerning the hidden marvels of subterranean Nature; yet I believed these things had been recorded not so much rightly and sincerely explored — for want of the writers' own experiment — as by a simple report to which little trust could be given. I sought the αὐτοψίαν [Greek: autopsian, "eyewitness observation," seeing for oneself] of each thing; I demanded this one thing as, so to speak, utterly necessary for carrying out the project I had conceived. Tossed about by this vast surge of cogitations, it happened that at that very time, by command of my superiors, I undertook a journey to Sicily and Malta in the retinue of His Excellency the Prince Friedrich, Landgrave of Hesse [Friedrich of Hesse-Darmstadt] — now a most worthy Cardinal — whose confessor I was. I interpreted this occasion as

supplied to me, as it were, by the providence of the Divine Power, and as wonderfully opportune for at last carrying my undertakings into execution. Nor did my hope deceive me.

Having entered Sicily, I attained precisely that theater I had so long wished for with all my prayers — Nature explaining herself amid a wondrous variety of things. For whatever occurs in the whole Geocosm that is marvelous, rare, unusual, and worthy of admiration, I found gathered together here as in a kind of epitome of sagacious Nature's industry. And so, kindled with an immense desire to explore each thing, on a notable [galley] of the Maltese [i.e. *Melitensium* — of the Maltese galleys]

of those living there. With the Landgrave of Hesse, then Admiral of the fleet [Architalassus], ardently encouraging my undertaking out of the affection he bore toward me and my studies, I pursued my plan. Before all else, I climbed **Etna** [Ætna] — the thing I had most longed for — the source of all the prodigious effects that display themselves throughout Sicily, so that I might verify by my own experiment and αὐτοψία [Greek: αὐτοψία (autopsia), "eyewitness observation"] the marvels that historians of every age had written about it. Next I explored the **Aeolian** or **Hephaestian Islands** [Æoliae sive Hephaestiae Insulae, the Lipari Islands], and above all **Strongyle** [Strongylus, Stromboli] and the island they call **Vulcano** [Vulcanus]. I also explored — over a three-day investigation, with the utmost diligence — the **Mamertine Strait** [Fretum Mamertinum, the Strait of Messina], no less dangerous for its incredible reciprocations of tides than infamous for its shipwrecks. Moreover, at the famous Scylla and Charybdis, I examined the strange motions, the alternating cycles of boiling, and the causes of each individual symptom — wholly consonant, as it were, with my undertaking — with a great ferment of mind, perhaps no less violent than the surging of Scylla itself. Whatever astonishing things came up in each case, I committed to my notebook [palimpsesto], and once home again, I weighed them, measured against the exact balance of reason. The reader will find these described most fully, in the appropriate places, in the course of this work, as confirmation of the task I have undertaken.

When all these things had been duly observed, it pleased the Divine Goodness to open to me another theater — a fearful one, utterly filled with calamitous and tragic events — for no other purpose, so far as I can tell, than that, having seen the ineffable power of an angry Deity at work in Nature, I might enlarge my argument with an abundant harvest, not merely with the kind of things that would soothe the itch of an over-curious mind, but with things that would

implant the fear of GOD and the hidden abysses of His judgments in the innermost marrow of the heart. For while, having completed my observations by land and sea and being about to return to Rome, I was waiting for a suitable occasion to set out on my journey, I do not in fact know by what providence it came about that, detained at Messina against my own will for so long a time, and amid so many and so manifold opportunities to depart, I nonetheless — stripped of every opportunity — always held back. And just as we cannot sufficiently marvel at the hidden paths of Divine providence, by which He leads improvident mortals with more than fatherly care and solicitude, so too we are by no means permitted to investigate them, since they lie utterly beyond the limits of human understanding. Yet the light of truth first dawns upon us at that moment when, rescued from various

turns of events and from various perils of circumstance, we turn the inner eyes of our mind toward His immense goodness and mercy, by which alone we are sustained. This was made plainly evident by the delay I have mentioned in the port of Messina. It clearly appeared that GOD, the Best and Greatest [Deum Opt. Max.], had willed me to be not only an eyewitness of the evils that were soon to follow and were already all but imminent, but also — for the glory of His own name and as a trial of my faith — in some measure a sharer in them, so that those calamities, the like of which no past age has read to have befallen either Asia (when its twelve principal cities once collapsed) or Italy, I might not only relate in my writings but also, from my own experience, testify to — concerning the perils and the agonies of imminent death of those who find themselves in a like condition. For within a brief span of time nearly the whole portion of Hither Calabria [citerior Calabria] was reduced to desolation. And so this is how the matter stood.

CAPUT II.

On the dreadful earthquakes that arose in the year 1638 in Calabria, in the presence of which — over a span of fourteen days, and at great peril to his own life — the Author was present, and on whose occasion he learned great secrets of Nature.

In the year 1638, then, together with two religious of the Third Order of St. Francis [tertii Ordinis S. Francisci] and two other laymen, having hired a small boat, we set sail from Messina on the 24th day of March. That very day we reached the promontory of Pelorus in Sicily [Pelorum Siciliae promontorium], where, holding out for three days, we struggled with every kind of misfortune — so much so that all the assaults of the place and of the air seemed to have conspired against us. All these things were, as it were, the foreshadowing scenes

[proscenia] of the tragedy to come. Once and again we attempted to depart, but in vain; always driven back to the same place, partly by an unwilling sea and partly by the hidden hand of GOD (as later became clear) holding us back, we turned back. Had this not happened, all of us would have remained buried at S. Euphemia [Santa Eufemia], where we were hastening and where we had thought to stop a little while on business. From this wondrous disposition of Divine providence we learned how often a man does not know what he asks for, and how vain and fleeting are men's plans unless they are submitted to and sustained by the Divine will. And so, at daybreak on Palm Sunday, which was the 27th of March, weary of the long delay, we

set out on what was almost a forced departure. That very day the sea was surging beyond its custom, and it was driving huge whirlpools in a spiraling downward plunge, chiefly around the place of Scylla, so infamous for its many shipwrecks — so that the unusual sight struck terror not only into us but into most of the sailors as well. Since the sea's swell was thus against us, we steered our skiff [phaselum] toward Tyndaris or Mylae [the Tindari / Milazzo coast], so that from there, with the Euronotus [the south-southeast wind] driving us on, we might be carried by a shorter and straighter passage across the **Gulf of Cuja** [Sinus Cujacius] to the shores of Calabria. But when we reached that point of the sea which lies almost midway between Lipari, Mylae, and the **Vatican Promontory** [Promontorium Vaticanum, Capo Vaticano], I, gazing more attentively at Etna and Strongyle, noticed that they were belching forth, beyond their custom, those huge globes of smoke, like mountains. As these spread far and wide, the view not only of the Lipari Islands but of Sicily as well was entirely taken from our eyes. The horror was heightened by certain subterranean bellowings, as it were, which we perceived, and by crashes accompanied by a sulphurous odor — which, whispering I know not what fateful and deadly thing, seemed to have conspired by unanimous agreement toward the destruction of all Calabria and Sicily that they were preparing.

Terrified by these forerunners of impending calamities, I kept urging the sailors by every means and entreaty I could, that they should leave the Liparitan shore and make straight for the Vatican Promontory — adding that we were in great danger of being swept away by the sea's swell and of setting out on a journey from which there was no return. For though we were close to Strongyle, we nonetheless could not see it, veiled as it was in smoke; we only sensed the crashes, together with the heavy sulphurous stench it exhaled. Moreover, we all marveled that the sea itself was boiling and churning in the manner of boiling water, especially since the sky was silent and clear with serenity, and that it was

undergoing other unusual alterations of this kind. Anyone who has ever seen a lake in time of rain, seething with countless little bubbles, will be able to form a judgment from this of the boiling sea's fervor at that very moment. Furthermore, when we had now drawn near to the Vatican headland, and these same symptoms of the sea still persisting, I — as if sensing the calamities to come, out of an unaccustomed anguish of mind that gripped my spirit — openly foretold to my companions that a great earthquake would soon follow. Indeed I greatly feared that this whole tract of overhanging crags might be cast down and collapse, and therefore that we should not approach it too closely. The outcome proved my foreboding right: for after about two hours we heard that a great part of this Promontory, together with the neighboring

dwellings, had collapsed. Meanwhile, continuing our journey, we all came safe to **Tropea** [Tropaea], at last, and with the greatest joy — unaware of the perils we had just barely escaped a little earlier in the seething sea; only now, for the first time, were we beginning to be harried, and even though we were close to death we could not so much as suspect it, since the sky was clear and without the slightest cloud. But truly, scarcely had I crossed the threshold of our College when, behold, there came a subterranean sound and din — fearful, like that of chariots driven at top speed — and an earthquake so violent and horrible followed it that the College, together with the town and the mountain beneath it, seemed to be balanced as on a scale. The earth heaved with so violent a motion that I, no longer able to keep my feet, was suddenly dashed to the ground and thrown down on my face — running into the very thing I had earlier foreseen in my mind. Ceaselessly, with my life now given up for lost, I commended my soul to GOD. Oh, how in this point of anguish all the joys of the World grew worthless! How, in one blink of an eye, all honor, dignity, power, wisdom seemed to be nothing but smoke, a bubble, a stalk snatched away by the wind! — while, standing in the gateway of eternity, I was preparing to send forth my soul, freed from the bonds of the body, to take up the enjoyment of incorruptible life. And this would surely have happened that very moment, had it not seemed good to GOD, the Best and Greatest, to preserve me by His singular grace from the ruin of the walls, and to destine me to endure harder things for the honor and glory of His Name.

In this struggle of mind, both the crashes of the falling roof-tiles and the cracking of the splitting walls struck me with enormous dread, while I could not make out where to flee or on what side I might save myself, with ruin on every side now threatening me from the walls. Yet, having regained my courage, I escaped — though so dazed that, when I had come back to myself, I found myself without hat

or cloak. Once these had been recovered, I fled the town without delay and betook myself to our boat. Both our Fathers and all who accompanied me labored under this same consternation of mind, while each one, anxious for his own safety, busied himself as best he could in providing for the flight of his own life [vitae fuga] — like men struck dumb and deprived of all use of voice. On the following day, which was Palm Sunday, we continued our journey, and with the sea seething and swollen in a marvelous way we reached **Rochetta** [Rochetta]. But once we had disembarked, the earth's fever flared up again and shook it with so great a paroxysm that the boat, on account of the great danger which

the unbearable fury of the earth threatened us once more. Nearby stood a house suitable for receiving traveling guests, and we withdrew into it to gather a little rest. But as the earth's tremor flared up again, I—sensing the vast ruin that hung over us—declared openly: whoever wishes to secure his life, let him make for the shore with me. Moved by these words, my companions left the house at once and followed me. We had been allowed to linger on the shore scarcely half an hour when, behold, the earth raged again with even greater ferocity than usual. With a violent shock it struck many of the surrounding places, including the very lodging we had abandoned a moment before, and threw it down, leaving behind nothing but a heap of stones and lime. We therefore gave the greatest thanks we could to the Divine Majesty, who had snatched us from so imminent a danger through hidden promptings.

While we were searching for a place where we might keep ourselves safe and secure from the earth's great rage, we pressed on farther and reached Lopizium, the fortress that lies midway between Tropea and Saint Euphemia. There, while we waited for favorable winds with which we might cross the gulf, an indescribable terror was struck into us: on one side the sea boiled up in whirlpools, on the other lay an enormous wreckage of castles and villages, and we did not know which way to turn. While we were tossed about by these calamities, I, looking rather curiously at Strongylus [Stromboli], some sixty miles distant, noticed it raging in an unusual way: it appeared wholly filled with fires, in such abundance that it seemed to belch up whole mountains of flame—a spectacle dreadful to see, and one to be feared by even the most fearless spirit. Meanwhile a certain sound, like thunder, was heard—somewhat duller on account of the remote distance from which it arose—yet it took on an ever greater and greater increase within the subterranean passages, until it reached the underground spot on which we stood. There it shook the earth with such a roar and indignation that, unable to keep our feet any longer, each of us was

forced to grab whatever shrub or seaside bush was at hand and hold himself up, lest his limbs be wrenched apart by the excessive shaking.

In this same hour there occurred something worthy of eternal and immortal memory: the overthrow, namely, of the most famous town called Saint Euphemia. It was situated on the farthest shore of the gulf, under the jurisdiction of the Knights of Malta [the Knights of Malta]. And so, when at Lopizium we had been laid out flat upon the ground by the violent heaving of the earth, like men lifeless,

and finally, as Nature's paroxysm subsided, we cast our eyes upon the surrounding places and saw that the town just mentioned was enveloped in a huge cloud. This indeed seemed strange and unusual to us, especially since it was three hours past noon and the sky was clear. But as the cloud gradually dispersed, we looked for the town and did not find it—marvelous to tell—a most foul lake having sprung up in its place. We searched for men who might tell us something certain about the unheard-of event, but we found no one to report this dreadful disaster and so great a destruction. The sailors, as if thunderstruck at this spectacle and seized with incredible terror, threw down their oars, beat their breasts, and implored the Divine Mercy, expecting that any day they would meet either the same fate or the day of the Last Judgment. At last, comforted and cleansed by the sacrament of penance, with God as their guide they held their course amid the swelling waves of the sea to the opposite shore. There, having disembarked, we again searched for people, but apart from a boy sitting on the shore as though struck dumb with stupor, no one was found. When we asked him what had befallen Saint Euphemia, we extracted nothing from him, for he spoke not a word; so violent was his fear, and the event so frightful, that it had stunned both his tongue and his mind, so that we could not win over his spirit either with words full of compassion or with any act of charity. Overwhelmed by excessive grief and sorrow, he turned away entirely from all the food we offered him, and only by stretching out his fingers did he seem to point to the catastrophe of Saint Euphemia. Devoid therefore of all consolation, with a downcast face and like a man who had lost his mind, he withdrew from us and rushed off into the nearest wood, never to be seen again.

Continuing on our journey, we passed through Nicastrum [Nicastrol], Amantea, Paula [Paola], and Belvederium [Belvedere], and for two hundred miles we found nothing but the corpses of cities and the horrendous wreckage of castles, with people wandering scattered through the open fields and as if withered with fear—you would have said that the day of the Last Judgment was already, even now, at hand. Having seen these things to our great astonishment and grief, at last—

amid the enormous dangers of the seething sea, and by a truly unhappy voyage—we reached Naples [Neapolis]. What then happened to me, I shall set forth for the reader in a few words in what follows.

PRAEFATIO

CAPUT III.

On the exploration of Mount Vesuvius and of the other islands, made by the author.

After such great perils endured by sea and land, and after I had explored the incredible power of Nature working in her subterranean passages, a great desire came over my mind to learn whether Vesuvius too shared some commerce of hidden dealing with Strongylus [Stromboli] and Etna in so mighty a war of Nature. I went to Portici [Porticum], a town situated at the foot of the mountain. From there, with a faithful peasant guide who knew the roads—hired, to be sure, at a generous wage—I climbed the mountain in the middle of the night by difficult, rugged, and steep paths. When I had at last reached its crater, I saw—horrible to tell—the whole of it lit up with fire, together with an unbearable stench of burning sulphur and bitumen. Utterly astonished at this unaccustomed sight, I believed I was gazing upon the dwelling-place of the underworld, in which nothing seemed to be lacking except the horrible apparitions of demons. Dreadful bellowings and rumblings of the mountain were heard, an inexplicable stench, smoke mixed with darkish globes of fire, which both the floor and the sides of the mountain belched up continuously from eleven different places. Again and again they compelled me to utter that cry: *O the depth of the riches of the wisdom and the knowledge of God! How incomprehensible are thy ways!* If you display your power against the malice of the transgressing human race through such fearful portents of Nature, what will it be on that last day, when the earth, submerged in the wrath of your fury, the elements shall be dissolved with heat?

And so, as dawn was breaking, in order to explore the constitution of the whole interior of the mountain with all the diligence I could, I chose a safe spot, secure for planting my footsteps firmly: it was a huge rock with a flat surface, to which there was some access down the slope of the mountain. I let myself down there, and, taking out my pantometer [Pantometro], I began the measurement of the mountain. By geometric reasoning I found the circuit of the crater to contain nearly three hundred paces, and its depth eight hundred paces. The mountain was sheer on every side; with no incline given by which access to the interior

might lie open, it descended in its circuit in the form of a hollowed cylinder, πρὸς τὰς ὀρθάς [Greek: *prós tās orthás*, "at right angles"]. And although the floor seemed to our eyes to be enclosed within a narrower perimeter,

this nevertheless, according to the principles and laws of optics, came about only from the very great distance and depth measured from the innermost surface of the crater. At the center of the floor Nature seemed to have set up, as it were, her own hearth—truly the workshop of the Vulcanian kitchen, kept blazing by an everlasting outpouring of smoke and flames, busy with the boiling down of sulphur, bitumen, and the other kinds of minerals, with the melting and burning of them, and—by some hidden contrivance—soon to bring forth deadly destructions. For the vapors shut up within, since they cannot bear to be confined, with such force and violence, joined to dreadful crashes, shook off the burden imposed upon them, so that the mountain seemed to be agitated by an earthquake. Whenever this happened, the softer upper parts of the mountain—which were compacted out of ash, rain, and the other refuse of minerals—were shaken loose by the tremor and, collapsing like hills into the bottom of the abyss, set off, by the varied reflection of sound, such a crash as scarcely any man, however undaunted of heart, could endure.

The matter that was belched up continuously from the center of the mountain formed, as it were, a new mountain, endowed with a marvelous variety of striations. The varied bubbling-up of the liquefied minerals shaped these, by its flow into all the parts of the circumference, with Nature's ingenious brush, in colors now green from copper, now tawny from sulphur, arsenic, and sandarach [realgar], now red from cinnabar and minium [red lead], now black from vitriol mixed with water, or ashen-gray from the very ashes themselves. But the reader may consider all this in the figure provided. This little hill had grown so much after the last eruption of the mountain, which occurred in the year 1631, that one might conjecture from it that it would someday rise again to the same height it once held—unless it should be destroyed by another eruption supervening; which in fact happened in this very year in which I write this, 1660. For the mountain, raging with a new and dreadful eruption, so scattered the summit and crater of the mountain that today it appears much lower than as I described it a little while ago, and consequently it is found to be of greater circumference but of lesser depth.

When all these things had been duly examined, I returned to Naples. On the following day I betook myself to the island of Aenaria, which they also call Ischia, most famous in the renown of the ancient writers, and from there to the

Phlegraean fields of the Puteolan plain [the Campi Flegrei, near Pozzuoli] and the Forum of Vulcan [the Solfatara]. Whatever marvels both the ancients and the moderns have reported about those places,

I have found these accounts to be utterly reliable, but I will not waste space rehearsing them here; the reader will find each of them inserted at its proper place in the course of this work.

Once I had observed all the prodigies of Nature's works recounted above, together with the subterranean effects I have described, I began to turn over continually in my mind what force in the subterranean economy could be the author of such great and powerful things. And not infrequently, in my own heart, I would smile quietly at the opinion of those misled by a false persuasion — those who too simply suppose that the mass of the Geocosm was fashioned by God the World-shaper [Geoplasta] out of the slime of the Earth by a chance or random heaping-up of mud, rather than formed and compacted according to a fixed plan. They imagine it stripped of every interior arrangement of chambers, devoid of every use of Nature's storehouses, lacking every channel of its aqueducts — that it merely settled after the Flood, condensed out of slime and mud like some curdling of cheese, consolidated into a kind of useless, dead weight of the Earth, like an ἐτώσιον ἄχθος [Greek: etōsion achthos, "a useless burden" — a Homeric phrase], an idle mass. By I-know-not-what stubbornness of mind they wrongly persuade themselves of this.

But to those who recognize both the Majesty of the divine works and the providence in the sublime ends established by Nature — these will indeed admit that the inner fabric of the Geocosm has a constitution far different from the common conception of men. For in it the eternal Wisdom of GOD, when it laid the foundations of the globe of the Earth, sported with an ineffable ingenuity: working it out with that marvelous art, arranging it duly according to the architectonic measuring-line [amussis], and disposing the elements into innumerable receptacles for all the necessary uses of the whole of Nature. God labored to establish this fabric with no less care than that of the human body — distinguished by the workshops of so many vital members, equipped with the channels of so many veins, nerves, fibers, and muscles, and bored through with so many hidden siphons of its passages.

For this reason, spurred on by the usual ardor of a striving mind, I left no stone unturned, so that as far as possible I might penetrate more deeply into the constitution [syntaxis] of the things lying hidden in the subterranean realm of Vulcan — a thing so abstruse. Not at all content with what I had so far observed

myself, I drew out whatever bore upon the form of the terrestrial globe and the nature and properties of particular regions from the records of geographical reports. I gathered the ancient and modern Authors of Europe, Asia, Africa, and America — Historians, Natural Philosophers, Geographers — and the

undertaken endeavors of their oceanic expeditions around the whole globe of the Earth; and with equal care I weighed intimately whatever prodigies of nature had been discovered in finding new Regions and unknown seas. To these was added a most rich resource of reports made by our Fathers, arriving here at Rome from the Indies every three years: whatever things worthy of admiration they had seen and explored by land and sea, they set down in writing and, with a truly generous spirit, communicated to me, who was eager for such things. From contemplating these matters, it can scarcely be told how great an admiration seized my mind at the marvels — both those tested at my own peril and those received from others by reports not unworthy of my own — and how ardent a desire to inquire into their causes followed upon that admiration.

And so, when I had brought the particulars one by one to the anvil with the help of the Combinatorial Art [*combinatoria Ars*], and as I continually rose higher by the ferment of a studious mind, I at last undertook a subject perhaps until now untried — that is, the fabric of the Subterranean World. Having conceived it duly, so far as the weakness of my talent permitted, long since promised to the Republic of Letters and hindered by the manifold obstacle of delays, I have at last brought it forth into public light, to the glory of the Divine Majesty and the benefit of the common good.

In exploring all these things, my one purpose set before me has been the Glory of God: namely, that all things should be led back there, to GOD the Best and Greatest, whence, as from the origin of all good things, all things have flowed — to Him who is forever praised, blessed beyond measure, and loved for everlasting eternities by the affection of all possible Creatures. Farewell, Reader, and look kindly upon what I have begun.

PRAEFATIO SECUNDA

In which mention is made of those who, by their distinguished contribution of various observations, lent their labor to this Work.

When, at the prayers of many, I had taken up the care of this Work, and stood in need of resources for establishing — by legitimate authority — so many and such prodigious offspring of Nature (which present themselves to be seen, I will not say in the farthest shores of the Indies only, but in every single Province of Europe), I judged that I would be doing something worthwhile if I dispatched letters to the chief Provinces of Europe, and above all to the most expert men of our Society [the Jesuits]. In these letters, having explained the design of the Work I had undertaken, I asked that, if anything lay hidden in their regions — in waters, mountains, caves, rivers, mines, herbs, or animals — that was unknown elsewhere, or worthy of admiration for some exotic property of Nature, they would not find it burdensome to transmit it to me in writing, whether report or fact. And indeed, once the plan of the Work I was attempting had been perceived, each of them did not disdain to lend a helping hand, as it were as midwives to the birth, with all the care and diligence they could. So I too might not unjustly seem ungrateful if I were to pass over in silence the labor they bestowed for the benefit of the common good. For this reason it has pleased me to set down their names, here in the very forecourt of this first volume, to consecrate them to immortality.

FERDINAND III [Ferdinand III, Holy Roman Emperor], of glorious memory, ever-august Emperor of the Romans, who — by his wisdom and by that breadth of universal learning by which he shone before the World — was the first promoter of this Work, and did not cease to encourage me, however unworthy, toward the execution of the undertaken Work, both by his letters and by his monetary support. Following him, the imitator of a talent not unlike his own and of his father's virtues, and his successor in the Empire, **LEOPOLD I** [Leopold I, Holy Roman Emperor], Augustus — a wise Son — took up anew the web of the work left unfinished by the death of his most glorious Parent, and at last by his command and continued support brought it to completion, with the most serene Archduke **Leopold Wilhelm** [Leopold Wilhelm of Austria] acting as intermediary, who, out of his singular affection toward me and my

pursuits, devoted himself uniquely to this — that nothing should be lacking of those things that were necessary, both for the publication of my Works and,

above all, for preparing the Work of the *Subterranean World* for the press. To these, deservedly as the first and most munificent Patrons of my studies, if anything worthy of praise has come from me over the course of twenty years for the good of the Republic of Letters, I would wish a grateful posterity to credit it to their account.

To these was added His Eminence **Francis George** [Johann Philipp von Schönborn? — *recte* the text reads "Franciscus Georgius"], Elector of the Holy Roman Empire and Archbishop of Mainz; as well as **Charles Louis** [Karl Ludwig], the most serene Elector Palatine of the Holy Roman Empire, who did not cease to press forward the design of the work once begun with truly abundant resources. Following their example, the most serene and august Duke of Brunswick and Lüneburg, as well as the Primate of Hungary, **Ferenc Lippay** [Ferenc Lippay], Archbishop of Esztergom; then the most excellent **Bernard, Count of Martinitz** [Bernard Ignác Martinic], of the Holy Roman Empire, most deserving Burgrave and Viceroy of the Kingdom of Bohemia for the time being, together with his Brother **Maximilian**, who holds the second rank of dignity in the same Kingdom — with signal generosity they promoted and furthered this work at every season. When the most serene Archduke **Ferdinand Charles** [Ferdinand Charles of Austria, of Tyrol] had heard of these efforts of mine, he ordered that whatever was most intimate in Tyrol be collected and transmitted by his councilor.

Following these came the Fathers **Andreas Schaffer** and **Johannes Eiffert** of our Society. These transmitted whatever curious, rare, and unusual thing could be desired in the mineral mines of Hungary, sought out everywhere with incredible care and diligence in support of the work, and confirmed by the authentic attestation of the Prefects of the mines. By their labor not only this present Work, but also my Museum — enriched with the most diverse species of all minerals — will be able, together with the *Subterranean World*, deservedly to boast (as will appear in its proper place) as if of a most rich treasury. What support the Fathers N. N. — who came here to Rome from the Indies on business — contributed toward the perfection of the work, namely Father **Martin Martini** [Martino Martini], Father **Francis d'Orville** [François d'Orville], Father **Hyacinth de Magistris** [Giacinto de Magistris], Father **Philippe Marini** [Philippe Marini], and several others — Frenchmen, Spaniards, Portuguese — will be made manifest in the course of this work, where I shall bring forward the names of each. To all of these, as is fitting, we give the greatest and undying thanks.

But for myself — since I am so constituted by nature that, in the things handed down by Authors concerning the powers and prodigies of natural things,

[I am] so constituted that I do not readily give credence to the things handed down, unless either reports communicated to me by men of the highest trustworthiness, on indubitable testimony, or my own experience and the sensory inspection of the things themselves, render them entirely certain. To attain this certainty, it can scarcely be told how much time has had to be expended now over many years, how much expense incurred, and finally how many labors endured — while various journeys had to be undertaken to examine with my own eyes the prodigious works of nature themselves, while the hidden recesses of the mines had to be penetrated, the deep lurking-places of the subterranean bowels [of the earth] explored, the volcanic workshops [ergasteria] of Nature approached, and the quarries of stones and rocks examined. So nothing that seemed in any way conducive to the solidity of the work was left undone — lest there happen to me the same thing that happens to those authors who write about the differences of stones, gems, metals, and the other fossils, and about the most diverse species of plants — things not even known to them by name — and write, not to say describe, with futile and ill-considered labor.

I therefore took as my masters the men most expert in the said matters: the chemists themselves, I mean, the goldsmiths, the gem-cutters [gemmarii], and indeed the miners [fossores]; and those whom I could not have present with me, I undertook to consult by letter about the difficulties that arose. Made more learned and more refined by their instruction, I found by experience that I could philosophize about the hidden marvels of things on a somewhat more solid foundation. And so I would have you persuade yourself, reader, that nothing concerning hidden causes occurs in this work that has not been confirmed by experiments performed by me. For — moved by I know not what instinct — I firmly persuaded myself that I could then be said to have attained the innermost causes of natural things if, by art, I could produce in those matters the very prototype, true to life, of what nature does by the faculty implanted in her — in those things, that is, in which Nature suffers herself to be imitated. In this, unless my own φιλαυτία [Greek: philautia, "self-love"] deceives me, I have at least accomplished it according to my own small measure: so that, if I have not overcome the rock [scopulus] of the difficulties that arose by penetrating to its core, I may at least seem to others to have opened access to the proximate causes of things by paths now leveled and made smooth.

Perhaps there will be some other man, blessed with a happier portion of talent, who by the guidance of this Ariadnean thread [Ariadnei fili] will in due time open up the deeper sanctuaries of truth. As for me, what I could and ought to do

according to the weakness of my talent — in keeping with the talent entrusted to me by the Father of lights — I have accomplished.

And let no one persuade himself that I have written this with any end other than that single one which is the glory of God, who is wonderful in his works. But if from this work anything of praise, or of unfavorable censure, should arise against me, I am unconcerned; since I seek no other reward for my labors than Him who is "a reward exceeding great" [merces magna nimis] and the hope of all the ends of the earth. Farewell.

INDEX ARGUMENTORUM

of the contents of this work [in hoc Opere contentorum]

PRAEFATIO [Preface]

- **Caput I.** On the occasion of this work, and the author's travels.
- **II.** On the dreadful earthquakes that arose in Calabria in the year 1638, during which the author, present at the peril of his life for the space of fourteen days, learned, by their occasion, great secrets of Nature.
- **III.** On the exploration of Mount Vesuvius and of the remaining islands, made by the author.

LIBER PRIMUS [Book One]

Sectio Prima. On the wondrous Nature of the Center, and the supreme craftsmanship of God. p. 1

- **Cap. I.** Explanations of the definitions. 2
- **II.** On the Line of Direction [Linea Directionis]. 9
- **III.** Paradoxes concerning the Center of the Earth. 14

Sect. 2. On the motion of heavy bodies toward the Center of the Universe. 20

- **Cap. I.** Definition of the local motion of bodies, and of impetus. 21
- **II.** On the accelerated natural and violent motion of heavy bodies, and its proportion to the time in which they traverse the said space. 22
- **III.** On the motion of heavy bodies upon an inclined plane. 25
- **IV.** On the motion of pendulums. 28
- **V.** On the parabolic motion of projectiles, and its wonderful effects. 30

Sect. 3. The utilities that can be deduced from the Cosmocentric art. 35

- **Caput Unicum** [Single Chapter]. How the velocity of the motion of heavy bodies toward the center may be determined. *ibid.*

Sect. 4. Centrosophia applied. 38

- **Cap. I.** *ibid.*
- **II.** On the motions of pendulums. 41
- **III.** On the use and benefit of the said [pendulums]. 43
- **IV.** On the use of pendulums in matters pertaining to Geometry. 48

LIBER II [Book Two]

On the admirable craftsmanship of the Terrestrial Globe.

- **Cap. I.** On the end and purpose [scopus] of the Geocosm. 55
- **II.** The Idea of the Terrestrial Globe existing in the Divine mind. 56
- **III.** On the nature and composition of the Mundane globes, or stars, and how they influence the lower world. 56
- **IV.** On the Sun and its admirable craftsmanship, powers, and properties, by which it influences the Terrestrial World. 57
- **V.** On the nature and effects of the Lunar Body. 62
- **VI.** On the proportion of the Globe of the Earth to the Sun and Moon. 64
- **VII.** On the outermost structure of the Earth, and its magnitude. *ibid.*
- **VIII.** On the Mountains of the Geocosm, and their necessity. 67
- **IX.** On the hidden constitution of Mountains. 68
- **X.** On Mountains in particular, and the hidden architecture of the same [directed] to human uses. 70
- **XI.** On fire-vomiting [ignivomis] or Volcanic mountains. 75
- **XII.** Whether Mountains diminish with time, or grow again anew; and on the wondrous transformation of the earth's parts. 76
- **XIII.** On the Waters, or Ocean, surrounding the Geocosm, and on the communication of the seas through hidden channels. 85
- **XIV.** On the altitude of mountains and the depth of the Ocean and seas, where the altitude of Mount Caucasus asserted by Aristotle is discussed. 89
- **XV.** On the inequality of the World, of the sea — to which is joined the memorable history mentioned above. 98
- **XVI.** The measurement of the Strait of Sicily [fretum Siculum, the Strait of Messina] made by the author in the year 1638. 99

- **XVII.** On the magnetic constitution of the Earth, or on the bone-structure [ossatura] of the Earth. 103
- **XVIII.** The Geocosm, or terrestrial body, is by no means of homogeneous, but of heterogeneous nature; and on the wondrous variety of things of which the terrestrial body consists, and what may be the true and proper element of the terrestrial [body]. 105
- **XIX.** On the interior constitution of the Geocosm, its workshops [officinae], and its analogy to the members of the human body. 110
- **XX.** On Caverns, chasms, and the innumerable passages of the earth. 118

LIBER III. Hydrographicus [Hydrographic]

Sect. 1. On the nature of the Aqueous Element, that is, on the Sea and the continual motions by which it is agitated at every moment, and on the wonderful effects which it produces in the Subterranean World. 121

- **Cap. I.** On the diversity of the motions by which the sea is agitated at every moment. *ibid.*
- **II.** On the general Motion of the sea, which is from East to West. 123
- **III.** On the Motions which they call Currents, that is, repercussed or reflected [motions]. 124
- **IV.** On the general Motion of the Sea, and its effects around the Terrestrial Globe. 125

Sect. 2.

- **Cap. I.** On the second general motion of the Sea, composed of two contrary Motions, which they call the surge of the Sea [aestus Maris], or flux and reflux, also access and recess, or the swelling and subsiding of the Sea. 128
- **II.** By what power or quality the Moon moves the sea. 229 [recte: 129 — sequence between p. 128 and p. 132]
- **III.** Why the Sea exerts its force chiefly at the time of the New Moon and the Full Moon. 132
- **IV.** Why the Sea does not always ebb or flow every six hours in different parts of the Terrestrial Globe, and whence such irregular motions of the Sea arise. 136
- **V.** Why at London, in the River Thames, the greatest swelling of the Sea occurs when the Moon, set in the quadrants, is placed in the Austro-Zephyrean [south-west] region against the Moon in the Boreal [northern] signs; and when it is placed in the Euro-borean [north-east] region, then

the greatest swelling occurs, namely three hours before [the Moon] reaches the London Meridian. 140

- **VI.** Why at the mouth of the Garonne [Garumna], a river of France [Gaul], the water rises for seven hours but falls for only three; whereas on the contrary in the Senegal, a river of Africa, the seawater rises for four hours and falls for eight. 142
- **VII.** 143
- **VIII.** Why the Southern Sea, commonly called del Zur [Mar del Sur, the Pacific], near Panama makes such unusual and incredible fluxes and refluxes; whereas on the contrary in the Northern Sea, commonly called del Nord [Mar del Norte, the Caribbean / Atlantic], near the port of Nombre de Dios and the other shores of the American Continent, it causes a scarcely perceptible surge. 144
- **IX.** 146
- **X.** On the wonderful Whirlpool [Gurges] of Norway, the most celebrated and greatest in all the World. 146

Sect. 3. The Plemmyric Art [Ars Plemmyrica — the art of the tides]. 153

- **Cap. I.** On the use and practice of the marine tide [aestus marinus] in the art of Navigation. *ibid.*
- **II.** On the Pericyclosis or Circulation of the Ocean. 158
- **III.** On the saltness of the Sea, its origin and necessity, and other Accidents of the Ocean and seas. 161
- **IV.** Whether the saltness of the Sea is equal, dispersed throughout all the channels of the Ocean. 165

LIBER IV. Pyrologus [Discourse on Fire]

Sect. 1. On the nature of subterranean fire, its situation and operations. 168

- **Cap. I.** On the necessity and essence of Subterranean fire, whether it be a true element. 168
- **II.** What may be the true element of fire, and where its proper place is. 170
- **III.** On Subterranean fire diffused through all things, and why in some places it is perpetual, in others not. 175
- **IV.** On the Phlegraeian Field [Phlegraeus Campus] in the territory of Pozzuoli [Ager Puteolanus]. 178
- **V.** That the fire-vomiting Mountains, conspicuous on the outermost surface of the earth, sufficiently demonstrate that the earth is full of fires. 179

- **VI.** On the perennial duration of the fire, and its fuel or kindling. 183
- **VII.** A description of Etna, in which, as in a kind of prototype of the subterranean fires and of their unfailing fuel, the reasons are demonstrated, as the saying goes, to the eye. 186
- **VIII.** A description of the Crater of Etna. 187

Sect. 2. On the causes, nature, powers, and variety of Air and Winds, which dominate both on the outer surface of the Geocosm and in the internal cavernous regions of the Subterranean [world]. 191

- **Cap. I.** On the manifold cause of Winds, their division and definition. *ibid.*
- **II.** On the general Wind, and how and from what cause it is born. 193
- **III.** On periodic or annual winds, which the Greeks call Etesian [Etesiae], and on their causes. 196
- **IV.** On the annual winds in the Ocean observed by Spanish, Dutch [Batavian], Portuguese, and English sailors. 198
- **V.** The causes of the various Winds are explained. 200
- **VI.** On the transverse motion of Winds, and its cause. 211
- **VII.** Whence arise the tremor, undulation, and various degrees of intensification and remission of the impetus of winds, [and] how these may be recognized by sound. 212
- **VIII.** On the nature and property of Winds. 213
- **IX.** On the production of artificial Winds, which contribute both to the recreation and to the benefit of men. 218
- **X.** That there is no meteor which does not derive its origin from the Subterranean World, and that meteors of every kind are produced in it, just as on the external surface and in the aerial region. 219
- **XI.** That all meteorological impressions which are generated on high are demonstrated to draw their origin from the Subterranean fires. 223

Index Argumentorum (continued)

LIBER V.

On the origin of Lakes, Springs, and Rivers.

Section 1. On the origin of Springs, Rivers, and Lakes, and their various nature, powers, and properties. — 226

- Cap. I. On the manifold cause of the origin of springs. — 227
- II. On the principal and general cause both of springs and of rivers. — 229
- III. On the remaining modes and explanations. — 235
- IV. On the origin of lakes in plains. — 241

Section 2. On the various differences and qualities of Waters. — 243

- Cap. I. On simple spring water, and on its goodness and badness. — *ibid.*
- II. On water-divining [De Aquilegiis], or on the signs by which one can recognize where water may lie hidden somewhere underground. — 244
- III. On mixed or compound waters, on medicaments in general and their causes, and on the diverse mode and manner of mixture with minerals. — 246
- IV. On the mixtures of medicinal waters. — 251
- V. Description of the hydrometer [Hydrometrum], by which the heaviness and lightness of waters is tested. — 254
- VI. On the heat and warmth of Thermal springs [Thermae], its cause, and how they are mingled with so very different a tincture of minerals. — 256

Section 3. On Thermal springs and Medicinal Waters, and their wonderful powers and properties in particular, in which it is demonstrated that they all have their origin from Subterranean sources. — 259

- Cap. I. On the principal Thermal springs or medicinal waters that occur here and there over the surface of the Geocosm. — *ibid.*
- II. From what source the medicinal power of thermal springs flows out against so many and so different diseases. — 270

Section 4. On the miracles of Waters, and the prodigious nature and property of certain springs. — 273

- Cap. I. On the color, taste, smell, and noxious vapor [mephitis] in certain springs and gleaming thermal waters. — 274
- II. On the heaviness and lightness of certain waters, and their miracles. — 276
- III. On deadly waters and the Charonian pits [scrobes Charonei], endowed with a destructive force. — 281
- IV. On the ebb and flow of certain springs and the various alteration of their waters, as well as on springs that foretell scarcity of grain [annonae caritatem praenunciantibus]. — 282

- V. On the metamorphic power of springs, rivers, and lakes, which convert whatever is thrown into them into stones or other metallic species. — 286
- VI. On the remaining miracles of waters. — 288
- VII. On the various metamorphosis of lakes, rivers, and springs, and the transmutations of terrestrial parts. — 290

LIBER VI.

On the fourth of the natural Elements, which we call Earth, and on the things produced from it — the first fruits of the Subterranean World.

Section 1. On the wonderful variety of the Earth, and whether it is truly and properly an Element, and what and of what kind it ought to be understood to be. — 295

- Cap. I. On the Element Earth. — *ibid.*
- II. On the great variety of things that are contained in the womb of the terrestrial globe. — 296
- III. On the incredible variety of things which, by the power of salt together with the auxiliary resources of the other Elements, are produced in the vast womb of the Megacosm — and first indeed concerning salt and its differences. — 297
- IV. On the differences of salts. — 299
- V. On the manner of extracting salts. — 302

Section 2.

- Cap. I. On Niter [Nitrum], and its species Saltpeter [Salnitrum], Aphronitrum, and Halinitrum. — 304
- II. On Saltpeter [Salnitrum], the third species of salt. — 305 [recte: see anomaly (a) — "tertia" is inconsistent with Cap. I treating Salnitrum as a species of niter]
- III. On the Generation, Nature, and powers of Saltpeter. — 307
- IV. On the manner and method of preparing niter-based gunpowder [pulvis pyrius], and its various uses in the art of pyrotechnics [arte Pyrobolica]. — 309

Section 3. On Alum [Alumen], the third species of salt. — 312

- Cap. I. On the Name, Definition, and Variety of Alum. — *ibid.*

- II. On the Nature, Quality, and Preparation of Alum. — 313
- III. On the medicinal powers and the other uses of Alum. — 315

Section 4. On Vitriol [Vitriolum], and its wonderful properties. — 316

- Cap. I. On the definition, division, and origin of Vitriol. — *ibid.*
- II. Whether Iron can be truly and really converted into Copper [in Aes] by means of the spirit of Vitriol. — 319
- III. On the variety, powers, properties, and use of Vitriol. — 321
- IV. On artificial Vitriol [Vitriolum factitium]. — 322

Appendix. On the fourfold kind of salts. — 323

LIBER VII.

On the Nature, Property, and Use of Minerals or Fossils, which properly partake of the terrestrial Element; and on the perpetual circulation [pericyclosis] and revolution of the Geocosm which comes about through their motion.

Section 1. On the Terrestrial portions and sandy bodies that are enclosed in the womb of the Geocosm. — 326

- Cap. I. On Sand, Gravel, Shingle, and Ash [De Arena, Sabulo, Glarea, Cinere]. — *ibid.*
- II. On the Quality and Use of Sand. — 327
- III. On the wonderful Nature of the Pericyclosis. — 329

Section 2. On the Hylocinesis [De Hylocinesi] (the matter-motion) of the Terrestrial Globe — that is, on the great and perpetual separation of Terrestrial Matter brought about by the motion of Sand, Gravel, and Shingle, or on the resolution of clay, stones, and metallic mixtures. — 330

- Cap. I. On the Causes of the Geocosmic alteration. — *ibid.*
- II. What Earth properly is, from what it is generated, and on the various terrestrial substances which they commonly call "Earths" [Terras]. — 333
- III. From what source so great a difference of Earths arises. — 335
- IV. On the Use of the various Earths. — 337
- V. On the requisites for the cultivation of Fields. — 340
- VI. On the Terrestrial bodies which come into use among individual craftsmen [Plastae] and Painters. — 343

Anacephaleosis Dictorum [Recapitulation of what has been said]. — 345

Catalogus Librorum — Catalogue of the Books published hitherto by Fr.
Athanasius Kircher of the Society of Jesus. — 346

LIBER PRIMUS — CENTROGRAPHICUS

which is also called CENTROSOPHIA.

Section I.

On the wonderful Nature of the Center and the supreme Workmanship of God.

PREFACE.

[Margin: De Natura Centri — On the Nature of the Center.]

As I set about bringing the wonders of the Subterranean World to light, it seemed right to begin the foundations of my discourse from the Center — since that is, not without reason, recognized to be the basis and foundation of all things. For just as in the whole fabric of the Corporeal World, infinite divine power shines forth in the order and arrangement of created things, so in the construction of the Center the wisdom of the Maker shines forth as most especially admirable and inexhaustible. Hidden within it is something — I know not what — utterly admirable, rivaling (so to speak) divinity itself, in which the greatest most closely coincides with the smallest: for it folds together all the bodies that shine throughout the whole vast extent of the World, draws them all into itself and compresses them, and unfolds them all outside itself again. It is truly an admirable work, the work of the right hand of the Most High, founded by no power save that of Almighty God. Just as He drew forth from the center all the offshoots of the world's framework, so into that same center He brings all things back; and He willed all things to be bound to it by a law so constant, by so great a binding-together of bodies, that it would be easier for the framework of the whole World to be dissolved than for bodies to be removed from this law, once it was established by the ineffable disposition of divine providence.

To this Center all the Systems of the heavenly globes look first of all, since by their perpetual revolution they point to nothing other than that without which they would seem to have been produced by God in the nature of things in vain — destined never to yield any effects of their influences. The System of the Elementary World has so necessary a dependence on the Center that without it the system could obtain neither any operation in the efficient action of things, nor

any energy in the propagation of generable things. And although this Center is — on the testimony of Proclus — ἀόρατον καὶ ἄτομον [Greek: *aoraton kai atomon*, "invisible and indivisible"], that is, the very smallest thing, inconspicuous and individual, yet it is so great in its power that it supports all things, preserves all things, animates all things, and strengthens all things. Without it there is no order of things, no efficacy of the elements; without it, in the subterranean World, no increase of mineral nature, no vegetative power, no operation of the sensitive faculty would attain its end. In a word, the World would be utterly compelled to pass into nothing. And lest we should seem to the Reader to be putting forward ἄπιστα καὶ παράδοξα [Greek: *apista kai paradoxa*, "incredible and paradoxical things"], we have resolved to demonstrate all that has been said thus far in the course of this Centrosophy. And so that we may proceed by a more solid method, we shall first set down the Definitions, Axioms, and other things necessary for forming a complete art.

DEFINITIONS.

[Margin: Definitiones — Definitions.]

1. The midpoint of the Universe is a point.
2. The midpoint of the Universe is immobile — it is what is called the Center of the World — and all things seek it.
3. The center of gravity of any heavy thing is the midpoint of that same heavy thing.
4. The center of magnitude is the midpoint of any figure whatsoever, through which the figure, however it be cut, is always divided into equal parts.
5. The center of Virtue [Centrum Virtutis] is the midpoint of a physical body, from which its virtue exerts itself most strongly.
6. The line of direction [Linea directionis] is that which directs the motion of heavy things, and is understood to be drawn from the Center up to the vertex, through the Center of the heavy thing.

CAPUT I.

Explanations of the Definitions.

[Margin: Quid sit Centrum — What the Center is.]

DEFINITION I.

The Center is the least and first point in space, simple, devoid of all composition and division, neither a whole, nor a quantity, nor great, nor commensurable with any quantity; yet it is that which all heavy things naturally seek, and toward which all light things are borne upward.

I demonstrate this whole matter κατὰ τὴν διάλυσιν καὶ σύνθεσιν [Greek: *kata tēn dialysin kai synthesin*, "by analysis and synthesis"] as follows.

If the central point is not the least in space, then something smaller than it can precede it in space; but this is impossible, since nothing smaller than a point can be assigned. It is therefore the least in space, and consequently the first; if first, then it will be simple; if simple, then devoid of all composition; if devoid of all composition, then indivisible; if indivisible, then it can be called neither a quantity nor a whole, since it lacks parts; if neither a quantity nor a whole, then neither great; and because not great, it will be neither greater, lesser, nor equal; and consequently it ought to be called neither a measure, nor a thing measured, nor commensurable with a quantity. Therefore, conversely, because it is commensurable with no quantity, it can be compared with no quantity; and since it is not comparable with a quantity, it cannot be a quantity; and since it is not a quantity, it is not divisible; and since it is not divisible, it is not partible; and because it is not partible, it is not a whole; and because it is not a whole, it has no parts; and because it has no parts, therefore it is simple; and because simple, therefore the least and first in space; and because it is first in space, therefore it has a situation in space; and because it has a situation, it also has a position in space, and consequently it asserts a relation to the points, lines, angles, surfaces, and bodies that are in space. From this arises that paradox.

The Center of the World, although it is a point, is nevertheless in a certain way commensurable with a periphery of any size whatever — so that the circumferences and surfaces even of any greatest Circle may seem to be contracted into a single, as it were, Central point, according to all their parts, and to be commensurable with it. For, on the testimony of Proclus, the circumference is joined on every side with the Center, and forces and contracts all its parts into the Central point. For if from some point an infinite number of concentric circles be described, and from the greatest of all the circles lines be drawn through all the intermediate ones to the Center from which they were described, it is certain that the smallest circle, than which no smaller can be drawn, coincides with the Center. So that from this very consideration you may recognize the necessary dependence of the Center upon the circumference — such that you can conceive

neither the Center without the circumference, nor the circumference without the Center. For since divine Wisdom unfolded the sphere out of the Center, take away the Center and there will be no unfolding of bodies; if no unfolding of bodies, there will be no amplitude of the World; if no amplitude, there will be no arrangement of worldly bodies in the world, no order, no influence, no motion. And since all these things are absurd, all things therefore are ordered toward the Center from which they were unfolded. The Center, then, is what all things seek; the Center is what all things encircle; the Center is what all things regard, inasmuch as it is utterly necessary for the conservation of the Universe and the union of bodies. By the virtue of the Center all the powers of natural and elemental motions emanate; without the virtue of the Center, no vegetable could take on increase, no bird could fly, no quadruped could walk, nor could man perform any bodily action — as will afterward be demonstrated. All things, therefore, are from the Center, and all things are ordered toward the Center. But that all these matters may become plainer, we have judged that we must first explain the difference between the Center of magnitude and the Center of gravity.

DEFINITION II.

[Margin: DEFINITIO II.]

The center of magnitude is the midpoint of any figure whatsoever, through which the figure is bisected.

[Margin: Quid sit Centrum Magnitudinis — What the Center of Magnitude is.]

A midpoint, taken according to its whole breadth, is called the midpoint of any given thing; and it is a point of continuous and finite quantity, marked out either in act or in potency — either in the quantity itself and its boundary, or outside it — with a definite relation, whether of extension, or of intervening distance, or of the disposition of the parts, to that thing of which it is said to be the Center. And in this respect it belongs not only to bodies, but also to surfaces and lines. But properly the Center of a figure is that midpoint in a circle and a Sphere from which all lines drawn to the periphery are equal to one another. In rectilinear figures, however, it is the point in which all the straight lines either joining opposite angles are bisected, or in which the lines drawn from the angles to the bisected sections of the opposite sides are divided in the same ratios. The center of magnitude is the point which is equally distant on every side, in respect of magnitude and extension, from the extremities. This [description] applies...

this applies, of course, to every finite quantity—that is, to lines, surfaces, and bodies—but not to all of them individually. For when a line is regular and

bounded at both ends, the Center is the point that bisects it. Among surfaces, only the circle among plane figures (and the sphere among solids) properly has a Center of Magnitude. In regular polygons and polyhedra it has its place only improperly, since in these the sides themselves and the area [ἔδρα, *hedra*, "seat" or "face"] are equally distant from this Center only when they are considered as wholes, not part by part. By this reasoning the Center of Magnitude can also be found *outside* the very quantity whose Center it is said to be—as happens with curved lines that return upon themselves, such as the circular and the elliptical, in the surfaces and bodies of zones, coronas, and annular figures. Among the Arab geometers I read that this is called the *point of magnitude*: the point that bisects straight lines, that divides a surface into two equal parts, and that in bodies is the point through which any plane whatever passing divides the body equally (just as was said of a surface), bisecting it so that the parts taken separately are equal. From all this it is clear that the Center of Magnitude and the Center of figure are exactly the same thing in lines and surfaces, and likewise in bodies.

DEFINITIO III

The Center of Gravity of any heavy body is the midpoint of that heavy body; and the midpoint of the Universe—that is, the point that all things seek—is called the Center of the World [Centrum Mundi].

[Margin: What the Center of Gravity is.]

This definition is taken from Aristotle [Aristotle], and we may confirm it in his own words and reasoning. For when he establishes that the Earth is spherical, among other very strong arguments he offers this one. *"It is not difficult,"* he says, *"for those who attend even a little and make the distinction, to see how we suppose that anything possessing magnitude, however great its weight, is carried toward the midpoint itself."* The Philosopher seems to require first an intent and focused effort of mind, with all confusion set aside, for this study of natural forces and motions; he then expressed in plain words that all heavy things are carried toward the midpoint. And he shows clearly that the midpoint is aptly called the Center in a sphere—or rather in the very definition of a sphere that Cicero [Cicero] used—for thus he speaks of the World: *"It was fashioned spherical"*—what the Greeks call σφαιροειδής [*sphairoeidēs*, "sphere-shaped"]—"such that its whole surface is touched by radii equal from the midpoint." So says Cicero. As for the Center of Gravity, Aristotle likewise says: *"For it is evident that it does not touch the extremity of the Center precisely, but rather the larger part must prevail until it has fully received the midpoint as its own midpoint."* This reasoning of

Aristotle's is indeed best suited for grasping the nature of the Center of Gravity, and I explain it as follows.

Suppose the Earth were removed from the midpoint, and imagine some heavy body let fall—say from the concave surface of the Moon. It will certainly move toward the Center, and it will not come to rest when it has touched the Center with its outermost part. For there is no force at the Center, as many suppose—no magnetic force that holds attracted bodies fast so that they do not move from there. Rather, in the heavy bodies themselves, and in each of their parts, there is a certain appetite that draws them toward the Center. Therefore, when that outermost part of the body which touches the Center—and which would come to rest if it were separated from the other heavier parts—is pressed by the other heavier parts standing above it, and cannot resist them as they bear down, it necessarily must give way: it is displaced from the Center and carried to the opposite side, until it has brought with it as many equally-weighting parts as remain on this upper side. Now all that I have said applies to one line only, the line along which that heavy body moved in a straight path; and this, which we have so far demonstrated of the motion along that line, will be shown in exactly the same way, by the same reasoning, for any other line of any other motion that might occur from the concave surface of the Moon to the Center of the World. From this it follows that the body cannot come to rest before its own midpoint reaches the midpoint of the World; for then the body will stand balanced, weighed down on every side by the equal weight of its parts pressing in all directions.

Plato [Plato] confirms all this in the *Phaedo* in these words: "*This, then, I have fixed firmly and unshakably in my mind: if the Earth is in the middle of the Universe, surrounded on every side by the heavens at equal distances, then it needs no support to keep it from falling—neither air nor any other necessary prop. To hold it in place, it is enough that the heaven is everywhere alike with respect to itself,*"—καὶ τῆς γῆς αὐτῆς ἰσορροπίαν [*kai tēs gēs autēs isorropian*, "and the equilibrium of the Earth itself"]—"and that the Earth itself is in equilibrium. For a thing in equilibrium, set in the midst of something uniform and uniformly disposed, will be unable to incline more or less in any direction, but, remaining in like condition, will lean to neither side, and will stay constant."

And thus the definition of the Center of Gravity handed down by Pappus of Alexandria [Pappus of Alexandria] also fits well. "*The Center of gravity of any body,*" he says, "*is a certain point set within it, such that, if one imagines the heavy body suspended from it, then while it is carried it rests and keeps the position it had*

at the beginning, and is not turned about during that motion." Frederico Commandino [Federico Commandino] sets this out a little more clearly in his book *On the Center of Gravity*: "*The Center of gravity of any solid figure,*" he says, "*is that point set within it, about which the parts of equal moments stand on every side.*" We ourselves explain it thus. Since in bodies both figure and weight can be assessed, and since in some bodies the weight and the figure agree with each other—as can be seen in the sphere and in similar figures—this does not, however, always hold. For in most bodies the ratio of figure and of weight is very different, and the midpoint of figure...

lies far from the midpoint of weight. Rightly, then, does Aristotle warn that account must be taken of the weight alone, not of the magnitude or bulk—and he hints at this when he says *the midpoint of the heavy body*. But when he says that, if a plane is drawn through such a Center, cutting the figure in any way whatever, it will always divide the figure into parts of equal weight, the words *cut* and *divide* are not to be taken as signifying a separation of the parts from one another. For it most often happens that a heavy body, divided into two equally-weighing parts by some plane passing through its Center of gravity, is not separated at all. The reason is that, once the parts of the heavy body have been divided, each of them has its own relation to its *own* Center, no longer to the prior Center, which was the Center of the whole. From this it follows that the same location most often takes on a different relation of weight with respect to one Center than the relation it had with respect to another. The chief reason for this can be given as follows: the parts, the more or less distant they are from the Center, weigh the more or the less, as will be shown below.

The sense of those words, then, will be this. If a plane is understood to pass in any way whatever through the Center of gravity, the parts of equal weight will stand about the said plane. As for the view of certain people that the Center of magnitude and of gravity are the same, on the grounds that the Center of gravity nowhere weighs—they are mistaken. For although the Center, of itself and by its own nature, does not weigh, it is nonetheless a foundation within the heavy body, in virtue of which the body, when a section is made through it into however many parts, always leaves the parts equal in weight—which never happens in the Center of magnitude. For suppose a sphere were given, one hemisphere of which was made of lead and the other of wood: it is certain that in this sphere the Center of magnitude differs from the Center of gravity—so much so that the Center of magnitude may be said rightly to occupy the middle of the sphere, as being the midpoint of the figure, while the Center of gravity recedes from the midpoint the farther, the lighter is the hemispherical portion out of which the

sphere is constituted: namely, to the point such that, if the sphere is cut at it, it leaves the parts *ισόρροπας* [*isorropas*, "of equal balance"], that is, of equal weight. It is nonetheless true that in a homogeneous sphere, composed without any admixture of differing material, the Center both of magnitude and of gravity coincide and are exactly the same.

It must be supposed that the same thing happens in the Terraqueous globe. For since water has a relation of differing weight to the structure of the earthy parts, it is certain that the Center of gravity in the earthen globe is distinct from the Center of magnitude—yet it always agrees with the Center of the World, inasmuch as it is borne toward it by an innate force, like all other things. But let me confirm the matter with this example. Let A B be the globe of the Earth, and let its Center of gravity C coincide with the Center of the World, the same C. Now let the segment D E be cut off by divine power—or any other segment whatever. Once this is removed, it is certain that the Center of gravity no longer remains at C, but is at F; and so, in order that it may again coincide with the Center of the World, it will at once accommodate itself to it, so as to stand balanced about the Center of gravity.

Diagram. A circle representing the globe of the Earth, with a chord D–E drawn across the upper portion (the segment to be removed).

- A (lower left of circumference): label of the globe
- B (lower right of circumference): label of the globe
- D (left end of upper chord): endpoint of the cut segment
- E (right end of upper chord): endpoint of the cut segment
- C (center of circle): the original Center of gravity, coinciding with the Center of the World
- F (just below C): the displaced Center of gravity after the segment D–E is removed

COROLLARIUM

From this it is clear that the Earth, if it were raised by divine power outside the Center of the World, would *not* stand still there (as some suppose), but, once released, would by its own proper power—like all heavy things—seek the Center of the World again. It is also clear that there is a great difference between the Center of gravity and the Center of magnitude. Therefore, just as it is proper to the sphere—solely because it has a point in the middle, surrounded on every side by equal parts—that the sphere is divided into two equal parts by a plane passing through that midpoint (for it can in no way be divided into two equal parts by a

plane not passing through the midpoint), so likewise, because every heavy body has its own midpoint of gravity, it will be cut into two equal parts by a plane passing through the Center, and it cannot be understood to be divided into two equal parts by a plane unless the said plane passes through that midpoint. The Canons follow.

Canones de Centro gravitatis & magnitudinis

(Canons concerning the Center of gravity and magnitude)

If the Center of gravity did not exist in things, then consequently there would be no motion. If there were no motion, all things would grow sluggish—indeed, it would necessarily follow that the whole of Nature reverted to its own Chaos. Therefore provident Nature implanted in heavy things an appetite for the Center, which all things seek. But since they could not descend to the Center by their own power, it seemed necessarily required that something direct their appetite for the Center of the Universe in their motion—which is nothing other than the Center of gravity proper to each heavy thing; for under this guidance all things attain their goal. But how this Center exists in individual bodies, and how it can be found, remains to be explained—since without knowledge of it, what we are going to say in the course of this work cannot be perfectly understood.

It must therefore be noted that the Center of gravity existing in solid bodies cannot be fully grasped unless it is first demonstrated in the surfaces of the sections of those bodies. For, as will be clear from what follows, since a Center of this kind, as being...

as being internal to solid bodies, is not open to the eyes, it certainly cannot be brought from the hidden into the open except through the surface, which is laid bare only by the sectioning of the said bodies. For the Center of gravity that is shown to exist in any body must also be reckoned to be a Center of gravity in that surface which passes through the midpoint of the cut body; and therefore let no one be surprised if he sees us inquiring after a Center of gravity in surfaces, which are entirely devoid of all weight. For this we arrange only with a view to finding the Center of gravity of the solid body—as will be clear when the reader has understood what follows.

But let us show the matter by example. In a globe and a cube of homogeneous material, the Center of gravity, since it is internal, is not visible. But if you cut the said bodies through the middle, in any part, into two halves, then at once, once the section is performed, two surfaces are left, whose midpoint of magnitude is

also the Center of gravity; and when these are joined together again into one body, the Center of gravity in the sphere or cube is the same as what it displayed in the surface—and you will judge the rest by like reasoning. With these preliminaries set down, let us now pursue the subject we have begun.

CANON I

In all regular figures the Center of magnitude and of gravity is the same.

Let there be, then, the regular figures: circle, square, pentagon, equilateral triangle. And since A is a circle, it is certain that the Center of the circle is the same as the Center of gravity—and this is clear from the second and third definitions. For just as in a circle a section made through the Center always divides the circle into two equal halves (that is, into two equal semicircles), so if a section were made through the Center of gravity, all the semicircles would be of equal weight. What is said of the circle can also be said of the square, whose Center of magnitude and of gravity is there where the diagonal lines C D and E F cut each other at the point S; for through this point, however the section is made, it always leaves parts equal both in quantity and in weight. The same must be said of any regular polygonal figure. For if you circumscribe the figure about a circle, the Center of the circle and of the circumscribed figure will be exactly the same; hence the figure, cut through it in any way, always leaves parts equal both in quantity and in weight. In an equilateral triangle the Center of magnitude and of gravity is there where the lines D L, I M, N O cut each other; hence a bisection made through this Center always leaves parts equal both in weight and in quantity.

Diagram. A circle with its center marked A.

- A (center of the circle): the Center, coinciding with the Center of gravity

Diagram. A square with both diagonals drawn, intersecting at the center.

- E (upper left corner): vertex
- D (upper right corner): vertex
- C (lower left corner): vertex
- F (lower right corner): vertex
- S (intersection of diagonals C–D and E–F at center): the Center of magnitude and of gravity

Diagram. An equilateral triangle with the three medians drawn from each vertex to the opposite side, meeting at the center.

- N (apex, top): vertex
- M (lower left): vertex
- L (lower right): vertex
- D (on left side, between N and M): bisection point / median endpoint
- I (on right side, between N and L): bisection point / median endpoint
- O (on base, midpoint between M and L): bisection point / median endpoint
- (the three lines D L, I M, N O intersect at the center, the Center of magnitude and gravity)

CANON II

In squares, parallelograms, rhombi, and rhomboids, the Center of gravity and of magnitude is properly that point where the diagonal lines, or diameters, of the said figures cut each other—as appears in figures S, B, C, D.

Diagram. Four quadrilaterals, each with both diagonals drawn intersecting at its center: a square (S), a rectangle/parallelogram (B), a rhombus (C), and a rhomboid (the figure labeled near its center).

- S (center of the square, lower left figure): Center of gravity and magnitude
- B (center of the rectangle, upper right figure): Center of gravity and magnitude
- C (center of the rhombus, right figure): Center of gravity and magnitude
- (lower middle rhomboid: center marked, label reads [?] — appears to be a fourth figure of the series)

CANON III

In regular polygons of any number of sides, the Center of the circle circumscribed about them is the Center of magnitude and of gravity. See figures E, F.

Diagram. Two regular polygons, each inscribed in a circle, with the center of each marked: a pentagon (E) and a hexagon or heptagon (F).

- E (center of the left polygon, inscribed in a circle): Center of magnitude and gravity
- F (center of the right polygon, inscribed in a circle): Center of magnitude and gravity

CANON IV

In rectilinear triangles of any kind, you will obtain the Center of gravity and of magnitude in this way.

Let A B C be an isosceles triangle, whose Center of perimeter is sought. Bisecting the three sides at the points D, E, F, and drawing the perpendicular A F, let E G be taken equal to F C; the line joining the points D, G will cut the perpendicular A F at I, which I say is the Center of gravity and of magnitude of the isosceles triangle A B C. I demonstrate this as follows. For when D F, F E, E D are joined, D E F E will be a parallelo...

Diagram. An isosceles triangle A B C (apex A at top, base B–C at bottom) with internal construction lines, midpoints, and the perpendicular from the apex.

- A (apex, top): vertex
- B (lower left, base): vertex
- C (lower right, base): vertex
- D (midpoint of left side A–B): bisection point
- E (midpoint of right side A–C): bisection point
- F (midpoint of base B–C, foot of the perpendicular A F): bisection point
- G (on right side, with E G equal to F C): construction point
- I (intersection of line D–G with the perpendicular A–F): the Center of gravity and of magnitude

gram, by [Elements] II.6; therefore, by [Elements] I.29, the angles D G E and F D G are equal. But the angle G D E at the base D G of the isosceles triangle D E G is equal to the same angle, by [Elements] I.5; therefore the angles F D G and G D E are also equal, and so the whole angle G D E is bisected by the straight line D G. But the angle D I E is also bisected by the straight line A F. Therefore the common point of section, I, is the sought Center of gravity of the isosceles triangle A B C; for when it is bisected through this point, it always leaves the parts equal in weight.

Next, let A B C be a scalene triangle, in which, if from D, the midpoint of the base A C, and from E, the midpoint of the hypotenuse C [?]
[recte: the midpoint of side C B / the hypotenuse]—you draw the lines from D B and from C E, the point of intersection of the lines B D and C E, at the point F, will be the sought Center of gravity. It is therefore clear that the Center of gravity of every triangle lies on the straight line drawn from an angle to the middle of the base—that is, where the straight lines drawn from the angles of the triangle to the midpoints of the sides

meet. It is also clear that the Center of gravity of every triangle is the point lying on the straight line drawn from an angle to the bisection of the base, which divides that line such that the segment toward the angle is double the remaining segment toward the base.

Diagram. A scalene triangle A B C (A at lower left, B at apex, C at lower right) with two cevians drawn from the vertices to the midpoints of opposite sides, intersecting at F.

- A (lower left): vertex
- B (apex, upper): vertex
- C (lower right): vertex
- D (midpoint of base A–C): bisection point
- E (midpoint of side C–B / hypotenuse): bisection point
- F (intersection of cevians B–D and C–E): the Center of gravity

In triangle A B C, let a section parallel to B C be made through the line D E, such that D A to D C, or A E to E B, are double; I say that the Center of gravity of that triangle is the point F, the midpoint in the line D E. You will also obtain this by an extremely easy method, if you divide one of the two legs, either A B or A C, into three equal parts; for a line drawn parallel through the [point of division] to the cathetus [base] B C, and bisected, will give the Center of gravity. But whoever desires demonstrations of all these, let him consult Archimedes [Archimedes], Commandino, Luca Valerio [Luca Valerio], and Guldin [Paul Guldin], where he will find everything demonstrated at length.

Diagram. A right triangle (vertex C at upper left, base B–A at bottom running from B at lower left to A at lower right) with a line D E drawn parallel to the base and the point F marked on it. The base is marked off in three equal divisions (3, 2, 1).

- C (upper left): vertex (right angle)
- B (lower left): vertex
- A (lower right): vertex
- D (on the left leg, upper): division point
- E (on the base, marking a division): division point
- F (on line D–E): the Center of gravity
- (the base B–A is graduated: 3, 2, 1 marking the three equal parts)

CANON V

To find the Center of gravity in a trapezium.

Let A B C D be a trapezium, whose Center of gravity is to be sought. On the bounding lines B C and A D, let the bisection points E, F be joined; divide that line [E F] into three equal parts, and through the points of division let lines I H and S T be drawn parallel to A D or B C; then from A and from [?] let two other lines be drawn to E and to C. With these set down, if through the points where E C and A E cut the lines I H and S T you draw the line L M, it will cut the line E F at the point G, which is the Center of gravity of the trapezium. For the demonstration, see Luca Valerio.

Diagram. A trapezium (quadrilateral) A B C D—A at lower left, B at upper left, C at upper right, D at lower right—with internal construction lines, the transversals I H and S T parallel to the sides, the median E F, and the diagonals, meeting at G and M.

- A (lower left): vertex
- B (upper left): vertex
- C (upper right): vertex
- D (lower right): vertex
- E (midpoint of side B–C, top): bisection point
- F (midpoint of side A–D, bottom): bisection point
- I (left end of transversal I–H): division point
- H (right end of transversal I–H): division point
- S (left end of transversal S–T, lower): division point
- T (right end of transversal S–T, lower): division point
- L (on transversal I–H, interior): construction point
- G (intersection on the median E–F): the Center of gravity of the trapezium
- M (interior construction point, lower): construction point

CANON VI

To find the Center of gravity in a semicircle.

In a semicircle you will obtain the Center of gravity if you describe the *tetragonizousa* [τετραγωνίζουσα, "squaring curve"], that is, the quadratrix, according to what we handed down in the *Ars Magna Lucis et Umbrae* [*The Great Art of Light and Shadow*], Book 3. Let A B C be a semicircle; let the *tetragonizousa*,

or quadratrix line, be described from the semidiameter A to D B, which is A E; I say that the point E, at which the *tetragonizousa* A E ends, is the sought point of gravity of the semicircle A B C. See the reasoning in the cited passage.

Diagram. A semicircle A B C standing on its diameter A–C, with the radius/vertical D B drawn from the midpoint D of the diameter up to B at the top of the arc, and the quadratrix curve drawn (as a dashed line) ending at the point E.

- A (left end of diameter): endpoint
- C (right end of diameter): endpoint
- B (top of the arc): apex
- D (midpoint of diameter A–C, foot of the vertical D–B): point
- E (where the quadratrix curve ends, on the vertical D–B): the Center of gravity of the semicircle

CANON VII

To find the Center of gravity in a parabola.

You will obtain the Center of gravity in a parabola if you divide the axis B G, which bisects the base A C, into five equal parts. For if you draw the straight line V T parallel to the base A C through the $\frac{2}{5}$ part [per $\frac{2}{5}$ partes] along the axis B G, it will give the point S of intersection, the sought Center of gravity in the parabola. Since all these things are demonstrated at length by the authors cited a little earlier, and are by now well-worn, we will not dwell on them.

Diagram. A parabolic segment standing on its base A–C, with the axis B–G running vertically from the apex B down to G at the midpoint of the base. The axis is graduated into five equal parts (5, 4, 3, 2, 1), and a horizontal line V–T is drawn across, meeting the axis at S.

- A (left end of base): endpoint
- C (right end of base): endpoint
- B (apex, top): apex
- G (midpoint of base A–C, foot of axis): point
- V (left end of the horizontal line): endpoint
- T (right end of the horizontal line): endpoint
- S (intersection of line V–T with the axis B–G, at the $\frac{2}{5}$ division): the Center of gravity of the parabola
- (the axis is graduated 5, 4, 3, 2, 1 from top to bottom)

CANON VIII

To find the Center of gravity in homogeneous solid bodies.

It remains for us to show briefly the method by which the Center of gravity may be found in any solid bodies whatever. This, being proper to our undertaking, we have judged should be treated somewhat more thoroughly, since many things to be produced in what follows depend upon this proposition. Let it be required, then, to find the Center of gravity in a globe or a cube made up of homogeneous material; one proceeds...

proceeds as follows: since the center of gravity of a globe coincides with its center of magnitude, I say that the center of the globe is the center of gravity sought. And since the cube too is a regular body, I say that the center of the cube—which lies at the midpoint of the cube's diagonal—is the center of gravity sought. The matter requires no demonstration, being self-evident, and it has already been fully demonstrated by Archimedes and by his commentators cited above.

CANON IX.

To find the centers of gravity in cylinders and prisms.

Since a column or cylinder is generated by carrying around a circle, the midpoint of the cylinder's axis P Q—the point B—will necessarily give the center of gravity sought. You will have the same result in a prism of any number of sides. Let there be, for example, a parallelepiped I R S formed by carrying around a square, having its axis drawn through the centers I S of the square sides; the midpoint of its axis, the point R, will give the center of gravity sought. The same is to be said of a prism of 5, 6, 7, 8, etc. sides, and so on to infinity.

Diagram. Two solid figures side by side, illustrating Canon IX. On the left, a rectangular prism (parallelepiped) shown in perspective with a vertical axis; on the right, an upright cylinder with its circular top and bottom and a vertical axis.

- L (top edge of prism): vertex label of the parallelepiped
- I (top edge of prism): adjacent vertex label
- R (interior, mid-height of prism): the midpoint of the axis = center of gravity
- S (bottom edge of prism): lower vertex label
- M (bottom edge of prism): lower vertex label
- P (top of cylinder): top of the cylinder's axis

- B (interior, mid-height of cylinder): midpoint of the cylinder's axis = center of gravity
- Q (bottom of cylinder): bottom of the cylinder's axis

CANON X.

To find the centers of gravity in a cone and a pyramid.

In cones and pyramids of any number of sides you will find the centers of gravity if you divide the axis of these bodies so that the part toward the vertex is double the remainder—that is, if you divide the axis into three equal parts, the center of gravity will be the point of division third from the vertex along the axis. For the center of the figure, through which the axis passes, is also the center of gravity—both of the base and of that parallel plane through which the section is made under the given proportion. See the adjoining figure M N O P, in which the center of gravity is the point T, and in the figure A B D of the pyramid, the point C.

Diagram. Two figures side by side. On the left, a cone with apex M and a circular base O N P, its axis M N marked off with division numbers 1, 2, 3; the center of gravity T is marked one-third of the way up from the base along the axis. On the right, a triangular pyramid (shown in perspective, one face shaded) with apex A and base B D, its axis likewise divided into segments 1, 2, 3, with the center of gravity C marked along the axis.

- M (apex of cone): vertex of the cone
- 1, 2, 3 (along the cone's axis from apex downward): the three equal divisions of the axis
- T (on the cone's axis, one-third up from base): center of gravity of the cone
- O (left end of cone's base): base-circle edge
- N (midpoint of cone's base): foot of the axis
- P (right end of cone's base): base-circle edge
- A (apex of pyramid): vertex of the pyramid
- 1, 2, 3 (along the pyramid's axis from apex downward): the three equal divisions of the axis
- C (on the pyramid's axis): center of gravity of the pyramid
- B (left base corner of pyramid): base vertex
- D (right base corner of pyramid): base vertex

CANON XI.

To find the center of gravity in a frustum of a pyramid. See the figure of Canon V.

If a pyramid is cut by a plane parallel to its base, the center of gravity of that frustum will be given by the center of the trapezium considered in the plane of the axis. Let the frustum of a cut pyramid be B C D A, its axis E F, and the trapezium in the plane of the axis be A B C D. If, following the preceding Canon V, you find the center of gravity of this trapezium—say G—then that G will also be the center of gravity of the proposed frustum of the pyramid.

CANON XII.

To find the centers of gravity of the five regular bodies.

The five regular bodies are the cube, the tetrahedron, the octahedron, the dodecahedron, and the icosahedron. If circles [spheres] are circumscribed about them, the center of the circle and of the five regular bodies will be one and the same—precisely the center of gravity sought. For the demonstration, see Stevin [Simon Stevin], Proposition 14.

CANON XIII.

To find the center of gravity in a hemisphere.

If you bisect a hemisphere, the plane of the section will necessarily be a semicircle. So if you find the center of gravity in this semicircular plane by Canon VI, that same point will also be the center of gravity sought on the axis of the hemisphere. Or otherwise, in this way: divide the axis of the hemisphere into eight equal parts; the point that marks off five parts downward from the vertex—or three upward from the base—is the center of gravity sought. The same is to be said of a paraboloid body. For the center of gravity that the parabolic plane yields through a section of the body taken along the axis will likewise give the center of gravity of the paraboloid body.

CANON XIV.

To determine mechanically, by means of a plumb-line, the center of gravity in any body.

Let a thread or plumb-line be dropped from the end of the body, and mark the line that the thread traces on the surface of the stone. Then apply the plumb-line at any other point of the stone, and again mark the line that the thread traces on the surface of the body. Where this line cuts the first, earlier line, there is the center of gravity on the surface of the stone. Now repeat both observations on the opposite side of the body, and in the same way mark the point where the lines

intersect. For if these two points—observed on the two surfaces—are imagined as joined by a line, the midpoint of that line will be the center of gravity sought. This is indeed true in regular bodies; but in irregular bodies more observations must be made to attain your aim.

COROLLARIES

from what has been said.

From this it follows that with all the bodies demonstrated up to now—spherical, cubical, cylindrical, prismatic, and the like—even if they are hollowed out so that the sphere leaves only a ring, the cube leaves only twelve solid struts connecting the cubic body, the cylinder turns into a tube, and the prism of any number of sides resembles a well—the center of gravity, conceived by the imagination in the empty space, will still be the same as it was in the solid bodies. Thus the center of a circular ring, of a hollow cube, and of the other figures will be the center of gravity in the imaginary middle, always supposing the homogeneous parts to be equal.

On the center of gravity that lies hidden in heterogeneous bodies.

CANON XV.

In a sphere made of uniformly heavy material, the center of gravity and the center of magnitude are the same, as we indicated above. But if it is composed of heterogeneous or dissimilar materials, the two can be either the same or different.

Three cases arise here. The first is when the whole globe is homogeneous, and then the center of gravity and the center of magnitude, as has been said, are always the same. The second case is this: suppose that in the following sphere—say, a leaden one—segments E F D and G C H are cut off from the axis A B at equal distances, and other equal segments are put in their place, but made of dissimilar material—say, of wood or wax. Let these named segments be E F D and G C H. If these segments are supposed to be of equal weight, then in the mutilated sphere they do not shift the center of gravity and magnitude; rather, they preserve the position the sphere first had when whole. The third case is this: if, the segment E D F having been removed, a segment of heterogeneous material is substituted in its place—of wood, wax, glass, metal, or gold—then once this is done the center of gravity will move from the axis A B toward C, coming nearer by as much as the substituted segment E F D is lighter; or toward F by as much as the substituted segment E D F is heavier than the material of the sphere. The center of

magnitude, however, always keeps its place, which is the center of the heterogeneous globe. These things are to be understood of all the regular bodies described above as well.

Diagram. A circle (representing the sphere in section) with a horizontal diameter A B drawn through its center. Near the top, a chord E D cuts off the upper segment, with F marked at the top of the circle above it; near the bottom, a chord G H cuts off the lower segment, with C marked at the bottom below it. The figure illustrates Canon XV's segments E F D and G C H.

- F (top of circle): apex of the upper cut-off segment
- E (upper left, end of upper chord): left end of the upper segment's chord
- D (upper right, end of upper chord): right end of the upper segment's chord
- A (left end of diameter): left endpoint of the axis
- B (right end of diameter): right endpoint of the axis
- G (lower left, end of lower chord): left end of the lower segment's chord
- H (lower right, end of lower chord): right end of the lower segment's chord
- C (bottom of circle): apex of the lower cut-off segment

CONSECTARIES

from what has been said.

From this it follows, first, that the center of gravity of any solid can be displaced from its place when something is added to it or taken from it, or when its parts are arranged in another way. Let the center of gravity of a cube A B made of uniform—that is, homogeneous—material be C. I say that it can be shifted in three ways. First, if a body E D B G is added to the given body: because if weight is added to the cube A B, a new center will necessarily recede from its place toward the added part. Second, what amounts to the same: if A E I R is taken away from A B, then since G B D E preponderates, the center of gravity C will likewise recede from its place toward B D. But if equal weights F R and E D are added to the intermediate body B F D A on either side, the center of gravity will remain unmoved at C, according to the laws of equilibrium [Greek: ἰσορροπίας (isorropias, "of equal balance," equilibrium)].

It follows, second, that a sphere—even if it is put together from segments of varied composition—still does not shift its center of gravity. Let there be a sphere A B C D, whose segments A E B and its opposite C H D are of wax, the other two A F C and B G D are of chalk, and A B C D, the innermost body of the sphere, is of lead. I say that even though the sphere is made up of segments of heterogeneous

material, it still shifts neither its center of gravity nor its center of magnitude. For since the segments A E B and C H D, equal and made of the same material—say wax—are of equal weight on both sides by hypothesis, the center of gravity C will not recede from its place, according to what Archimedes demonstrates concerning bodies in equilibrium. And the gypsum [chalk] segments A F C and B G D are likewise of equal weight. Therefore, since the globe is composed of opposite segments—even though of different weights—the center C will nevertheless not shift. Therefore, if the sphere, etc.—which was to be demonstrated. But if even one of the opposite segments were made of dissimilar material, then the center of gravity too would necessarily have to yield its place.

Diagram. A rectangular box (parallelepiped) drawn in perspective, illustrating the displacement of a cube's center of gravity. The center of gravity C is marked in the interior. Vertices are lettered around the front and back faces.

- E (top edge, upper left of front): vertex label
- B (top edge, front left): vertex label
- F (top edge, upper right): vertex label
- I (top edge, far right): vertex label
- C (interior center): center of gravity
- G (bottom edge, lower left rear): vertex label
- D (bottom edge, front left): vertex label
- A (bottom edge, front right): vertex label
- R (bottom edge, far right): vertex label

CAPUT II.

On the line of direction.

The line of direction is the line that directs the motion of heavy bodies, and it is conceived as drawn from the Center of the World to the top of the heavy body. For all heavy bodies are carried by their natural weight toward the middle, which is contained within the compass of the earth. And therefore, of all the things around us, some are moved while others are at rest; they are not moved because they are hindered and held back. But of those that are moved, some are hindered in their motion and others are unimpeded—just as is plain in water spread around the earth. For since water cannot descend straight down, it makes its way to the center by detours of descent, until, received into a suitable receptacle, it comes to rest; but if no obstacle stands in the way, it descends straight, joined to

its center. Now that line which directs such motion—or which would direct the motion if the obstacle were removed—is called the line of direction. This line must necessarily proceed from the Center, or tend toward the Center, which is the same thing; and it is nothing other than a line standing perpendicular to the horizon—or, what is the same, a line drawn from the pole of the horizon (that is, the zenith) through the Center of the World. The axis of the horizon, as astronomers call it, agrees with it exactly, and so the two are everywhere taken as the same. And if these lines are considered on the surface of the earthly globe, they are, as far as the senses can tell, parallel—as plainly appears in shadow-casting gnomons [gnomonibus sciothericis], which, however far apart in the day, are nonetheless reckoned parallel, with no harmful error in gnomonic work. This is also clear from the practice of architects, who lay out the walls of a building precisely parallel to the level [ad amussim], with no regard to the Center—although those walls, if drawn out to the Center, would no longer be parallel but would coincide in it. But on these matters see what we have written at length in Book 5 of the *Ars Magna Lucis et Umbrae* [Kircher].

PROPOSITION I.

All things that move necessarily move under the line of direction.

In every heavy body the center of gravity lies on the line of direction and moves along it, so that the center of gravity by its motion describes the very line of direction. For since all the parts of a heavy body, compared with respect to the center of gravity, are in equilibrium, the middle point of the heavy body will necessarily constitute the line of direction, while the remaining extreme parts of the body by their motion describe lines likewise parallel to the line of direction. Let there be a heavy spherical or cubic body A B, whose center of gravity is C. I say that the center of gravity C, by its motion to D, describes the line C D, which is the line of direction, while the points A B bounding the body describe lines A E and B F, parallel indeed to the line of direction C D on the surface of the earth, yet converging about the Center of the World, like all the parts of the heavy body, in the Center which they seek, nodding toward it. But if anyone denies that the motion takes place along the line of direction, let it then take place along A E or B F. But since those parts lie outside the middle line, and since no moment of equilibrium [Greek: ἰσορροπίας (isorropias, equilibrium)] can be established at B or A, it is impossible for the line of direction to be established at A or B. Therefore the line of direction is necessarily drawn through the middle point of the heavy body, which we have said is the center of gravity—which was to be proved.

Diagram. A circle with an inscribed square A B (top corners), center C marked inside, from which a long tapering vertical figure (like a pointed leaf or spindle) descends to a point D at the bottom; the lower corners E and F flank the descending lines. Illustrates Proposition I: the center of gravity C descending along the line of direction C D, with the bounding points describing A E and B F.

- A (upper left corner of inscribed square): bounding point of the body
- B (upper right corner of inscribed square): bounding point of the body
- C (center of circle): center of gravity
- E (lower left): point describing line A E
- F (lower right): point describing line B F
- D (bottom point): the point toward which C descends

PROPOSITION II.

The forward motion of a man must take place along the line of direction.

Let a man walk forward on the surface of the earth; I say that the forward motion takes place only under the line of direction. Let the surface of the earthly globe be A B C, its center D; let a man, or any other animal, be placed at the point F. I say that the man cannot walk by his natural gait except under the line F D, which is the line of direction. For along this path he would tend if he were to descend to the Center of the earth; therefore under this line he is truly and properly balanced and directed, to carry out his operations more conveniently. If anyone denies this, let him then go along the line F E; but since this lies outside the center of gravity and the line of direction, he will descend obliquely from the point I to K, and from K he will begin to ascend to E. Since these motions are not natural but violent—being outside the line of direction—it is impossible for anyone naturally to proceed except under the line of direction F D, which was to be shown.

Diagram. A large circle representing the earthly globe, with center D and several radii drawn from the center to the circumference like spokes. Tiny human figures stand on the upper rim at points I, K, and at the ends of the chord F...E; ships (or instruments) are shown at points C and G on the rim. A dotted radius D G descends vertically, and a dashed radius runs from D toward the upper right. Illustrates that men standing on the globe stand erect along radii (lines of direction) to the center D.

- B (top of circle): point on the rim
- I (upper rim, left of center-top): a man's position

- K (upper rim, center): point on the upper chord
- F (upper left rim): the man's starting position
- E (upper right rim): point toward which oblique ascent ends
- A (left of circle): point on the rim
- C (right of circle): point on the rim
- D (center): center of the world
- G (bottom of circle): point on the lower rim
- (additional small human and ship figures stand at the rim points, oriented radially)

CONSECTARY I.

From this it is clear why men or ships moving about the earth's surface are always erect, and on every side see all things above them—as at the points E, G, [F?]. Because, since they are heavy, they are necessarily carried downward, along the line of direction, to the Center, which all heavy bodies seek.

CONSECTARY II.

From this it is clear that every body resting on a point then stands, when the line of direction passing through the point on which it rests also passes through the body's own center of gravity; but it falls, if the line passes outside the center of gravity. Let the surface of the earthly globe be A D B, its center [D], the line of direction C D. Place, for example, a pyramid with its apex on the point D, so that the line of direction A C [?] passes precisely through the center of gravity of the pyramid at I. I say that the pyramid will remain erect; for since all its equally-weighting parts stand at an equal distance from the said line, and no parts can draw the rest toward either side, it cannot happen that, balanced in this way, the erect pyramid should fail to stand. But if the center of gravity declines from the line of direction C D even in the slightest, the pyramid must necessarily fall, since the parts on the side from which the center of gravity declines weigh more than the rest. But these matters will be further drawn out by examples in the following Proposition.

Diagram. A semicircle (dome) representing the earth's surface, with horizontal base A B and the base midpoint C; from the top of the dome a small triangle/pyramid F A G [with apex A above] stands balanced, its center of gravity I marked, and a vertical line of direction descends through D at the dome's summit to the center below. Illustrates Consectary II: a pyramid resting on point D, balanced when the line of direction passes through its center of gravity I.

- A (apex of the small pyramid at top): vertex of the balanced pyramid
- F (left base corner of the small pyramid): base vertex
- G (right base corner of the small pyramid): base vertex
- I (interior of small pyramid): center of gravity of the pyramid
- D (summit of the dome, foot of the pyramid's apex): the resting point on the line of direction
- A (left end of the dome's base): base endpoint [the base-line A B; the apex label A also appears at top]
- C (midpoint of the dome's base): base midpoint
- B (right end of the dome's base): base endpoint

CONSECTARY III.

From this it is also clear that a pike [sarissa] or huge spear, held balanced beneath the line of direction by the hand of a fencing-master [lanista], does not weigh down—except with the very lightest of all weights—nor does it fall: for since the length of the pike lies beneath the line of direction, all its equally-weighting parts will necessarily nod toward the Center, and consequently, with the skill of the fencer wielding the pike so as always to hold it straight beneath the said line, it will necessarily stand and will not weigh much. But if it declines even a little outside the line, it will at once acquire weight and the pike will fall; and the more it declines, the greater and ever greater the weight it acquires, until—parallel to the horizontal line—it can no longer bear any further weight. The reason for this is none other than that the pike O Y, held erect and resting freely on the palm of the fencing-master La[nista], has all its parts carried by natural motion toward the Center beneath the line of direction, and consequently acquires no weight. But if it is set outside the line of direction, as at A, then all the parts of the pike B C D E—being placed outside their natural position—must necessarily increase the weight, since each and every one of them weighs; and indeed by so much the more, the nearer it is to the horizontal, and by so much the less, the nearer to the vertical position.

Diagram. A woodcut showing a standing man in a hat and long coat balancing a long pike on the upturned palm of his raised hand. The pike rises diagonally from his hand at point O up to point I at its upper tip; along the inclined pike, points B, C, D, E [the latter near O] are marked, each dropping a vertical plumb-line of dots. Illustrates Consectary III: the pike held beneath the line of direction.

- A (upper left, start of the inclined pike) [recte: the inclined pike-line is labeled A at top-left where it leaves the page edge]

- B (along the inclined pike): division point
- C (along the inclined pike): division point
- D (along the inclined pike, lower): division point
- E (near the hand): division point
- O (at the man's palm): the point of support
- I (upper tip of the upright pike held vertically): top of the pike

CONSECTARY IV.

From this it is also clear why tightrope-walkers [funambulones] walking on a rope walk so steadily: because, balanced by the pole or transverse rod they carry in their hands, they walk continually beneath the line of direction. The result is that, with the ends of the rod or pole in equilibrium, the center of gravity—which lies on the line of direction—is also perfectly balanced, so that no fall need be feared.

PROPOSITION III.

Heavy bodies will then stand still, when the line of direction—drawn through the middle of the quantity on which the heavy body rests—passes through the center of gravity.

Let there be a heavy body A B C D, whose center of gravity is E, and let it rest on the quantity B C. So if the line of direction E F, passing through the point K, the middle of the quantity B C, also passes through the point E, then the heavy body will certainly stand still; for the parts of the heavy body that surround the point E are in equilibrium, and therefore they can neither draw those others nor be drawn by them. From which it comes about that the whole heavy body is at rest. But if the heavy body is increased on the other side by the quantity C D G, so that the center of gravity is H, and if the line of direction passing through the extremity C of the quantity B C, extended, passes through the point H, I say the body will likewise remain erect. The reason is that if the body rested on the point C only, by the second Consectary of the preceding Proposition it would stand. Nothing, therefore, can prevent it from standing, resting on the whole quantity B C. Again, if the line F C, extended, does not pass through the point H but advances it toward E, the heavy body, as before, will stand. For if the heavy body [on the point...]

Diagram. A solid figure drawn in perspective—a slab or wedge-shaped block A B C D with an added quantity C D G on one side—standing on a narrow base, with a long line of direction F descending below. Interior points H, E, K, Y and the base

points are lettered. Illustrates Proposition III: the body resting on quantity B C, with centers of gravity E and H and the line of direction through K.

- G (upper left, top of added quantity): vertex of the added block C D G
- S (upper right, top edge): vertex label
- D (upper front): vertex label
- A (right edge): vertex label
- I (left interior): point label
- H (interior): center of gravity in the augmented case
- E (interior, center): center of gravity
- Y (interior, right of E): point label
- F (lower, near base): foot of the line of direction
- K (base): midpoint of the quantity B C
- B (base, right): base vertex
- F (bottom, descending line): lower end of the line of direction

Liber I (Centrographicus), Sectio I

Caput II — De Linea directionis (continued)

[Continuation of the demonstration of Proposition III.] ...the point C can rest there, how much more, then, will it be able to stand resting on the line C K, on which the center of gravity necessarily lies? For it is impossible that a quantity A B C — whose center was E, now augmented on the side toward E — should draw the center of gravity back to the opposite side, namely toward E. Therefore the center will necessarily remain between the points H and E, the line of direction will pass between the points C and K, and so the body will stand.

From this it follows that if the center of gravity falls outside the space E E [recte: H E][?], for example at L or at V, and the line of direction is carried outside the line C K, the body will necessarily fall — since the quantity that is greater in weight will draw the lesser, and so it will fall on the side of G or of S, because the center of gravity is found in the heavier part, outside the line of direction F E [?]. Consequently the greater weight prevails, and so the body cannot keep standing.

Consectarium

From this it follows why one sometimes finds walls that seem on the verge of collapse, yet stand firm and unshaken forever. Of this kind is the leaning wall at

Rome, set into the walls outside the Porta Flaminia [Flaminian Gate], which everyone who passes shudders at, dreading at every moment that it is about to fall because of how steeply it leans. So, to let those unfamiliar with such matters understand more deeply the cause of the remarkable effect they marvel at, I have decided to give the explanation here.

Diagram. A rectangular block (the whole mass of the wall) seen in oblique view, A B C D F, with the upper face A L H B and a near vertical face that is "retorted" — leaning over — into a parallelogram, the inclined face E B C D. The line of direction G D runs down through the figure; G marks the center of gravity of the stone mass, set on that line of direction.

- A (upper left front corner): A
- L (top edge, left of center): L
- H (top edge, right of center): H
- B (upper right corner): B
- E [recte: P][?] (interior, just below H, top of the inclined face): label as printed
- I (left face, interior): I
- G (center of the figure): G — center of gravity of the whole mass
- C (lower right, foot of the inclined/leaning face): C
- K (bottom edge, left of center): K
- F (lower left corner): F
- D (lower right corner): D

Let the whole mass of the wall, then, be A B C D F, and let its leaning, inclined surface be E B C D, which deviates 20 degrees from the line of direction. Let the center of gravity of the whole stone mass be G, lying on that same line of direction G D. I say it is impossible for the wall E B C D to fall. For since the center of gravity of the whole mass is G, the part of the wall H B D C E will necessarily counterbalance the other part A H G D F. Consequently the wall, balanced beneath the line of direction, will stand — however much it is twisted and bent — since the part H B D C [recte; the leaning portion] cannot outweigh the rest, A H F D. But if the portion A L B K [?] were removed from the whole mass, then the portion H B C D E would necessarily fall, since the remaining part L H K D would be insufficient to resist the weight H B D C, the greater prevailing over the lesser. From all this it is plainly clear how the overhanging crags of mountains, and likewise towers, sometimes hold up under their own mass without falling. But on

these matters see our *Iter Hetruscum* [Etruscan Journey], on the Leaning Tower of Pisa.

Propositio IV

No motion or locomotive action can take place except under the line of central direction.

Divine providence, through its own art — that is, Nature — has so arranged the world that no locomotive action can occur without reference to the center. Everyday examples of this are not lacking in human movements. For what person could lean himself forward or backward, or to the sides, unless the line of direction — passing through the outermost part of the quantity he rests upon, on the side toward which he leans — also passes through the center of gravity of his body, or hangs over the quantity he rests upon? Otherwise he must necessarily fall. For this necessity Nature has provided, teaching a man, when he leans (as I said), to stretch his left foot backward, so that like the arm of a balance it counterweights the head. For, as I said, he cannot stand unless either the line of direction passes through the center of his face [?], or he extends [his foot] on the side opposite to the one toward which he leans.

For if someone joins both feet together and fits his whole body — back turned — against any upright wall, with his lower part kept against the wall, and then tries to lean forward, he will necessarily fall. From this he will learn that a man, guided by a kind of natural instinct, performs the things we have described whenever he leans. These same things happen to a man when seated; for there he has no need to direct his legs and the rest of his hanging body. But once he wishes to stand on his feet, it is necessary that the center of gravity of the whole body be as close as possible to the line of direction that passes through the feet he wants to stand on. And so he tucks his feet beneath his body and thrusts his head forward, so that he rises above his own feet, and, aided by his natural strength, raises himself up. Without this bending he cannot stand erect — especially if he rises too slowly, since the speed and impetus of the motion sometimes arises from these very movements, and brings it about that the others are not noticed by the senses.

The same must be said of people lying on the ground: if they want to get up, they first raise the head, then with hand or arm — as with a kind of lever — they raise themselves into a sitting position; then, drawing in the feet, and finally helped by both hands, they lift themselves into a standing posture. These actions are done for no other reason than that the body may fit itself to the line of direction and so

attain its end. As for the fact that tightrope-walkers [funambulones], stretched out flat like logs, seem to raise themselves in an instant with no advance preparation by any of the aforesaid methods — they appear to achieve this through long practice and speed of motion, which, just as it does not present the said actions to the senses, so too renders the spectators

deceived by the speed of the actions, and persuades them that these things are done without any adaptation of the body to the line of direction — although the said adaptation to the line of direction always intervenes, even if (as I said) it is imperceptible because of the speed of the action. I do not, however, deny that a practiced man can sometimes impart to himself such an impetus that he seems not at all bound by the laws of heavy bodies, indeed superior to them. But since this is a violent motion, we are not dealing with it here, but only with the natural motion of heavy bodies, which governs human actions that depend on local motion.

Propositio V

Four-footed animals cannot advance except under the perpetual support of the line of direction.

As in all other things, so in the progressive motion of animals the wonderful providence of Nature shines forth. For it has so constituted four-footed creatures that it is impossible for them to advance except by a diagonal progression of the feet. I explain the matter by the following figure.

Diagram. A tall rectangle representing the four feet of an animal seen from above (or in schematic plan): the two front feet A and B across the top, the two hind feet C and D across the bottom. Two diagonals cross from corner to corner, intersecting at the center G (the center of gravity). The horizontal line E F runs across near the top (the line of direction connecting the front feet); a corresponding line runs across near the bottom.

- A (top left): A — front foot
- B (top right): B — front foot
- E (top, on the upper crossbar): E
- F (bottom, on the lower crossbar): F [printed as Γ/F]
- G (center, intersection of the diagonals): G — center of gravity
- C (bottom left): C — hind foot
- D (bottom right): D — hind foot

Let the animal's four feet be A B C D: the two front ones A B, the two hind ones C D. I say that the animal cannot advance if the two feet on one side, B D or A C, are lifted at the same time. For in that case the line of direction E F does not coincide with the center of gravity of the said animal, which in a standing animal is found at the point G. Moreover, since the raised side E B F D would outweigh the other side A E C F, the animal would necessarily fall. Hence by Nature's marvelous shrewdness it comes about that two diagonally opposite feet always either rest on the ground or are raised — namely A D, or C B. For in this way the animal is perfectly balanced by the equipoise of the parts C B D and A B C about the center of gravity G and the line of direction E F, and so it advances without any fear of falling.

Here in the Roman Capitol there may be seen two huge horses of white marble, set at the top of the staircase, of which the one on the right as you ascend has its two lateral feet raised, the other two lateral feet resting on the pedestal [abacus] — which proves the great unskillfulness of the sculptor, since, by what has been said, it is impossible for a horse, or any other animal, to raise the two feet of the same side at one and the same moment without falling. Had he observed nature, he ought to have raised two diagonally opposite feet, with the rest resting on the pedestal — as was done in the bronze statue of the Emperor Antoninus mounted on horseback, in the square of the Capitol, an object of the highest admiration to all. In it the artist used better judgment, since he shaped the walking horse after the model of nature, so that only the two diagonally opposite feet are raised, the rest resting on the pedestal. This I thought worth adding here as the occasion arose, so that it may be apparent how much architects, sculptors, and similar craftsmen need judgment in representing nature.

Propositio VI

The motion of birds cannot take place except toward the line of central direction.

Nature too seems to have been by no means idle in providing the things necessary for the bird kind to carry out their actions properly. For whether they take food, or walk, or do anything else, it is always necessary that the rule of the line of direction, under which they keep their balance, be observed. As we know from daily observation, in order to take food on the ground they bend the feet forward while inclining the head toward the earth, so that in this way they may perform their actions more easily, well balanced.

Diagram. A small woodcut vignette in the margin: a long-necked, long-legged bird (a stork) in flight, neck stretched forward and legs trailing back, illustrating

how the bird balances its body about the center of gravity. No point-letters or labels.

When they fly, they are supported by their two wings as though by two props [fulcra], lest the whole body, preponderating toward the front or the rear, should tip over; rather, the body's weight is balanced evenly. This would not happen unless the line of direction passed through the prop and the center of gravity. And since different birds have different bodily constitutions, Nature did not fail to form them by such a method, and by such art to constitute the body, feet, tail, and wings, that they may carry out their operations unimpeded. For this reason Nature also gave longer legs to the longer-necked birds, as may be seen in storks: so that they may keep themselves perfectly balanced while flying, Nature taught them to stretch the neck forward and the legs backward by an equal interval, so that, accommodating the body to the center of gravity and the line of direction, they may continue their flight more conveniently.

Birds have been taught by Nature yet another way of balancing themselves. For when they wish to raise the front part upward and lower the rear, they extend the wings — that is, the props by which they are supported — toward the front; but when, on the contrary, they direct their flight downward, they draw the wings back toward the rear. By this means or that they easily bring it about that the center of gravity is shifted to another place in the flying body. By the same method, drawing back the wings on the side toward which the body inclines, birds are accustomed to balance themselves as if on a steelyard [trutina]. For they do what a man would do who removed a weight from the beam on which a balance rests, or removed the beam from the weight: in either way the weight would be brought into equipoise.

Propositio VII

Vegetable nature cannot grow except under the line of central direction.

Whoever considers with care the growth of plants will never be able sufficiently to marvel at the admirable wisdom of God, the supreme, best, and greatest, who has provided for them with so many and such great supports to preserve themselves, and has subjected them to the same laws of the line of direction, which they observe so earnestly that no violence can wrench them from this position. And so trees and plants alike raise themselves on high in a straight line by natural appetite — and this beneath the line of direction, since without it they would never attain their end. How persistent Nature is in preserving her own rights, the countless experiences made upon plants teach us. If you draw the

branches of a tree apart through the cracks of walls, as soon as they reach the open air, mindful again of their own right and seeking straightness from the horizontal position, they raise themselves on high.

Diagram. A woodcut: at the left, a tree or branching plant whose lower branches have been bent down and trained through and around a brick wall; a weight (a round ball) hangs from one branch. The upper shoots, marked G G, turn upward toward the light despite the constraint. The wall is the brick masonry at center; to the right of the wall stand two upright trees marked N and M, growing straight up from the slope/wall base.

- G, G (upper shoots of the trained tree, turning upward): G G
- A (on the tree, near the wall): A
- B (lower part of the trained tree): B
- I (at the foot, where the hanging weight is): I — the weight hung on the branch (cf. "in I" / "in L" in the text)
- N, M (the two upright trees right of the wall): N, M

as appears in the figure, at A G and B. But if someone hangs a weight on some branch, as at I [text: "L"], intending to twist it downward, the branch is still so tenacious of its own right that, as soon as the branch is bent, the topmost shoot G — not knowing how to tend downward — raises itself as much as it can and is allowed, so as to apply itself to its own line of direction. Here appears the persistence of nature in all trees and plants everywhere that emerge from the slope of mountains or the faces of cliffs, as is evident at N and M. Nature, then, willed them to grow according to the laws of the line of direction, without which they can never reach their end. For just as a man turned upside down cannot take food and drink, being set by nature in a contrary position, so plants cannot take, while inverted, the nourishment that is propagated upward from the deepest roots. Hence there is in them so great an appetite for turning upward that by no art can they be moved from it — sooner ready to die than to obey those who try to prescribe to them laws contrary to their nature. For a tree is the more stable the straighter it is; and since it cannot preserve itself without this straightness, it seeks the position agreeable to its preservation, which is along the line of direction.

To this is added that trees and plants, because they crave heat and life from the heaven and the stars, are carried up into the sky by a kind of natural instinct of motion, as experience abundantly teaches. For trees that are born in shady places rise higher than the rest, so that they may enjoy the kindly influx of the Sun's

heat. I have more than once marveled at the vehemence of this appetite. For trees and shrubs set among walls that face the North, as if weary of places uncongenial to their nature, if they find either a window or an open opening, send their branches by a kind of natural longing toward the Southern region — as being filled with more abundant heat — insinuating themselves through the said openings, so that warmed in this way by the kindly heat of the Sun they may attain their end. You would say they know, by a kind of instinct, how to discern what things are necessary for their own preservation.

It is remarkable what those curious about Indian voyages have observed concerning certain plants. The first of these (which they call *Sargassum*) is seen on the voyage of the Western Ocean, spread about like a meadow, and, agitated by the wind, it shows itself not fixed in one place but moved according to the storms, to be seen in various stretches. This plainly shows that it does not cling to the bottom by fixed roots, but, torn loose, lives in the midst of the water on the nourishment of the surrounding moisture, its roots detached from the bottom. Its stalk is of such size that it sometimes reaches 50 feet, with leaves two, three, or four palms in length raising themselves above the water — a marvelous prodigy of nature, with many broader leaves also unfolding to the surface of the water, struggling by a kind of hidden design of nature lest the root or the more extended stalk should press the leaves below the water by its weight.

The other is the rice [*Oryza*] of China, whose harvest is brought to completion not on land but in the very waters; whence it is first sown in pools of standing water, and, having conceived its fruit, sends its leaves up along a long stalk beyond the surface of the water, and, enjoying the free air, finally ripens into grain — to the great and sole benefit of the inhabitants. And this too is in this plant most worthy of admiration: that if the pools rise with the increase of the rains, then the plant itself also raises itself above the water in proportion to the increase of the waters. All of which I received from Fr. Martino Martini [Martino Martini], an eyewitness and most diligent investigator of Indian matters, who, while I write this, holds here at Rome the office of Procurator for China — things which are also described at length in his *Atlas Sinicus* [*Novus Atlas Sinensis*], which he published in print not long ago.

But you will object that some herbs depart from this law — such as wild thyme [*serpyllum*], ground ivy [*hedera terrestris*], and the like — which never seem to raise themselves perfectly, but, creeping along the earth's surface, while they never rise up, are held up by the foreign support of the ground. The same must be said of all the species of bindweed [*convolvulus*], of ivy, and of similar plants that

live by the support of trees or walls. I reply: there is no creeping thyme that does not crave to be raised upward; and since the leaves cannot do this, being without a stalk, the stalk

nevertheless — which bears the seed, flower, and fruit — always raises itself from the center of the plant, by whatever means it can, so that in this position it may preserve the propagation of its species, without which it would not attain its end. By the same reasoning, bindweed and hops [*lupulus*], since they cannot live without a stake [pedamentum], seek out foreign supports — shrubs, trees, and other stalks — that they may thence acquire both life and nourishment, seizing them by a kind of singular instinct. And bindweed indeed, by a marvelous industry of nature, when it cannot climb straight because impeded by the mass of its stalk or its flower-cluster [thyrsus], twists itself into spirals [helices] and forms a cone whose axis is the support [fulcrum]. For in this way, while in its oblique position, wound into spirals, it embraces the stake, it clings more tenaciously and more abundantly exerts its power in producing flowers and seeds. Ivy, however, by a kind of tyrannical force invades trees and the faces of walls, so that it may preserve, by the invasion of another's right, the life that it cannot obtain by its own weak stalk-constitution and feeble feet. From all this it plainly appears that nothing in the whole economy of vegetable nature lies hidden that does not direct itself to the line of direction, so as at last to attain the end prescribed to it by nature.

Propositio VIII

All natural operations of minerals in the subterranean world take place either toward the center or from the center.

In the Subterranean World, which is the matrix and receptacle of all minerals, besides water and fire — of which the latter tends from the center, the former toward the center — there are also juices, salts, mixtures of earthy faculties [facultates], metals, and stones of every kind, the origin of all of which depends on nothing but the center of the World. For the Subterranean World is like a kind of distilling furnace, in which fire and water joined together — by means of spirits, vapors, and exhalations, conveyed through innumerable channels into the hidden receptacles of the various mountains and subterranean caverns, which are like a kind of alembic — contrive all the workshops [officinae] of mineral nature. So it is that the moisture lurking in the bowels [of the earth] behaves after the manner of an active principle; from the reciprocal action and passion of these, the spirits latent in the earthy parts are roused, and, through vapors and exhalations, according to the nature and quality of each earthy portion, pour out

the essence of its mineral, the spermatic principle [ratio] of which that earthy portion contains.

Since all these things cannot take place except with reference to the center, it has been wisely provided by nature that light things should tend from the center to the circumference, while heavy things — such as moisture — should, on the contrary, tend from the circumference to the center. For from a marriage of this kind, with nature mediating as bridesmaid [paranympa], the generations of all subterranean things must necessarily flow forth. But since we shall be treating of these matters expressly in the whole third book, it has seemed superfluous to describe so large an argument more fully in this place. Therefore let it suffice to have demonstrated here that all actions of the subterranean world necessarily bespeak a reference to the center of the World. For if you take away the center, then, as we demonstrated above, all things will be at rest, all bodies will be devoid of motion; and with motion ceasing, the generations of all things must necessarily cease. Therefore the sole and single cause why light things tend upward and heavy ones downward, to bring about subterranean generations, is the center of the Earth.

Caput III — Paradoxa de Centro Terræ

Paradoxum I

How a wooden, circular, elliptical, square, or triangular bridge, hung in the air, can be built without any support.

I suppose first that the entire Earth, in the vicinity of the center, is hollow for many miles. This being granted, if around the center of the Earth a wooden or stone bridge, circular or elliptical, is built, I say that it will stand in the air without support.

Let there be around the center of the Earth I a wooden bridge A B C D, all of whose parts, since they incline toward the center, terminate at I. Being equally balanced, it will necessarily hang in the air, gravitating equally on every side. But if anyone should deny this — let it then rest at some one of the points A B C D. But since at none of the said points is the center of gravity of the whole mass (by Canons 1 and 2), it cannot rest there either.

Diagram. A ring-shaped bridge drawn as a double-walled circular masonry band (a circular bridge with crenellated/buttressed projections around the outer rim), with the center of the Earth marked I at its center. Four cardinal points are lettered around the ring: B at top, C at right, D at bottom, A at left.

- B (top of the ring): B
- C (right of the ring): C
- D (bottom of the ring): D
- A (left of the ring): A
- i (center of the ring): I — the center of the Earth

Rather, by the isorropic [equilibrium] laws, all the parts will accommodate themselves to the center of the middle — that is, the center of the world — which we have amply shown above to coincide with the center of gravity, so that they may there obtain a firm state;

Liber I (Centrographicus), Sectio I, Caput III — Paradoxa de Centro Terræ (continued)

since it is impossible for it to stand in any other way. A wooden bridge, then, built in a circle — or of any other material whatever — will necessarily stand in the air around the Earth's center without any support, which is what was to be shown. The same would happen if a ring or a huge wheel were thrown into the Earth's center. The same would happen with a bridge built in an elliptical form, with this one difference: only the four points A, B, C, D would have a level surface, while the remaining surface — from B and D toward C, or from B and D toward A — would slope upward and present something mountainous. So men at H and M, even though they are in opposite positions on the elliptical surface, would both be climbing uphill, until they reached one of the four named points A, B, C, D, where they would stand on a level surface.

Diagram. An elliptical ring-bridge, drawn with a serrated (brick-like) outer band, encircling the Earth's center. The center is at the meeting of several radial lines. Two small human figures stand on the inner rim of the right side, each leaning toward the center.

- B (top of ellipse): vertex label
- A (left of ellipse): vertex label
- C (right of ellipse): vertex label
- D (bottom of ellipse): vertex label
- H (upper-right inner rim): position of one man
- M (right inner rim, below H): position of the second man

CONSECTARIUM (Corollary)

[p. 53]

From this it is clear that if some bridge of square or prismatic form were built around the Earth's center, it too would hang suspended in the air. For since the center of gravity of a square and of an equilateral triangle is the same as the center of magnitude — as we demonstrated above (Canon 1) — a bridge built according to the laws of such bodies will necessarily hang in the air. For with each and every part of the mass leaning toward the center with equal force, the bridge will stand in equilibrium, since there is no reason why it should lean toward the center more on one side than on the other. But suppose, if it were possible, that the portion A B D M of the bridge N B H M leaned toward the center I more than the portion N H A D. In that case the equal would surpass the equal: those parts would counterbalance and yet not counterbalance — which, being absurd and contrary to the hypothesis, proves the opposite. Therefore, with the parts all around counterbalancing one another and tending toward the center with equal force, a bridge of square shape will remain suspended in the air, which is what was to be shown.

Diagram. A square with an inscribed circle. The square's corners are lettered, the center of the circle marked, and a diagonal is drawn from one corner toward the center.

- A (top side, center): label on the top edge
- N (top-left corner): corner label
- B (top-right corner): corner label
- E (left side, middle): label on the left edge
- C (right side, middle): label on the right edge
- I (center of the circle): the center
- H (bottom-left corner): corner label
- D (bottom side, center): label on the bottom edge
- M (bottom-right corner): corner label

The same must be said of a triangular bridge A B C D E F. The difference, however, between progressing across a square or a triangular one is this: a person walking across the square bridge would find a level surface only at the four points A, C, D, E [recte: at the four corners] — for going from A toward B he would climb steadily, and from B toward C he would descend steadily — and the same holds for the triangular bridge A B C D E F: at the points B, D, E [recte: B, D,

F] we must imagine a level surface, from which one would always climb or descend toward A, C, E. Thus the four corners of the square structure, or the three of the triangular one, behave like mountains, whose roots are at those points (or, in the triangular one, B, D, F), while their peaks are at the square's points B, H, N, M, and in the triangular one A, E, C [?] — since departing from the circular plane is nothing other than either climbing from the plane upward or descending from the height to the plane.

This same principle also appears on the surface of the terrestrial globe in the case of mountains: the steeper they are, the sharper the angle that the line of direction, along which we walk, makes with the slope of the mountain. Consequently a person must wrench his whole body violently toward the line of direction; and this wrenching, being violent, is contrary to nature. It is no wonder, then, that a person is so worn out in climbing steep mountains.

Now, what we have said about bridges to be set up immediately around the Earth's center must also be said of similar structures to be built in the air around the Earth's surface. But let us demonstrate the matter. Suppose that, by divine power, a triangular bridge A B E D F C [recte: A B C D E F] were built around the Earth's surface C B D, and that lines of direction were now drawn toward the outermost surface of the bridge. It is certain that a person advancing from B toward A would be climbing steadily as though up the highest mountain, and could nowhere stand upright except at the points E, B, D — namely, where the line of direction strikes the sides of the bridge at right angles. But as he advances, as the lines of direction between E and A show, he can no longer stand upright on the surface of the bridge, and the lines of direction no longer fall perpendicularly on the side of the bridge. Instead they make angles with the sides of the bridge that grow sharper the closer he comes to the apex A. Hence it follows that a person...

Diagram. A triangle with an inscribed circle, set over the Earth's curved surface. From the apex region a fan of "lines of direction" radiates outward to the bridge's surface, each topped by a tiny human figure standing perpendicular to its line; figures stand at various points up the sloping sides.

- A (apex, top): triangle vertex
- E (left base region, inner): point where the line of direction meets the side perpendicularly
- E (right side, inner) [?]: the text names points E, B, D as the perpendicular-incidence points; the right-side label appears to read E
- F (bottom-left corner): corner label

- D (bottom, center): base label / perpendicular-incidence point
- C (bottom-right corner): corner label

so that, to keep himself within the arrangement of the central line, he must bend his body toward the slope and stand on the very tips of his toes — since on a mountain slope it is impossible to stand upright without danger of falling.

CONSECTARIUM (Corollary)

[p. 54]

From this it is clear that at the Earth's center no structure fit for human use can exist except a circular one.

PARADOXUM II (Paradox II)

[p. 54]

Fire, water, sand, and other fluid bodies at the Earth's center will at once shape themselves into a sphere.

Suppose that, by divine power, a great quantity of water were conducted through a channel into the Earth's center. I say that at the Earth's center it would at once shape itself into a sphere. For since the center of gravity of any homogeneous sphere is the same as its center of magnitude — as we showed in the first Canon — it is certain that the water cannot stand in any other way than under the form of a watery globe. For suppose, if it were possible, that it stood under the form of a square or of any other figure whatever: then the water in this state would stand around the corners of the square against nature and by force. But this is absurd. Therefore it will necessarily shape itself into a globe. For in this position the individual parts, leaning toward the center with equal force, will support one another more perfectly and will stand counterbalanced on every side. The same must be said of fluid sand.

CONSECTARIUM EXPERIMENTI (Corollary by experiment)

[p. 54]

From this it follows that if someone were to put into a spherical flask four liquids of different kinds — representing the four elements by their weight and lightness, as we taught should be done in our *Ars Magnetica* — experience teaches that, at the Earth's surface, these liquids lie parallel to the horizon, one resting upon another, in such a way that: the heaviest, representing earth, holds the lowest

place; the second, of an airy color, representing water, holds the second place in the flask, above the earthy liquid; the third, airy, holds the third place above the watery one; and finally the fourth, fiery, occupies the fourth and topmost place in the flask above the airy one. And so they all stand distinct and unmixed on the Earth's surface, holding the position that flask A B exhibits.

Now let someone descend with this flask, by divine power, toward the Earth's center. I say that the more these liquids approach the Earth's center, the more they contract into less perceptible arcs. But when the flask reaches the Earth's center, then the individual liquids — according to the position they hold around the Earth — will compose themselves spherically: so that the earthy liquid contracts into a complete sphere, while the three remaining liquids, surrounding it, each compose themselves around the earthy one according to a certain analogy commonly conceived among the elements, as figure H here appended sufficiently demonstrates.

The reason is plain from what precedes. For since these liquids are unmixable, and one always heavier than another, the heaviest — earth — will necessarily accommodate itself in the manner of a sphere, its parts of the same kind leaning toward the middle. The watery liquid, resting on the heavier one, since it cannot be mixed with it, will form itself into a ring-shape around the earthy globe; the airy around the watery; and the fiery around the airy — by a certain wonderful artifice of nature. And this can happen nowhere except at the Earth's center, and perhaps in imaginary space outside this sensible world, if the said flask were carried there by divine power. See what we have treated more fully on these matters in the *Ars Magnetica*, Book 3.

Diagram. A spherical glass flask ("phiala") on a turned pedestal foot, shown at the Earth's surface, with a stopper at top (A) and the base joint at the foot (B). Its interior is divided into four horizontal bands, each engraved with a label and small naturalistic figures (flames at top, birds, a sailing ship in the watery band, plants at the bottom). The bands, top to bottom, are lettered C, D, E, F down the left edge.

- A (top, stopper): label of the flask's mouth
- B (foot, base joint): label of the flask's base
- C (top band, left edge): *Ignæus liquor* — "fiery liquid" (with flames)
- D (second band, left edge): *Aerius liquor* — "airy liquid" (with birds)
- E (third band, left edge): *Aqueus liquor* — "watery liquid" (with a sailing ship)

- F (bottom band, left edge): *Terreus liquor* — "earthy liquid" (with plants)

CONSECTARIUM II (Corollary II)

From this the empty and stupid boasting of certain alchemists is exposed — those who pride themselves that, by means of chemical liquids conglobated into spheres, they can represent in a glass sphere the whole artifice of nature (that is, the orbs of the sensible world), and so the entire fabric of the universe, outside the Earth's center. Since this exceeds the limits not only of human but even of angelic power — being reserved to the power of almighty God alone — I cannot sufficiently marvel at the crude ignorance of men of this sort, who are not ashamed to pour out such enormous nonsense upon the world. Either, when they think such things, they convince themselves they are not in error; or, when they see that they are in error, they more confidently imagine to themselves that their flagrant deceptions cannot be detected by true philosophy. Let there now cease, then, that empty preconceived opinion held among the common people about so insane a chemical work, and let them be firmly persuaded that it cannot be accomplished except at the Earth's center.

CONSECTARIUM III (Corollary III)

[Margin: *Infernus in Centro* — Hell at the Center.]

If it is true — as is handed down by the nearly unanimous consensus of all the holy Fathers — that Hell was established by God in the lowest place of the Earth, so that those who by the weight of their sins removed themselves as far as possible from God should deservedly occupy the last and most remote place in the sensible world; and since this place can be no other than that vast Abyss of a fiery crater set around the Center of the universe — then it is plainly clear from the premises that, after the universal resurrection of the flesh, the bodies of all the damned must be heaped together into a single globe, since no surface can there be conceived except a circular one. Therefore, just as herrings are packed in a cask, so they, conglobated, will endure punishments worthy of their sins — as long as God shall be God, that is, without any end — the harsher the closer they are to the Earth's center, throughout all eternity.

Let the Christian mind learn from this to draw back from sins and to pursue the good, lest, by the sentence of the most just Judge, it be cast headlong into this most horrible place of torments, into this dreadful pit of perpetual darkness — where, with all the bars of the earthly mass shut fast, no light ever shines, no day

breaks — and pay the penalty of everlasting horror. But let these things, said in passing, suffice.

PARADOXUM III (Paradox III)

[p. 55]

At the Earth's center no one will be able to stand on his feet or hold himself upright.

For since (as we showed in what precedes) all heavy bodies at the Earth's center arrange themselves according to the center of gravity, and since the center of gravity cannot lie in the feet — the extremities of the human body — it follows necessarily that a person will adhere to the Earth's center by the navel, or by the part near it, as appears in the figure. From this arises another paradox: that a person, stretched out in this position, will, with both halves of his body — feet on one side, head and chest on the other — tend upward at one and the same time.

But if, by divine power, a leaden globe of proportionate size — say six or seven feet in diameter — were set up at the Earth's center, I say that a person, since the globe would not resist by its weight, would stand on it in a natural posture and could walk around it, as appears in the figure.

Diagram. A circular globe seen in cross-section, with a man standing upright on top of it (his feet at the top, head above), poised on a horizontal bar spanning the top from A (left) to B (right). Arrows point outward in four directions (up, left, right, down), representing the lines of direction radiating from the center.

- A (left end of the top bar): endpoint of the horizontal line
- B (right end of the top bar): endpoint of the horizontal line
- N [?] (top center, near the bar): a small label appears at the top center; reading uncertain

CONSECTARIUM (Corollary)

[p. 55]

From this it follows also that if, upon the said leaden globe A B, a surface equal to its diameter were superimposed, a person could stand upright nowhere except at the middle point of that surface. Likewise a small globe N thrown onto that surface would come to rest nowhere except at that single point through which passes the line of direction drawn through the middle from the center — which is the shortest of all the lines drawn from the Earth's center to the surface. Again, this small globe would rest at any point of the leaden globe placed beneath it,

since it is everywhere equidistant from the center by an equal interval, and the line of direction is everywhere the same. All of which is clear from what has been said.

PARADOXUM IV (Paradox IV)

[p. 55]

A person placed at the Earth's center could neither eat nor drink.

Suppose that, by divine power, someone were placed at the Earth's center in such a way that his mouth coincided with the center's midpoint. I say that he could neither eat nor drink in this position. For since in this position his whole body, whichever way it is turned, is inverted, and his head always rests at the Earth's center, he will be able to pass neither food nor drink into his stomach — inasmuch as, being wholly inverted, he tends upward on every side by his feet. Yet as soon as his head emerges from the center, even by the distance of a foot, he will then indeed be able to swallow, but only up to the part that corresponds to the center, and no further; for he will always pass food the better, the further his mouth is from the center. But these things are clear.

PARADOXUM V (Paradox V)

[p. 55]

If the whole terrestrial globe were cut horizontally through the Earth's center — that is, diametrically — then in this cut plane, by mathematical position, only one person could stand upright in a natural posture; by physical position, several.

Suppose the surface of the terrestrial globe is cut horizontally, or in any manner whatever, as A B C D. I say that on the said surface only one person can stand upright in a natural posture by mathematical position — namely at the center E. For since all the lines of the said surface tend downward into the center, it is impossible for anyone to plant himself firmly at any point other than the center. For suppose someone tries to support himself on the line A E or C E: but since those lines...

Diagram. A disk-shaped slice of the terrestrial globe, seen in oblique perspective (its thickness shown as banded layers at the bottom edge), with a man standing upright at the center, arms outstretched. The rim is lettered at four points.

- B (top, far edge): rim label
- A (left edge): rim label

- C (right edge): rim label
- D (bottom, near edge): rim label
- E (center, at the man's feet): the center point

are lines of direction, he could plant himself firmly on them and yet not plant himself firmly — which is absurd and impossible. Therefore he will stand in a natural posture at the center of the said surface alone. With this qualification, however: if on the said surface he is given a perpendicular position, he could stand on his feet; but if he obtains a position parallel to the vertical plane, he will then adhere to the Earth's center in a natural posture not by his feet, but by his navel. The reason is that one standing perpendicularly on a plane has something beneath him to be supported by; but if he has a position parallel to the vertical plane, he will not then be able to stand on his feet, but his body will be fixed at the center according to its center of gravity — as appears in the second figure, where the plane L M N O is exhibited in a perpendicular position. There it clearly appears that a person can nowhere stand upright on the line L N, nor indeed stand on his feet even at the center S, but his body will first be fixed when the center of gravity of the heavy body corresponds to the Earth's center. All of which is clear from the figure.

Diagram. The slice of the terrestrial globe shown edge-on (a vertical plane), drawn as a disk seen from the side with banded layered thickness. A man lies/floats across it horizontally through the center, his body parallel to the plane. The plane's corners/axis are lettered L (top), M (left), N (right) [?], O, with the center marked S.

- L (top): label of the vertical plane L M N O
- M (left): plane label
- N (right) [?]: plane label; the text names the plane L M N O and the line L N
- O [?]: fourth corner label of the plane (not clearly visible)
- S (center): the center point

CONSECTARIUM (Corollary)

[p. 56]

From this it follows also that, in whatever way the terrestrial globe is cut — whether perpendicularly, horizontally, or at a sloping angle — the same result always follows. For a plane of this kind will always obtain a position perpendicular to the center. Hence we have called the plane A B C D "horizontal" only insofar as it appears such to our imagination, even though it is in no way

horizontal but is a perfectly perpendicular surface. For just as no one can naturally and freely stand on a wall or flat partition built up to him, so neither can he stand on the said surface, which behaves like some vast wall, perpendicular on every side; the middle of it is the Earth's center.

PARADOXUM VI (Paradox VI)

[p. 56]

At the Earth's center, any wheel set turning will be carried neither upward nor downward.

On the Earth's surface no wheel can be turned without one of its halves always ascending and the other descending. But at the Earth's center the said wheel, when turned around, will be carried neither upward nor downward, but will always keep the same position relative to the Earth's center, from which it is everywhere equidistant and which it everywhere counterbalances. Nor will there be any difference among its parts — right, left, oblique, upper, or lower. Moreover, into whatever direction it is turned, it always rests in that position, since it inclines no more to one side than to another, but is indifferent to every position in which it is placed.

CONSECTARIUM I (Corollary I)

[p. 56]

From this it follows that if the buckets of a mill-wheel, standing perpendicular, were filled with water, the wheel when turned would pour out none of the water it holds — since all the buckets press straight toward the center.

CONSECTARIUM II (Corollary II)

[p. 56]

From this it also follows how — something that many of the ancient Fathers could not conceive — the Antipodes move in a natural posture with their feet opposite to ours. Let A B C D be the watery-terrestrial globe; let the Antipodes be F G, E S [?], who walk with their feet turned toward us. I say that they walk in a natural posture, because each opposite part inclines toward the center D through the lines of direction F D and S G. The same must be understood of ships, since they all tend on every side toward the Earth's center along the lines of direction beneath which they are carried. Nor — as simpler folk falsely imagine to themselves — is the falling of men or ships on the parts opposite to us to be

feared. So if certain of the ancients had known the nature of the center, they would not have reasoned so unskillfully about some Abyss and whirlpool of the Earth, which they imagined to exist below the horizon.

PARADOXUM VII (Paradox VII)

[p. 56]

At the Earth's center, two men tending toward opposite parts will both ascend naturally.

Let A be at the Earth's center, with a ladder B C set against it. I say that from the center A two men — one of whom ascends from A toward B, and the other from A toward C, at one and the same time — both, although they ascend toward the opposite parts A and B [recte: B and C], nevertheless ascend naturally. The reason is clear of itself.

Diagram. A circle (the Earth's center region) with a vertical ladder running across it from B (top) to C (bottom), the center marked A on the ladder's midpoint. Two small human figures climb the ladder — one above the center, one below — each oriented to climb "upward" away from the center in opposite directions.

- B (top of the ladder): upper endpoint
- A (center of the ladder/circle): the Earth's center
- C (bottom of the ladder): lower endpoint

The ladder, too, moved into whatever direction, will there have its natural position.

PARADOXUM VIII.

The flight of any bird around the Center of the Earth will be easiest and most natural either along a circular path or along a helical line; every other motion will be violent.

A bird will move around the Center of the Earth with a natural and easy motion when it moves along a circle or a helical line. This is clear in the case of circle A, which the bird traces out in its flight, because in this way it sustains no violent motion. Violent motion is what happens to birds when they are carried upward. The same must be said of flight along a helical line: since that line is composed of the circular and the inclined, it will accelerate the flight most of all, and the bird cannot make for the Center of the Earth more easily than along this line. But if it were to move along the line A–B, I say that the bird would undergo nothing but

violent motion. From D it would be carried upward toward A or toward B along a straight line, which is most violent for birds; and the most violent of all is motion along a perpendicular line, so that there is scarcely a bird that could sustain it. Hence, by a certain instinct of nature, all birds in their flight prefer the helix, whether they are heading upward or downward. For this reason, a bird would remain fixed at the very Center of the Earth: since nothing is so contrary to birds as perpendicular upward motion, and at the Center of the Earth there is no ascent except along the perpendicular, the bird would stay put there — held back both by the difficulty of the ascent and by its own Center of Gravity.

Diagram. A bird's flight path drawn as a spiral (helix) winding inward toward the central point. A horizontal straight line runs across the top of the figure from A on the left through D at the center-top to B on the right. The spiral coils inward to a small central point marked I (the Center of the Earth). Two small birds are drawn on the spiral curve, illustrating the natural helical flight path.

- A (upper left): left endpoint of the horizontal straight line
- D (upper center): midpoint of the horizontal line, above the center
- B (upper right): right endpoint of the horizontal straight line
- I (center): the central point (Center of the Earth), toward which the spiral converges

PARADOXUM IX.

If the seed of some plant were thrown into the Center of the Earth, it would flower out in every direction into the shape of a radiating star.

If seeds of some plant, embedded in a mass of earth, were thrown into the Center of the Earth, I say that they could flower out only in the form of a radiating sphere. For since individual plants are naturally carried upward along the line of direction — as was also stated above — and at the Center of the Earth the lines of direction point upward in every direction, the seeds sprouting along them would raise their stalks spherically, since they cannot achieve their end under any other arrangement.

Diagram. A small woodcut showing a star-shaped or rosette arrangement: stalks radiating outward in every direction from a central point, like the petals of a flower or the rays of a star, illustrating how a seed planted at the Center would sprout outward in all directions to form a radiating sphere. No labels.

PARADOXUM X.

Fire kindled at the Center of the Earth is spherical.

For since fire by its nature is carried upward, and at the Center it would be conceived as moving upward in every direction, it would necessarily, being diffused in all directions, take on a radiating body.

PARADOXUM XI.

On establishing a perpetual motion at the Center of the Earth.

I cannot pass over at this point the empty contrivances and notable fallacies of certain people who suppose — indeed strive to demonstrate — that an artificial perpetual motion can be produced in a certain way at the Center of the Earth. They try to show it by the following argument.

First, let two supports G–K and H–I be set up, together with the axle G–H. Around this axle let a gnomon A–B–C, with a leaden globe C fixed to it, be applied in such a way that it can revolve about the axle by its pivot A. This being set up, they say it will come about that the gnomon A–B–C, once set in motion, will perpetually continue its motion about the axle G–H, driven in the circle B–D–E–F. They assign as the reason for this that the leaden globe fixed to the gnomon — since, being impeded, it cannot descend toward the Center A along the line of direction C–A — perpetually presses by its own weight toward D; and thus, since the motion, weighed down by the load, can come to rest nowhere as it passes from D toward E, and from F toward E, and from there toward B, it will repeat the circle again and again with an ever-new revolution, in a perennial motion. In this way, then, they falsely persuade themselves that a perpetual motion can be produced about the Center of the Earth.

Having very often observed this device — so impressive at first sight — I could not help laughing at the deceptive illusions of the human imagination. And so, since this is contrary to the propositions I have set down in this book, I decided it should be refuted, so that henceforth others may not wear themselves out in the useless labor of demonstrating it.

Diagram. A schematic of the proposed perpetual-motion machine. A large circle is drawn, at whose center is point A. Across and within the circle runs the gnomon (a rigid arm) with its parts labeled, carrying a leaden globe; the supports and axle frame the device. The circular path traced by the arm is marked by points B, D, E, F around the circle.

- A (center): the Center, the pivot point of the gnomon
- B (top of circle): top point of the circular path; upper end of the gnomon arm
- C / d (upper right): the leaden globe fixed to the gnomon (drawn as a small circle at upper right)
- I (between B and A, upper area): a point on the gnomon/arm near the axle
- E (left of circle): left point of the circular path
- D (right of circle): right point of the circular path
- d (left-center, on inner arm): a labeled point on an inner arm of the gnomon
- F (lower part of circle): lower point of the circular path
- G–H (center region): the axle, about which the gnomon revolves (H marked near the center-right)
- K (lower left): lower end of support G–K
- L (lower right): lower end of support H–I (marked at bottom right)

The supports G–K and H–I are drawn as two vertical bars descending below the circle to K (left) and L/I (right).

First, then, they set up two supports G–H [recte: G–K], H–I, together with the axle G–H, and they suppose that the axle and the supports have the same position about the Center of the Earth that they have on its surface — which is the mockery of a ridiculous and false imagination. For if the supports could be arranged about the Center of the Earth, they would certainly not be allotted a perpendicular position, as they have on the surface of the Earth, but the opposite: namely, an oblique position, sloping upward. In the same way, one half of the axle, G–A, and the other, H–A, would both tend upward alike. If, then, plumb lines fitted with leaden balls were attached at G and H, the extreme ends of the axle, it would clearly be seen that, given the position of the supports, these balls could by no means fall downward, since they lie outside the line of direction. They would therefore fall into the Center A, where they would come to rest. The supports, then, since they would tend upward against nature, cannot stand up.

Having shown this, let us now see whether a gnomon revolving about the axle G–H can produce a perpetual motion. Let it move, then, if it can, from C toward D through the arc C–D. But since this motion, being violent, lies outside the line of direction A–C, it is impossible for it to continue its motion without a fresh impulse. The gnomon will therefore come to a stand, together with the globe fixed to it, at whatever point of the circle B–D–E–F. This I show as follows. Since the

whole assembly of the gnomon A–B–C behaves as a single solid mass, by Definition III and Canon 4 its Center of Gravity will be at I; and consequently, wherever it is placed, it will come to rest, because the Center of Gravity I conforms perfectly to the line of direction. As was fully demonstrated in the first Section, a thing cannot move of its own accord into points [outside the line of direction], unless it is drawn into it.

Nor does it bear at all on the matter that the globe is falsely supposed to preponderate and always to strain forward. For preponderation of this kind does not come about by a natural motion forward, but toward the Center A, along the line of direction beneath it — as is also plainly established from the preceding paradoxes. For if a channel were made about the Center of the Earth, twisted into the circle B–D–F–E, and a globe were placed in it, it is certain that the globe, once set in motion, would not be moved perpetually, but would come to rest at some point of the channel. The same is to be understood of water poured into the channel: it would not flow, but would hold itself at rest along the lines of direction, without motion. Therefore what I assumed at the outset — that perpetual motion at the Center is, in the manner described, impossible — is what was to be demonstrated.

SECTIO II.

PHYSICO-MATHEMATICA.

AND IT IS

On the motion of heavy bodies toward the Center of the Universe.

PREFACE

Since all heavy bodies are carried toward the Center by a certain innate appetite, if there were no Center, all motion too would cease, since the heavy body would have nothing it sought. If there were no Center, the locomotive power would also cease, since — as we demonstrated above — no locomotive action can be produced without an essential reference to the Center. If there were no Center, light bodies would not tend upward, because there would be no motion from the Center to the circumference, just as there would be none from the circumference to the Center in heavy bodies. The Center, therefore, is the cause not only of local motion, but of all elementary motion. But what this motion properly is, and how it is accomplished, we have decided to set out in this Section.

CAPUT I.

Definition of the local motion of bodies, and of impetus.

We are not dealing here with intrinsic motions, which are those of the intellect, of the will, and of the various affections of the soul, but with the local motion of things, natural and violent, whether intrinsic or extrinsic: with rectilinear and circular motion, and finally with mixed motion — mixed both from the natural and the violent, and from the rectilinear and the circular — and with reflected motion; in short, with all motions that cannot be produced without reference to the Center.

The natural downward motion of heavy bodies is an intrinsic appetite toward the Center of the Earth, which all things seek. It is not, as some have persuaded themselves, due to an attractive force of the Earth, nor to some rarefied matter that solicits the heavy body to motion, nor to air set in motion and driving it back from behind (as Pererius [Benito Pereira] holds), nor to some gravity superadded to the stone during its very motion (as some Peripatetics hold). Rather, as I said, it is due to an innate appetite, whose whole force comes from impetus or impulse.

But before we proceed further, let me make clearer the nature of impetus or impulse. It should be known that impetus or impulse is nothing other than a certain quality that demands the motion of its subject. For since the motive potency and faculty is active, in order that it may produce something, it is necessary [that it produce something]; but it produces nothing other than impetus. Therefore, without impetus, a heavy body could not move naturally. Impetus or impulse is therefore necessarily connected and connatural to the motion of heavy bodies — even though it is something distinct from the substance of the moving body, since a moving body at rest can exist without impetus, whereas one actually in motion cannot be conceived without impetus.

From this I conclude that impetus produced from without is not produced by a quality, nor by a resisting power, nor by anything other than impetus, which is most of all the connatural cause of another impetus. Yet it acts upon what is external only insofar as it removes an impediment. Hence, according to the differing nature of the impeding object, it acts now more, now less — and most of all when the impediment is greatest.

From this it follows, secondly, that an intense impetus can produce a remitted impetus, if the impulse of a smaller moving body is carried into a larger one; and a remitted impetus can produce an intense one, if the impetus or impulse of a

larger moving body is carried into a smaller one. But if the moving bodies are equal, they will produce an equal impetus — which happens most of all when the Centers of Gravity of both moving bodies are connected by the line of direction, as will later be demonstrated.

Thirdly, since there is a natural downward motion of heavy bodies from an intrinsic source, it cannot exist except from an impulse — both because its acceleration cannot be explained without an impulse, and because a heavy body falling downward imprints an impulse on a body it meets, which would not happen if it were devoid of impulse from within. And so, that motion is naturally accelerated is plain even from this: since motion in a free medium is not impeded, and the impulse produced in the first instant is not preserved in the second instant by the cause that first produced it but by another — and since the cause is the necessary cause of the moving body's substance — certainly in the second instant it produces a new impulse; and the same is to be said of the third, fourth, and fifth instant. As the cause of motion thus grows, the motion itself also grows. Hence, in equal times, equal increments of velocity are acquired, because a necessary cause in equal times produces an equal effect.

§ I.

The true account is set out: why a heavy body in motion is faster at the end.

The motion of heavy bodies, like the motion of all things, has rightly tormented the minds of philosophers; and so it must also be explained with the greatest care, so that the most hidden cause of so plain an effect may be known.

I suppose, first, that the active principle of motion and the active principle of gravity are, as to the thing itself, identical; and I say that this principle is nothing other than a propensity, in first act, of tending toward something. Motion and gravity, on the other hand, are of second act, and are diversified as effects from that one principle — in much the same way as, on the Peripatetic view, light and heat produced by the Sun are different effects of one principle, namely the Sun. Indeed, motion is the effect of a natural propensity or inclination that is unimpeded, whereas gravity is the effect of the same propensity or inclination when it is impeded. For a body weighs precisely because it propends toward something and, in order that it may not be moved, is impeded; for if all propension were removed, certainly all gravity would necessarily cease.

I suppose, secondly, that every heavy body subsists in the same faculty and the same act, both when, released, it runs, and when, impeded, it weighs. For a bent bow, when relaxed, drives the arrow with as great a force as the impetus presses

upon the obstacle. Hence, with the impediment removed, the weight passes into motion, and with the obstacle imposed, the motion passes into weight — all of which is established by experience.

I suppose, thirdly, that every heavy body, as was also shown above, has received from the Author of nature a certain propensity of tendency toward the Center of the Earth, so that it perpetually seeks the Center of the World. This proneness is such that, together with the moving body or heavy body in which it exists, it is always [?] [continues below]

always [?] vigorous in act; and the moving body, to which it is always intimately present, it continually solicits — by a certain added stimulus — either to move or to weigh. Nothing is so opposed to this propensity as ever to turn it away from the affection innate to it — whether the moving body is composed in rest or is violently snatched away — since by that natural activity of its own it cannot necessarily be deprived of the effect that follows from it, even if it is assailed by a most violent and contrary seizure.

From this I conclude, first, that a body placed outside the Center either, when unimpeded, moves, or, when relatively impeded, weighs. I added "relatively" on account of the weak impediment that often occurs; for then the moving body partly weighs and partly moves. I conclude, secondly, that the velocity of motion is greater, and is discerned to be greater, in a moving body when the body itself traverses an equal space in a shorter time, or a greater space in an equal time. This too is manifest: that motion can be increased to infinity, if a motive power is present — so much so that, as far as the moving body is concerned, it could always traverse some designated space in a shorter and shorter time, according to the division of the parts of time to infinity.

These things being laid down, I demonstrate what I intended at the outset: that the velocity of a moving body must be greater at the end of its motion than at the beginning or in the middle. I suppose, however, that the medium is always full of a uniformly fluid body, and that it shows itself apt to be divided uniformly by the falling body; for whatever things occur in the medium, since they are extrinsic and help or retard only by accident, are to be disregarded in the demonstration.

Let the space A–B be traversed by a moving body in natural motion, and let the space itself be divided into equal spaces, which are C, D, E, F; and let the moving body be released from place A. It is certain that it must, by the natural propensity innate to it, first be carried through space C. In its first course, let us say that the degree of velocity of the moving body itself must be as one. But now, since at

point O the moving body, gliding without impediment, is not deprived of its natural propensity of tendency toward the Center, but preserves the motion once acquired — preserving the formation of that motion perpetually — it is therefore carried through space D by its innate propensity, agitated as if by a continual stimulus. For besides that adventitious motion from the first mover, which procures the formation of motion and what has been acquired once, that internal natural propensity toward the Center is vigorous: it continually stimulates and, as if by hand, drives, by the production of ever-new and new impulses. Therefore, since that stimulation claims its own effect for itself — just as one candle added to another candle increases and intensifies the light in a chamber — the moving body, thus formed by motion and stimulated by the natural impulse, will traverse space D in a shorter time than it would have traversed by the merely acquired violence at that point; and thus it will traverse the part of space D with a greater degree of velocity than it had completed the part of space C — let this degree of velocity be called, as I say, [a unit?]. In like manner, by the production of ever-new and new impulses, the moving body, set in motion, will traverse space E in a shorter span of time than it had completed in D, and in F in a still shorter span of time than in E, and so on to infinity. The moving body, therefore — both by that natural propensity of tendency toward the Center of the Universe, and by the production of ever-new and new impulses — will be driven faster and faster toward the end; which was to be demonstrated. But what the proportion of this motion is with respect to time must now be set forth.

Diagram. A vertical straight line representing the space A–B traversed by a falling body, with A at the top and B at the bottom. Along the line, division points mark the equal subdivisions of the fall (C, O, D, E, F, G, H), illustrating the successive spaces traversed with increasing velocity.

- A (top): the starting point of the fall, top of the vertical line
- C (below A): first division point
- O (below C): a marked point on the line (where the body glides without impediment)
- D (below O): division point
- E (below D): division point
- F (below E): division point
- G (below F): division point
- H (below G): division point
- B (bottom): the endpoint of the fall, bottom of the vertical line

CAPUT II.

On the accelerated natural and violent motion of heavy bodies, and its proportion to the time in which it covers the said space.

It cannot in the least be denied that the keenness of the lynx-eyed philosophers of our age, in scrutinizing the secrets of motion, has reached such a point that they seem to have left all the Ancients many leagues [parasangs] behind. For I find no one among the Ancients, so far as I know, who assigned the genuine proportion of accelerated motion; and yet, without that proportion being assigned, it does not seem possible to see how the account and property of motion (I am always speaking of the motion of heavy bodies, whether natural or violent) could be established. And since the matter is full of subtlety and ingenuity, I have decided to discuss it here somewhat more fully, following the doctrines and discoveries of the modern philosophers. In order to do this as well as possible, I must first set down a few things for the easier grasp of beginners.

It should be noted, then, first, that it is manifest to everyone that the motion of things falling from a height is faster at the end than in the middle, and faster in the middle than at the beginning. It should be noted, secondly, that the velocity of motion of heavy bodies multiplies its increments in such a way that, from the very first moment of the fall, when the moving body departs from rest, its motion is continually accelerated more and more — or, what is the same, ever more and more increments of velocity are uniformly added to those previously acquired. It should be noted, thirdly, that these increments can be compared [continues]

[these increments] can be compared either with parts of time or with parts of space. For one can first designate a certain interval of time — say, a first minute or a second of an hour — to which equal succeeding intervals can be assigned, so that the whole time that the falling body takes in descending is divided into many such parts of an hour. Or one can designate a certain length of space — say, of one foot or one cubit, or some similar measure — to which other equal lengths can be taken in the space that follows, so that the whole space traversed by the falling body is understood to be divided into many such parts. Or again, the motion can be compared to some first velocity, namely the one acquired at the end of that first interval of time, to which other equal velocities are added on by the succeeding motion — just as degrees are usually added to degrees in qualities capable of intensification. In this way the velocity acquired at the end of the

motion is the most intense, being constituted from all the velocities, or degrees, that were acquired while the motion continued, each of them equal to the others and to that first one.

With these preliminaries set down, let us first of all bring forward the definition of the accelerated motion of heavy bodies, so that once it is understood the rest may be grasped more easily. Galileo [Galileo Galilei] defines the accelerated motion of heavy bodies tending toward the Center as follows: *that which, departing from rest, acquires in equal times equal increments of speed and momentum [celeritatis momenta incrementaque].*

Some explain this definition wrongly. They suppose that the velocities behave like the spaces — that is, that just as many equal degrees of velocity are first acquired as there are equal parts of space traversed after the first degree has been passed. For example: if a certain space were divided into ten feet, and at the end of the first foot of space the body acquired one degree of velocity, in the second two, in the third three, in the fourth four, and so on for the rest, then in the tenth they suppose ten degrees of velocity to be acquired. But this, as experience refutes, can in no way be asserted. For it would follow that the last degree of velocity is equal to the first, which is contrary to our supposition, and plainly conflicts with the common axiom that *motion is faster at the end* [motui in fine velocior]. Others suppose that the time in which (for example) some body traverses AB is double the time in which it traverses BC — which likewise neither ought to be nor can be asserted. For it would necessarily follow that, given the time in which the part AD has once been traversed, another time equal to it could in no way be reached except after an infinite space had been passed. To make this plainly evident: let the line AB be understood as produced to infinity and divided into the equal parts AB, BC, CD, DE, EF, FG, and GH. If, then, the time in which AB is traversed were double the time in which BC is traversed, it would necessarily follow that the time in which BC is traversed is double the time in which CD is traversed; and this, double the time of DE; and that, double the time of [EF]; and the time in which EF is traversed [is double that in which FG is traversed], and so on. Nor is there any greater reason for the one than for the other. For since the time in which BC is traversed is half the time in which AB is traversed, it is necessarily concluded from this that the space traversed in CD is $\frac{1}{4}$ of the first time; and that of DE, $\frac{1}{8}$; and of EF, $\frac{1}{16}$; and of FG, $\frac{1}{32}$; and of GH, $\frac{1}{64}$ of the first time's portion. And so on, the diminution of the parts proceeding to infinity in a double proportion of the diminution corresponding to it. Yet all these taken together will never equal the first time AB, being parts of it — unless an infinite space, and within it infinite equal parts, be admitted, parts that would

correspond, by infinite analogous halvings of halves, to the things understood within the very time in which AB is traversed.

The definition, therefore, is by no means to be understood in this way, but in the way we shall now set out. It is certain that the increments of velocity bear a fixed proportion to the spaces — not, indeed, the proportion that uniform motion immediately exhibits, but the one that uniformly accelerated motion exhibits, whose velocity grows continuously and uniformly, so that there is no moment of the succeeding time in which the motion is not faster than in any preceding one, and in which the velocity is not increased by the same ratio.

[The figure that the text describes here — a right-triangle with side AC divided into five equal parts — is rendered at the foot of the page as a tall narrow schematic; see the diagram metadata at the foot of this page.]

Hence Galileo sets forth the increments of the said velocities by means of the following triangle ABC, whose side AC is divided into any number of equal parts — say, five: AD, DE, EF, FG, GC. From these are drawn just as many parallels to the base BC: HD, IE, KF, IG [recte: LG]. For in this way the parts of the side AC express equal times, while the parallels express the degrees of velocity, which grow equally and uniformly in equal times. Thus A represents the place of rest, from which the body falls; the parallel HD represents the velocity that the body acquires by falling through AD; the parallel IE marks the velocity that the body, falling from A, acquires through the space AE; and so on for the rest. But since this velocity grows continuously from moment to moment without any interruption, without any pause or leap, uniformly from a fixed time into a fixed time, it is certain that the degrees of velocity from A up to the acquisition of the degree HD — which happens in the time AD — are infinite, corresponding to the infinity of the instants of the time AD, or of the points of the line AD.

But let us set out the matter a little more clearly. It must be noted, then, that all the velocities BC are reckoned as composed of all the preceding ones, just as the line of times AC is reckoned as composed of all the other parts. But the surfaces of the triangles that the parallel lines form with the lines of times —

Diagram. A tall, narrow right-triangle drawn with a long near-vertical hypotenuse from the apex A down to the base point B at the lower left. The right side AC (here drawn as the right vertical edge) is divided into equal segments, with horizontal parallels carried across to the hypotenuse.

- A (apex, top): A — the place of rest, start of motion
- B (lower left, foot of hypotenuse): B

- The right (vertical) edge is divided at points D, E, F, G, C downward; the corresponding parallel chords meet the hypotenuse at H, I, K, L respectively.
- Parallel chords labelled (top to bottom): HD, IE, KF, LG — the degrees of velocity acquired through successive equal times AD, AE, AF, AG.

— that is, of the kind that the triangles AHD, AIE, AKF, AIG [recte: ALG], ABC are — increase in the ratio of the squares of the times, or, what is the same thing, in the doubled ratio of the times. In this way the triangle AIE exhibits the space traversed during the time of the motion from A to E, and it is quadruple the triangle AHD — namely the space traversed during the time of the motion from A to D; for this line AD is double the time AE [recte: AE is double the time AD], and consequently the surface of the triangle AKF is nine times greater than the surface of the triangle AHD, just as the space that the body covers in the time AF is nine times greater than the one it covers in the time AD. Hence, since the time AE and the velocity EI stand to the time AF and the velocity KF as 2 to 3, the spaces (or surfaces of the triangles) AIE and AKF will necessarily be as the squares 4 and 9. If, then, the whole space is distributed into the parts of the said times, the first part will contain 1, the second 3, the third 5, the fourth 7, the fifth 9, and so on, proceeding to infinity according to the progression of the odd numbers — just as the surfaces of the triangles exhibit:

Triangle	Value
AHD	1
HDIE	3
IEKF	5
KFLG	7
LGBC	9

But that you may grasp my meaning more clearly, I have judged it well to clarify what has been said by means of another diagram, which Gassendus [Pierre Gassendi] also uses in his letters. Let a triangle ABC be made, whose sides AB and AC are divided into any number of equal parts: the side AB into ADFHKMO, and so on, and the side AC into AEGIL, and so on, in successive order. Let the points where they meet on the two sides be joined by the lines DE, FG, HI, KL, and so on. Then from each of the points of the two sides let other lines, parallel to the sides, be drawn to the base BC of the triangle ABC — namely E α , G β , I γ — and parallels from the points of side AC to the points of the base, as well as parallels from the points of side AB, DFH, to the points I, θ , H of the base of the triangle, sufficiently

demonstrate it. For when these have been drawn, the whole triangle ABC is distributed into other smaller triangles, similar to one another and entirely equiangular in a continuous analogy with the larger one.

This being laid down, the point A in this triangle can be taken either for the beginning of time, or for the beginning of space, or for the beginning of velocity — the three things regarded here in motion, as was said above, which begin together with it. And the equal parts of each side, AE, EG, GI, IL, and so on, or AB [recte: AD], DF, FH, HK, into which it is divided, can be established as the equal moments of time flowing from the beginning, that is from the point A — so that AE marks the first moment, EG the second, GI the third, IL the fourth. The parallel lines within their own triangles — for example, in ADEHKMO [recte: in the triangles formed at A, D, E...], and so on — can be taken for the velocities by which the motions are accelerated, corresponding to and equal to the moments of the sides; and the triangles, for the parts of space that the body traverses in each of the said moments.

But let us apply each to each. Let there be a line PQ along which some body runs toward the Center with even and uniform motion, and let PQ be divided into 16 equal parts, which represent the parts of space through which the body slides from P to Q — say, through sixteen cubits. Surely the triangle, by its ingenious arrangement, beautifully shows that the body covers spaces in equal times. For the first triangle ADE shows, on the line PQ, the first space PR — of one cubit, say — which the body traverses in the first moment of time. The three next triangles show that the body, in the second moment, traverses three cubits, which on the line PQ they express as RS.

Diagram. A large equilateral triangle ABC with apex A at top and base BC at bottom, filled with a lattice of small similar triangles arranged in successive rows. Each small upward-pointing triangle is inscribed with the odd-number sequence (1, then 1·2·3, then 1·2·3·4·5, etc.) row by row, the rows increasing as the odd-number progression. To the left of the triangle, a dotted serpentine (S-shaped) curve runs alongside a vertical scale line marked P at top, then R, S, T, and B at bottom, graduated 1, 3, 5, 7 (and totalling 16 at B) — the line PQ of the text mapped against the cumulative fall distances.

- A (apex): A — origin of time, space, and velocity
- B (lower left base corner): B
- C (lower right base corner): C
- Left side, descending: D, F, H, K, M, O — division points of side AB

- Right side, descending: E, G, I, L, N (with further points) — division points of side AC; outer right margin also carries running tick-labels
- Left diagonal caption (along side AB, reading upward): *Tempora Quadrata* [the squared times]
- Right diagonal caption (along side AC, reading upward): *Momenta Temporis* [the moments of time]
- Base strip caption (hatched band along BC): [Latin band caption, abraded — [?]]
- Below the base, a row of Greek letters: $\alpha, \beta, \gamma, \delta, \epsilon, \zeta, \eta, \theta, \iota$
- Vertical scale at left: P (top), R, S, T, B (bottom); tick values 1, 3, 5, 7 with cumulative total 16 at B

Five triangles, enclosed within the parts FG, HI in the triangle ABC, indicate that the body in the third moment GI traverses five cubits, which on the line PQ the space ST indicates. And seven triangles, enclosed between the parallels HI and KL, show that the body in the fourth moment IL traverses seven cubits, which on the line PQ the space TQ indicates. And so on for the rest, proceeding to infinity in the same way, it must be laid down.

From all this it clearly appears that the aggregates of the triangles behave like the squares of the times. For just as ADE is one triangle, so the space PR is also one, and the moment of time AE, in which the body traverses the said space, is likewise one (squared). But since within AG there are two spaces, these multiplied into themselves will give 4 — the square, namely, which just so many small triangles enclosed within the triangle AFG mark, and to which on the line PQ corresponds the aggregate of the parts enclosed between P and S. So you see that the aggregate AHI in the triangle ABC is 9, just as the —

— aggregate of the parts enclosed on the line PQ between Q [recte: P] and T, just as also the square of the line AI, divided into three parts, which marks three moments of time, is 9. Finally AKL, which on the line PQ corresponds to Q, is 16 — just as the square of AL, the line composed of four moments, is 16.

Furthermore, just as AL [recte: AE], the moment of the first time, can be divided to infinity, so from the infinite points of the line AE infinite parallels can be drawn from them up to D; so that, just as these lines grow continuously from the point A into the line DE, so the velocity grows continuously from the beginning of motion up to the last point of the first time, which E represents. And because the velocity, increasing thereafter, can again be represented by larger and larger lines drawn between the sides of the triangle, it follows from this that the line FG

represents the velocity acquired at the end of the second moment, the line HI the velocity acquired at the end of the third, and the line KL the velocity acquired at the end of the fourth. So that it is hence clearly evident that velocities behave as the times do; for as DE is to EA, so FG is to GA, and HI to HA [recte: IA], and KL to LA.

And from all this it is clear that the accelerated motion of heavy bodies tending toward the Center acquires the increments of its velocity continuously, equably, and uniformly according to the progression of the odd numbers from unity, as the definition set down above teaches; while the aggregates of the velocities turn out in the doubled ratio of the times. This is so true that there is no motion — whether natural or violent, whether straight or inclined, whether circular, or reflected in pendulums, or finally the lapse of water enclosed within channels — in which it is not verified; which I have judged fit to demonstrate in as many chapters.

CAPUT III.

De motu gravium supra plana inclinata.

[On the motion of heavy bodies upon inclined planes.]

Just as, in the preceding perpendicular motion of heavy bodies, the bodies are carried with accelerated motion, under a continuous and uniform increase of velocity, toward the Center, in just the same way they do this upon any planes inclined in any manner whatever — provided, however, that the inclined plane is supposed to be very smooth and highly polished, the body too exactly round, and its surface so disposed that it offers no impediment to the motion.

These things being laid down: let there be two inclined planes AC and AD, along which some body runs down to the horizontal point A; and let the line CB be perpendicular, along which a heavy body is moved by natural motion toward the Center. Then from DB [recte: from B] let perpendiculars BT and BI be drawn to each of the inclined lines CA and DA. Galileo therefore says that, at the same time and moment at which the body, falling from C, reaches the last terminus of motion, B, at that same time and moment the body, having slid down from C along the inclined plane CA and along the inclined plane DA, reaches its own terminus — the one from C at T, the other from D at I — namely the termini assigned by the perpendiculars BT and BI on the inclined planes AC and DA. The same is to be understood of any points whatever of the inclined lines that are assigned on CA and DA. And if the point A be determined as the last on the line

CA, he says that the body from C will descend to the terminus of its motion in the same time in which the body, falling from C to S, does so — which assigns two termini by means of the perpendicular line AS, defined on each line, both AC and CS produced.

From this it plainly follows that the time of the perpendicular fall stands to the oblique fall as the declined motion stands to the perpendicular. For example: the time of fall of some weight from C to D stands to the time of fall of the same weight from C to A, or from D to A, as CB to CA, or as DB to DA. But you will perceive the matter better in the second Figure.

Diagram. A fan of lines from a vertex A at the left, opening toward the right. Two inclined lines run up-and-out from A; a near-horizontal line AB runs to B; perpendiculars from B drop onto the inclined lines at the labelled points.

- A (left vertex): A — the horizontal point where the planes meet
- B (right): B — terminus of the perpendicular fall
- T (upper, on inclined plane CA): T — terminus of the slide along CA
- I (upper, near D): I — terminus of the slide along DA
- D (upper right): D
- S (lower right): S — terminus assigned by perpendicular AS

Diagram. A right triangle with apex A at top, a near-vertical right edge descending to D at bottom, and B at the left. A point C lies on the right edge between A and D, with B joined to C (BC, the half) and the angle at B marked.

- A (top): A
- B (left): B — angle B is 30 degrees
- C (right edge, between A and D): C — AC is the sine
- D (bottom): D

I say, then, that just as AC stands to BA, so the motion from A to C stands to the motion from A to B; and consequently the body will fall from A to D in the same time in which the body goes from A to B. This I demonstrate as follows. Since the angle B of the triangle ABC is 30 degrees, the line AC will be half of BA, which is the whole sine. Just as AC is the right sine of 30 degrees — such as the angle D of the triangle ABD also is — its sine AB is half of the radius AD, which is quadruple CA; and BA is the mean proportional between AC and AD, for it is double AC and half AD. And if we suppose AC to be a space of three feet, some weight will traverse it in the time of half of one second, and the other three parts, which run from C to D, in the time of another half of one second. This being laid down, we

say that the said weight is moved in the same time along the inclined plane AB as along the normal or vertical AD; from which it follows that the body, in the time of one second [unius secundi minuti], takes twice as much time as the body does in going from A to C. From which it again follows that the ratio of the time of the motion AB to the time of the motion AC is the same as that which the line BA of six feet has to the line AC of three feet — since the line AB is double AC, just as the time of fall AB is double the time of fall AC. Or, otherwise: Since —

— Since the times are in the sub-doubled ratio of the spaces, the ratio of the time in which the body falls through AC to the time in which it falls through AD will be as the root of the space AC, 1, to the root of the space AD, 2. The ratio of the line AC to BA, and of AB to DA, is also the same; for since AB is the mean proportional between AC and AD, it will stand to the said lines as the roots of the spaces AC and AD stand to one another.

SCHOLIUM.

[Scholium.]

Although Galileo has shown the motion upon inclined planes by ingenious arguments, no one who has weighed the matter on a finer balance will be able to deny that many falsehoods lie hidden beneath them, utterly contrary to experience.

The first thing, then, that can be objected to this is that a notable difference comes to light between straight or vertical motion and motion upon inclined planes. If anyone rightly compares these two motions with each other, he will see that it cannot be that a motion on an inclined plane, determined by the perpendicular, should exactly correspond to the one that takes place along a vertical line. For since in vertical descent the body has no other impediment besides the air, it will certainly cover its space far more quickly and freely than a body in descent along an inclined plane, where — at however many points some body touches it — just so many impediments and interruptions must be reckoned.

Secondly, there are experiments by which Mersennus [Marin Mersenne], in his *Harmonie universelle* [Mersenne, *Harmonie universelle*, bk. 2, fol. 113], and in a letter sent to me, sufficiently and more than sufficiently shows how far Galileo's conjectures stray from the truth. There he reviews the experiments he made, in these words:

In order, then, to examine more exactly the motion upon inclined planes described by Galileo, I first chose a height of 5 royal feet; then I had a plane made, as polished

as could be, so constructed that it could be directed at the operator's pleasure according to various inclinations. Finally I let two leaden globes of equal size and weight fall, the one along the inclined plane, the other along the vertical line, at the same time and from the same height of 5 [feet]. And we found that the globe running along the inclined plane of 5 degrees had completed only one foot on that plane, while meanwhile the other, falling along the vertical line, completed the 5 feet; whereas the globe on the inclined plane ought to have completed 16 inches on that plane, if Galileo's reasoning had been true, and not one foot.

Again we inclined the said plane to 25 degrees, and on the fall of the globes being repeated, we found that the globe along the inclined plane had completed only one foot and a half, whereas it ought to have completed two feet, one inch, and one third of an inch. In this way, on a plane inclined to 30 degrees, the globe completed only two feet, when from the prescribed rule it ought to have completed 2½ feet. Furthermore, upon a plane inclined to 40 degrees, the globe — which by the rule ought to have run three feet, two inches, and a half — on a most exact experiment being made, gave only two feet and 9 inches. Upon a plane of 45 degrees it ought to fall 3 feet and 1[?], but experience taught that it does not fall except three feet. Upon a plane inclined to 50 degrees, it ought to make three feet and ten inches, when nevertheless it made only two feet and 0 [?] inches.

All of which, with the utmost diligence, in the presence of many men skilled in the art, were carried out not merely once, but very often, from fear of an error which we suspected might perhaps have crept in somewhere, and were repeated. And this was seen as most wonderful and paradoxical: that the globe on a plane inclined to 50 degrees did not descend more quickly than on a plane inclined to 40 degrees, although the former was inclined by ten more degrees. And this too is to be noted: that the inclinations of planes of 50, 60, and 65 degrees obtain almost the same motion as that which takes place upon a plane inclined to 45 degrees — so that the motion on a plane inclined to 75 degrees does not differ from the earlier ones by more than half a foot. From all of which it appears how often speculations contradict experience. Thus far Mersennus.

If these things are true — as the diligence of so great a man persuades us they are most true — I for my part would not say that the cause of this great discrepancy is any other than the frequent interruption and interpolation of the motion on the said planes, by which the violent velocity of the motion is impeded. But as to why, on planes inclined beyond 45 degrees, the velocity of the motion is nearly the same as on planes before 45 degrees, I find no other cause for this than that on

the most steeply inclined planes the globe does not advance with so regular a motion as on the less inclined ones, but reaches its terminus by leaps upon leaps.

Hence it comes about that the globe, by frequent leaping and collision, is necessarily torn away from the straight line of its motion; and so it loses, by frequent leaping torn from the straight motion, that very time which, along the straight line on the most steeply sloping surface, it ought to have covered according to the calculated proportion of velocity. If, then, a globe could be rolled along some inclined plane on the condition that it touched the said plane as little as possible, but were carried only through the air, there is no doubt that Galileo's reasoning would have its plausibility — or perhaps even the flow of water within inclined channels would exhibit the said laws of motion more easily. But of these things in what follows.

The third thing that makes Galileo's reasoning doubtful is the very nature of the inclined plane. For he supposes, as most others also do, that the inclined planes one commonly meets with incline equally toward the horizon in all their parts and points — which is repugnant to mathematical reasoning. Let there be, for example, an inclined plane AD, a horizontal line BC, a vertical AC. I say, in strict mathematical rigor, that the point A on the inclined line AB inclines otherwise, the point E otherwise, the point B otherwise, and all the remaining intermediate points otherwise. And although, because of the smallness of the plane compared with the Center of the earth, this may not appear to us at all, nevertheless there could be given some plane in which the diversity of inclinations would be most [great] to us —

would be most perceptible; and so it could pose no slight obstacle to the truth of demonstrations that rest on what is indivisible. But let us prove what we have claimed.

So let EF be a horizontal line, touching the Earth's globe DNOP at D.

Diagram. A large circle (the Earth's globe) labelled D at the top, N on the right, O at the bottom, P on the left; its center is S. A horizontal line EF runs left-to-right tangent to the circle at the top point D, with E at the far left and F at the far right. Along EF, at successive points to the right of D, sit six small circles (drawn as little wheels, numbered 1 through 6 from left to right), each representing the globule placed at a different position. From the center S, straight lines are drawn up to the successive points on EF where the globules rest. The points of tangency along EF, from D rightward, are labelled D, X, H, L, V, Q. Letters I and S mark the tops of

the line of central directions through the first and last globules; M is near the sixth globule.

- D (top of circle): point of tangency, the natural resting point
- N (right of circle): cardinal point of the globe
- O (bottom of circle): cardinal point of the globe
- P (left of circle): cardinal point of the globe
- S (center): center of the Earth's globe
- E (far left of horizontal): left end of line EF
- F (far right of horizontal): right end of line EF
- X, H, L, V, Q (points along EF rightward of D): successive resting positions of the globule
- 1, 2, 3, 4, 5, 6 (small wheels on EF): the globule shown at each successive position
- I, M, S (above EF): endpoints/marks of the central direction-lines

Moreover, let there be a globule running along the line EF. Now since the globe first placed cuts the horizontal line EF at right angles by means of the vertical or central line I-S, at this position—where it stands upright on the horizon—it rests at no other point of the line EF except in this natural position, as we have already demonstrated elsewhere in what precedes. Now let the globe be placed at point X on the line EF. I say that it no longer has its natural position, since the central or direction-line SX no longer makes a right angle with EF, but one smaller than a right angle. As a result it begins gradually to incline toward the horizon. But if the globe is placed at H, the central line SH will now make a still greater inclination with the horizontal line EF; and so, always greater and greater at the remaining points L, V, Q, just as the figure itself shows. At all the points of EF, then, the globe will acquire a different inclination—which is what we wanted to indicate. From this it also follows that the moving body acquires different moments of velocity, by reason of the globe's center of gravity, at the various points of the said line EF.

You see, therefore, that this globe—placed as it is outside its natural position—can rest at no point of the said line EF except at point D. There, of course, the direction-line coincides exactly with the center of the globe, which it also bisects. For at any other point of the line EF the central line does not pass through the globe's center of gravity; instead the lines SX, SH, SL, SV, SQ, drawn through those points at which the globe touches the horizontal EF, always cut the globe into unequal portions. From this division it follows that the larger portion of the

globe, being heavier, outweighs the smaller, and consequently always acquires greater moments of velocity, until it comes to rest at D as its natural place.

The same thing happens—at least in mathematical rigor—on every inclined plane. Let AC be an inclined plane in triangle ABC; and let the surface of the Earth's globe be CBV, whose center is X.

Diagram. A circle representing the Earth's surface, with center X at the bottom. At the top is point A, from which two lines descend: AB (the vertical) reaching the circle's surface at B, and AC (the inclined plane) reaching the circle at C on the left. A chord CB is drawn across the circle from C to B. V marks a point on the circle at the right. The line AX (vertical) passes from A through B down to the center X.

- A (top, apex of triangle): release point of the globe
- B (on circle, below A): foot of the vertical AB
- C (left, on circle): foot of the inclined plane AC
- X (center of circle): center of the Earth's globe
- V (right of circle): point on the Earth's surface

Now suppose a globe falls from A along the inclined surface AC, and another from the same point and at the same time from A toward X. It is certain from what has been said that the globe gliding through the air from A to X—being, if you set aside the air, subject to no other impediment—covers the distance AX much more quickly than the globe from A reaches C. For the globe, just as it takes on a new configuration at every part of the inclined plane, so it acquires new and disparate moments of velocity. Hence its motion must be variously impeded, on account of the globe's varying section—made by the lines drawn from the center, which cut the globe unequally at the place where it rests on the plane. Since this section nowhere touches the globe's center along the plane, necessarily, because of the differing weight of the larger, outweighing portion of the globe, it induces a varying ratio of motion as well.

And so, since (as appeared in the preceding figure) the farther the globe is from point D, the more unequally it is divided by the central line, and the nearer to point D, the more equally—it follows that a larger portion of the globe at a greater distance from D, because of its greater weight, moves faster than where the portions cut by the central line are more nearly equal, being closer to rest, as is the case at point D, where the globe is bisected perfectly into the two hemispheres of the globe by the central line.

From this I conclude that the proportion of the motion can in no way be applied to it by means of numbers. For when, in the prior figure (for example), the globe placed at F begins to run, the globe is divided at that same place into an unequal measure—namely, into the smallest portion QIF and the largest QSF. It necessarily follows that the weight of the larger portion QSF is carried with a greater impetus, because of its inherent gravity, than at V, where the larger portion of the globe VTM is greater than the larger portion at QSF; and at the remaining points L, H, X, the larger portion of the globe is always smaller than at the preceding points, inasmuch as they tend ever more toward equality. And so, with gravity always diminishing and the globe drawing ever nearer to the place of rest that exists at D, it is plainly evident that the motion too, from A all the way to D, continually decreases through the intermediate parts of the plane.

But from Galileo's reasoning the opposite follows, since he says that the globe moves more slowly at the beginning, but faster at the end, on the said plane. It is true, however, that from the impetus acquired at the beginning the velocity is increased at the following points—but not in the ratio that the proportion of odd numbers prescribes for us. For the differing weight, by which the globe...

is moved through the inclined plane under an ever new and new diminution of weight, somewhat inhibits it; and so, beneath the plane, it must proceed under a certain disturbed proportion.

These, then, are the difficulties that seem to undermine Galileo's reasoning about motion carried out over different planes. Unless they are overcome, all the labor in assigning a definite proportion of motion over inclined planes, as compared to natural motion through the air, is rightly wasted in vain. Hence it is plainly evident from these considerations how many things are often bound up by geometrical laws which, nonetheless—when weighed in a more exact balance—are at last found false through constant experiment. I do say, however (as I also hinted above), that if some globe could be moved along a plane in such a way that it touched it at no part of itself—as happens with bodies carried straight downward by vertical motion—then Galileo's reasoning could be defended in some manner. But since motion of this kind seems to conflict with nature, no other account will be able to supply the deficiency of this motion except the one carried out by weights attached to pendulums—of which it now remains to speak.

CAPUT IV.

On the motion of pendulums.

[De motu pendulorum.]

It cannot happen that some globe should move freely along the convex surface of a sphere without, the moment that surface is abandoned, being carried downward in perpendicular motion by the appetite inherent in it toward the center. Hence it came about that the Lyncean philosophers of this age, in order to investigate the motion of weights more exactly, bound those motions to the laws of circular motion by the fastenings of cords and chains. So let LBK be a semicircle, in whose center A a cord is attached, weighted with a fixed globe so as to be raised up to L; and, the weight being let go, the pendulum necessarily descends from L to B, through the quadrant LB of circle LBK.

Diagram. A semicircle drawn on a horizontal diameter, opening downward. The diameter runs from K (far left) through A (center top) and on to I, N, L at the right; A is the center of the semicircle. From A a vertical line drops to B at the bottom; just to the left of B is C, and just to the right of B is D. M lies on the vertical line between A and B. From A a cord/radius runs out to the rim at the lower right, where O sits on the arc. The arc descends from L (upper right) through O down to B (bottom) and around to K (upper left).

- K (upper left, end of diameter): left end of the semicircle's diameter
- A (center top): center of the semicircle, the cord's pivot
- I, N (on diameter, right of A): division points of the line toward L
- L (upper right, end of diameter): the raised starting position of the pendulum
- O (on arc, lower right): intermediate point on the quadrant LB
- M (on vertical AB): point where line CD crosses AB
- C (lower center, left of B): point on the arc near the bottom
- B (bottom): lowest point, the natural resting point (representing the Earth's center)
- D (lower center, right of B): division point of the arc near the bottom

The cord, descending together with the weight, will obey differing laws of motion in the individual intermediate quadrantal parts—in such a way, namely, that the nearer it has come to point B, the faster it moves: it moves faster at O than at L, faster at D than at O, and faster at B than at D.

But before we compare the velocity of pendulums of this kind, agitated through the quadrant of a circle, with the velocity of weights tending naturally and perpendicularly downward, it must be noted that we here suppose the ratio of the spaces which the weights cover along two lines to be in the doubled ratio of the times—as when we compare the lines NO and ID, insofar as the arcs LO and LD correspond to them.

So I say, first, that the weight, while it descends through LDB, does not reach point B as quickly as while it descends along the vertical line AB from A to B; but if AB were prolonged so far that it equaled the quadrant-arc LB in its length, I say that in this case, in the same time, the weight will arrive both through the arc LB and through the line AB prolonged from A to its endpoint. For since AB the semidiameter is to the line of the quadrant LB as 7 is to 11, and the time in which the weight falls through the prolonged line is 30 thirds [tertia], it will, falling from A to B, take a time of only 23 thirds, and so will reach the endpoint B six thirds [tertia] sooner than the weight on the pendulum [reaches it] from L to B.

So let the cord AB be three feet long and divided into 500 parts; and let the arc LB likewise be divided into three equal parts—namely into LO, OD, and DB. It will then come about that, when the weight, falling from A along the line AB, has reached point M (namely the line AM equal to the sine of 30 degrees—now a space of 250 parts, of which AB is 500), it shall be reckoned to have completed [its first stretch]; and when it has touched that point at which the line CD cuts AB, it shall be reckoned to have completed a space of 433 parts. This space, indeed, is equal to the sine of 60 degrees; and if you subtract from it the prior 250 parts, there will remain 183, for the parts which the weight will cover by running through the arc OD. If, further, you subtract 433 from the radius of 500 parts, there will remain 67 parts, which the pendulum covers by its motion while it passes under the arc DE.

These things being laid down, in order that we may find the time which the pendulum takes for each individual space, proceed thus. Take the root of 500 parts, of which we have supposed the semidiameter AB to consist; and then take the root of 250, whose ratio is similar to the 30 thirds of a minute which the pendulum consumes in falling from L to O. You will have the two roots, $23 \frac{29}{141}$ and $12 \frac{6}{5}$, which stand to each other as $7 \frac{26}{141}$ to 5. Therefore, as $7 \frac{26}{141}$ stands to 5, so 30 thirds of a minute to another [number]; and there will come out $21 \frac{207}{397}$ thirds, the time which the pendulum takes in falling from L to O—that is, 250/500 parts. By this procedure you will find the time of the pendulum's fall from O to D to be $6'' 30'''$, and the time of the pendulum's fall from D to B to be $4''$

20^{'''}. From this it certainly follows that perpendicular motion attains its end faster than the motion of pendulums through an arc.

But here, above all, two things must be presupposed, as confirmed by infallible experience. The first is that a pendulum loaded with a weight, swung from L past B toward K, completes its vibration or "diadrome" [diadromus, single swing] in the time of one half-second; and although the diadromes from L to K are greater than those from O or D toward K, nonetheless even those smallest ones, between D and B, are nearly of equal duration with the greatest and with all the others. I said "nearly," because it has been ascertained that the largest diadrome exceeds the smallest by a span of time so imperceptible that, after 50 returns, the smallest returns lose no more than 1 [unit] relative to the largest return.

Second comes the consideration of the makeup of the cord. For the heavier the weight by which it is tensioned, the longer the time it lasts; on the contrary, when it is tensioned by a lighter weight, it completes its diadromes in proportionately less time. For example: a leaden globe, whose gravity contains twelve times the gravity of a wooden globe of the same size, lasts four times longer than the wooden one—where, however, each takes up its motion from an equal distance AB. For the wooden globe was found to make 40 diadromes while the leaden one in the meantime completes only 39, and so the wooden one [makes] one diadrome more than 40. But if the cord is six times thicker, it will gain one diadrome more than 260—in such a way, indeed, that the diadromes of the thicker cord are always diminished more than the diadromes of the finer cord; and the cords stand to one another as the weight attached to them stands to [its] weight.

So let us suppose, first, a cord AB of three feet, and a leaden globe attached to it of eight ounces, or half a pound. I say that this cord runs down from L to B all the faster the nearer it is to point B, which represents the center of the Earth. Second, I say that the velocity of the pendulum's motion through the quadrant of the circle follows the velocity of the whole weight falling through the vertical line. But from the comparison of the one with the other, I am confident the reader will more easily grasp my meaning.

We said above, in Caput 2, that the moments of velocity in the natural [motion] of weights downward occur according to the proportion of odd numbers—so that, if some weight covers the first part of the space in a given time (for example, in one moment), it covers three parts of the space in two moments, five parts of the space in the third moment, seven in the fourth moment, and finally, in the fifth, nine parts of the space; and so, in five moments—that is, in a duration of unequal

given [times]—the weight will exceed 25 parts of the space, as is clear from the figure set here.

The same must be said, in some manner, of the motion of pendulums agitated through a semicircle. I said "in some manner," because, since pendulums are carried by a twofold motion—the natural one, namely, in descending through the quadrant, and the violent one, in ascending through [the other quadrant]—the pendulums will follow the same ratio.

Diagram. A semicircle on a horizontal diameter, opening downward, divided by a vertical center-line and several horizontal parallel lines. Along the top diameter, from left to right: Q, P, O, N, M (left side) and A at the center top, then G, H, I, K, L descending the right side. The vertical center-line drops from A through points marked B, C, D, E to F at the bottom; numbers run alongside it (1, 3, 5, 7, 9 on the right of the center-line near B, C, D, E, F; and 2, 4, 6, 25 on the left). Horizontal parallel lines cross from the left arc to the right arc at the levels of B/H, C/I, D/K, E/L, etc.

- A (center top): apex / pivot, top of the diameter
- F (bottom): lowest point of the semicircle
- Q, P, O, N, M (left side of diameter/arc, top to bottom): left-hand endpoints of the parallels
- G, H, I, K, L (right side of diameter/arc, top to bottom): right-hand endpoints of the parallels — the lines BH, CI, DK, EL named in the text
- B, C, D, E (on the vertical center-line, descending): division points of the descent
- 1, 3, 5, 7, 9 and 2, 4, 6, 25 (alongside the center-line): the odd-number / cumulative-square progression of velocity moments

We said above, in Caput 2, that the moments of velocity in the natural [descent] of weights downward occur according to the ratio of projectiles [cast] upward, whose impetus is diminished upward in the same proportion as it grows in descending. In this way the pendulum AG, dropped from G, will increase the increments of its velocity according to the same proportion that the parallel lines BH, CI, DK, EL demonstrate in the semidiameter AF. In the same way the pendulum, swung by violent motion from F toward Q, diminishes its moments of velocity in the proportion in which, descending, it had increased them—as the parallels ME, ND, OC, PB sufficiently demonstrate above. So says Galileo.

But not even here is a place found where our intellect may rest, since the descent and ascent of the pendulum differ much from vertical motion downward—both

because of the resistance of the air and because of the resistance [renisus] of the cord. For since the cord, along its whole length, together with the globe attached to it, must overcome more air than if the globe alone were carried naturally from on high toward the center, it comes about that—as we said above—a globe descending freely and straight down always reaches its endpoint faster than a pendulum agitated in various ways through the windings of a circle. Yet since the difference is not so very perceptible, I would judge that the use of pendulums is not on that account to be rejected, especially since in physical matters the mathematical rigor is not always to be attended to. And although Galileo thinks he has found certainty in the matter by an infallible experiment repeated quite often, in the small three-foot pendulum which he himself used, I will readily grant it. But if the experiment were taken with a 30-foot pendulum, then without doubt a noticeable difference between the velocity of the pendulum and of the freely falling weight would be observed. For if we have found a difference of six thirds [tertia] of a minute, by which the weight in natural motion reaches its endpoint faster than the pendulum, then certainly this difference must grow in proportion to the length of the pendulum—there can be no doubt.

The same thing happens with two globes of equal [size] but composed of different material, if they are dropped from a height not so very great, [where] both, struck, strike against a horizontal plane: the eye judges them to arrive at the plane together and at one and the same time. But when the experiment has been made at a height of 600 palms, a very great and perceptible difference in the motion of each is constituted—the leaden globe always anticipating by some first minutes the globe composed of lighter material. And if this [were done] at a height of 600 feet...

what would happen at 1000? what at 10,000?

Next, I argue thus. Where the motive force is greater, there the motion is greater; but the motive force that [comes] from Q, [moving] in F, is greater than that by which it is moved from F to G; therefore this motion will be greater. I prove the minor [premise]: because the motion in the space QF is from its own gravity and from a continuously conceived impetus; but in truth, while it is moved through F G, the impetus alone moves it, and gravity does not conspire but resists; therefore the motion from Q to F is greater than from F to G. Which was to be proved.

CAPUT V.

On the parabolic motion of projectiles, and its marvelous effects.

[De motu projectilium parabolico, & miris ejus effectibus.]

From this admirable proportion of motion it was noted by the distinguished mathematicians of this time that heavy bodies, bound by no fastening, when thrown by the impulse of the one casting them, describe—out of the force of this declared proportion—a line which I-know-not-how affects a parabola. But let us look into the matter a little more deeply. For since two motions can be considered in any thrown heavy body—the natural and the violent—and since the natural seeks straight motion while the violent [seeks] motion toward that part toward which the heavy body was obliquely impelled, it comes about that in bodies obliquely thrown a certain mean motion is produced, by which the heavy body describes a line most closely resembling a parabola, according to the proportions of motion given in what precedes.

But let us show the matter in a piece of artillery. Let us suppose, then, that the line TO represents a cannon in a position parallel to the horizon (or in any other position), whose mouth is O. The globe, then, by the force of the ignited powder—if it had no gravity and met no resisting air—would without doubt finally be terminated in a straight line, by uniform motion, at Q, since it would find nothing to draw it back from the motion begun. But since, by its inherent gravity, it seeks the center along the normal line, it comes about that, displaced from the line TO begun by the force of gravity, it cuts a certain mean path.

Diagram. A rectangular grid (a parallelogram divided into cells by vertical and horizontal lines). Along the top edge, left to right: T, D, G, N, O, H, M, R, Q. Along the bottom edge, left to right: A, Δ [Delta], T, I, X, V, R, II, Y. From a cannon (a small barrel drawn at the lower left, with point T just above it) the line of fire rises to O at the top; a parabolic curve descends from O across the grid down to Y at the lower right. Point Q (cannon ball mark) sits above O. Inside the grid, descending along the second vertical from the left toward the curve, are intermediate points 5, B, F (top), then E, then 3, then L, then Z, then 5, then P, then 7, with K on the right limb of the curve and C near the lower right. The numbers 3, 5, 7 (and a 1 near the top) mark the odd-number progression of the vertical fall.

- O (top center): the cannon's mouth, start of the trajectory
- Q (above O): the point of pure uniform (gravity-free) motion

- T, D, G, N, M, R (top edge, left of/around O): division points along the horizontal of uniform motion
- H (top, right of O): division point
- A, Δ, T, I, X, V, R, Y (bottom edge): the foot-points OB, OL, OP, OX of the normal (vertical) fall — endpoints of the verticals
- B, L, P (descending the normal line from O): cumulative fall-points (the lengths OB, OL, OP, OX)
- E, F, Z, K, C (on/near the parabolic curve): points of the trajectory where it meets successive verticals
- 1, 3, 5, 7 (alongside the vertical): the odd-number progression of the fall increments

So let the time in which the globe would traverse TO be divided into four equal parts, and let this time be equivalent to a long note in music; and let the divided parts be OH, HM, MR, RQ. It is certain that the globe passes through each such part in one musical time, as appears in the margin. If, as I said, it were not heavy, and no resistance of the medium were given [it would continue straight]. But since gravity impels it toward the center, let us suppose that gravity, in the time in which the globe is moved through OH, displaces the globe from the line OQ by the space of the line OB, which is part of the line of normal motion OX.

In like manner let the line HV be drawn through point H parallel to OX; likewise also through the points M, R, Q let there be drawn MR, RΠ [?], QY, each and all parallel to one another and to OX. And let the displacement of the globe from the line OQ—as soon as it has touched the line MK—be as great as the portion OL of the normal line OX; and let the displacement of the globe from the line OQ, as soon as it has touched the line RΠ [?], be as great as OP; and let the displacement of the globe from the line OQ, as soon as it has touched the line QY, be as great as the normal line OX.

Then let there be drawn through the points O, B, L, P, X lines normal to OX and parallel to one another—SF, EK, ZC, AY—and others normal and parallel to TO: TA, ΔΔ [?], ΓΓ [Gamma], NI. These being laid down, the globe will be displaced from the line OQ, while it covers the space OH, by the quantity of the line OB or HF (which, being opposite sides in the parallelogram B F, are likewise equal); in the same way, while the globe is moved through HM, it will be displaced from OM in K, and through MR in C, and through RQ in Y. And since the displaced spaces of the globe of this kind are equal to the spaces OB, OL, OP, OX—that is, while they take their increment according to the quantity of the lines OB, BL, LP, PX—it

necessarily follows that these are increased according to the series of odd numbers continued from unity.

So if we set $OB = 1$, then $BL = 3$, $LP = 5$, $PX = 7$; or $OL = 4$, $OP = 9$, $OX = 16$. And in this same way the squares proceed: OH , OM , OR , OQ , or BF , LK , PC , XY , which are equal to the former, being opposite sides of the parallelograms. So since the square BF is 1, the square LK will be 4, and PC the square 9, and XY the square 16. And it will come about that as OX is to OP , so XY is to the square PC ; and as OP is to OL , so the square PC is to the square LK ...

and as LO is to OB , so is the square LK to the square BE . If, then, a semiparabola were described next to the points O , Y — or the whole parabola AOY (which would pass through point O and through the points A , Y) — the squares enclosed between OX and the parabola AOY would have the same proportion to one another that OX , OP , OL , OB have among themselves, as I showed at length in *Ars Magna Lucis et Umbrae* [*The Great Art of Light and Shadow*], in the chapter on conic sections [*De Conicis Sectionibus*]. The sides of these squares will therefore match the sides PC , LK , BF , and the sides PZ , LE , BS . The ball, then, at the points O , F , K , C , Y , will always lie on the parabola AOY . The same can be demonstrated for any other projection of a heavy body. Therefore a projected ball, by its rolling, will *approximate* a parabola — which was to be demonstrated.

I said it will *approximate* a parabola, because I do not believe that a line of this kind, produced by projectiles, is a perfect parabola — as most mathematicians of our day, following Galileo, suppose — but rather something resembling one. The ground of my doubt is this: it has no source from which it might be generated. Every parabola takes its origin from the section of a cone; but in projectiles no conic section can be conceived, as it can in matters of the sundial [in *Sciatherico negotio*], where light and shadow by their circuits found true cones, which are then cut by the plane of the horizon, acting as a cutting-plane [*Conotomo*], and produce conic sections of every kind. Where, therefore, the foundation of the conic sections is missing, there too the true properties of the sections can in no way be conceived. So too with a larger and heavier cord: if it is suspended from its two ends, it tends, on account of its weight, to sag downward somewhat in the middle and form a curved figure — which seems to approximate something parabolic, yet cannot properly be called a parabola, since it lacks the foundation from which one is generated, namely the cone. For if it were a true parabola, there would be no reason why it should not also produce a hyperbola, an ellipse, and similar curves — none of which, however, can be seen in effects of this kind, any more than in projectiles or in cords stretched by their own weight. As for the

fact that the proportions of the odd numbers fit this case exactly, that is an *a posteriori* matter. For since lines of this kind produced by projectiles are very like parabolas, they can easily be fitted to true parabolas. It is indeed the nature of geometrical and arithmetical objects that they are readily applied to physical things of every sort, even though no foundation of these properties exists in the physical things themselves.

COROLLARIUM. [COROLLARY]

From this it is also clear that the oscillations [diadromos] noted in the vibration of stretched cords do not describe mathematical parabolas, as some have claimed, but something approximating a parabola — for exactly the reason given concerning the cord.

Modern philosophers, instructed by experience drawn from the motion of projectiles, hold that a body shot obliquely and violently upward describes a true and perfect parabola, both in its ascent and in its descent. Its axis, they say, is the median normal line drawn from the vertex of the parabola down to the horizontal line lying beneath it — the line that writers on conics call the *ordinately applied* [ordinatim applicata]. Just as this ordinate stands at right angles [Greek: πρὸς ὀρθὰς γωνίας (pros orthas gōnias, "at right angles")], so it bisects the whole parabola; so that the ascent of the body, through one half of the parabola, has a violent motion, and through the other half, a natural motion — the whole motion being judged to be composed of the violent and the natural. They suppose, moreover, that the body takes just as much time in ascending, and just as much in descending, as a body would take in falling straight down, normally and naturally, along the axis of the parabola. So hold Galileo and his other followers — Gassendi, Torricelli, Cavalieri [Cavallerius] — and they think the matter can be demonstrated by the firing of cannon by the parabolic art, or by incendiary projectiles, as also by the motion of jets of water, all of which seem to describe a parabola. Others hold that this happens only with a mortar [pyrobolus] and with the leap of waters, when discharged with a sloping motion; but in a horizontal motion they judge that it produces not so much a parabola as a certain figure composed of a circle and straight lines. However that may be, the matter has not a few difficulties, which I have decided to untangle here, so that at last it may be known what is to be concluded. For it is certain — as we also hinted above — that geometrical principles, although they are readily applied to physical things, are nonetheless so constituted that they cannot in the least preserve the laws of mathematical rigor in their demonstrations, when these are noted only by sensible experience; and since this is fallacious, and the senses for

the most part deceive, it cannot be that infallible trust be placed in them. But before we carry the matter further, it seemed best first to bring forward here the demonstration that Cavalieri, following Galileo's principles, sets down, and then we will set out our own, so that it may be known what is to be concluded about each.

Cavalieri, like Torricelli, in setting out to demonstrate the parabolic motion of projectiles, reasoned thus. Since two motions can be considered in any projected heavy body — the natural and the violent — and since the natural seeks the center along the normal, while the violent tends upward toward that part toward which the heavy body was obliquely impelled, it comes about that in obliquely projected bodies a certain mean motion arises, by which the heavy body describes a parabolic line; and it describes it according to the given proportions of the odd numbers, through the several intervals of space that correspond to those proportions. And this they demonstrate in the case of a piece of artillery and of mortars. Let us therefore suppose that the line T represents the...

cannon, whose mouth-position relative to the horizon is parallel; or it is the same in an oblique position, whose mouth is T. The ball, then, by the force of the ignited powder, if it were subject to no gravity and met no resisting air, would doubtless at last be carried by uniform motion along the straight line TO and terminate at Q, since it would find no hindrance to draw it back from the motion once begun. But since, by its innate gravity, it seeks the center along the normal line, it comes about that the ball, displaced from the line OQ it had begun on by the force of gravity, cuts a certain mean path. Let the time, then, in which the ball would traverse OQ be divided into four equal parts, and let the several parts OH, HM, MR, RQ correspond to one second each. It is certain that the ball passes through each part of this kind in one second — if, as I said, it were not heavy, and no resistance of the medium were given. But because gravity drives it toward the center, let us suppose that, in the time in which the ball moves through OH along the line OQ, the ball is displaced by the space of the line OB, which is part of the normal line of natural motion OX. In like manner let the line HV, parallel to OX, pass through the point H. So too let MR, R π , QY be drawn through the points M, R — all of them equidistant from one another and from OX. And let the displacement of the ball from the line OQ, as soon as it reaches the line MR at K, be as great as the portion OL on the normal OX; and let the displacement of the ball from the line OQ, as soon as it reaches the line R π at C, be as great as the portion OP on the normal line OK; and let the displacement of the ball from the line OQ, as soon as it reaches the line QY at Y, be as great as the normal OX. Then let there be drawn through the points O, B, L, P, X the normals — parallel to one

another and to OX — SE, EK, ZC, AY, and others perpendicular to OT and parallel to one another: TA, OΔ, ΓΓ, NI, HV, MR, Rπ, QY.

With these laid down, let the ball be displaced from the line OQ. Meanwhile it accomplishes the space OH, of the magnitude of the line OB, or HF, which, being opposite sides in the parallelogram OF, are accordingly also equal. In like manner, while the ball moves through HM, it will be displaced by the impulse of gravity from OM to K, along the line FK; and from K to C, along KC; and from C to Y, by the normal lines MR, Rπ, QY. And since the spaces of the ball thus displaced, compared with their perpendiculars, are equal to the spaces OB, OL, OP, OX — that is, since the increments of velocity are taken according to the magnitude of the lines OB, BL, LP, OX — it necessarily follows that they increase according to the series of odd numbers continued from unity. If, then, we set the line OB to be one space, BL will be three spaces, LP five, PX seven; or, what is the same, OL will be as 4, OP as 9, and OX as 16. But in this same way proceed the lines OH, OM, OR, OQ, and BL, LK [recte: BF, LK?] [?], PC, XY, equal to them, because they are opposite sides in parallelograms. Therefore, since the square of the line BF is as 1, the square of the line LK will be as 4, the square of the line PC as 9, and the square of the line XY, finally, as 16; and it will come about that as OX is to OP, so XY is to PC; and as OP is to LO, so PC to LK; and as LO is to BO, so LK to BF. If, then, a semiparabola were described next to the points O, F, K, C, Y, or the whole parabola AOY, which would pass through point O and through the points A, Y, the sides of the squares too — that is, the lines OY, PC, LK, BF, or, from the opposite side, XA, PZ, LE, BS, equal to these — enclosed between OX and the parabola AOY, will have the same proportion to one another that the spaces OX, OP, OL, OB have among themselves. The ball, then, carried upward through the points A, Z, E, S, O, and likewise downward through the points F, K, C, Y, will describe a perfect [perfectam] parabola; and it will take just as much time, carried by natural motion from P to X, as, again, from Z to E, ascending from A to Z, and from there to E, and from E to S, and to O, as it takes from X to P, and from there to L, and so on from L to B, and to O, spread out violently and vertically. Again, descending by natural motion from O to E, and from there to K, C, and Y, it will take just as much time as in falling by natural motion from O to B, and from there to L, P, and X. Since, then, the ball, falling by natural motion along the line OX, accomplishes the spaces OB, BL, LP, PX according to the proportion of the odd numbers, it certainly must observe the law of the same proportion in the parabolic spaces OF [recte: OE?], FK, KC, CY — which was to be demonstrated.

And this is Cavalieri's demonstration, by which he thinks he proves that the motion of projectiles describes nothing other than a parabola. An ingenious

invention, I admit — if only the physical principle of the motion corresponded to it, or if experience held firmly consistent with itself. But since we showed above that the path of the moving body, according to the proportion of the odd numbers, has not yet been demonstrated mathematically, surely this demonstration, if it be taken as a geometrical one, will never satisfy the experts, since the mind always remains in doubt and suspense over the deceptiveness of the experiment. But let us examine the several parts of the demonstration.

Cavalieri assumes, indeed presupposes, that the motion of a ball from a cannon set in a horizontal position...

directed and discharged, begins at O, the vertex of the parabola — which experience teaches cannot at all be said, and which evidently convicts the whole discussion and that demonstration of resting on a false assumption. For the ball does not begin to describe a parabola as soon as it leaves the cannon, but rather seems to approximate straight lines for some distance in the impetus of its motion, and only then bends into the form of a parabola. Moreover, it does not seem consistent that the ball should accomplish equal parts of the horizontal line through equal spaces of time, as he himself supposes — since in every projectile the moving bodies seem to move ever more slowly, as is evident to the senses. It is also established that, just as in natural motions the velocity is always increased, so in violent motions it is always diminished. Let us therefore suppose that the mouth of the cannon is set at T. The ball will approximate a straight line for some distance, until, the impressed force flagging, it takes on the form of a parabola; nor can those spaces TD, DG, GN, NO be assumed equal, for the reason stated — since in the space TD the ball is carried with a swifter motion than in DG, and in this one swifter than in GN, and so on for the rest of the spaces. And therefore these spaces ought to stand exactly as the spaces OP, PL, LB, BO on the line OX, unequal among themselves. In no way, then, ought it to be said or supposed that the ball, in the several equal spaces of time, accomplishes equal parts on the horizontal line, compared to the arcs of the parabola. Furthermore, it is uncertain whether the parts of the parabola OF, FK, KC, CY — which correspond to the parts OB, BL, LE, EX on the vertical line XO — are traversed in exactly the same time in which some heavy body passes through the said parts of the line OX. For experience teaches that a ball or mortar-shell, as soon as the impressed force is extinguished, no longer keeps the parabolic path, but tends straight down and strikes the earth with perpendicular motion — which happens most of all in the last stage of its motion; whereas into a parabola nothing rectilinear can fall. From which it follows clearly that, in the last stage of its motion, the mortar-shell descends with a much swifter motion — being a natural one — than in the

remaining spaces CK, KF, FO. Since, then, the moving body in the parts of the line OX — being borne by natural appetite into the center — moves faster than in the parts of the parabola, which are composed of the violent and the natural, it necessarily follows that it makes a greater delay in the latter than in the former, since they both tend obliquely and sustain the resistance both of the air and of the violent motion. But if the character of these motions were established for us by experience, surely I myself would gladly subscribe to them; but since up to now there has been no one who has made an experiment in a matter exposed to so many tricks of the eyes, surely a certain demonstration about them cannot be handed down, and so the truth...

[the right column continues:]

would undergo a deflection from the line, so as soon to describe the parabola OB — since, as I said, in the first violence of its impulse it describes some rectilinear something or other, until, the force flagging, it at last conforms itself into E. But, to say what I feel, it seems more in keeping with experience that, if a cannon set in a horizontal position is fired, it will come about that, immediately upon leaving, the ball does not at once deflect from the straight line AB in proportion to the impulse, but is carried for some distance on a straight track on account of the force of the impetus, as appears in the line AC; until, the impetus flagging, its own weight urges the ball into a certain parabolic motion — and so the vertex of the parabola is to be set by no means at O, as Cavalieri set it in the preceding figure, but at V; from which then, according to the measure of the lasting impetus, it describes the other side of the parabola, OS [recte: VS?] [?]; but where, the impetus flagging, the impressed force is gradually extinguished, then it describes nothing further parabolic, but something wholly rectilinear, with natural motion — that is, perpendicular — striking the earth.

Let the mouth of the cannon be A, which when fired describes nothing parabolic from A as far as C,

Diagram. A trajectory figure illustrating Kircher's own account of cannon-shot. At upper left is a small drawing of a cannon (the mouth A) firing horizontally to the right. The trajectory runs as a nearly straight horizontal line from A across the top (passing through C) toward B at the far upper right; it then curves downward through V and continues down through T to S at the lower right, forming a quarter-turn that becomes a vertical straight descent near the bottom. A separate straight line (the tangent) runs from the curve obliquely down-left toward the lower-left of the figure.

- A (upper left, at the cannon's mouth): origin of the shot
- C (along the top, between A and B): point up to which the path is straight; "from A as far as C nothing parabolic is described"
- B (far upper right): end of the horizontal tangent line AB
- V (right side, where the horizontal path begins to curve down): the true vertex of the parabola (Kircher's correction of Cavalieri)
- T (right side, below V, on the descending curve): point on the descent
- S (lower right, foot of the vertical descent): end of the path; the segment TS is "under the ratio of a straight line"

inasmuch as the ball forms the part of the tangent AB of the parabola as far as C; then, however, it forms the arc of the supposed parabola [putaticiae parabolae] as far as V, its vertex, and from there the other arc of the parabola as far as T — where, the vigor of the impetus failing, it accomplishes the remaining space TS, under the ratio of a straight line, as a portion of the tangent BS of the parabola, or descends on a track parallel to it. And although to everyone the moving body seems to trace out something parabolic, yet it is not truly parabolic, since both at the beginning and at the end of the motion the ball moves along the tangents AB and BS of the parabola — which is absurd, since the tangents of a parabola cannot touch the parabola except at a point. Nor can it be said that the ball, immediately upon leaving the cannon, inclines into a perceptibly curved line; for experience teaches that a ball fired even to a distance of two hundred paces from the target [meta] describes, near the end, an arc scarcely perceptible; and that sometimes it tends wholly under a straight line — according to the ratio of velocity or impetus, along the path of the line of sight — toward the point of the target. But the ball ought, in order to...

describe a true parabola, to begin the description of the parabola at once, from the very first moment of its leaving, point by point — which is contrary to experience. So, just as the rectilinear is confounded with the curvilinear in the motion of projectiles, so too it is vain to seek any parabolic principles under them. There is the further point that a parabola of this kind, as was said a little before, has nothing from which it might be generated.

Every parabola takes its origin from the section of a cone; but in projectiles no section can be conceived, as it can in the theory of the sundial [in *Sciatherica theoria*], where light and shadow by their circuits found true cones, which then, according to the character of the sundial-plane, produce conic sections of every kind. Where, therefore, the foundation of the conic sections is lacking, there too the true properties of the sections can in no way be conceived. For if some heavy

body, whirled about by violent motion, described a true parabola, there would be no reason why it should not by the same reasoning describe also a circle, and a hyperbola or an ellipse — of which, however, no trace appears in projectiles. But, that the truth of the matter may stand out more clearly, I have decided to demonstrate it in this way.

Let the line AX in the present figure be the vertical line representing the natural motion, and the line AB the horizontal line, along which the moving body is led. Then let an arc be described from the point X,

Diagram. A geometric construction for Kircher's proof that the projectile path is none of the conic sections. The top edge is the horizontal line AB, with A at the upper left and B at the upper right; it is divided into equal segments by the points L, M, N, O, P. From A a quarter-arc AI is struck (centered, by the text, at X) curving down to I at the lower right. The left edge descends from A through V, K, C down to X at the lower left; AX is the vertical line. The bottom edge runs from X to I. Within the figure, perpendiculars dropped from L, M, N, O, P meet a row of points on the curve (E, F, and points labeled G, S, T near the curve), and the descending trajectory curve passes through these toward I, marked at one point H. Faint construction lines run from A to several of the lower points.

- A (top left corner): origin; the cannon's mouth / start of motion
- B (top right corner): end of the horizontal line AB
- L, M, N, O, P (along the top, A→B): equal foot-divisions of the horizontal AB
- V, K, C (down the left edge below A): points on the vertical AX marking the construction
- E (on the left, just below A; first curve-point under L): point on the line of motion
- F (below E; curve-point under M): point on the line of motion
- G, S, T (along the row of curve-points toward the right): successive points on the line of motion [?]
- H (on the descending curve, mid-figure): point on the curve
- X (bottom left corner): center of the arc AI; foot of the vertical
- I (bottom right corner): end of the arc AI and of the line of motion

and let it be AI; let the horizontal line AB also be divided into several equal feet, A, L, M, N, O, P, B; and when perpendicular lines have been drawn parallel to the horizontal line AB, there will be born six squares equal among themselves, AQ, LR, MG, etc. With these laid down, I assert, first, that in the line of motion of

projectiles there is neither a circle, nor a parabola, nor a hyperbola, nor an ellipse.

That it is not a circle, I demonstrate thus. Since the triangles APT, AEV are similar, EV will be to AV as AP is to TP. But TP is the fifth part of the line AP. Therefore AV too will be the fifth part of the line EV. And since the square of EV, or AL, is equal to the rectangle — that is, the parallelogram — contained under AV and the line AP, while EV is taken to be 10 parts of which AV is 2, its complement, namely the line AP, will be 50 parts, and the whole diameter 52 parts. Again, since CG is triple AC, and its square is equal to the rectangle contained by AC and its complement to the diameter of the circle — the square of CG being 900 parts and AC 10 parts — the remaining segment will therefore be 90 parts; but the whole diameter is 100 parts. Yet it is also 52 parts; therefore the line of motion AEFghi is not the circumference of a circle.

But neither can it be a parabola. For suppose, if it can be done, that it is the line of a parabola; then, as the straight line AC is to the straight line AV, so will be the square of the semi-ordinate CG to the square of the semi-ordinate VE. And since CG is triple, its square EV [recte: of EV] will be ninefold that square. But AC is to AV as 10 to 2 — that is, fivefold; therefore it is not as AC is to AV, so the square of CG to the square of VE; and consequently the line AEFg is not a parabola.

Now suppose, if it can be done, that it is a hyperbola. Let its diameter be taken as 8 parts, of which AC is 10 and AV is 2. Then the right-angled triangle [rectangle] contained under AV and the side composed of AV together with the diameter of the figure will be 20 points; but the rectangle contained under AC and the side composed of AC and the diameter of the same figure will be 180 points; and the ratio of the latter to the former is ninefold. But the square of the semi-ordinate CG is also to the square of the other semi-ordinate VE [in the same ratio], inasmuch as the side CG is triple the side VE. Since, then, the rectangles under the segments of the axis of the hyperbola have the same ratio to one another that the squares of the semi-ordinates have, there will be, by permutation, the same ratio of the rectangles under the segments of the axis of the hyperbola to the squares of their semi-ordinates; and consequently the points E, G lie on the same hyperbola. But again, since AOS, ARF are similar triangles, and AO is the square of [recte: AO to OS as] OS [?], so too AF will be [as] the square of AK; and AK is 8 parts, of which KF is 20. Therefore the right-angled rectangle contained under AK and the side composed of AK and the diameter of the figure will be 65 parts; but the rectangle contained under AV and the side composed of AV and the diameter of the same figure is 20 parts. Now the ratio of 65 to 20 is smaller than the ratio of the square

of KF to the square of VE. Therefore, by permutation, the ratio of the rectangles under the segments of the axis to the squares of the semi-ordinates is not the same; and consequently the points E, F are not contained on the line of a hyperbola.

Finally, that this line of motion is not an ellipse either, is proved thus. Let AX [recte: A] be produced to Z, which the perpendicular line IZ cuts. Since, then, at L the gravity becomes equal to the impulse, IZ will be greater than all the straight lines that fall perpendicularly from the line of motion to the diameter AZ; and consequently it will be the semi-diameter of the figure. But IZ is made equal to the semi-diameter AZ, whereas it ought to be unequal; therefore the points A, E, F, G, H, I are not contained on an ellipse.

It is therefore clear from what has been said that the line of motion in projectiles describes none of the conic sections.

to write. We must therefore conclude that the line of motion which any moving body traces does not proceed by a homogeneous motion, but by a heterogeneous one — that is, from rectilinear and circular motion imperceptibly mixed. For if the ratio between natural and violent motion held firm for us, certainly and geometrically, according to the proportion of the odd numbers, and if its true demonstration could be established, then certainly everything said up to this point would be correct. Nevertheless, since in my judgment no truer or closer proportion for demonstrating the principle of this motion can be assigned — nor has one been assigned up to now — we may legitimately use that proportion, as one does in any mechanical undertaking; and in what follows we shall in fact use it.

THE COSMOCENTRIC ART

SECTION III. PRACTICA [Practical]

or, The Uses That Can Be Derived from the Cosmocentric Art

CAPUT UNICUM [Single Chapter]

How the Velocity of the Motion of Heavy Bodies Toward the Center May Be Determined

Although in the preceding pages we showed clearly that the proportion of the motion of heavy bodies toward the center cannot be demonstrated geometrically according to the increment of the odd numbers from unity, nevertheless —

because no proportion more probable or nearer the truth has yet been assigned — most of the philosophers and mathematicians of our time assume this one as if it were true, and apply it in practical work without notable error, as will appear later. With the aid of this stated proportion, then, Galileo, Mersenne, and others believe they can determine how much time a stone takes in falling from the Moon, the Sun, and the stars down to the center of the Earth. Yet this matter rests on slender foundations, and so can never produce a solid certainty in the minds of judicious men. Therefore, before we develop the subject more fully, we must necessarily lay down certain assumptions, so that, once these are established, the reader may discern what to think.

I assume, first, that a stone or any other weight, in the natural descent of its motion, preserves in the increments of its velocity the same proportion that the odd numbers from unity preserve among themselves; from which it follows, consequently, that we must assume the velocity of the motion to be in the squared ratio of the times — or, what is the same, that it behaves as the square does to its roots.

I assume, second, that the medium through which any heavy body falls must be homogeneous, everywhere equally rarefied, and subject to no impediments of differing kind. For experience teaches that a heavy body descends more swiftly through a clear, still, and tranquil medium than through one that is dewy, foggy, or suffused with somewhat thick air.

I assume, third, that the constitution of the falling weight must above all be taken into account. For it is certain, and experience teaches, that a sphere or any spherical body descends more swiftly than a flat body, or one obstructed by various angles, even if they are equal in weight. Likewise a column dropped straight down along its length, perpendicularly, consumes less time in its descent than if it fell positioned along its horizontal length, because in this position it would meet greater resistance from the air than in the former. By the same token, porous and pumice-like bodies — such as cork and pumice, and countless others of this kind — when dropped from a height do not reach the end of their motion as quickly as less porous bodies of more solid composition, even if they are equal in weight or magnitude. Nor should we listen to those who say that a wooden ball and an iron or leaden one, released from any height, strike the ground in equal time; for in the Cochlea of St. Peter [the spiral staircase of St. Peter's], a place of notable height, repeated experience has taught me the exact contrary. It is true, however, that at a height of 100 or 200 feet the difference scarcely varies perceptibly; but from a notable height, the body that is heavier

strikes the ground sooner. For at a notable height, the compression of the air, owing to the violence of the pressing weight, is so tenacious that it can scarcely be cleft except by the gravity of the weight; whereas the lighter body does not descend straight, but wavers this way and that, variously agitated by the strength of the crowding air, which does not know how to yield. And if the air does this at a height of 400 feet, what will it not do at

[Margin: How much time a stone takes in falling from the Moon to the center of the Earth.]

a height of 1000, 2000, 3000, and so on feet? With these assumptions, then, let us now see whether some ball could fall from the globe of the Moon and from the peripheries of the other heavenly bodies, and, if it could, how much time it would take in falling. I am not unaware that various men have variously determined a time of this kind. [Scheiner?] thinks that some ball would take six days in falling from the Moon to the center of the Earth — but he is mistaken; for the Moon, carried about in its orbit by a wholly uniform motion, traverses that space [in that time]. A heavy body, by contrast, descending by natural motion, accelerates the increments of its velocity not by a uniform motion, but according to the proportion of the odd numbers. That proportion was not yet known at his time, and they perhaps held some other proportion of motion congruous to its acceleration. Galileo, wishing to correct Scheiner, comes nearer the truth, yet he too did not attain it; and so I have judged that I should disclose in this place what seems right to me.

PROBLEMA I. PROPOSITIO I.

To determine how much time a weight of one hundred pounds, falling from the heaven of the Moon, takes to reach the center of the Earth.

Assuming, then, that some heavy body acquires the degrees of its velocity according to the increments of the odd numbers, and that the spaces increase according to the squares of the times: let there be, for example, a certain ball — following Galileo, of 100 pounds — which in the time-span of five seconds falls from a height of one hundred cubits (and let this be confirmed by experiment by Galileo). He says that in a smaller time than 4 hours it [completes] its course — which is from the Moon to the center of the Earth — by its motion. For if you wish to know how much space it traverses in the time of one first minute, which is $\frac{1}{60}$ of an hour, you will have the desired time if you multiply 100 cubits (by which we said the ball falls in the span of five seconds) by the square of 12, that is, by 144 — because 5 seconds multiplied by 12 make 60 seconds; the square, therefore, of a

time of 5 seconds is 12, which, as I said, multiplied into itself give 144; and these again multiplied into 100 cubits give 14,400 cubits, for the time in which it falls to the earth in the space of one first minute.

[Note: "the square of 12 ... is 12" reflects the text's own loose phrasing: 12 is the multiplier ($5'' \times 12 = 60''$), and $12^2 = 144$. Transcribed as printed.]

But if you wish to know how much space the said ball traverses in falling over the course of one hour, multiply the square of 60 first minutes into the number just found, 14,400, and there will result cubits equivalent to 17,280 miles, the space sought. If, finally, you wish to know how much space it consumes in an interval of 4 hours, multiply the square of 4 hours, namely 16, into the 17,280 found just before as the space of one hour, and there will result 276,480 miles — which space is greater than the

semidiameter of the Moon's orbit. For according to the calculation of the astronomers, the semidiameter of the Moon's orbit is only 196,000 miles — or, what is the same, 56 semidiameters of the Earth; and the semidiameter of the Earth contains 3,500 miles, while one mile contains 3,660 cubits. If, then, the calculation is carried out exactly, we shall find that a ball falls from the concave [surface] of the Moon to the center of the Earth in less than 4 hours' time, namely — according to Galileo — three hours, 22', and 4". For since by supposition the ball falls from a height of 100 cubits in a time of 5'', it will necessarily, according to the rule of proportions, in a time of three hours, 22', and 4", traverse a space of 196,000 miles — or 588,000,000 cubits — which space is equivalent to 56 semidiameters of the Earth. And this calculation agrees very well with Galileo's experiment. But according to the experiment made by Mersenne, that ball would descend from the concave [surface] of the Moon to the center of the Earth in a time much smaller still. For when Mersenne brought Galileo's experiment to the anvil [tested it anew], he found that the ball — which Galileo found to traverse a space of 100 cubits in a time of 5 seconds — traversed a far greater space, namely 180 cubits, in a smaller time, namely 3'' 43''' 20''', and not in 5''; so that, according to Mersenne's observation, the said ball traversed an interval of 108 feet in precisely three seconds, and at last 300 feet — that is, 180 cubits — it traversed in a time of 5'', which differs not a little from Galileo's experiment. From this experiment it is concluded that a ball, falling from the Moon all the way to the center of the Earth, takes only a time of two hours, 29' 14".

PROBLEMA II. PROPOSITIO II.

To determine in how much time some ball, falling from the Moon to the center of the Earth, traverses the space lying between the surface and the center of the Earth — or, what is the same, the semidiameter of the Earth.

It must be noted, first, that the motion of a weight toward the center of the Earth can be considered under a twofold aspect: first, by way of *initiation*, as when someone, by divine power, should allow a ball to fall from the center of the Moon to the center of the Earth; second, by way of *continuation*, as if some ball, by divine power, fell from the surface of the Earth to the center of the Earth. For this latter motion, since it arises from a continual augmentation of the velocities, is much swifter; and so it also completes that space of the terrestrial semidiameter in a shorter time than if the ball slid from the very surface itself to the center of the Earth. We shall assign here the duration of each motion, so that the difference between the two motions may appear more clearly. Since, then, in the preceding Proposition we showed that a leaden ball, in falling from the Moon to the center of the Earth, [traverses] an interval of 196,000

miles in a time of 2 hours, 29' 14", while from the Moon to the surface of the Earth, according to Mersenne's calculation, it [traverses it] in a space of 2 hours, 17' 54", you will easily learn how much it traverses from the surface of the Earth to the center, by the motion continued from the Moon to the center. For if you subtract the motion from the Moon to the surface of the Earth from the motion from the Moon to the center of the Earth — namely, 2 hours, 17' 54" from 2 hours, 29' 14" — there will remain 11', 20", 18": the time, that is, which the motion continued from the surface of the Earth to the center takes. But if you wish to know how much time a leaden ball, released from the surface of the Earth all the way to the center, traverses, you must assume, first, that a stone in the time of one second traverses a space of 12 feet, and in a time of 5" traverses a height of 300 feet. This being granted, according to the aforementioned operations the stone or leaden ball will traverse the space of the terrestrial semidiameter in a time of 19' 56".

PROBLEMA III. PROPOSITIO III.

To determine how much time a leaden ball takes in falling from the surface of the Sun, and of the fixed stars, to the center of the Earth.

We suppose, first, by the common tradition of the astronomers, that the Sun is distant from the center of the Earth by 1,142 semidiameters. If you apply the rules of operation given above to these, you will find that the ball traverses the

whole space interposed between the center of the Earth and the disk of the Sun in eleven hours, 13' 50" 48'''; while the space interposed between the Sun and the Moon it traverses in ten hours, 57' 12" 54'''. These, subtracted from 11 hours, 13', leave 16' 43" from the Moon all the way to the center of the Earth. Again, the ball will traverse the space from the Sun all the way to the surface of the Earth in 11 hours, 13', 38", 57'''; and these, subtracted from 11 hours, 13', 56", 48''', leave 17', 51", for the time in which the said ball would traverse the remainder of its journey from the surface of the Earth to the center. Further, if anyone should more curiously wish to know how much time the said leaden ball takes from the Firmament all the way to the Sun, the Moon, and the center of the Earth, he must first assume that the Firmament is distant from the center of the Earth, according to the tradition of the astronomers, by 14,000 semidiameters of the Earth. If, then, you have operated according to the rules handed down above, you will find that the ball traverses that whole immense space from the Firmament all the way to the center in not more than 39 hours, 19' 41", 57", 54'''. The space, however, between the Sun and the Firmament it traverses in 37 hours, 4', 24", 37''', 21'''; and from the Sun to the center of the Earth, 1 hour, 39', 17", 20''', 33'''; from the Firmament all the way to the Moon, 39 hours, 14', 58", 50'''; and from the Moon, finally, to the center of the Earth, 4', 43", 23''', 4'''; and from the Sun all the way to the Moon, one hour, 53', 35", 52''', 39'''; from the Firmament, finally, all the way to the surface of the Earth, 39 hours, 19', 36", 54'''; and from there to the center of the Earth, 5", 4''', 15''''.

[Margin: We suppose first by the common tradition of the astronomers...]

Epilogismus temporis [Summary Reckoning of Time]

That a leaden ball, [falling] from the Earth, the Moon, the Sun, and the Firmament, takes all the way to the center.

A leaden ball traverses the space from the surface of the Earth all the way to the center — 1,145 leagues (each of which has 5,000 feet) — in a time of 19' 56".

From the Moon all the way to the center, a space of 196,000 miles, it traverses in a time of two hours, 29', 14".

From the Sun all the way to the center, a space of 3,997,000 miles, it traverses in a time of eleven hours, 13' 56".

From the Firmament all the way to the center of the Earth, a space of 49,000,000 miles, it traverses in a time of 39 hours, 19', 41".

From the Firmament all the way to the Sun, it accomplishes in a space [time] of 37 hours, 4', 24".

From the Sun all the way to the Moon, by the motion continued from the Firmament, a space [time] of 1 hour, 33', 33".

From the Sun all the way to the center of the Earth, by the motion continued from the Firmament, it accomplishes a space [time] of 39', 17".

From the Moon all the way to the center of the Earth, by the motion continued from the Firmament, it accomplishes in a space [time] of 4', 43".

From the surface of the Earth all the way to the center, by the motion continued from the Firmament, it traverses a space of 3,500 miles in a time of 5", 4".

And this is the reckoning of the time which any weight from the heavenly bodies takes in its fall to the center of the Earth, if it were to acquire the increments of its velocity according to the proportion of the odd numbers — a reckoning which we have arranged according to the experiments of Mersenne, as has been shown.

CONSECTARIUM I. [Corollary I]

From this it is clear how incomprehensible to the human mind is that velocity by which a ball, fallen from the Firmament, traverses the space of 3,500 miles from the surface of the Earth to the center in only 5" (which correspond to six regular pulse-beats of the vein). Hence many, compelled by the excess of such a velocity, openly denied a motion of this kind, lest they fall into absurdities. I say with certainty that, from so great a height, the velocity increases to such a degree that there is no body in the nature of things so solid that it could withstand the excessive impetus of such a motion; indeed, I do not doubt that a metallic body, melted by the violence of the heat kindled from the impetus, would soon be dissolved. Second, I say that nothing can be compared to the motion of this velocity — neither the casting of missiles and darts, nor the motion of birds, nor of the potter's wheel — except only the motion of the Firmament, which completes its period in a space of 24 hours; for a ball falling from the Firmament would reach its terminus 9 hours — that is, 15 hours — sooner, [its terminus] being the center of the Earth; and thus

from this motion of the Firmament its velocity may in some way be inferred.

CONSECTARIUM II. [Corollary II]

From this you will gather how unutterable is the velocity of spiritual substances, since they complete any space whatever, however far removed, as if in a

moment. But let this suffice concerning the fall of heavy bodies; and so let us pass on to other matters.

THE COSMOCENTRIC ART

SECTION IV. ARS COSMOCENTRICA [The Cosmocentric Art]

AND IT IS CENTROSOPHIA APPLICATA [Applied Centrosophy]

CAPUT I.

In the preceding Section we gave our judgment concerning the proportion of motion; in this Section we shall explain the use and application of the things that have been said. And although physical things applied to mathematical ones cannot — owing to the slipperiness of experiments and their hidden fallacies (the condition of matter being such) — exhibit true and geometrical demonstrations, nevertheless, abstracting from all resistance of the medium and from all the inconstancy of fallacious matter, we here bring forward some demonstrations by which the conditions of local motion may be demonstrated, so far as suffices for physical proofs — lest we should seem to have prejudged anything against the modern mathematicians. And that this may be done by the right method [εὐμεθόδως, eumethodōs, "in a well-methodical way"]:

I assume I: In every local motion, whether natural or violent, the moments of velocity behave as the increments of the odd numbers from unity.

II: The spaces, or lines, of the descent of heavy bodies are in the squared ratio of the durations or times; or, what is the same, the increments of velocity have the same ratio that the times have to the square.

PROPOSITIO I. THEOREMA I.

Motions along a vertical line and an inclined line, whose endpoints are joined by a straight line drawn perpendicular to the inclined line, are equal to one another.

When we say that the motions taken here are equal, we mean it not as to velocity, but as to duration. For it is certain that movable bodies are carried more slowly up [along] an inclined plane than by natural motion along the vertical. Let some movable body, then, descend from C to D, and another equal one from C to A — the former along the vertical line, the latter along the inclined line. Let any point be determined on the perpendicular line C E — for example, E — from which a normal drawn to the inclined line C A points out, at D, the terminus of the line C

D, upon which the movable body, rolled down, takes a time equal to that motion which occurs along the vertical line C E. For since the triangles A D E and A E C are equiangular and similar, the angles A D E and A E C will be equal — the straight line E A D being common. As, therefore, A C is to A E, so A E is to A D; whence the times along A D and C D are equal.

Diagram. A right triangle illustrating Theorema I, the equality (in duration) of motion along a vertical and an inclined line. The vertical leg runs from C (top) down to E (bottom left); the inclined hypotenuse runs from C down to A (bottom right); E and A are joined along the base. A circle (the rolling movable body) sits on the inclined line C A near the point D, which lies on the inclined line where the perpendicular from E meets it.

- C (top apex): vertex; origin of both the vertical line C E and the inclined line C A
- E (bottom left): foot of the vertical line C E
- A (bottom right): lower terminus of the inclined line C A
- D (on inclined line C A, near the rolling circle): point where the normal from E meets the inclined line C A

Marcus Marci [Jan Marek Marci of Kronland], by another argument, ingeniously demonstrates this same thing. For he says that the impulse of bodies rolled down an inclined plane is increased in proportion to the distance of the center [of gravity] of any heavy body from the fulcrum [hypomochlio, ὑπομόχλιον]. Let there be, in the figure, a ball rolled down from A to D; let the line of the fulcrum be E F, the center of gravity of the ball I, and its distance from the center

of gravity of the ball I, and its distance from the center [of gravity] and from the line of the fulcrum E F, let it be I Z. It will then be: as D I is the greater impulse to the lesser impulse D Z, so is the motion along A E to the motion along A D; for the triangles are similar to one another, and consequently the sides are analogous — the side I D to the side A C, and E Z to the side A E. Therefore, as C A is to E A, so is I D to I Z; and as A E is to A C, so is I D to Z D.

Diagram. A larger right triangle illustrating Marcus Marci's lever-based demonstration. The base runs horizontally from C (bottom left) to E (bottom right), with F marked on the base between them; a vertical rises from F to the apex region; the hypotenuse runs from C up to the apex at the upper right. A small circle (the rolling ball) is drawn near the top of the vertical, carrying the lever-and-center-of-gravity labels (H, e, I, Z, G, D) of the fulcrum construction.

- C (bottom left): lower terminus of the base / start of the inclined hypotenuse
- E (bottom right): right end of the base (also lettered as terminus of line E F / E Z construction)
- F (on base, between C and E): foot of the vertical; point on the fulcrum line E F
- A (apex, upper right): top terminus of the inclined line (the ball rolls down from A to D)
- H (at the small circle, upper left of circle): label on the rolling-ball / lever construction
- e (at the small circle, top): label on the rolling-ball construction
- I (within the small circle): center of gravity of the ball
- Z (within the small circle, near I): endpoint of the distance I Z from the fulcrum line
- G (below the small circle): point on the vertical near the circle
- D (at the small circle, right): point to which the ball rolls down

PROPOSITIO II. THEOREMA II.

Motion along a less inclined plane is faster than motion along a more inclined plane, in the ratio of the sines of the complements of those inclinations.

By a "less inclined" line or plane I mean here the one that departs less from the vertical or perpendicular line; a plane is "more inclined" when it departs further from the perpendicular. With this established, from the point A on the circle A L T R draw the lines A B, A C, A D, A E. Let A B be the horizontal line and A T the vertical — which is the same as the diameter of the circle. I claim that one and the same moving body — say the ball O — moves at unequal speeds along these lines: faster along the plane A E than along A D, and faster along A D than along A C, and so on for the rest. In each case the ball moves all the faster over a less inclined plane the closer that plane approaches the vertical or perpendicular line, and all the slower the closer it approaches the horizontal plane. Thus the velocity along the inclined line A E stands to the velocity along the line A D just as the sine of angle A T S stands to the sine of angle A T R.

From the points of contact of the ball — Q, R, S — draw the perpendiculars Q T, R T, S T to T. Then from those same points of contact Q, R, S draw further lines parallel to the diameter A T of the circle: Q G, S H, R I. Let these be called the lines of the fulcrum [lineae hypomochlii]. These lines touch [recte: cut — *secant*] the ball at the points K, N, V. Next, from the center of the moving ball draw the

perpendiculars αo , $o\beta$, $o\gamma$ to the lines of the fulcrum. Now since the external angle $T S L$ is greater than the angle $I R H$, the angle $\gamma \gamma o$ will consequently be greater than the angle $\beta \gamma o$; and the side γo will be greater than the side βo — these being the distances of the ball's center of gravity from the lines of the fulcrum. Therefore, since there is a greater impulse at the greater distance γo of the center of gravity from the line of the fulcrum than at the lesser distance βo , it follows that along the line $A S$ — that is, on the less inclined plane — the motion will be

faster than along the line $A R$, which is less inclined [recte: more inclined]. For the fulcrum-line $V S$ takes off the smaller portion $V X S$ from the ball, whereas the fulcrum-line $N R$ takes off a larger portion. Consequently, along $A S$ the ball moves faster, because of the preponderant larger portion of the ball $V Y S$, than along the line $A R$, where the fulcrum-line $R N$ leaves the larger part of the ball less preponderant.

That the velocity of the motion is in the ratio of the sines of the complements of the inclinations, I demonstrate as follows. As $S O$ stands to $o\beta$, so does the diameter $A T$ to the chord $A S$; and as $R O$ — equal to $S O$ — stands to $o\beta$, so does the diameter $A T$ to the chord $A R$. But as $A S$ and $A R$ stand to one another, so do their halves $A L$ and $A M$ — the sines of the angles $A P L$ and $A P M$, which are equal to the angles $A T S$ and $A T R$ respectively (because of the parallels $T S$ and $P L$, and $T R$ and $P M$), and which are the complements of the inclination of the planes $T A S$ and $T A R$. Therefore, as $o\gamma$ is to $o\beta$, so are the sines of the complements of the angles of inclination to one another — which was to be demonstrated.

Diagram. A large circle with horizontal diameter $region$, used for Theorem II on inclined-plane velocities. From the top point A several straight lines radiate downward to the right toward the circle and beyond. $A B$ is the horizontal line drawn to the right; $A T$ is the vertical (the diameter) descending to T at the bottom. The point L lies at the left extremity of the circle, and P lies on the horizontal at center. From A radiate the inclined lines $A C$, $A D$, $A E$ (with B , C , D , E lettered along the right margin from top to bottom). Several small circles (the rolling ball O in successive positions) are drawn along the inclined lines, with the contact-points and fulcrum constructions K , M , N , Q , R , S , V , X and the three small ball-circles labelled $K(\alpha)$, $R(\beta)$, $V(\gamma)$ with paired centre sub-letters (α/o , β/o , γ/o near the lowest), and the contact point S adjacent to the lowest. The diameter terminates at T ; index "III" appears near the foot at right.

- A (top of circle): apex from which all lines radiate

- B (upper right): end of horizontal line A B
- C (right margin, below B): end of inclined line A C
- D (right margin, below C): end of inclined line A D
- E (right margin, lowest): end of inclined line A E
- L (far left of circle): left extremity
- P (center, on horizontal): point on line A B
- T (bottom): foot of vertical diameter
- K, M, N (mid-figure): construction / contact points
- Q, R, S (mid-figure, near ball positions): points of contact of the ball
- V, X (lower interior): fulcrum-line / ball-portion points on the lowest ball-circle
- three small ball-circles K(α), R(β), V(γ): centre sub-letters α/o , β/o , γ/o (γ/o the lowest)
- G (foot, near T): noted with index "III"

PROPOSITIO III. THEOREMA III.

Bodies released from the same point and rolling down along the chords of a circle — which represent inclined planes — traverse the spaces of those chords in the same time in which bodies sliding down naturally along the diameter of the circle complete it.

Let there be a circle B C A G with diameter B A, and let chords be drawn from the point B to the periphery of the circle, representing inclined planes: B E, B F, B G, B H, B I. I claim that the time taken to traverse the chords B E, B F, B G, and so on, is equal to the time in which moving bodies finish their motion along the diameter B A of the same circle.

For if from the point A the straight lines A E, A F, A G, A K [recte: A H], A Y [recte: A I] are drawn, the angles A E B, A F B, A G B, and the rest, being inscribed in a semicircle, will be right angles. Consequently, by Theorem I, Proposition I of this [Sectio], the motion along B A is equal in duration to the motions along B E, B F, B G, B H, B I. The same will follow if, from the

arcs of the periphery B E, F G, H I, the motion is made to terminate at A through the chords E A, F A, G A, H A, I A — since the lines B E, B F, F G [recte: B G], B H, B I are perpendicular to those chords.

I therefore claim that the motion along the chord B E is equal to that along the chord E A; the motion along the chord B F is equal to that along the chord F A; the

motion along B G equals that along G A, just as those along B H and B I equal those along H A and I A. The reason is this: since the moving body — whether along the said chords B E, B F, B G, B H, B I, or conversely along I A, H A, G A, F A, E A — terminates in the circle, nature accordingly fixes, at the points E, F, G, H, I, at the extremities of the shortest lines through which it operates, the limits set to its motion by gravity, which it cannot overstep. For between these limits and the vertical line (the diameter A B of the circle) lies the smallest distance from the center of the Earth A. And since the angles A I B, A H B, A G B, A F B, A E B are right angles, having the same base A B, they will lie — by Euclid III.31 [Euclid, *Elements* III.31; printed "1 5. l. 4."] — in the same semicircle B E F G H I A, whose diameter B A is vertical: namely the distance between B and the Center of the World.

Suppose, then, that the lines — say B I — were to run beyond the circle to S or to T [?], and the line B H to N. They would then be moving against the Center, which is absurd. Therefore, at the points I, H, G, F, E — that is, by means of the shortest lines — nature fixes the limits of motion set by gravity, so that at these points, by means of the chords they bound, the moving body would attain its end and rest, in the same time in which the body that moves naturally along the vertical line B A attains its rest. Therefore the moving bodies, etc. — which was to be proved.

Diagram. A circle B C A G with vertical diameter B A (B at top, A at center-bottom of the inner circle). A horizontal line runs across the top through B, with points Y, Z, D marked to the right of B. From B several chords descend to the right toward the periphery and to outer points; from A several lines radiate to the right. The points E, F, H, I lie along the right side of the circle between B and A. Outer points U, M, N lie to the right, and S, T below A; P at the bottom; C and Q at the left.

- B (top): upper end of the vertical diameter; origin of the chords
- Y, Z, D (top, right of B): points along the top horizontal line
- A (center): lower end of inner diameter / Center of the World
- E, F (upper right, on circle): chord-endpoints
- H, I (mid-right, on circle): chord-endpoints
- K (right, near F): point on a chord
- U (right): outer point
- M (far right, on horizontal through A): outer endpoint
- N (lower right): outer point beyond the circle
- S (just right of A): point on the diameter line
- T (below A): point on the descending line

- P (bottom): foot of the vertical
- C, Q (left): points on the left of the circle

down [recte: along] the arcs of the periphery B E, F G, H I, let the motion be made to terminate at A through the chords E A, F A, G A, H A, I A, since the lines B E, B F, F G [recte: B G], B H, B I are perpendicular to those chords. I therefore claim that the motion along the chord B E is equal to that along the chord E A; the motion along B F is equal to that along F A; the motion along B G equals that along G A, just as those along B H and B I equal those along H A and I A.

The reason is that the moving body — whether along the said chords B E, B F, B G, B H, B I, or conversely along I A, H A, G A, F A, E A — terminates in the circle. So nature, at the points E, F, G, H, I, at the extremities of the shortest lines through which it operates, fixes the limits set to its motion by gravity, which it cannot overstep — since between these limits and the vertical line (the diameter A B of the circle) lies the smallest distance from the center of the Earth A.

And since the angles A I B, A H B, A G B, A F B, A E B are right angles, having the same base A B, they will lie — by Euclid III.31 [*Elements* III.31; printed "1 5. l. 4."] — in the same semicircle B E F G H I A, whose diameter B A is vertical: namely the distance between B and the Center of the World. Suppose, then, the lines — say B I — were to run beyond the circle to S, or to T, and the line B H to N: they would then be moving against the Center, which is absurd. Therefore at the points I, H, G, F, E — that is, by the shortest lines — nature fixes the limits of motion set by gravity, so that at these points, by means of the chords they bound, the moving body attains its end (which is rest), in the same time taken by the body that, moving naturally along the vertical line B A, attains it. Therefore the moving bodies, etc. — which was to be proved.

COROLLARY.

From this it follows that the perpendicular motion of a rectilinear figure stands to its inclined motion in the ratio of the semidiameter of the moving figure to the segment of it lying between the figure's center and the line of the fulcrum.

Let there be some plane O B declining from the perpendicular O Z, on which some body L moves — say a tetrahedron, a cube, or a pentahedron. Now, by what I taught in the first Sectio of this Book concerning the pyramid, the prism, and the tetrahedron, the center of gravity in a body cut through its center of gravity is P. Draw the line of the fulcrum from N in S, parallel to O Q; and from the center of gravity P draw P Q perpendicular to O Q — this is called the semidiameter of the figure.

I claim that the vertical motion along O Q stands to the motion along the inclined line O B as Q P, the semidiameter of the figure, stands to the segment intercepted between the center of gravity P and the line of the fulcrum N S — that is, to P R. For since the moving gravity is equal to the motion, and the whole or vertically-acting gravity stands to the gravity acting at P Q along O B as P Q to P R, it follows likewise that the vertical motion along O Q stands to the inclined motion along O B as P Q to P R — that is, as the semidiameter P Q to its segment between the figure's center P and the line of the fulcrum.

In the same way, the motion of a cube on the inclined plane [E L — *recte* uncertain] [?] will stand to its motion along the perpendicular O Q as the semidiameter of the cube K Z [recte: K L?] [?] stands to the segment K L between the center K of the cube and the line of the fulcrum N O. Likewise the motion of the pentahedron along the inclined line O B stands to its motion along the perpendicular O Q as the segment I X stands to the semidiameter T V of the pentahedron.

Here it should also be noted: the more the lines incline — that is, the more they recede by their inclination from the vertical O Q — the less the portion of the figures outside the line of the fulcrum weighs, and consequently the more slowly the body traverses the plane; but it rolls all the faster the more the portion of the figure outside the line of the fulcrum weighs — until the line of the fulcrum divides the figures in half. Once that has happened, the body rests perfectly, being situated, as it were, on a horizontal line.

It is therefore clear that from this foundation countless hidden principles may be brought in to enrich mechanics — and these few indications must suffice. Whoever wants more should consult the ingenious little book *On the Proportion of Motion* by Joannes Marcus Marci [Jan Marek Marci of Kronland].

Diagram. A construction for the Corollary, showing three rectilinear bodies on an inclined plane. A long inclined line runs from the upper left (near O, S) down to B at lower right, with several vertical dotted plumb-lines descending from the bodies to a horizontal base near Z. At top: a small triangle with vertices labelled O, S above and Q, R, P, M across, with N just below. In the middle: a pentagon (the pentahedron) with V and the cross-mark X, T at its center. Below it: a tilted square (the cube) with V at top, and z, L, K marking the fulcrum-line and center, with O at its lower corner.

- O, S (top left): top of the perpendicular / fulcrum points

- Q, R, P, M (upper triangle, left to right): center of gravity P, segment-points Q and R, outer vertex M
- N (below the triangle): fulcrum-line point
- V, X, T (pentagon, center): semidiameter construction of the pentahedron
- z, L, K (cube, center): fulcrum-line z, segment L, center K of the cube
- B (lower right): foot of the inclined line O B
- Z (lower left, base): foot of the perpendicular O Z

PRAGMATIA.

To make an instrument by which the equalities of motions with respect to duration may be exhibited.

Let a compass — the kind called a proportional compass — A B C be made, with its two legs divided into a hundred (or fewer) equal parts on each leg. Then let a cross-bar D be made, whose end D always rests at right angles against the side A C, the bar being movable along the side A C. Let the side A D represent the perpendicular line of the downward motion of some weight, while A C represents the inclined plane, which can be adjusted to fit any inclination once drawn out.

I claim that the bar, applied perpendicularly at D, marks the limit of motion on the inclined plane A C, and that the point at S marks the limit of the perpendicular motion that a perpendicularly falling weight reaches in the same time in which the weight at D is rolled down the inclined plane A C; and in the same time it reaches G as it reaches F, and I as it reaches H. For since the angle A [recte: A D S]

is a right angle, by Euclid III.31 the point will necessarily lie in the semicircle A D S, and the points F and H likewise in their own semicircles A F G and A H I.

Now since in Proposition 3 we showed that these are the shortest lines on inclined planes, by which nature reaches the limit of motion, and that the motions are equidiurnal [equal in duration] with the motions made along the perpendicular A I, it follows that the motion from A to D is equidiurnal with the motion from A to S; the motion from A to F stands to the motion from A to G [as equidiurnal]; and the motion from A to H is equidiurnal with the motion from A to I.

For if you imagine the cross-bar always standing perpendicularly on the side A C with one of its ends, running down the plane, and cutting the perpendicular line with its other end, it necessarily follows from what has been said that the body moving over the inclined plane A C describes a motion equidiurnal with that over

the perpendicular A S. The same follows if you spread the side A C of the compass into any inclination, great or small; for the equally divided parts in the legs indicate the spaces that the moving body covers in equal moments on the side A Y [recte: A C]. The sense of the proposition is therefore clear.

Diagram. The proportional-compass instrument for the Pragmatia. From the apex A a curved boundary descends to the right to D, with chords A S, A D, A F [?], A H drawn within. The compass leg A C runs from A down to C at the lower right; the leg A B descends to B at the lower left, with the index "I" near B. Cross-bars and the segments S, D, P, F, G, H mark the successive limits.

- A (apex): vertex of the compass
- S (upper, on inner arc): limit of perpendicular motion in semicircle A D S
- D (upper right): limit on the inclined plane
- P (left, mid): point on the leg A B [?]
- F (mid-right): limit-point in semicircle A F G
- G (lower left): foot-point of the semicircle A F G
- H (lower right): limit-point in semicircle A H I
- B (lower left): foot of leg A B (with index "I")
- C (lower right): foot of leg A C

CAPUT II.

De pendulorum motibus.

On the motions of pendulums.

Since the motions of pendulums along the arcs of a quadrant behave in exactly the same way as motions along inclined planes — which are nothing other than the chords subtending the arcs of a quadrant — and since infinitely many such chords can be considered in the arc of a quadrant, the pendulum too must be reckoned to traverse, in its vibrations, infinitely many planes that are now more, now less, inclined. The following Propositions concern these.

PROPOSITIO IV.

The motions of pendulums acquire many affections or properties. The first is that all single courses [diodromos], whether greater or smaller, traverse in equal time the space that lies between the beginning of the pendulum's motion and the line of direction (the line of the Center). The second is that all the outward swings and return swings are equidiurnal among themselves. The third is that all single

courses are mixed of natural and violent motion. The fourth is that all single courses — that is, both the outward and the return swings, though ever smaller and smaller — are nonetheless equidiurnal. The fifth is that different pendulums are in the doubled ratio of their times. Of all these, each in turn:

A pendulum from any point of the same circle returns in equal time to its station, that is, to the line of direction or of the Center; and its outward swings are equidiurnal with its return swings, in whatever arcs of the periphery.

For since the motions of pendulums behave as sines, and their intervals as the arcs intercepted by the sines, and since these intervals become continuously smaller, and at the last point of the semidiameter have no interval at all, while the motions continuously fall short of that point by an ever smaller interval — it follows necessarily that the motions of a pendulum, from whatever point of the periphery they begin, return in equal time to the last point of the semidiameter of the quadrant. Yet a pendulum set in motion at any point does not rest at the line of the Center, but swings beyond it, until — after the agitation of its repeated forward and return courses has been carried out — it finally comes to rest at the line of direction.

And since the pendulum swings out and back through ever smaller arcs, the impulse must necessarily be diminished in that ascent — because gravity and impulse are mixed together. In the descent along the same line, gravity and impulse move it (the impulse arising from gravity in a continuous flow); but from the line of direction (which we have established as the semidiameter of the quadrant), gravity continuously resists the impulse. For the contrary impulse, reborn from that same gravity, removes an equal part there, so that the remaining motion is equal to the excess of the greater. For just as the impulse continuously decreases by the same increments by which it had increased, so the velocity, from its maximum increment all the way to the end of the motion, becomes continuously smaller.

Let a pendulum be fixed at A; let it run down from E to N, and from N to F, and thence to M, and thence to G, and so on for the rest. I claim that the pendulum running down from E to N traverses this arc in the same time in which the pendulum running down from N to E does so, and thence to M in equal

Diagram. A semicircular fan of pendulum-radii hung from the apex A, illustrating the equidiurnal swings. From A a horizontal line runs left to O and right to B. The semicircular arc below carries, from upper left around to upper

right, the points N, M, L, V, I, K, H, G, F, E, with radial lines from A to each. The lowest points V, I, K lie near the bottom of the arc.

- A (apex, top center): point of suspension
- O (upper left, end of horizontal): left terminus of the line of direction
- B (upper right, end of horizontal): right terminus
- N (left, on arc): swing-point
- M (lower left, on arc): swing-point
- L (lower left, on arc): swing-point
- V (bottom, on arc): lowest left swing-point
- I (bottom): lowest point near the line of the Center
- K (bottom, right of I): swing-point
- H (lower right, on arc): swing-point
- G (lower right, on arc): swing-point
- F (right, on arc): swing-point
- E (upper right, on arc): starting swing-point

time as [it swings out] to G; for since the impulses at E and N increase, while at F and M they diminish the velocity of the motion in equal proportion, the momenta of the velocity will be equal to its decrement. Accordingly the velocity gathered in the motion, through equal decrements of its increment, terminates in rest. Thus what the impulse acquires in velocity from E to N in the greater arc, it loses from N to F in the smaller. For just as in the return swing the velocity continuously and unequally increases, so it does in the outward swing; and because the violent motion decreases proportionally, so that its decrements equal the increments of the other — the first matched to the last — because both arise from the same gravity, which from the beginning of the swing exerts its weight through the more inclined lines.

Therefore, since gravity alone diminishes the impulse — being situated at equal intervals from the line of the Center, and, on account of similar inclination, the circle and the arc weighing equally among themselves — so too the impulse of that same gravity. And since the contrary impulse removes a part equal to itself, the outward and return swings will be equal among themselves, the time being equalized on this basis: so that what the pendulum's outward swing acquired by natural impetus in the greater arc, the violent motion takes away in the ascent through the smaller arc. The proposition is therefore clear.

COROLLARY I.

From this it is clear that if a pendulum were to run from E to the last point O of the semicircle, the pendulum's motion would be perpetual; for there would be no greater reason for it to go from E to O than the reverse — and so it would not return to E, and again to O — since the impetus is altogether equal in both the forward and the return courses, and they always measure out an equal space.

Hence some, examining the cause why a pendulum running from E never reaches O, the terminus of the semicircle, and ascribing it to the resistance of the intervening air, supposed that if a pendulum were to move in a vacuum, it would have no resistance and so would move perpetually. Whether motion can occur in a vacuum, let them see to it. For my part, saving the judgment of others, I boldly declare: just as in nothingness — such as a vacuum is — no relation to the Center can be conceived, nor can a line of direction have any place, so too in that same nothingness, nothing can be moved. And the matter is clear from Definition III at the beginning of the canons on the center of gravity [De Centro gravitatis].

COROLLARY II.

From this it is again clear that the motions of pendulums along the arcs of the same circle have the ratio that the sines of the doubled angles have — namely, the angles that are the complements of the inclination of the chords or subtenses.

Let there be arcs B D C I and b D C [?]; the angles A B I and A B C will be the angles of inclination of the chords B I and B C, and their complements B A I and B A C, because of the right angles at I and C [recte: T and C]. Therefore let the lines I H [recte: T H] and C G touch the circle at the points I and C [recte: T and C]; and from the center K let the lines K T, K C be drawn to the tangents T H, C G. Since, then, K H T [recte: K T H] and K G C are the angles of inclination of the planes,

the angles H K I [recte: H K T] and G K C will be their complements, and B A I, B A C will be at the periphery of the doubled [arc]. Just as, then, the sine of angle B K T stands to the sine of angle B K C, so does the velocity of motion at I stand to the velocity of motion at C. For since the motion at any point of the circle takes place along the tangent line, the ratio of the velocity at I and C will be that which is the velocity of the tangents I H and C G; and the velocity along I H stands to the velocity along C G as the sine B L of angle B K I stands to the sine B M of angle B K C. Therefore the velocity along C B [recte: at C] is as the sine of angle B K I to the sine of angle B K C — namely, the sines of the doubled angles, which are the complements of the inclination of the chords B T, B C. Which was to be proved.

Diagram. A circle with apex A at the top, used for Corollary II on pendulum velocities and tangents. From A several chords descend to the right toward the circle and to outer points O, P, T. The center K is marked at mid-left of the circle, with L, M to its right and the inner construction lines. Below the circle the construction continues to B, E, and the long lines descend to G at the foot.

- A (top of circle): apex / starting point of the chords
- O (upper right, on circle): outer point
- P (right, on circle): chord-endpoint
- T (right, on circle, below P): tangent-point (printed I in places)
- K (center-left): center of the circle
- L (right of K): point on construction line
- M (below L): point on construction line
- C (lower right, on circle): tangent-point
- D (lower mid): chord-point
- B (bottom of circle): foot of the vertical
- E (just below B): point on the descending line
- G (lower, on the long line): tangent-line terminus

PROPOSITIO V.

That the motions along similar arcs of unequal circles have the ratio that the sines of those arcs have.

Let there be unequal circles B L and C M; let the arcs in the larger circle B D and B F, and in the smaller circle C E and C G, be similar to one another. Then the motions of the pendulums will stand to one another — the motion from F to B, the motion from G to C, and the motion from D to B to the motion from E to C — as the sines of those arcs.

Draw the tangent lines P K, A I, T B, G H from the points of contact F, D, G, E. The triangles A F K, A I D, A B T, A C [recte values uncertain] [?] will be similar; and because of the proportionality of their sides, the angles at K, I, B, C [?] will be equal, and the angle A common to all the triangles, while the angles at D, F [recte: D, E, C?] [?] are right angles. Just as, then, F is to D, so is G to E; and as F is to D, so is the sine of arc F B to [the sine of arc D B]; and as G is to E, so is the sine of arc G C to [...]

to the sine of arc E C; and by alternation, as the sine of arc F B is to the sine of arc G C, so is the motion in F to the motion in G; and the motion in D is to the motion

in E as the sine of arc D B is to the sine of arc E C. Therefore the motions along similar arcs of unequal circles, and so on, which is what was proposed.

Diagram. A figure of two concentric circles sharing the common center A. A vertical diameter runs from L at the top, through M, the center A, and down through B to I at the bottom. The outer (larger) circle carries the points L (top), B (lower part of the vertical line), and F (on the right); the inner (smaller) circle carries M (top), C (lower part of the vertical line, on the inner circle), and G (on the right). Below the center A, a cluster of straight chords and tangent lines connects the points V, G, C, E, F, H, T, B, and D, forming the similar triangles used in the proof. The construction compares the chords/sines B G and C V (of the two circles) and the motions along the corresponding arcs.

- L (top of outer circle, on the vertical diameter): vertex L
- M (top of inner circle, on the vertical diameter): vertex M
- A (common center of both circles): center A
- V (just below A, inside the inner circle): point V
- G (right side, on the inner circle): point G
- C (on the vertical line, on the inner circle below A): point C
- E (just right of C): point E
- F (right side, on the outer circle): point F
- H (below C, near the vertical line): point H
- T (between H and D): point T
- B (on the vertical diameter, on the outer circle): point B
- D (lower right, on the outer circle near B): point D
- I (bottom of the vertical diameter): point I

[continued at foot of the left column:] ...to the motion in G; and the motion in D is to the motion in E as the sine of arc D B is to the sine of arc E C. Therefore the motions along similar arcs of unequal circles, and so on, which is what was proposed.

Corollary I

From this it is clear that the motion in the smaller circle is faster than the motion in the larger circle. For since the motion in B F has to the motion in G C the same ratio that the sine B G has to the sine C V—and likewise A B is to A C as B G is to C V, on account of the analogy of the sides—and the line A B is greater than the line A C, the line B G will also be greater than the line C V. Therefore the motion in the line A B, over the greater interval A B, will be greater than the motion in A C. And

so the motion in the smaller circle will be faster; that is, it will take place in less time than in the larger circle.

Corollary II

From this it is further gathered that the motions of [bodies on] the circles stand in the ratio of their times, which the diameters have to one another doubled. For just as the sine B G is to the sine C V, so is the motion in F B to the motion in G C; and as B G is to C V, so is A B to A C—because the motion A B is equal to the motion B G, and the motion A C to the motion C V, by Theorem 2 preceding. But A B to the motion A C, and its double L B to M C, have the ratio that the times of the motions of the circles have. And consequently those times have the doubled ratio of the diameters to one another.

Caput III

On the use and benefit of the foregoing

Practical Problem I

To construct a table by which, given the time, you may know the height from which some weight has fallen from any place; and conversely, knowing the height, you may know the time it took in falling.

Let us assume, first, following the observation of Mersenne [Marin Mersenne], that a body in falling downward through a height of three feet takes a time of half a second. Let us assume, second, from what has been said, that the velocity of the falling weight is accelerated according to the proportion of the odd numbers. Let us assume, third, that the space through which the weight falls is [measured] in feet, of which one is divided into 12 inches; and that six such feet make one perch [*pertica*] or rod [*sexapeda*], that 15,000 such feet—or, what is the same, 250 decempedes [ten-foot measures]—make one French league [*leuca gallica*]. These things presupposed, let half-seconds be set down in order in the first column up to 60, so that the 60 half-seconds are equivalent to 30 seconds. This done, let a series of the odd numbers be set down in order in the second column, as appears in the table below. In the third column let the squares of the times be set down in natural order, as you see. In the fourth column [let there be] the feet, or the space, through which the weight falls in any given second, or half of one. Since, then, by the supposition the observed weight in the time of half a second covers a space of three feet, these three feet will hold the first place in the column; the rest you will continue in order in this manner.

Multiply these three feet by each of the odd numbers placed in order in the second column, and set the products in order opposite, in the fourth column. For example, the number 3, placed in the second position in column II, multiplied by itself produces 9, which are to be placed opposite in the second position of the fourth column. Again, let 3 be multiplied by the next following number, the five [i.e. 5], and let the product 15 be set down opposite in the fourth column. Then, finally, let 3 be multiplied by the number 7 placed in column II, and let the product 21 be set down opposite in the fourth column. And so you will be able to continue the table to infinity, always multiplying the number three [i.e. the ternary] into all the odd numbers placed in order in column II, and placing the products opposite them in the fourth column.

The fifth column is composed by this device. In the fourth column join the second number—namely 9—to the first in column V, namely 3, and you will have 12, which you set in the second place of column V of the table, opposite the 9. Again, add 15 in column IV to the number 12 just produced, and you will have 27, which are to be placed in column V after 12, opposite 15. Further, 21, which is the fourth number in column IV, let it be added to 27, the third in column V, and 48 will result, which set opposite 21 in column V. In this way you will proceed with the remaining numbers in order, always joining the numbers in column IV to the numbers just produced in column V; and you will have a table suited to your uses, as follows.

TABULA

From which it is known how much space any given weight covers.

Explanation of the Table

The first column of this table shows half-seconds, 120 of which make one first minute; hence any two consecutive numbers taken together make one second, and so the whole column, which contains 60 half-seconds, is reckoned to contain 30 seconds. And these are the times by which the spaces through which some weight falls are measured.

The second column contains the series of odd numbers from unity, which have been treated fully in the preceding pages, and which can be fitted to any measure once the time is given in the first column. Thus, if in one half-second the weight falls through a space of one foot, then at the end of the next half-second it is reckoned to fall through three feet, and in the third half-second through five, and in the [fourth] half-second through 7, and so on with the rest.

The third column shows the squares of the times, that is, the aggregates of feet that the weight covers in a given time. Thus, if the weight falls one foot in the first half-second, and three in the second half-second, these added to 1 give 4, the aggregate of feet which the weight covers in the first and second half-seconds—and so the square of the second half-second. But, in order to show the principle of the proportion by another example, we have here arranged column IV, in which the feet are set down according to the observation of Mersenne, who found that in the time of one half-second any weight covers a space of three royal feet [*pedes regii*]. Hence in two half-seconds it will necessarily cover a space of 9 royal feet, and in three half-seconds a space of 15 feet, and so on with the rest.

Column V shows nothing other than the aggregate of feet that some weight covers in the time corresponding to it in the first column. For example, if some weight falls three feet in one half-second, it will cover a space of 12 feet in the second half-second, because in column IV 3 and 9 joined together make 12—just as, if in one half-second the weight covered a space of one foot, it would cover 3 feet in the other half-second, to which the first foot joined makes 4, namely the square of two half-seconds, as appears in the second and third columns; and everything is made abundantly clear from the structure of the table just indicated. So the aggregates of the numbers placed in column IV are exactly the same numbers as those in table V; for 3 joined to 9 give 12, which holds the second place in column V; while 15, joined together with 9 and 3 in table IV, give the third number in column V, 27—the same that you will get if you join 15 to 12, which immediately precedes 27. In the same way, if you join 21, 15, 9, 3 into one, 48 will result, the fourth number in column V, which likewise emerges from the addition of 21 to 27, the one immediately above it in column V.

The remaining numbers following in order, aggregated together, give the number of feet that the weight covers in the time corresponding to the half-diameters [*semidiametri*] placed in column I.

Example

If you wish to know how much space some weight covers when thrown from a certain height in the time of 10 half-seconds—or, what is the same, 5 seconds—see what number in the second column corresponds to 10 half-seconds, and you will find it covers 19 feet (granting, however, that in one half-second the weight falls through a space of one foot). But if, following Mersenne's observation, it covered three feet in one half-second, and you wish to know how much space it covers in the time of 10 half-seconds—that is, 5 seconds—then look in the first column for the number 10, and you will find in column IV the corresponding 57, which indicates the space the weight traverses in the given time. But if you wish to have the aggregate of all the feet that the weight covered over 10 half-seconds, add all the numbers in order up to 5 [recte: up to the 10th row] to the first number in column V, and 300 will result, which you will find again in table V opposite the 10 half-diameters as the corresponding entry..")

Further, if by experiment you should find that some weight covers 6 feet in the space of one second, you will obtain a table of observation by this method: Let the seconds be placed in the first row, then the odd numbers from unity; third, multiply the number placed in the first position in the third table by 3—that is, into the second odd number in column II—and you will have 18; then multiply 3,

namely the odd number 5, into 6, and you will have 30, which you place under 18; again multiply 6 into 7, namely into the fourth odd number, and you will have 42; and so always multiply 6 into all the odd numbers in order, and the sum will give what is sought, as the table shows, presented in only ten half-seconds. In this way, given the time and the space through which any heavy body falls, you will be able to construct tables with no trouble. But anyone who has understood the structure of the preceding table will find no difficulty in constructing the remaining ones, infinite in number.

Practical Problem II

Continuation of the preceding table to infinity.

If you wish to continue any table to infinity, proceed thus: Multiply the squares of the cases [*Casus*] into the last number contained in the column, and you will have what is sought.

Example

If you wish to know how far a stone falls in the time of 60 seconds, or 120 half-seconds—that is...

[continuation, left column:] ...in twice as long a time as it falls in 60 half-seconds or 30 seconds, proceed thus: since the last number of the fifth column is 10810, you will multiply this by 4—that is, by the square of the number two, which square is contained in the third column opposite the 2—and you will have 43240, the number of feet through which the said stone falls in the time of 60 seconds or 120 half-seconds, that is, in one first minute. Again, if you wish to know how far it falls in three times as long a time as it fell in 60 half-seconds, then you will again multiply the last number in the fifth column, 10810, by the square of the number three contained in the third column—that is, by 9—and 97290 feet will result, the space sought. Further, if you wish to know how far it falls in four times as long a time as it fell in 60 half-seconds, let the square of the number four contained in the third column—namely 16—be multiplied into the last number of the fifth table—namely 10810, as before—and you will have 172960, the space of feet sought. And so, proceeding to infinity, if you always multiply the squares contained in the third table in natural order into the last number of the fifth table, the product will always give a number of feet, the greater in proportion as the square—by the number constituting it—is greater.

For example, if you wish to know in how long a time it covers a space sixty times greater than the one it covers in 60 half-seconds, then you will multiply the

square of the root 60—that is, 3600—into the last number of the fifth table, 10810, and you will have 17316000 [recte: 38916000], the space of feet that the stone covers in the time of 3600 half-seconds. Divided by 15000 feet—for so many make one league—these constitute 1154 $\frac{2}{3}$ leagues, which some stone would cover, of which leagues 1145 [recte: 1154] equal the half-diameter of the Earth. Accordingly, the half-seconds, 3600 divided by 60, will yield us a time of 25 hours [recte: of 30 minutes — 3600 half-seconds = 1800 seconds = 30 minutes], in which the stone would cover a space of 1154 $\frac{2}{3}$ leagues.

Corollary

From these things it is clear how you may calculate the time in which some stone would fall from the heaven of the Moon, of the Sun, of Jupiter, of Saturn, [or] from the Firmament. Since these matters are abundantly established from the examples here explained, and can be calculated with no trouble, I leave them to be computed by those who have more leisure.

§ II

How to find the space that some stone covers in the last [half-]minute.

If you wish to know how much space some stone covers in the last half-second of its motion: supposing the stone covers the whole height of 43200 feet in 60 seconds or 120 half-seconds, which are equivalent to one first minute, proceed thus. Look in the column of half-seconds for the number 120, and see...

[continuation, right column:] ...what odd number corresponds to it, and you will find 239, which if you multiply by 3, you will have 717 feet, the space sought, which it covers in the last [half-]second [of fall]. But since it is tedious to continue the half-seconds in a table, you will find at once, with almost no trouble, any odd number whatever by this device: double the proposed number of half-seconds, and unity taken from the doubled number will give what is sought. For example: let the odd number corresponding to the thirtieth half-second be assigned; double 30 and you will have 60, from which, 1 being subtracted, 59 remains, which is the odd number sought, corresponding to the 30th half-second. If again you wish to know what odd number answers to the 120th half-second, from this number doubled, 240, unity being subtracted, leaves 239, the odd number sought.

Likewise, if you wish the odd number corresponding to 3600 half-seconds—which are equivalent to 30 first minutes—double 3600, and you will have 7200, the odd number sought, with unity subtracted, that is 7199; in just the same way you will find any other number for given half-seconds. These odd numbers, if you

multiply them by the odd number of one half-second, the sum will give you the feet that the stone covers in the last half-second.

I will give another example. If you wish to know the fall over one hour: 3600, the square of 60, multiply into the case of one second [1"]—namely 7200—and 25920000 perches will result, that is, 155460000 feet, the sought fall over one hour. If you should wish to know the fall of this in the last second, multiply the odd number 14399—the one corresponding to this, smaller by unity—into the case of the half-second of one hour, which you will also multiply by 5, as has been said, and you will have 43197 feet, the sought fall of the last half-second.

[continuation of the left column, lower:] ...and you will have 43197 feet, the sought fall of the last half-second.

From these things it is clear how you may calculate the time in which some stone might fall from the heaven of the Moon, of the Sun, of Jupiter, of Saturn, [or] from the Firmament. [Note: this Corollary text mirrors the §-corollary above; the left column carries the numerical example continuing the half-second fall, the right column the Consectaria.]

the last half-second of one hour, which you will also multiply by 5, as has been said, and the following result. And so the half-seconds, 3600 divided by 60, will yield us a time of 25 [recte: 30 min] hours, in which the stone would cover a space of 1154 ⁴/₇ leagues.

Corollary I

Since violent motion has the same ratio—albeit inverted—as the motion of heavy bodies downward from on high, as we showed above, you will gather from this that the lengths of the spaces in the air which the motions of guns [*sclopi*], arrows, and any other missiles whatever cover can easily be obtained. For to know this, nothing else is required but an equal time, in which the said [bodies] take up their motion. For example, if in the time of 10 seconds some stone falling from on high covers a length-space of 300 feet, while some missile likewise takes up a time of 10 seconds, you will infer that the space traversed is in the same way 300 feet in length.

Corollary II

From this it is also clear how the exact spaces of individual missiles can be determined by reckoning, by comparing the motions of these with the motions

according to nature—or, what is the same, how the motion of projectiles by violent...

at moment B at times 5", 6"; and if it has moved from S into T, the weight likewise falls from B into D in the same time — 5", 6" — of minutes. And if the Earth has moved from T into V — that is, has traced out three of the portions of the arc A O — the stone in the meantime traverses the space from D into E.

so that you may reduce these matters that have been discussed to the measure of natural motions and to the laws of geometry. So that we should not seem to the curious reader to have fallen short in any of these operations, I have thought it worth setting down a few of them here.

PRAGMATIA III.

To discover what sort of line a leaden globe would trace as it falls from the surface of the Moon to the Earth, supposing a daily motion of the Earth about its own axis.

If the Earth, according to the mistakenly conceived opinion of Copernicus [Nicolaus Copernicus], moved about its axis and completed its course in the space of 24 hours, the Lynceans [Lyncei — the Lincean Academy / its followers] suppose that a stone would fall not along a straight line to the Earth's center, but along a semicircle, and that the whole body of air is carried uniformly around the Earth. Since this opinion involves many absurdities, I have decided to refute it here.

First: this motion would occur either from a surface corresponding to the terrestrial equator, or from the surface of a parallel (that is, from suitable smaller circles), or finally near the terrestrial poles along the axis. In the first case it would in fact describe a helix in the plane of the equinoctial; in the second, the same helix but wound about a cone, as we shall show later; in the third, a straight line. Therefore it cannot possibly describe a semicircle.

Second: since we have shown above that the motion of acceleration occurs according to the proportion of the odd numbers, it is impossible for a motion of this kind to be exhibited if it described a semicircle — indeed the motion would turn out to be utterly contrary to the motion of acceleration.

Third: it would follow that a motion of this kind exhibits the same motion as that of the Moon in its own circle, and so that the stone, falling downward, would cover in six hours the same space — 60 degrees — that the Moon traverses in its own circle. This is contrary to our supposition, since a stone falling from the

surface of the Moon covers the intervening space in only two hours and 29', as we demonstrated above.

So first we shall show what sort of line a stone describes as it falls from the surface of the Earth to the center, on the assumption — though not the concession — that the Earth moves about its axis.

Diagram. A narrow circular sector (fan shape) with apex at C (the Earth's center) at the bottom and the arc A...O at the top. Two radii A C and C O bound the sector; they enclose an angle of $6^{\circ} 22'$ at C. The arc A O at the top is divided into 5 equal parts by the points A, T, V, X, O (the small intermediate tick-marks read, from left to right, A — T — V — X — O along the top edge). The radius A C is divided into 25 parts; the marked division points down the left radius are labelled (top to bottom) 1, 3 [recte: $\frac{1}{2}$?], A, 5, 9, 16, 25 — successive cumulative divisions. A dotted curve runs from A near the top, through B, D, E, F, to C at the apex, representing the curved path A B D E F C that the falling stone would trace. The value "25" appears at the apex beside C.

- A (top left of arc): start point of the arc and of the left radius
- T, V, X (along top arc): successive division points of the arc into 5 equal parts
- O (top right of arc): end point of the arc; right radius runs O–C
- B, D, E, F (along the dotted interior curve): successive positions of the falling stone
- C (apex, bottom): center of the Earth
- 25 (beside apex): number of divisions of the radius

Let two lines A C and C O be drawn, each representing a semidiameter of the Earth; let these two lines enclose an angle of $6^{\circ} 22'$. If, then, the line A O is set at a radius of 100,000 parts, the subtended chord A O will necessarily be 11,178 by the tables of sines. For divide the arc A O into 5 equal parts, each comprising one degree with 16 [minutes]; and divide the line A C into 25 parts, in such a way that the first, A B, is $\frac{1}{25}$, that is, makes up one part out of the 25 parts; the second, B D, 5; the third, 7; the fourth [recte: third in printed text reads "Tertia 5. Quarta 7. Quinta 9."], and so on. Then draw from the center C through each of the parts the arcs.

This being set, it comes about that when the Earth has moved from A into S, the weight in the same time falls from A into [the point reached in] 5", 6", of minutes; and if the Earth has moved from T into V — that is, has traced out three of the portions of the arc A O — the stone meanwhile covers the space from D into E.

And when the Earth reaches from V into X, the stone covers the space from E into F; and as the Earth comes from X into O, the stone covers the space from F into C, in an equal interval of time, namely 5'', 6''.

The stone, therefore, falling from point A toward the center of the Earth (which moves about its own axis), will not make a straight line — except by falling at the poles — but at any other point of the Earth would describe the curved line A B D E F C. Thus the proportion of acceleration would be preserved according to the ratio of the odd numbers, together with the doubled proportion of the times, which the motion of the Moon in the arc A O measures.

But if a weight were let fall from a place removed 526 terrestrial semidiameters from the Earth's center, it would then reach the center in the space of six hours, and the line of its fall would form a line not far from a semicircle, supposing nonetheless the proportion of the doubled ratio. But if the proportion were as the versed sine to the arc, then under the given altitude it would describe a semicircle. Beyond this distance, however, it would describe a helix, if the altitude were greater than 526 terrestrial semidiameters. All of which can easily be concluded from what has been said before.

CONSECTARIUM.

It is therefore clear from what has been said that Galileo's demonstration concerning the stone tracing a semicircle — on the assumption of the Earth's daily motion about its axis — does not stand at all, and that no argument for the Earth's motion can be drawn from it, as those suppose who, willing or unwilling, drive the Earth too boldly into its circles. Nor does the motion of a stone falling from the crow's-nest of a moving ship into the same spot where it would have fallen with the ship at rest do anything to establish the Earth's motion. For the stone produces this effect in every progressive motion: whether one throws a stone aloft while carried in a carriage or while running, whether the Earth is at rest or in motion. But since we have demonstrated the reasons and causes of this experiment elsewhere at length, I have judged it superfluous to repeat the same things here.

CAPUT IV.

On the use of pendulums in matters pertaining to geometry.

PRAGMATIA I.

To measure the heights of things by means of pendulums.

For example, let a cord with a lamp attached to it be hung from a dome down into the lower part of a church, and suppose someone wishes to know the height of the dome above the ground. You must first have, as an instrument, a thread one foot long with a lead bob. Once this is obtained, proceed thus. Note how many vibrations the one-foot cord makes while the [large] hanging cord, set swinging, makes a single vibration. I find, for example, that the shorter, one-foot cord makes eight vibrations — that is, runs out and back eight times — while the longer cord runs out and back once. Therefore multiply the eight vibrations into themselves (that is, square them) and you will have 64, the height of the dome sought, up to the lamp's lower end. If to this you add the height from the lower end of the larger cord to the surface of the pavement, you will have the total height. For since we showed above that the motion of pendulums is in the doubled ratio of the times, it necessarily follows that the eight time-units which the shorter thread measures by its eightfold running out and back, multiplied into themselves, give the height.

CONSECTARIUM I.

Vibr.	Altit.	Vibr.	Altit.
1	1	22	484
2	4	23	529
3	9	24	576
4	16	25	625
5	25	26	676
6	36	27	729
7	49	28	784
8	64	29	841
9	81	30	900
10	100	31	961
11	121	32	1024
12	144	33	1089
13	169	34	1156
14	196	35	1225
15	225	36	1296
16	256	37	1369
17	289	38	1444

Vibr.	Altit.	Vibr.	Altit.
18	324	39	1521
19	361	40	1600
20	400	50	2500
21	441	60	3600

From this it follows, from the table set out here, that the height of anything whatsoever can be measured with no trouble, by the aid of the one-foot thread alone. For if you find that your thread runs out and back six times during one vibration of the longer cord, the second column will give you, in the row opposite 6 in the first column, the height sought — namely 36 feet. If it runs back ten times, you will have a height of 100 feet. If twenty times, 400; if thirty times, 900; and if finally it runs out and back forty times, you will have a height of 1,600 feet — even though you can scarcely find a cord of such length.

CONSECTARIUM II.

But if you wish to know how many vibrations the one-foot thread makes for any given height, take any square number whatever, and its root will give what is sought. For example, suppose someone wishes to know how many vibrations the shorter cord makes while a longer cord, 3,600 long, makes one vibration: extract the root of 3,600, and you will have the 60 vibrations sought in the shorter cord. Let there be a cord of as great a length as the distance of the center from the surface of the Earth — namely 16,975,000 feet, which represents the semidiameter of the Earth — and suppose you wish to know how many vibrations the 1-foot cord makes while the cord equal to the Earth's semidiameter completes one. Extract the square root of 16,975,000 and you will have what is sought, namely 4,120 + 600 vibrations.

PRAGMATIA II.

To construct another table, so that, the lengths of the cords being given, one may know how much time — that is, how many seconds — each vibration of the given cords lasts.

This table is constructed as follows. Place in the first column, in order, the seconds — as far as you wish, for example up to 60. When these are squared, the squares of the corresponding times are produced in the second column; and these are had with no trouble, since each second, taken in order and multiplied into itself, yields them. Thus the numbers of the first column show nothing other

than the roots of the squares set out in the second column. The third column contains the lengths of the cords in feet, whose vibrations are shown to last for as much time — that is, for as many seconds — as correspond to them in the first column.

This third column's table is constructed by the following device. We suppose first that a thread three and a half feet long completes one vibration in the time of one second; whence this number, as the foundation of the whole table, rightly takes the first place in the third column. For from this number, multiplied by the numbers in the second column, and by the numbers in the first column (in the manner we shall teach), once aggregated, the sums in the third column are produced, as you will see in the example. First, $3\frac{1}{2}$ in the third column — the first number — multiplied into the second number of the second column, that is, into 4, gives 12; to which if you add 2, the second number in the first column, the result is $14\frac{1}{2}$, the second number in the third column — that is, the length of the cord whose single vibrations (or *diadromi*, "swings") last two seconds.

These things being set down, these propositions are formed, each of which has two operations: the first operation is done by multiplying $3\frac{1}{2}$ into the squares of the second column simply, without fractional numbers; the other is done by multiplying the fractions, as follows.

PROPOSITIO I.

To find the length of a cord whose single swings last three seconds.

So proceed: multiply $3\frac{1}{2}$ into 9 — that is, the first number in the third column, $3\frac{1}{2}$, into the third [number] of the second column, namely into 9 — and you will have $29\frac{1}{2}$. To this add the sum of 1 and 3, namely 4, which is the same as the product from multiplying the half of the number three, $1\frac{1}{2}$, into the whole of which it is the half; and you will have $31\frac{1}{2}$, the length of cord sought, as the table shows.

PROPOSITIO II.

To find the length of a cord whose single swings last four seconds.

Multiply the number $3\frac{1}{2}$ into 16, the fourth square in column II, and you will have 48. Again multiply the half of the number four, that is, 2, into the whole of which it is the half — namely into 4 — and add the product, 8, to 48, the number found just before, and you will have 56, the length of cord sought.

PROPOSITIO III.

To find the length of a cord whose single swing lasts five seconds.

Again multiply $3\frac{1}{2}$ into the square of 5 seconds, that is, into 25, and you will have $87\frac{1}{2}$. Then take the half of the number five, $2\frac{1}{2}$, into the whole of which it is the half — that is, into 5 — and add the product to $87\frac{1}{2}$, the number found just before, and you will have $87\frac{1}{2}$ for the length of cord sought, as the table shows.

PROPOSITIO IV.

To find the length of a cord whose single swing lasts six seconds.

Again multiply $3\frac{1}{2}$ into the square of six seconds, that is, into 36, and to the product, $108\frac{1}{2}$, add the product 18 from the half of the number six, namely 3, into the whole of which it is the half — namely into the resulting 6 — and you will have 126, the length of cord sought.

PROPOSITIO V.

To find the length of a cord whose single swing lasts seven seconds.

Multiply $3\frac{1}{2}$ into the square of 7 seconds, that is, into 49, and to this product add the product $24\frac{1}{2}$ from the half of the number seven, that is, $3\frac{1}{2}$, into the whole of it, that is, into 7; and you will have $171\frac{1}{2}$, the length of cord sought.

PROPOSITIO VI.

To find the length of a cord whose single swing lasts eight seconds.

Multiply $3\frac{1}{2}$ into the square of 8 seconds, namely into 64, and you will have 192; and then multiply the half of eight again into 8, its whole, and add the sum, 32, to 192 — the aggregate, 224, will give what is sought.

PROPOSITIO VII.

To find the length of a cord whose single swings last 9 seconds.

Multiply $3\frac{1}{2}$ into the square of 9 seconds, 81, and you will have 243; to which if you add 46, the product from multiplying the half of nine, $4\frac{1}{2}$, into its own whole — that is, into 9 — you will have for the sum 283 feet, the length of cord sought.

PROPOSITIO VIII.

To find the length of a cord whose single swings last ten seconds.

Multiply $3\frac{1}{2}$ into the square of 10 seconds, 100, and you will have 350; to which the product from the half of ten into 10, its whole — that is, 50 — when joined, gives 350 [recte: 400] for the length of cord sought. In the same way, the square of 11 seconds, 121, multiplied into $3\frac{1}{2}$, and joined to this the product from the half of eleven into 11, its whole — namely 60 — gives $423\frac{1}{2}$, the length of cord sought. And in just the same way, multiplying all the squares of the seconds in order by $3\frac{1}{2}$, and joining to each product the product from the half of the number into that number itself, the seconds [results] referring [to them], you will proceed, until you have completed the whole table — which by this method you may extend to infinity.

Note, reader, that the first operation is performed by multiplying $3\frac{1}{2}$ into the squares of the seconds contained in the second column, simply without fractional numbers, since the reckoning of fractions is carried out in the second operation. Of these things we thought you should first be warned, lest you might think we had proceeded less than honestly in the calculation.

THE TABLE FOLLOWS.

Radices (Roots)	Quadrata (Squares)	Longit. chord. in ped. (Cord length in feet)
1	1	$3\frac{1}{2}$
2	4	14
3	9	$31\frac{1}{2}$
4	16	56
5	25	$87\frac{1}{2}$
6	36	126
7	49	$171\frac{1}{2}$
8	64	224
9	81	$283\frac{1}{2}$
10	100	350
11	121	$483\frac{1}{2}$
12	144	504
13	169	$551\frac{1}{2}$
14	196	686
15	225	$787\frac{1}{2}$
16	256	896

Radices (Roots)	Quadrata (Squares)	Longit. chord. in ped. (Cord length in feet)
17	289	1011½
18	314	1099
19	361	1263½
20	400	1400
21	441	1543½
22	484	1694
23	529	1851½
24	576	2016
25	625	2187½
26	676	2366
27	729	2551½
28	784	2744
29	841	2943½
30	900	3150
40	1600	5600
50	2500	8750
60	3600	12600
70	4900	17150
80	6400	22400
90	8100	28350
100	10000	35000
500	250000	875000
1000	1000000	3500000
5000	25000000	87500000
10000	100000000	350000000
100000	10000000000	35000000000
1000000	1000000000000	1500000000000

That is: if a cord 18,299 long, in leagues or terrestrial semidiameters, were given, it would make one swing in 11 days, while a one-foot cord made 1,000,000.

USES OF THE TABLE.

This table cannot serve beyond 30" of seconds. For since the cord corresponding to this is 3,150 feet, it can scarcely happen that such a height could be assigned in the sublunary world, from which a cord might hang. Hence the number 20 — to which corresponds a height of 400 feet, such as the mountain Pico [Pico del Teide] in the Canary Islands [Insulae Canariae], if it could be bored through, might furnish — could be of use; but since even this is difficult, the use of this table can serve only up to 15 seconds.

For example, if you wish to know how great some cord ought to be that completes one swing while in the meantime a cord of $3\frac{1}{2}$ feet completes 15 swings: you will seek the number 15 in the first column, and the corresponding entry in the third column will give what is sought — namely a cord of $787\frac{1}{2}$ feet in height. In the same way, 10 will give a cord of 350 feet, and so on for the rest.

But the numbers contained in the table beyond 30 up to 1,000,000 show only how great some cord ought to be that makes one swing while in the meantime the three-foot cord makes 30, 40, 50, 60, 80, 90, 100, 1,000, 1,000,000. It is asked, then, how great a cord ought to be that completes one swing while meanwhile the three-foot cord makes 1,000,000. I say that this cord ought to be 1,500,000,000,000 feet long, which, resolved into leagues, give 1,600,000 leagues; these, into terrestrial semidiameters — of which one contains 1,145 leagues — resolved, give 18,299 terrestrial semidiameters; and so it would complete one swing in the space of 11 days.

And just as the cord exceeds the height of the firmament by many parasangs [parasangae], so too its vibration — that is, the cord's motion — completed in the space of 11 days, would be no more perceptible than the growth of plants. Add to this that the weight which would have to keep the cord taut would have to exceed the whole mass of the terrestrial body many times over in order to stretch it; and the 12-foot cord would have to have a diameter such that it could bear the weight, since otherwise it would be torn apart by its own weight — all of which can be deduced by mathematical reasoning.

Add too that a cord weighted with any weight whatever describes, in its swings, not a semicircle but a semi-ellipse — the weight attached to the cord, namely, by its gravity stretching the cord beyond a semicircle; whence the weight, gravitating more and more according to the cord's inclination, would necessarily describe some spheroid, or elliptical [figure]. This, however, would not happen if the weight were attached to an iron chain.

PRAGMATIA III. Astronomical.

To construct a chronometer that marks off the smallest parts of the hours.

No astronomer is unaware of how great a matter, in astronomical practice, is the exact division of the hours and of their smallest parts; so that the measurers of celestial things have labored at nothing more than at how a clock [horologium]...

a clock [horologium] capable of displaying the smallest parts of the hours, persuading themselves it could be done — which in fact they never managed to achieve. Here we shall demonstrate that this can be accomplished abundantly by the help of a single three-foot cord.

Take a cord of three and a half feet, properly fitted with its own weight. By the observation of Mersenne, in its forward and return swing this cord will precisely complete the time of one second — that is, $1/60$ of a first minute, or $1/3600$ of an hour. The most excellent physician and mathematician Joannes Marcus Marci [Jan Marek Marci], for use in astronomical work, takes a pendulum of five fingers and a little more. He found that a single vibration of this corresponds exactly to the beat of the artery [pulse], so that in the space of one hour, since the artery produces 4850 pulse-beats, the pendulum must be reckoned to make the same number of vibrations. But since this motion, being very swift on account of the smallness of the circle, lasts a shorter time, it suffices to extend the pendulum until its motion becomes equal to one second. Such a pendulum, thus extended, will be equal to the pendulum of three and a half feet established by Mersenne and fitted to measure one second.

You may also construct a pendulum of this kind by your own observation and experiment, using this procedure. Take any pendulum somewhat lengthened, set it swinging, and observe how many forward-and-return swings it makes in the space of one quarter-hour. You will find that it goes forward and back 300 times. From this you will gather that in the space of one hour it goes forward and back 1200 times — which is what you wished to know. As for how the motions of the stars are to be measured by a cord of this kind, see the matter treated at length in the *Almagestum Novum* of the most learned Father Giovanni Battista Riccioli, where you will find whatever can be desired concerning this business.

But of all the horometric devices invented hitherto by ingenious craftsmen, the palm is carried off by a new kind of clock invented not so long ago [1657], which by the vibration of a single simple pendulum alone displays exactly not only the hours but also the quarters, the first minutes, and beyond that the seconds. And just as this is indeed a beautiful and most rare invention, so it can scarcely be told

into how great an admiration it carries all who behold it, when they see the pendulum agitated as though by some perpetual motion. Moreover, for the exact measurement of time and for the exact observation of the motions of the heavenly bodies, nothing more convenient, more reliable, or more excellent could be desired by astronomers. But since we have described its construction and uses at length in our *Itinerarium Hetruscum* [Etruscan Journey], we refer the reader there.

PRAGMATIA IV. Geographical.

Whether the longitudes of places can be found by means of the chronometer cord.

[Margin: Whether the longitudes of places can be found by means of the chronometer cord.]

There have been some among the moderns who think that this business — the investigation of the longitudes of places — can be undertaken by means of this cord. At the very moment of departure from harbor, let the hour of the day be precisely observed by an astrolabe; then, at the same moment when the ship sets out due East or West, the vibrations of the instrument must be counted, granted that it makes 1200 forward-and-return swings in the time of one hour. So if, the ship having advanced along a straight course and with an equal force of wind, you find that 2400 forward-and-return swings have been made on the instrument, you will gather that the ship is two hours' distance from port; if 3600, three hours; if 4800, four hours' distance from port; and so on in succession.

But anyone who examines this practice more deeply will easily see that it cannot stand, since it rests on so slippery and inconstant a foundation. For here it is presupposed that the motion of the ship is always uniform and its course steady — which the sailors solemnly assure me can scarcely be maintained for even a single hour, on account of the inconstancy and variety of the winds. A second point is that an artifice of this kind appears to have no success except when the ship holds the South-West rhumb [Rhombum Notozephyrium], that is, when it heads straight East or West. Added to this is the difficulty of counting the vibrations, since it can scarcely be done that so many and such great vibrations be carried through for two or three hours without error or disturbance — unless the operators relieve one another in turns — while the eyes are gradually dimmed with the utmost weariness at such minute things. Therefore, since this business is in practice exceedingly tedious, and liable to countless errors on account of the shouts and tumult of the sailors, besides the difficulties suggested above, I judge that it should by no means be employed in geographical work. But

about these matters I had discoursed more exactly in our *Concilium Geographicum* [Geographical Council], which, if it had not been stolen from me by theft, the reader might perhaps find in it things not unworthy for the proper performance of this task.

PRAGMATIA V. Medical.

To find the differences of the pulses of the artery by means of the chronometer cord.

[Margin: To find the differences of the pulses of the artery by means of the chronometer cord.]

First let an instrument be made, in the manner and by the procedure that follows. Let a little beam A B be made, the upper surface of which you will divide into any number of equal parts — for example, into a hundred or fifty. Fasten this divided beam upon a support C D in such a way that it cannot be moved from its place; and let the foot of the support, joined with lead, give stability to the instrument, so that it cannot waver in the slightest. This done, take a string of such fineness as the smallest in a small lute [chelys minor] usually is, and pass it through the holes made at A and B at the ends of the beam, in such a way that, with weights E and F fastened at each end of the string, the string can be lengthened or shortened at will, and

Diagram. A woodcut of the pulse-measuring instrument. A horizontal graduated beam runs across the top, marked off in numbered divisions; from its two ends hang weighted strings, and the whole rests on an ornate central pedestal-support standing on the ground.

- A (left end of beam): start of the graduated scale
- 10, 20, 30, 40, 50 (along the beam, left to right): scale graduations
- C (center of beam, between 20 and 30): midpoint of the scale
- B (right end of beam): end of the graduated scale
- G (just below center of beam): a marked point (the movable "gemma"/node on the string)
- R (below beam, right of center): the fortieth-division reference point
- F (bottom of left hanging weight): left pendulum-weight
- E (bottom of right hanging weight): right pendulum-weight
- D (base of central pedestal): foot of the support, weighted with lead

[End of Pragmatia V instrument setup; the text continues with the instrument's use.]

The continuation of Pragmatia V (its use):

So you will have the instrument ready, whose use is as follows. Intending therefore to explore the differences of the pulses of the artery, look for the first vibration that corresponds to a single beat of the artery for that time which you are measuring, by lengthening or shortening either end of the string. For if the pulse is faster, the string must be shortened; if slower, lengthened. You will proceed in this way until you find the vibration of the string exactly equal to the beat of the artery — say A F or B E; for this will be the length of the pendulum whose single vibration is equal to a single pulse-beat, which you will carefully mark by this device. In the upper part of the string contained between A and B, insert a gem or knot so tightly that it can be moved only with difficulty, and move this gem above the first division of the divided beam A B — the fortieth, at R — with this precaution: that the string A B not be displaced from its original length.

If then on another day you should wish to discern the difference of the pulse, you will then, by lengthening or shortening, move either end of the string so far until you obtain that length of pendulum at which a single vibration corresponds to a single beat of the artery. This done, observe which division the gem cuts off on the beam; for this will be the difference of the pulses between today and yesterday.

For example: let the length of the string B E be such that by its vibration it equals a single beat of the artery of a person established in the best health, and let the gem mark the fortieth division at R. But on the following day you again test the pulse and find it faster; therefore the string B E must be shortened so far until you find that a single vibration of the shortened string corresponds to exactly one pulse-beat. This done, observe which division the gem cuts on the line of the beam A B. Let us suppose that, from the shortened string, the gem has been moved forward — or rather drawn back — from R to G, where it now cuts off at the 30th division. You will conclude that the difference between the pulse of the earlier and the later day is 10 — that is, faster by 10 divisions. But if the pulse of the later day should be slower, then the string A E must be lengthened until you find the equality of the vibration of the string with the pulse; and note in addition which division on the line of the beam the gem cuts off, and you will find it, say, resting at the 50th division. You will then infer that the difference of the pulse is again 10 — that is, the pulse of the earlier day is slower than the pulse of the later day by 10 divisions. You will proceed no differently in other cases.

APPENDIX

On the harmonic motion of strings.

Since the motion of strings in musical instruments behaves exactly by that same principle as the motion of pendulums, we shall here repeat some things treated at length in our *Musurgia*, so that we may not seem to have omitted anything necessary to Centrosophy [Centrosophiam]. It is known by daily experience that the strings with which musical instruments are usually strung, when struck, run forward and back no differently than pendulums, until they come to rest in the middle line of their direction — as if in their own center, which they seek — by exactly the same principle as a stone cast toward the center of the Earth would not rest as soon as it reached the center, but, swinging beyond and back, would continue the reciprocations of its violent motion with a proportional diminution and decrement, until at last it came to rest at the center. In the same way the string A B, stretched and drawn violently to E, will run back to F, and from there to G, and from there run back to H, and from H to I, and from there finally come to rest at K as at its center. The same thing therefore a pendulum will do: lifted to E, it would run back to F, and from there to G, and from there to H, and from there to I, and at last to K, the center of rest.

From these things it follows: that the greatest [first] diadrome [diadromus] of a struck string completes its whole space in the same time as the smallest, or the intermediate ones; and that both the arc E F (the greatest) and I K (the smallest), and all the intermediate ones, are of equal duration. For since the violence and impetus by which the string A B is drawn out of the line of rest A B into

Diagram. A semicircular fan-figure illustrating the decreasing swings of a string or pendulum. From a central apex at the top (E), radial lines descend to a series of points along a semicircular arc, with a baseline running through the lowest points.

- E (top center, apex): the point of maximum displacement / suspension point
- F (upper left on the arc): an outer swing-point
- G (upper right on the arc): an outer swing-point
- H (lower left on the arc): an inner swing-point
- I (lower right on the arc): an inner swing-point
- K (bottom center, on the baseline): the center of rest

Diagram. A rhombus/lens-shaped figure illustrating the diminishing reciprocal swings of the string between its two fixed endpoints A and B. Two outer

endpoints A (left) and B (right) are joined by a horizontal central line, and a vertical sequence of points marks the successively smaller swing-amplitudes above and below that line.

- A (left vertex): fixed endpoint of the string
- B (right vertex): fixed endpoint of the string
- E (top vertex): point of maximum upward displacement
- G (below E, on the vertical): an intermediate swing-point
- H (below G): an intermediate swing-point
- K (center, on the horizontal axis): the center of rest
- I (below K): an intermediate swing-point on the lower side
- F (bottom vertex): point of maximum downward displacement

E F is greater, the further [it goes], hence that swing will also traverse the space F G the more swiftly, the greater the interval of the first diadrome is. From this it necessarily appears that the remaining diadromes in order are of equal duration; since, by however much there is taken away from them in that length, magnitude, and impetus of the diadromes, by just so much is added to the brevity of the space that they have to complete — and thus the length of the diadromes is in inverse proportion to the time.

For example: let the string A B complete 100 diadromes, and let it make one foot in the first diadrome E F, and the hundredth part of a foot in the last, that is, in the hundredth diadrome I K. I say that the first diadrome E F is a hundred times faster than the hundredth, since this latter is a hundred times slower and less violent than the first, being nearest to rest. It is therefore evident that the ratio of the number of the vibrations of strings is the inverse of their length. But whether the string can be said to rest at the points terminating the diadromes, we have discussed at length in our *Musurgia*, fol. 428. And whether by any device at all we can come to a knowledge of the number of the diadromes has likewise been treated at length in the same place.

HARMONIC COROLLARY

From what has been said it is evident that the whole principle of music rests on these our principles. For since any sound is composed of as many degrees of sharpness and depth as there are points of the reflected diadromes, by which the eardrum is struck so many times in a given time by the agitated air, it is luculently clear that all sounds, as well as all consonances and dissonances, are nothing other than the various numbers of the motions of the air striking against

the ears, carried all the way to the mind by the action of the acoustic nerves [nervorum acusticorum]. For example: if the eardrum is struck twelve times in a given time, the sound then heard will be composed of 12 degrees of sharpness; and the soul, through its auditory faculty, will perceive itself affected far otherwise by these 12 degrees than by any other number of percussions.

Let us make it clear by an example. Let there be two strings A B and C D, of which A B has struck the air twelve times by its vibration, and C D six times, and let them have struck the ear in the same time and with the same duration. The soul will necessarily [perceive a consonance, which they call the Octave [Octavam]], considered under the double proportion of the vibrations. For since the string A B is to the string C D, and 6 vibrations of the air to 12, so the motions of the air, born in the eardrum, are related to one another. And if these two motions are in double proportion, then the motion of the air in the eardrum will also be in double proportion; that is, while the string C D runs forward and back six times, the string A B runs forward and back twelve times. The Diapason, then, or Octave, must necessarily be perceived, since the string A B moves twice as fast as the string C D, from the principles laid down above.

COROLLARY II

Hence is evident the generation of all consonances and dissonances. For just as all numbers emanate from unity, so from the unison all harmonic numbers, that is, the consonances and dissonances. Let us give an example. Let two strings of equal thickness and length be stretched and tuned with the same weight, or by a peg [verticillo], in such a way that both sound a unison with one another. It is certain from the foregoing that, just as string is related to string, and weight to the tensioning weight of the string, so are the vibrations related to one another. And since therefore the strings are equal, they will perform equal vibrations in equal time. A B will therefore run forward and back as many times as C D.

Diagram. Two horizontal line-segments illustrating the unison and its divisions. The upper segment is the full string A—B; the lower is the string C—D, marked with intermediate division points.

- A (left end of upper line): endpoint of the first string
- B (right end of upper line): endpoint of the first string
- C (left end of lower line): endpoint of the second string
- G (interior of lower line, toward the middle): the bisection point of C D
- I (interior of lower line, right of G): a quarter-division point of C D
- D (right end of lower line): endpoint of the second string

A unison, then, must necessarily be perceived, since neither surpasses the other in speed. But if you cut either string, C D, in two — for example, C D at G — and set G D vibrating against A B, then, since A B is double to G D or C G, a Diapason or Octave must necessarily arise, since G D or C G moves twice as fast as A B. Again, if you divide the string C D into 4 equal parts and set one fourth part of C D vibrating together with A B, then the consonance Disdiapason will arise, which they call the Fifteenth [Decimamquintam]. For since this consists in the quadruple proportion, and the part I D is related to A B under the same proportion, as 1 to 4, it follows necessarily that the string I D moves four times as fast as A B — so that while A B completes one vibration, I D in the meantime is reckoned to have made 4 vibrations. And since the sharpness of one sound is related to another sound as a vibrating string is to a vibrating string, I D will consequently sound four times sharper than the string A B, inasmuch as it is four times more tense than the string A B. Hence a Diapason, or the Fifteenth consonance, must necessarily arise. You see, therefore, how from this single example the generations of all consonances can be drawn out. But whoever desires all this demonstrated more thoroughly, let him consult Book 6 of our *Musurgia*, part 1, which is called *Chordosophia*. There the curious reader will find that nothing has been omitted of those matters which savor of something secret and paradoxical.

COROLLARY III

From what has been said so far, it is evident that there is nothing in this universe so motionless that it does not produce some motion, even if imperceptible to us. So much so that, if God were to strengthen the auditory faculty of man, in proportion to the infinite variety, condition, and quality of the motion of bodies struck by the air, he would also perceive a perpetual harmony. But nature seems to have

begrudged this very thing to man; for by frequent experiment I have found that, as soon as the diadromes of any stretched string present themselves to the eyes by a perceptible manifestation — that is, fall under enumeration — at the same time all sound ceases, so that what the eye discerns the ear cannot judge. But if we stretch the string a little more strongly, some sound is indeed perceived, yet under vibrations of the trembling string so rapid and swift that what the ear judges, the eye can in no way discern. So stubbornly is nature tenacious of its own right that it seems to be unwilling on any account to permit sound and the vibrations of the string to exist at the same time. Hence those people seem laughable who wear themselves out with useless labor in trying to reduce the

`1/100000000000000000000000000000000000000000000000000000`

[The denominator is a 1 followed by 60 zeros — printed as a long row of zeros below the rule.]

And these are the things which, concerning the nature, property, and quality of the Center, we have thought fit to set down in this first book of the *Mundus Subterraneus*. Now let us apply our mind and pen to describing those bodies which surround the Center.

SIVE — De admirando Globi Terreni opificio.

CAPUT I.

(On the end and purpose of the Geocosm.)

The terrestrial globe, which we call the Geocosm or terrestrial world, is the end and center of the whole of creation. And so it too was arranged by the divine Wisdom, the maker of all things, with such art and care that whatever powers there are in the universe, whatever hidden properties lie concealed in the particular globes of the stars — all of it seems to have been gathered into this one body as into a kind of epitome. Nor should this seem astonishing to anyone. For

God placed man here as a lord of the world, so that from this vantage point, as from a watchtower, he might contemplate the greatness and beauty of the divine works, and that inexhaustible abundance joined to an infinite variety; that by contemplating he might wonder at them; that by wondering he might seek out, with anxious searching of mind, the Architect of so great a work; that by seeking he might find Him; and having found Him, possess Him forever.

[Margin: The terrestrial globe leads to heavenly things.]

And since man, through the cunning of the devil's craft, by the sin of our first parents [Protoplasts], had fallen away from God — by the unsearchable depth of the divine counsel, the only-begotten Son of God, the Word of the Father, in order to restore lost man to his former state of dignity, clothed in human flesh, having contracted (as it were) a marriage with human nature, deigned to appear in this earthly world, and here to work the salvation of mankind. *And the Word was made flesh, and dwelt among us* (John 1:14). Indeed, so great was the height and sublimity of this prerogative that it deservedly surpassed the excellence of all the divine works by infinite "parasangs," as the saying goes. And so, on this ground too, we may call this terrestrial world the end and Center of the whole Universe.

[Margin: Why the Geocosm was made for the sake of Christ.]

For it is certain that the whole machine of the world was created by God, the Best and Greatest, for some end. But what end is that? Surely it ought not to be regarded as created chiefly for its own sake alone, nor for the sake of the angels, nor on account of any need of God the Creator — since, having no need of a corporeal world, He could derive no help from such things. Therefore, it was made for the sake of something else; therefore for the sake of a creature — for man's sake, I say — who, standing on the borders of corporeal and intellectual nature, the very confines of being, was endowed with this single prerogative above all bodies: that whatever of powers and admirable properties lay hidden throughout the whole machine of the world should be poured out into the single Earth as into a kind of epitome, as we said above. Thus, just as man, the heir of the whole world, embraces all the gifts of the world in himself — a true Microcosm — so too the Earth, the kingdom of the human race, enriched with all the influences of the world, may truly be called a little world.

[Margin: How the Geocosm is enriched with all the influences of the world.]

That this is so, the innumerable variety and abundance of things necessary for man's good and blessed living, presenting themselves to the senses, more than sufficiently demonstrate. Since, then, the terrestrial globe is such and so great, it

is certainly an object most worthy of careful consideration. Both reason and the very dignity of the matter seem to demand, above all, that it be described with the greatest possible care and diligence. And this indeed we shall attempt in this work, according to our small measure, and so far as the weakness of our understanding permits. May God, the maker of the world and the giver of all light, be present to our endeavors.

CAPUT II.

Idea Globi Terreni in mente Divina existens.

(The Idea of the terrestrial globe as existing in the Divine mind.)

Just as an architect, about to build a royal palace, first turns over in his mind each and every detail, and with deep searching of heart examines and weighs the suitability of the site — so that at last, by a kind of careful design [Ichnography], he may lay out the structure of the whole future mass, both for the prince's delight and for the practical use of the necessary parts. Then, according to the ground-plan [Ichnography] as a kind of archetype, he lays foundations proportioned to sustain the building. He arranges the subterranean chambers into workshops for craftsmen, baths, and workrooms; he divides the floors into various ranks of rooms, galleries, and halls; he raises towers on high, adorned with various ornamental reliefs, for the pleasure of prospects and spectacles. He lays out garden plots flourishing with plants, flowers, and fruits; and finally he arranges hidden channels to supply the fountains. At last he adorns the completed palace with every kind of tapestry, statue, and the most precious furnishings.

In just the same way, the eternal Wisdom of God, about to build a palace for the human race — the terrestrial world, I mean — so that nothing which might serve either for delight or for the use of necessary things should be left unmade, first laid the foundations of the globe of the earth. And although this globe rests on no mass of supports, on no prop of substructures, yet, balanced by its own weights and appointed by Divine providence, it was furnished with all the things that can be desired for living well, comfortably, and blessedly,

and was established in the middle of the Universe, so that it might be illuminated on every side by all the bodies of the world and the globes of the stars, made fruitful by influences from above, and quickened into offspring of every kind of generation. With a spreading of waters He surrounded the whole mass, lest anywhere so necessary an element should be lacking. He set the mountains as a

kind of barrier against the spreading of the waters — both to beat back the unruliness of the waves, and to irrigate that same mass with a perpetual and never-failing supply of moisture. He pierced it with innumerable tunnels, and carved out caverns within it like certain workshops of nature, filled some with fires, some with waters, for the purpose of producing various effects of nature — so that whatever nourishment of nature Vulcan has cooked up by long labor in his vast kitchen, in the hidden receptacles of the caves, might be aptly distributed to each and every part through little channels, as through the veins of a great Body.

[Margin: The various subterranean workshops of the Earth.]

From this admirable distribution arises the variety of innumerable things, both within the inward parts of the earthly mass and on its outer surface. Thus the most beautiful broad domains of things have come forth, with the richest storehouses of metals and inexhaustible treasuries of precious stones, both for the delight of life and for the necessary use of the human race. And on the outermost surface, immense green expanses of forests have emerged — divided by mountain ridges as by certain towers — and wide-open paradises of fields, luxuriant with abundance of trees, plants, flowers, and fruits of every kind, watered by the innumerable winding courses of fountains and rivers.

[Margin: The outward adornment of the Earth.]

We have seen, then, a rough ground-plan [Ichnography] of the terrestrial globe. Nothing further remains except that we tackle the whole structure part by part. This will best be done if, with the diligence that is fitting and with exactness [Greek: ἀκρίβεια (akribēia, "precision, accuracy")], we carry out the office of a careful Anatomist in describing exactly each and every member of the great mass, both interior and exterior.

[Margin: The stability of the Earth.]

[Note: the marginal note "Quid Terra sive Geocosmus sit" (What the Earth, or Geocosm, is) and the passage it marks appear in the first column of this page, treating the Earth's immobility — see below.]

[A passage printed in the first column of p. 56 reads:] ...though it should remain immovable for all ages, yet it was so confirmed by the efficacy of the divine power that there is no strength of so great a force, no fury of raging winds, no impetus of the sea and its tumultuous waves so great, that it could move the Earth even a hair's breadth — I do not say from its seat, but not even to the smallest

part, could it shift it from its place. [Margin: What the Earth, or Geocosm, is.] The Earth, therefore, is nothing other than the watery-and-dry globe of the world, given by God to the human race to dwell in.

CAPUT III.

De Mundanorum globorum seu stellarum natura & compositione, & quomodo in Mundum inferiorem influant.

(On the nature and composition of the worldly globes, or stars, and how they exert their influence upon the lower world.)

That the world is filled with innumerable astral bodies, only that man can fail to know who has been imbued with no knowledge of the discipline of Astronomy. Of these, some have obtained the name of *planets* or wandering stars; others, that of [Greek: ἀπλανῶν (aplanōn, "of the fixed stars")] — that is, fixed stars. Yet to each and all bodies or globes of this kind, three things above all belong in common. First, that each is composed of a fluid and a solid. Second, that each is made stable by its own Center. Third, that, set in motion in a circular path, by exerting influence both upon the Earth and upon one another, they conspire toward the preservation of the Universe.

All these matters, since we have treated them very fully in our *Itinerarium Exstaticum*, I do not wish to repeat here. But in general only, I shall here discuss a few points that seem to bear most upon the purpose of our argument. And the question is this: whether all the stars differ in their properties and powers, and whether all of them exert their influence upon the terrestrial body.

As to the first point: it is certain that the Creator, the Best and Greatest, made the universe not only for the sake of ornament, but for innumerable ends known to the Maker-of-the-World [Cosmotechnites] alone — of which the weakness of human understanding grasps only three. Namely: first, the glory of the Creator, *for the Lord has made all things for Himself* (Proverbs 16:4); second, for the sake of man and for the use of the rational creature, and consequently for the sake of the terrestrial globe, which is the proper seat and dwelling-place of the human race; third, for the preservation of the Universe. So that, just as in the Microcosm of the human Body one member nourishes another, and by a kind of reciprocal warming all the members affect each single one, and each single one affects all — so the stars of the Megacosm, or great World, like certain members, affect one another by reciprocal influences and by powers proper to each. And whether by the immediate influence of neighboring stars, or by the mediating influence of

intermediate ones, they warm, nourish, and strengthen one another; and again, bound together by this mutual bond of union, they preserve one another perpetually.

But this preservation of the worldly bodies would have been idle, had it not looked toward a higher end — which was the ultimate preservation of the terrestrial globe, and thereby of man, the Microcosm. For whatever scattered powers there are throughout the whole machine of the world, whatever endowments there are in the globes of the stars, all of it has been gathered into the single globe of the Earth as into a kind of epitome — so that for man (who was to be all things in all things, the compendium of all the things shining forth in the world, and a little World) it might prepare a dwelling-place proportioned to him, with like furnishing, all the things of the world conspiring toward the attainment of this end. For all the globes of the stars, just as they are endowed with no offspring of a vegetative or sentient nature, so they have coalesced merely from a pure composition of the Elements. And both by the will of God and by reason of the position which each one has obtained in the immense expanse of the ethereal Ocean,

each of them, and also by the hidden powers of neighboring stars influencing them under one configuration and another, has acquired certain specific and peculiar and appropriated endowments — by which, through their perennial influence, they may bless the terrestrial body with so great a variety of things as we daily marvel at. The terrestrial globe alone, therefore, receives into itself, fosters, and turns to the use of mankind whatever powers lie hidden in the Universe, as the common subject of all. But how this comes about, it is now time to show, so that the secret mysteries of our Geocosm — that is, of the Subterranean World — may shine forth more and more. It must be shown, then, from where so great a variety of things shining forth in the body of the Earth proceeds, and how it is produced.

It is certain, by the reckoning of all philosophers, that lower things are subject to the motions of the higher, and that so great is the connection between these that it is impossible for the lower world to subsist without the perennial influence of the supernal bodies — just as it cannot happen that a passive principle should produce anything without an active one. For mixed bodies, whose innumerable variety is observed in this globe of the earth, since they perpetually need the offspring of the Elements from which they took their origin, while the earth itself remains immovable, fixed in its own seat — it necessarily follows that some mobile, sympathetic body must be given, which may stir the seminal reasons

[spermatikas rationes] implanted in each mixed body toward generation, so that by its perennial influence it may both foster what has been generated, and preserve what has been brought forth in the vigor of its propagation. And this the supernal bodies of the stars accomplish. Since their influences are perceptible, they must be necessary for some purpose — for nothing is in vain, neither in nature nor in what is made and produced by God. If, then, they are necessary, surely they must be necessary for the lower World, both to animate it and to preserve it. And since they are the finer — and therefore the more efficacious and more potent — portions of the Elements and the principles of nature, it is necessary that they concur in the composition of all mixed bodies. And the infinite multitude of mixed bodies argues an infinite multitude of supernal bodies, too, and an abundance of the powers implanted in them. But having set out these things in general only, let us now proceed to the particular powers of the stars.

CAPUT IV.

De Sole & admirando ejus opificio, viribus, proprietatibus, quibus in Mundum terrenum influit.

(On the Sun and its admirable construction, powers, and properties, by which it exerts its influence upon the terrestrial world.)

THE SUN, the chief star of the world, the source and origin of all the heat and light of the whole world, the spring of life and of the whole lower world. Indeed, the natural element of fire too, drawn forth by God the Best and Greatest from the primeval chaotic mass of the world, and congealed from a great part of the primeval light,

consists of a solid and a liquid — as in these modern times has been made abundantly clear by the aid of the optical tube [the telescope]. By its use, the Sun is seen, no otherwise than a kind of immense Ocean, to boil and seethe with perpetual ebullition, like vast waves; and to be agitated also about its own Center. The spots — which are nothing other than vast evaporations of this fiery Ocean — clearly indicate its inconstant nature and sudden alteration. Of all these phenomena of the Sun, since we have treated them very amply in our *Itinerarium Exstaticum*, I refer the reader there.

That most wise Architect of the world, GOD the Best and Greatest, when He determined to fabricate this worldly machine — seeing that without a primary instrument it could neither subsist nor be fit for the generations of things — set

before it this admirable thing, by which we all live, move, and have our being: namely, that admirable instrument, a kind of image, as it were, of His own Divinity, a work truly of the Most High. The Sun, I say, He established as a kind of heart and soul, or a certain mind, and the principal governance of nature (if it is permitted so to speak), and a Deity [Numen], the Vicar of the true Deity — so that by it the world might be governed, and the hidden Sacraments of the wisdom of God, drawn out from the chaos and abyss of darkness, might be made manifest; and that from this visible and material deity, the majesty of that invisible and supramundane Deity might become known to mortals.

To this Sun, moreover, imparting various motions —

Mind stirs the mass, and mingles with the great body (Virgil, *Aeneid* VI.727)

— He did not wish to bind it to circles, but to be moved by a perpetual heaping-up of spiral coils, from Tropic to Tropic, so that He might render the whole world, impregnated by its fruitful motion, a partaker of its power. And in this work nothing more clearly points to the Divine providence in the nature of things. Nor with respect to the terrestrial world alone, but also with respect to itself, has the Sun in these latest times been found to vary its motions and to change its courses — all of which has been most wisely ordained for the production of certain effects in the terrestrial world, as will later be seen. For if God and Nature do nothing in vain, even in these lowest and smallest things — which are otherwise the most worthless and are commonly reckoned among chance occurrences — such great powers sometimes shine forth that they savor of nothing but the heavenly. Surely to this visible image of God (to speak with Plato), so sublime, so constant, so regular, beyond all others, we must suppose that the highest and altogether heavenly causes underlie it. Of these I would not hesitate to call the most divine and the first its *intention and end*: the purpose for which God, the Creator of the Universe, from the time the world was founded so ordained it — namely, that the human mind, raised up to such admirable effects of Divine Wisdom, might know the Creator of things and the ultimate end of all things so notable and communicated with a certain incomprehensible goodness; might love Him; and in Him might at last rejoice eternally.

Concerning this fountain of light, then, and its marvelous constitution and faculties, we have determined to speak first, before we proceed to the miracles of light. The question is asked, therefore, first: what is that luminous substance which we daily behold and at whose incomprehensible beauty we stand

astonished — even though it has been granted to no one yet to reach the quiddity of its substance.

I say, then, that the Sun is a fiery Body, concreted from an ethereal flux, the material Sphere of the world's primeval light, filled with a certain seed-stuff [spermia]. From this, as from a kind of inexhaustible fountain of light and fire, the seedbeds of heat and light are derived into all things — that is, by the vehicle of light it pours qualities fit for the preservation of individual things into individual things; which then, mixed with their own seeds congenital to each thing, at last generate that admirable variety of things which we daily behold in this world.

The Sun, therefore, is a Spherical body — not mathematically, but physically — consisting of fluid and solid by reason of its roughness and unevenness. This might not without reason seem astonishing to someone, had not the most evident observation of it, made more than once through the most excellent telescopes, made us more certain. That it is a fiery, rough, and uneven Body has become known in these latest ages by the following experiment.

If you direct a telescope (of that kind which are fabricated of the greatest power, for the use of contemplating the stars), in the manner customary in Dioptrics, at the Sun at various times, and receive the image of it, transmitted into a closed and darkened chamber, upon a white plane, you will see — first, not without wonder — and then, the whole surface of the apparent solar hemisphere composed heterogeneously of shadows and bright points; and that same Sun, like a sea roughened with waves and rippled all around with fluctuating waters. Nor does it do this in the same way, but at different times it turns through different changes — today otherwise than yesterday, and tomorrow otherwise than today, and so never with the same pattern, the same aspect of countenance. Fixed in utmost amazement, you will behold this, as the Figure teaches.

[Note: the text refers to a Figure ("ut Figura docet") of the sunspots, but no figure is printed on this page; the plate appears later in the work.]

All these things not I alone, but our most distinguished Scheiner [Christoph Scheiner] — with truly Herculean labor of many years — has demonstrated by investigation, in his whole work the *Rosa Ursina* [The Orsine Rose], most subtle and full of the most recondite observations. In this same body, moreover, vast spots too are sometimes beheld with the utmost wonder, like shadows and opposed lights set against them. Some of these, decreasing in size, are attenuated at the same time into the subtlest shadow — so that at last you can scarcely

distinguish it from the rest of the Sun's surface, except by adjustment of the instrument. And such a shadowy trace sometimes lasts for one or several days; sometimes it vanishes utterly in haste; and sometimes all these things happen with an accompanying

(Continuing Caput IV, "On the Sun and its wondrous workmanship.")

There are also certain spots that, once attenuated into a thin and uniform shadow, then break up into minute, discontinuous spots like points, so that between them the remaining spaces of the solar surface shine through. And once this division into tiny spots has occurred, they nonetheless advance in their own order over one or several days, and they do so in various ways: some fade away into the common surface of the Sun, others retreat back into a single continuous shadow, while both kinds—as though led by a kind of regret—separate from one another so as then to vanish; and finally, out of these faded remnants, as though bubbling up from the substance of the Sun itself, they revive and grow into a new brood of bright facets and shadows. Indeed, the same spot sometimes reappears after a separation of one or another day.

But lest anyone suppose that a φαίνόμενον [Greek: phainomenon, "appearance"] of this kind has occurred through a flaw of the eye or of the glass, let him know that irrefutable experience has hitherto taught beyond doubt that this happens on the very surface of the solar disc itself—always, at every moment of the day, in any part of the Sun, yet indifferently under a fixed position of the stars. Anyone who has ever seen molten copper [aes] in smelting furnaces, in great cauldrons, will be able to grasp in some measure the true causes of the solar phenomenon. For just as in cauldrons of this kind the seething of the surging material rolls up such swells from time to time that it seems not unlike a sea agitated by fiery waves and curved into whirlpools of surf—where black soot, joined to the most brilliant flames, displays a marvelous whiteness of bright patches and shadows, and where others are continually substituted in place of those that fade—so too the molten copper, while it is actually being poured out, has a splendor so like the splendor of the Sun that no other thing in the nature of things displays the Sun's splendor better.

I recall having observed the Sun disfigured by this mantle, first in the year 1625 on the 4th of April at Mainz [Moguntia], and then at various other times here at Rome together with Scheiner, not without astonishment—whence I have judged that the figure of the phenomenon should be set down here. Now that these phenomena of shadows and bright spots in no way occur outside the solar disc,

but rather seem to bubble up from the very surface of its body, is confirmed by the following arguments.

First, because the Sun—whether variegated with shadows, or glittering with bright patches, or lacking both—just as it appears in one place, so it has been found to appear to the whole world. Likewise, when new spots arise, or when they occupy a certain place on the solar surface, this happens everywhere at the same time and place of the Sun—indeed, in different years too, provided they are observed at similar times and in the same parallels, as has become known to us by the constant and concordant testimony of Galileo [Galilei], Scheiner, [Charles] Malapert [Malapertius], [Pierre] Gassendi [Gassendus], [Johannes] Hevelius, and others observing in the Indies (whom you may see among the authors cited). Second, whether the intervals of the shadows and spots be taken lengthwise, or breadthwise, or in combination, they will always be found to inhere in the Sun's surface—which, as is clear from optics, would by no means happen if they adhered to some other sphere outside the Sun.

I said in the definition ("filled with a certain panspermia") because the Sun is endowed not only with the quality of simple light, but also has, mixed with its light, the powers of all seminal things. Thus, having been established by the Architect of the World [Opifex Mundanus] as a kind of soul of the world and father of all things, it contains within itself, in their power, the potencies of all the seminal principles [seminales rationes]; and these, joined with the seeds of each individual thing, bring about the generation of all things in the world. For (as Aristotle rightly says) the Sun and man generate man; but by light and motion alone it does not generate—therefore it does so by something else, namely by warmth, conveyed as if by a vehicle and mixed with each individual thing, and so it produces this effect. No one will easily deny that heat is the chief instrument of the Sun, except one who has been deprived of all sense.

In the definition of the Sun given above, I said that the body of the Sun is rough—rounded physically, not mathematically, as many would have it. For just as the Earth, constituted with its atmosphere, is girded with an uneven mantle of vapors and exhalations and has various dispositions of its parts—for in one place we find it dense, in another subtle and thin, everywhere imbued with a varied mixture of forces and qualities, and in some places and others producing this thing and that according to the nature and condition of the evaporating part—so exactly is it to be thought that the Sun consists of its uneven pyrosphere [pyrosphaera], as irrefutable experience has taught from the perpetual alternation of spots, smokes, mists, and bright patches on its surface, now bubbling up, now again

fading away. And thus no one who has more deeply contemplated the foregoing will doubt that the solar body is engaged, like a certain fiery ocean, in perpetual motion and agitation; and that, being thus agitated, it causes various effects in the nature of things according to the varied nature of the evaporating solar region. For there is the same account of all the bodies of the world, so that what we say of the Earth must be said of the Sun, the Moon, and the other planets; the diversity is found only in this, that each of these bodies, just as it has been allotted a different nature, so too pours forth a different sphere of its own exhaled power. I say no more: whoever has more profoundly searched out these miracles of the Sun will without doubt easily see the origin of comets arising in the upper region of the aether. Many philosophers too, while they rashly ascribe to the empyrean heaven, in many instances, the hidden causes of certain extraordinary effects, will satisfy themselves more fully if they consider this pyrosphere of the Sun and its various effects.

Furthermore, the powers of the Sun are light, heat, and—

[Margin: Wisd. 16, no. 27 (*Wisdom 16:27*)]

—and these seeds of things, conveyed by its light, carried down into these bodies, brought in by its heat and warmed, are the mingled cause of things and of the generation of all things. For its light, just as it is the bearer of the seeds of things, is likewise their measure, number, and kindling. For while it illuminates, entering the bodies of the whole universe and permeating them, with heat as its companion it now separates, now gathers together, purges and moves, penetrates, nourishes, augments, perfects, renews, and vivifies them—containing all things, yet contained by all—so that all bodies long for it as their generator, their mover, their warmer, their illuminator, and finally as the giver and preserver of life. For it instills and imparts all these into bodies, both by the manifest powers of its light and by hidden and incorporeal actions; so that the Wise Man seems to have had regard to these admirable qualities of the Sun when he says: τὸ γὰρ ὑπὸ πυρὸς μὴ φθειρόμενον ἀπλῶς ὑπὸ βραχείας ἀκτῖνος ἡλίου θερμαινόμενον ἐτήκετο [Greek: "For that which was not destroyed by fire was melted, being simply warmed by a brief ray of the Sun"]. *That which could not be exterminated by fire, melted away as soon as it was warmed by a small ray of the Sun.* The conjoined instruments of the Sun, therefore, are light, heat, and seeds, for the producing of all things that are in the world.

Now, in order that the Sun might more equitably and rightly communicate to the bodies of the world these truly admirable powers innate to its whole body, the most wise Architect of Nature willed that it should be moved about its own axis,

in a daily and yearly span ordained on the model of the daily and yearly motion (a portent, indeed, which has at last become known in these latest times to the lynx-eyed astronomers [Lyncei Astronomi]), so that there should be no part deprived of the fruitful administration of such necessary light. Since, moreover, the radiant aspect of the Sun is most effective, lest by the continued intensification of heat it should harm the Earth, He willed to establish the atmosphere, raised up from terrestrial exhalations and watery vapors by the action of the Sun, so that in it the excessive heat, as though blunted, might fill the whole world with a certain proportioned intensity of warmth.

Since it is established that from every point of the Sun turned toward the Earth there comes forth some single, individual, perpendicular ray, which is always carried in a straight course both through the atmosphere and through the air (as we teach in our *Ars Anaclastica* [Kircher, *Ars Magna Lucis et Umbrae*, the anaclastics]), we say that this is the cause of the diversity of heat in different climates. For if the ray falls straight upon the Earth's surface, it will undoubtedly exercise a most powerful action; if it inclines toward the vertical, it will produce a more effective heat the nearer the angle it makes with the surface is to a right angle. But since the ray of the rising or noonday Sun, falling upon objects standing perpendicularly erect on the terrestrial surface, falls in exactly the same way as one positioned at the vertex in the middle of the sky under the right sphere [sphaera recta], one might rightly wonder why the Sun's rays, cast perpendicularly upon the walls of mountains, towers, temples, and houses of this kind—and likewise upon the perpendicularly erect surfaces of pyramids and columns—do not produce the same effect that they produce under the right sphere.

But I reply that the cause of this effect is that the Sun's rays are refracted in the vaporous region, or atmosphere, which protects the Earth, clothed as though in a delicate garment, from the darts of Phoebus, so that it blunts their more vehement impact in various ways, according to the varied obliquity of the rays or to the rarity and density of the said atmosphere. And thus the rarity or density of the diaphanous medium causes the quantity of refraction, while the opacity of the diaphanous medium causes the dulling of the rays. Since, then, both are found in the atmosphere, it is no wonder if it alone exercises authority over the radiant sphere of the Sun. From which it consequently appears that, if there were no atmosphere, these slopes of mountains—as well as all perpendicularly erect surfaces—would reflect exactly the same heat that the noonday and vertical Sun, together with the Earth, reflect under the equator. The oblique position, therefore, makes the Sun's ray near the horizon pursue a long path in that

atmosphere; and so, while it passes through the humid medium of the vaporous sphere, it loses much of its light and vigor and heat, as though blunted and dulled. Were it otherwise, the Earth would undoubtedly be uninhabitable from the Sun's heat—so that from this very fact you may see and admire the wondrous wisdom of God, the Best and Greatest, in the administration and preservation of the world. But concerning this marvel of nature and the usefulness of the atmosphere, see more in our *Ars Anaclastica*. From which, unless I am mistaken, the usefulness of the refracted solar ray in the preservation of the Earth is clear.

Furthermore, since the Sun, by the shadow of the Earth cast on the opposite side, always spreads densest darkness somewhere over parts of the globe, and consequently the Earth feels the absence of so much necessary light, lest anyone be able to cavil that divine providence was lacking even in this, He willed to compensate for all this defect of light by a kind of reflected ray of the Sun. For while with its immense light it illuminates the opposite bodies of the Moon and the stars, these, shining back the communicated light as though from a mirror onto the averted face of the Earth wrapped in the darkness of night—what else do they render but a kind of vicarious service of the Sun, expending it both in light and in reflected heat, thus, by inevitable necessity, as nature demands? See the figure set down here, in which the radiant light A B C D strikes both the Earth and the Moon and the other stars, which, reflected back by the rays E F G H onto the shadowed part of the globe I L opposite, there perform the office of the absent Sun with tempered heat and light; and there, according to the varied mixture of communicated power, they produce various effects.

Since the power of the Sun in the world is incredible and certainly admirable—for from the Sun comes all motion, and life,

[Top of page, continuing from the foot of the preceding column:]—and life, and preservation, and the adornment of things celestial and terrestrial—so that the more closely you contemplate it, the more things you will find in it congruous with that miracle, fit to be set forth. I judge it becomes a philosopher to search out all the treasures of nature.

Diagram. A large schematic of solar illumination and reflection. At the top center is the Sun, engraved as a radiant disc with a human face. From it broad fans of straight rays descend to the bodies arranged below. At the center sits the Earth, labeled **Terra**, drawn as a small globe; beneath it a cone of darkness (the Earth's shadow) tapers downward, with the shadowed/opposite face of the Earth marked by the points **I** and **L**. To either side and below are the Moon and planets, drawn as small spheres receiving the Sun's rays and reflecting them back; the lower-

corner bodies bear astronomical glyphs (the crescent ☾ Moon at lower left, and planetary symbols including ♂ Mars at the lower bodies). The direct rays from the Sun are lettered **A B C D** along the upper register; the reflected rays returning toward the Earth's shadowed side are lettered **E F G H** along the lower register.

- Sun (top center): radiant disc with a face; source of rays A B C D
- Terra (center): the Earth, a small globe struck by the direct solar rays
- I (on the Earth, shadow side): point marking the shadowed/averted face of the globe
- L (on the Earth, shadow side): second point marking the shadowed face, adjacent to I
- A (upper ray): direct solar ray
- B (upper ray): direct solar ray
- C (upper-right ray): direct solar ray
- D (right ray): direct solar ray
- E (lower-left ray): reflected ray returning toward the Earth's shadow
- F (lower ray): reflected ray
- G (lower ray): reflected ray
- H (lower-right ray): reflected ray
- ☾ (lower left, on a small sphere): the Moon, with crescent glyph [Margin glyph in figure]
- ♂ (lower bodies): planetary symbol (Mars) on a reflecting sphere [?]

(The dogmas, so much more worthy of being set forth, are congruous with so great a miracle.)

It is therefore fixed and established that, if the Sun stood still, the governance of this terrestrial world would be far otherwise—namely, it would have a most turbulent state; the globe of the Earth would not be everywhere habitable, nor would the disposition of the atmosphere be the same as we now experience it, because of the absence of the beneficent Sun that quickens and preserves all things. From which things the bountiful goodness of Divine providence shines forth, in that it gave to this star a motion—of longitude, the daily; and of latitude, the yearly and eccentric—so that by such a diversity of motions the atmosphere might be tempered to an even moderation, a temperature accommodated to human use. For from this we have the changes of the seasons—winter, summer, autumn, and spring; by this we pass through the courses of years, months, days, and weeks, whose diversity one and the same Sun produces by its presence and absence. The power of the Sun, therefore, is given to the terrestrial globe by

Divine providence through the local motion—daily and yearly—which conveys its forces and faculties.

But lest the Earth should always be struck by the same solar rays, and lest the other part of the solar body, turned toward the stars, should seem to be idle, Divine wisdom imparted to the Sun's body its own motions, distinct from all others; by these (as is established by long observation of astronomers) it would complete about one revolution around its own center in roughly twenty-seven days, and by the benefit of this rotation it would diffuse most abundantly, successively, whatever of light and whatever of power it contained, both into the Earth and into the surrounding globes of the celestial and ethereal regions.

And that this rotation of the Sun was indeed bestowed as a favor to the Earth by the Creator is clear from this, that it revolves not by a simple circuit, but by a yearly turning of the mobile axis about which the prior motion is described. Whence it comes about that the Sun inclines toward the Earth around its northern summit and its southern depression, and nods over the space of six months; and from that same alternating appearance of the mobile poles and axes above the solar horizon, and their concealment below it, it bends down. That this dizzying libration was made for the benefit of the Earth as well ought by no means to be doubted: for from it arises that through the 13 surveys by which it sweeps over the whole [Sun], just as the Earth is always imbued with one and another solar light, so too it is without doubt imbued with one and another solar power. This variety of influences is wonderfully promoted by the perpetual conjunction, separation, departure, and return of the motion of the spots, shadows, and bright facets. For if the shadow of the Moon in a solar eclipse so greatly alters the Earth, how great an alteration in things below the Moon must we believe the Sun would effect—the Sun which suffers eclipses from time to time by 50 or 60 spots and shadows of such magnitude that they seem to equal the faces of the Moon and the Earth? But since the Sun now,

[Margin: Aldrovandus, *l. de prodigiis* (*Ulisse Aldrovandi, book on prodigies*)]

—as though mourning in a spotted train of shadows, goes ahead; now, the doleful veil cast off, wholly serene, bright, calm, and smiling, it seems at one moment to belch forth flames, at the next black soot, as is beautifully shown in the figure. Certainly reason teaches that these things act on the Earth in various ways and produce dissimilar effects. For by this alternation they marvelously vary, impede, promote, increase, and diminish the very light of the Sun; and once this is changed, the solar influence upon the Earth and upon things below the Moon must consequently change too. That these things are so is proved by the

astronomical records of almost every age. Hence we often experience certain years as more abnormal than others—years which the astrologers ascribe to various aspects of the planets, but which we more truly ascribe to this variety of the solar phenomenon.

For since an immense quantity of bubbling solar evaporations is heaped up, it cannot but be that it vehemently hinders the Sun from acting as effectively with its light and heat upon these lower things. Suetonius relates that at the time when Julius Caesar was being slain, a kind of thick, sooty matter was seen around the Sun for a long time. In the time of the Emperor Justinian too, for a whole year the Sun, as though hedged about with a kind of veil, gave so little light, and so dimly, that it seemed to have been turned into the Moon. The Arabs observed a not dissimilar prodigy in the year 64 of the Hegira, as Haly [Haël] relates in his *Astrology*—a prodigy which was soon followed by a great desolation of things. In Paul the Deacon [Paulus Diaconus] we read that in the year 700 the disc of the Sun, as though suffused with a blood-red color, shone so dimly over all Europe for the space of many days—with the sky most clear and unclouded—that it almost spread darkness over the world. A great comet too followed this darkness. Cornelius Gemma in his *Cosmocritica* testifies that in the year 1569 the disc of the Sun appeared with the same countenance, and that this apparition was followed by both a comet and civil disturbances. Finally, in the year 1625, a little before the Swedish war, throughout the whole course of the year the disc of the Sun was covered with an enormous bubbling-up of spots, as was observed both by me in Germany and by our Scheiner at Rome (as appears from the *Rosa Ursina*). If astronomers were to note all these things diligently, then perhaps, from phenomena of this kind compared with sublunary effects, a new astrology, far more certain than that common planetary one, might be founded—though I do not deny that the causes of these solar maladies are none other than the unlucky and pernicious aspects of the surrounding stars, which, opportunely infesting the Sun's body, at last stir up in the solar body those tempests of which I have spoken.

On the Moon, our Cysat [Cysatus; Johann Baptist Cysat] noted an atmosphere, that is, an exhalation of vapors, in the eclipse of the year 1628, on the very day of the Lord's Nativity. Whence I do not doubt that the same occurs in the remaining globes of the planets, which, just as they constitute different centers from the center of the universe, so also constitute different spheres of exhalations. From which, indeed, unless I am mistaken, the genesis of comets kindled both above and below the Moon, and of new stars, manifestly appears. I could adduce many things in this place concerning the manner in which the Sun and the other planets pour forth the spheres of their exhalations, and how comets can thence

be born; but since we have amply taught this in our *Itinerarium Exstaticum Coeleste* [Kircher, *Itinerarium Exstaticum*], we refer the curious reader to it.

Caput V.

On the Nature and Effects of the Lunar Body.

[Margin: On the Nature and Effects of the Lunar Body. (*repeated as a running side-title*)]

That the greater variety of things and of effects might shine forth in this world, it was brought about by the unspeakable counsels of Divine wisdom that very many bodies in this universe should be constituted, each imbued with various and diverse qualities, so that these, impregnated by the fruitful rays of the Sun and by a mixture of seeds, conveyed to the Earth through the reflected ray, as it were, of the Sun's light, might there contrive new combinations of generable things. And that this might be done more conveniently, He willed the Moon to be turned about the Earth, and the planets about the Sun as their center, so that they might more conveniently pour out upon the Earth the rays received from the Sun.

Since the said bodies drink in the Sun's brightness not merely at the surface, but also in their marrow, and tinge it with their own native property, it comes about that the seminal powers created together with the Sun, propagated through the luminous rays into the said bodies, there mixed with the seminal power of the planets and of the other stars—each peculiar to itself—operate in different ways: partly through the reflected ray onto the Earth, partly through the direct and refracted ray into the atmosphere; and thus they produce diverse and innumerable effects, according to the disposition and capacity of the Earth, likewise filled with a certain panspermia [Greek: πανσπερμία, "all-seed," the universal seed-mixture]. And that this tincture is indeed thus, is clear from the very diverse colored lights of the planets, as the leaden of Saturn, the fiery of Mars, the silvery of Venus, the bright and serene of Jupiter; which variety of colors, that it does not derive wholly from the Sun's light, is proved by this, that at the same time they are imbued, not with a similar, but with a color appropriated to themselves, always and everywhere. Nor are the colors of planets of this kind to be derived from the medium, because, in whatever way the medium may be altered, they are always clothed, by their constant tenor, with light variously tinged in each one. Whence, from their own inborn colors—

the Sun's light reaching it [the Moon], and from there reflecting it back upon the Earth together with its own specific qualities — just as the Sun's rays, when passed through panes of glass tinted with various colors, are themselves imbued with those various tinctures. This must be granted. And no one should doubt that this influence upon the Earth produces various modifications of the said qualities, arising both from the approach and the recession of these bodies — toward the Sun as much as toward the Earth — and likewise from their varying position with respect both to the heavens and to the horizon.

Hence, lest the Earth be disturbed by the excessive heat and violence of the Sun's rays, the supreme Architect set against the Sun a certain Ethereal Earth — let me call it, with Plutarch, the Moon — as a kind of watery body endowed with countless powers. By its cooling, the rays are broken and tempered, and being made fertile with their own seeds and communicated to the Earth, there they might give rise to fresh offspring and new growth.

Now these two bodies — our Earth and that Ethereal lunar Earth — have a great likeness to one another (as will be shown in Book IV), by which the one nurtures the other and they mutually favor each other; and there are influences by which both bodies, and the parts of each, both live and are preserved and nourished. Indeed, that our seas are variously stirred according to the Moon's aspects needs no proof, since nothing is more commonplace; but a fuller opportunity for discussing these matters will be given in the cited passage at Book IV. [Margin: ?]

This sympathy consists in nothing other than a great agreement of both powers and actions; but the agreement of powers consists in nothing but a likeness of essence, since powers reside in a thing in proportion to its essence and proceed from that essence, and in proportion to those powers the actions too must be exercised. For since the Moon is a rough body and entirely similar to our Earth — dense and opaque, composed of solid and liquid — it not only perfectly absorbs the Sun's rays but, by a mutual communication of powers, reflects what it has absorbed back to us. And lest the influence should always be the same, the most wise Architect fashioned the Moon with such skill that it should look upon us with an ever-unequal aspect over the monthly span, and, according to its varying position, should strike the Earth with one degree of its action and then another, and thereby promote the generation of things according to the needs of nature.

But lest I should seem to have omitted anything of curious interest, I have thought it right to set down here the Phenomenon of the lunar body, just as it was observed — both in the Collegio Romano and by Eustachio Divini [Eustachio Divini] — with the finest telescopes. In it you will find a certain wonderful face

composed of shadows and little points of light, not unlike what appears in the foregoing solar Phenomenon, with this one difference: that the bright spots and dark spots on the Sun are perpetually inconstant, whereas on the Moon they remain perpetually the same and unmoved, holding ever to the same pattern.

You would say you were gazing upon some sea washing against vast tracts of land. Here, in the central depths, you see islands spread far and wide as if in some Ocean; elsewhere you see certain shadowy hollows, from whose center something — I know not what — seems to issue, which you would call a tremulous exhalation, and which the Observing Selenographers accordingly call the Moon's Atmosphere. Around the same rim you will gaze, not without wonder — especially when the Moon is at the half [in *Luna Dichotoma*] — upon what seem to be sheer crags and a range of chained-together mountains. And so, from this picture, with seas, terrestrial lakes, and mountains duly compared among themselves, you will infer, not improbably, that the Moon is a globe entirely similar to our Earth — namely, an Earthy body, that is, composed of moisture and a celestial earth, endowed with the countless faculties of latent seeds, which, mixed with the Sun's rays, produce in the Earth that multitude of things we daily marvel at, even though we can scarcely grasp the mystical reason for it in our minds.

That intense light diffused into rays we do not suppose to be some highly polished portion or surface of the more eminent part of the Moon, reflecting the Sun's rays more violently than the rest of its parts. If we were on the lunar body, looking out at the terrestrial globe, we would surely say that the inaccessible peaks of the loftiest mountains — such as the Alps, the Pyrenees, the Andes, the Caucasus — covered with perpetual snow, would reflect a like light upon objects situated on the lunar globe. For it can scarcely be told how intense a light of this kind they reflect — as I recall observing, not without delight, in the year 1638, while I was surveying Etna [Aetna], among the mountains of Calabria and the islands scattered round about. And that there are on the Moon prominent crags, as it were of mountains, the increase and decrease of the shadows at the rising and setting of the Sun on the lunar horizon sufficiently shows. For it has been observed by the lynx-eyed Astronomers of our time that certain more eminent parts of the Moon — which they call lunar mountains — are successively illuminated from one side and then darkened from the other, just as on our terrestrial horizon, at the rising of the Sun, mountains cast their shadows: smaller in proportion as the Sun has climbed higher, larger in proportion as it draws nearer to the point of rising. But let what has been said about the structure, use, and nature of the Moon suffice.

CAPUT VI.

On the proportion of the Earth's globe to the Sun and the Moon. [De proportione Globi Terrae ad Solem ac Lunam.]

In the *Itinerarium Exstaticum* we stated that the Sun, the Moon, and the rest of the Planets were created in such a magnitude of body as is fitting for each, and at such a distance of one from another, that each globe is always within the sphere of activity of another — that is, the several bodies affect one another by a kind of reciprocal exchange of their diffused rays. This is a clear sign of the admirable proportion of the length, or interval, by which they are distant from one another.

[Margin: The wondrous providence of God in distributing the Sun's light.] If, then, the Sun were larger or smaller than it is, under the same distance from the Earth that it has in the universe — if it were larger, then, with its excessive light, it would have scorched the greatest part of the terrestrial Orb, and so would have brought on the utmost disorder of things. At the Poles, moreover, it would have illumined the hemisphere for more than half the year and beyond half its surface; whence, over the whole orb of the Earth, the greatest inequality of days and nights would arise, the greatest and astonishingly disordered constitution of the year and of the four seasons, and it would have caused an utter and unavoidable confusion. But if the Sun had been smaller than it now is, all the losses of cold and darkness would likewise have followed, since it would have illumined only less than half the globe. Therefore the terrestrial globe has been constituted in such a proportion that there is no nation in the world that could complain of an insufficient portion of heat and light, or accuse Nature of any negligence in the distribution of the necessary, due light.

But on these matters see our *Ars Magna Lucis et Umbrae* [Ars Magna Lucis et Umbrae], folio 57. Furthermore, since the Sun's radiance could inflict much harm by the continual influx of diffused light and heat, the wisdom of the eternal Maker therefore set another body against the Sun [Margin: A body opposed to the Sun for tempering the Sun's heat], so that whatever the persistent Dog Star [Sirius] heat of the Sun's force had rendered parched, dry, and burnt up, this body might, by its own power and innate moisture, reduce to an even temperature; and lest, being nearer to the Earth, it should burden the Earth with more than a fair abundance and excess of moisture, He willed it now to wax and now to wane with light — both for establishing a more exact tempering of sublunary things, and for countless other uses and benefits, which will be declared in the course of this Work.

Nor should the remaining choir of Planets be reckoned idle, since each one carries out the parts of its office, which it diligently performs in the cosmic Economy, those parts which the law of eternal Wisdom has prescribed to each. Since we have treated of these in the *Itinerarium Exstaticum*, we refer the Reader thither. With these matters premised, let us now proceed to the fabric and constitution of the terrestrial globe.

CAPUT VII.

On the outermost structure of the Earth, and its magnitude. [De extima Telluris structura, ejusque magnitudine.]

You see, then, by what artifice this marvelous work of divine wisdom has been founded — that it lacks neither τάξις [Greek: taxis, "order"], nor διάθεσις [Greek: diathesis, "arrangement"], nor οἰκονομία [Greek: oikonomia, "economy" or "ordered management"] — in which there is nothing that is not in every way fitting, well-arranged, magnificent, and surpassing all admiration. For whether you look at the ornaments after the manner of columns, or the splendor of the paneled ceilings, or the solidity of the foundations, you cannot but be carried away into worthy raptures of admiration.

But how can the weight of this terrestrial globe be supported? What underpinnings? With what piling and pounding of stakes are they made solid, so that the Earth may be stabilized with such firmness above the unstable mass of the waters poured round about it? [Margin: The stability of the Geocosm and of the elements.] If we should wish to set up the other three elements of the world as columns for the terrestrial fabric, we shall see them to differ as much from these as Heaven differs from Earth. Who has ever been able to see columns enduring through a course of 5,000 years, in which even now the bases, supports, lintels, cymatia [moldings], the bands of the cushions [pulvini], abaci, acroteria, and the rest of the parts of the columns remain whole and immune from every blemish of corruption — when meanwhile the elements have now lasted nearly 6,000 years, throughout that span, in their integrity?

Who would not marvel at the roof of this fabric, which encompasses not only the upper part of the building but the whole building, a roof that, by the motion of its ceaseless revolution, is so perpetually turned that it perfectly covers the house — yet without weight being added to it; it is so drawn over the building that, so far from spreading darkness, it rather floods all the receptacles of that building with light and heat? This we call the Heaven, the magnificent machine of the eternal Architect; whose pavement is the Earth [Margin: The adornment of the heavens.],

placed in the central seat of the world, solid and on every side compacted into itself by its own gravitations, clothed with flowers, fruits, herbs, trees, and crops — of all which an incredible multitude is distinguished by an insatiable variety, at the sight of which you delight, on the taste of which you feed, and by whose fragrance you are refreshed; whose walls are the globes contiguous to the heavens, strong with a continuous turning of the spheres, firm, mighty by the perpetual law of revolution, translucent, gleaming, and conspicuous within and without by the light that the stars hurl forth. Add the variety and grandeur of its delights: the icy perennial flow of springs, the...

Diagram. A large engraved plate (left half of a double-page spread; the right portion is cropped at the gutter) depicting the body of the Sun [Schema corporis Solaris] as observed by the Author at Rome in 1635. The disk is rendered as a fiery, granulated globe ringed by a flame-like corona of solar fire, studded with numerous dark cloud-like sunspots (maculae) and bright flame-tufts (faculae), several of the latter marked with a small triangular symbol ($\triangle$). The surrounding field outside the disk is labeled as the Ethereal region. An ornamental cartouche held aloft by a winged putto at the upper right carries the title. A legend runs along the bottom margin. Several labels extend onto the cropped right half not visible in this scan.

Visible labels:

- Title cartouche (upper right): "Schema co[rporis] / SOLA[ris] / prout ab Authore et[iam] / Romae Anno 1635 / fui[t observatum]" — "A scheme of the body of the Sun, as it was observed by the Author at Rome in the year 1635."
- ÆTHEREUM (upper left, along the disk's edge): "Ethereal [region]."
- ÆTHEREUM (lower left, mirrored): "Ethereal [region]."
- Æquator (left, mid-disk): "Equator."
- Polus Bor[ealis] (upper right, near disk edge): "North Pole."
- Polus [Australis?] (lower right, cropped at edge): "[South] Pole." [?]
- R (upper area): point-label.
- S (upper left, near edge): point-label.
- T (left, near edge): point-label.
- D (left of equator): point-label.
- H (lower left): point-label.
- L (lower left, near edge): point-label.

- Δ (multiple, on bright faculae across the disk): symbol marking the brighter solar facula-tufts.

Legend along the bottom margin (partly cropped/abraded): "F.G. Axis Globi Solaris. D.E. [Ae]quator Solaris. B.F.C. Spacium Solis [?]... H.G.I. Sp[acium] Sol[is]..." — "F.G., the Axis of the Solar Globe; D.E., the Solar Equator; B.F.C., the space of the Sun [?]...; H.G.I., the space of the Sun..." [The legend text is small and partly truncated at the gutter and lower margin; several entries are illegible.] [?]

Marginal annotations on p. 101 (printed in the outer margin, partly cropped at the gutter on p. 103): Several short printed side-notes appear keyed to the text. On p. 101 a handwritten note in ink at the foot of the right column reads (approximately): "Schema D[?] vid[e] ad pag. 162 [?]" — apparently a contemporary reader's cross-reference: "See the figure... at page 162." [?]

Marginalia visible on p. 103 (cropped fragments at the inner edge of the right margin): Several truncated printed side-note fragments are visible but largely cut off at the page edge: "...epan- /...lathe- /...co- / in di- /...ione /...æ."; "...osthe- /...rimus /...men- /...e ag- /...iis."; "...la dari /...st cer- /...omni- /...regio- /...is con- /...men-". These belong to side-notes for text on the facing page (p. 104, the verso of which is largely blank/offset in this scan); they cannot be reconstructed from the visible fragments. [?]

Diagram. A large engraved plate (the right half of a folding plate showing the body of the Sun, marked "Tomus I. 64" at the upper right) depicting the solar disk covered with sunspots and surrounding evaporations, after the observations of Christoph Scheiner [Christophorus Scheiner]. A winged putto at the upper left holds the engraved cartouche bearing the title. The disk is ringed by a dense fiery margin of flame-like prominences; dark cloud-like masses (evaporations) cluster both on the face of the Sun and in the surrounding space. The word *SPATIUM* ("Space") is lettered twice in the field outside the disk (upper right and lower right). This is the continuation of the solar plate begun on the facing leaf (fig-p104-1 of the prior opening); the left margin of the engraving is cut at the gutter.

Readable labels:

- (upper-left cartouche, partly cut at gutter): "...na corporis [Schema corporis]...ARIS [Solaris],...re et P. Scheinero [...ore et P. Scheinero],...1635 observatum fuit." — i.e. "Diagram of the body of the Sun,... and by Father Scheiner,... observed [in] 1635."
- (upper left, at disk edge): "...s Borealis" — [Polus] Borealis, "North Pole"
- (lower left, at disk edge): "...us Australis" — [Polus] Australis, "South Pole"

- P (upper region, in space): evaporation cloud label
- O (upper right, in space): evaporation cloud label
- Q (left, at disk edge): label
- H (right side, at disk edge): label
- I (lower right, on disk): label
- N (lower right, in space): evaporation cloud label
- M (bottom, in space): evaporation cloud label
- A (several, on disk face, each beside a bright spot): "Putei lucis" — "wells of light"
- "Solaris" (right of disk, beside H): part of a label — [Limbus?] Solaris or [Globus] Solaris
- (legend at foot, partly abraded): "...[P]olu[s]... Spatium Solis torridum. A Putei lucis. L, M, N, O... Evaporationes una et macularum origo." — "...the torrid Space of the Sun. A: the wells of light. L, M, N, O: the evaporations, the one origin of the [sun]spots."

[The blank verso of the plate carries only two abraded marginal note-fragments, transcribed where they belong in the running text below; the marginalia heads are "Mira p[rovidentia]... Dei in... [di]stributio[ne] lucis So[la]ris" and "Stabili[tas] Geoco[smi] & elem[en]torum."]

LIBER SECUNDUS — Geocosmus

[Caput VII, continued — De extima Telluris structura, ejusque magnitudine]

[Margin: Delights.]

the translucent waters, the banks of rivers clothed in flowers at their loveliest, the lofty vaults of caverns, the ruggedness of crags, the summits of overhanging mountains, the immensity of the open plains — to say nothing, for now, of the vast and inexhaustible store of treasures locked away in the innermost recesses of the Earth, and of their abundance.

[Margin: The inhabitants of the Geocosm.]

And as for the inhabitants of this palace of so marvelous a Geocosm — how great their variety and number! Besides man, who is the end of all things, how great the diversity of living creatures differing in kind! How great the goodness and

wisdom of the Steward in providing for each thing what it needs to sustain and propagate itself! How great the beauty of the sea! How vast the multitude of islands! What charm there is in their coasts and shores! How many, and how unlike, are the kinds of fish and of huge sea-beasts, and of the creatures that cling to the rocks in their native shells! Here I pass over in silence the wonderful effects of air, water, and fire as they play together in the nature of things; I leave aside the inner constitution of the several organs of the terrestrial mass. But I cut short, before the proper time, the unrolling of my reflection on the inestimable works of God, lest, carried away by I know not what ardor of the mind, I be drawn too far from the subject set before me — farther than I could draw my foot back.

[Margin: The terraqueous globe.]

The Earth, then — which we call the Terrestrial World — is the sphere of the human race, a single globe compounded of water and land, fixed in the middle of the World and held there by its own weight. Its outermost surface is clothed partly with a terrestrial, partly with an aqueous covering, as with a garment, and in the excellence and variety of its contents it surpasses all the other globes of the World. Its magnitude and quantity, although attempted by very many mathematicians of every age — men endowed with the highest felicity of genius — has not, so far as I know, to this very day been worked out with any clarity. For most who take up this attempt assume the globe to be mathematically round, and assume a perfect solidity of this mass, abstracting from all the inner caverns of its bowels; and by this reasoning indeed they have arrived at some certainty of measurement, though no one has reached a precise determination of the magnitude.

[Margin: No one has truly measured the Earth's body.]

[Margin: Why the matter of the Earth does not fall under geometrical scrutiny.]

For — apart from the deceptiveness of measures that are changeable and unstable, and peculiar and proper to each (I will not say kingdom only, but even province and town) — there is added the inequality of innumerable mountains stretched far and wide in chained-together ranges, and the gap (unexplored to this day) of plains and deserts spread out beyond measure. All these things escape men's knowledge, and so it is impossible for them to be defined by human industry through any fixed and determinate measure.

Hence geometers, content with a pure and bare hypothesis, in order to establish something certain, consider the terrestrial body as a mass of aqueous and

terrestrial substance compacted spherically into a single globe — disregarding all the brows of the mountains and the depths of the

valleys that follow upon them — and they set up their measurements according to this hypothesis. But although many have attempted this in every age, they differ so widely from one another that the following saying seems not inaptly directed against them:

The farther I advance, the more I go astray into byways.

[Margin: Eratosthenes the first of the Greeks to attempt the measurement.]

The first to attempt it was Eratosthenes, by means of a scaphium [a sundial-bowl instrument], between Syene and Alexandria; and Archimedes, Hipparchus, Strabo, and Ptolemy also investigated it — but with a notable difference from Eratosthenes. King Almamon [al-Ma'mūn] made trial of so great an undertaking, at great expense, on the great plains, as is found in Abulfeda [Abū al-Fidā'] the Arab, no mean cosmographer. Later men investigated it too — all the mathematicians of more penetrating genius — with scaphia and other sundial-instruments, and by an exact measurement of some fairly level region along the meridian line that would correspond to one celestial degree. They examined the heights of towers and mountains in the hope of arriving at the longed-for knowledge — but in vain. For if you examine the efforts of them all, efforts truly most worthy of praise, you will scarcely find any one of them agreeing with another; and yet the rules concerning the proportion of the diameter to the circumference, and concerning the magnitude and quantity of the sphere to be found by means of it, are most certain and infallible; nor can the analysis of spherical triangles deceive, if geometry is consistent with itself. What, then, are we to suppose to be the reason for so great a diversity? I will explain it in a few words.

[Margin: The disagreement of the mathematicians in measuring the Earth.]

I judge there to be two things, above all, that frustrate all the labor of geometers in measuring the quantity of the Earth. The first is the very great diversity of the measures used in the different regions, provinces, and towns of the world — a diversity so great that there is scarcely a town that does not differ from another in the quantity of its measure, so that nothing is more difficult than to reduce all the difference of these measures to one stable and unchangeable measure, since the foundation of measure is lacking.

[Margin: No certain measure can be given that is common to all regions.]

For if you set up, as the smallest term of measure — for example — a grain of wheat or of mustard, those grains are of such differing size that you will find they acquire a notable difference of quantity according to the condition of the different climates, horizons, and soils. But if you take some part of the human body as a fixed foundation of measure — say a thumb's-breadth, a palm, a span, a foot, a pace, and the like — you will find under these too a difference of inequality all the greater in proportion as one man differs from another in the natural constitution of his body. And so, in order that something certain might be established amid so great a diversity, there ought to be furnished to all the mathematicians in the world a fixed and infallible measure, according to which they might conduct their operations — furnished by some Monarch of supreme authority; and that not inscribed on paper or parchment,

(since this too suffers its own damage from the change of air and of climates), but cut into bronze or some similarly durable material. Yet that even a measure assumed in this way could not hold good, I show as follows.

[Margin: Another difficulty.]

In the practical geodesy of this business there is necessarily required — indeed presupposed — the analysis of a triangle, from the proportion of whose sides and angles, the quantity of one side being known, we arrive at knowledge of the whole unknown quantity. But a triangle of this kind cannot be set up except by a visual ray, or by a solar ray in some sundial instrument or device; and that neither of these is sufficient for this business is so true that no one could doubt it — except, perhaps, the man who has not experienced for himself the inescapable rocks of difficulty that arise in dioptric astronomy.

[Margin: Sighting (collimation) is deceptive in measurements.]

A novice not much versed in astronomical work might perhaps suppose that the visual line, along which we sight through a sighting-vane toward some star, or toward the summit of a mountain or tower, runs so straight into the object that it cannot be that such a line is not exactly determined — which the alidade [Alhidada] demonstrates to be so straight. But those who know the deeper secrets of nature, and who scrutinize more exactly the unstable nature of refractions amid so great a diversity of media, find otherwise. To set this out a little more fully, one must know that the medium of the air, on account of the inconstancy of its fluid nature, is so variable — both by reason of time and of place — that scarcely an hour of the same day, scarcely a week or a month in the whole course of the year, can be assigned in which it does not, according to the different laws

of rarefaction or condensation, undergo its own alterations as well. To this is added the disparate condition of places, whereby it comes about that the aerial medium is one thing at the sea, the rivers, the lakes, the marshes, and another in the mountains and in desert and waterless places; one in southern, another in northern regions; one under the Torrid Zone, another under the Temperate, another under the Frigid; and so, according to the state and natural constitution of the horizons, it must be altered in one way and another.

[Margin: The fallacy in the refraction of the air.]

It is certain that the visual ray too — the foundation of the whole geodetic business — is, according to the said diversities, altered in a wonderful way, since the object seen is presented now higher, now lower, according to the proportion of the refracting medium. The horizon itself teaches this fallacy: by the power of its refracting nature it presents the luminous bodies of the stars as already risen and to be observed, which nonetheless, according to astronomical strictness, ought not yet to have emerged, being still hidden below the horizon. Islands suddenly come into view in the midst of a gulf of the sea, which before lay concealed. The summits of mountains, otherwise unseen, are disclosed — for no other reason than that refraction raises hidden things higher and higher beyond their natural position, according to the disposition of the medium. On these matters see Our Art of Anaclastics [Ars Anaclastica] in the work entitled *Ars Magna Lucis et Umbrae* [The Great Art of Light and Shadow], where we have pursued everything more fully.

This being laid down, then, I think it cannot be that anyone — however equipped with keen and subtle genius, and notwithstanding the excellence and reliability of his instrument — should attain the altitude of a star, or of a rather distant mountain, precisely and truly. And so I consider this to be the one cause why there is so great a difference among authors concerning the magnitude of the terrestrial globe.

[Margin: What is the cause of so great a difference in the observations.]

Those who, on a notable plain, set about a business of this geodetic kind by means of measuring-rods [decempedae] draw an equal hazard of difficulty. For so small a space — besides being imperceptible in relation to the whole circuit of the terrestrial globe — has corresponding to it the very smallest portion of the heavens; and that this should be reached precisely, through instruments, in first or second minutes, I judge scarcely possible — to say nothing of the defects of the measurers, inevitably committed in measuring lengths by rods or chains. But

granted that all these things have been carried out correctly and with the desired diligence, behold, a new difficulty presents itself: for we cannot know whether the said plain coincides exactly with the surface of the sea, whether it is higher or lower than it. For if it is higher, who does not see that the circuit of the circumference will be greater than is right, and if lower, smaller? And who will hit upon the mean? Surely He alone, who, as He made all things in number, weight, and measure, so He alone attains also the precise equality of the terrestrial surface with the aqueous.

There are others who think that, from some high watchtower, by a visual line touching the surface of the sea, they can arrive at the end of the geodetic business. But who will be able to mark with certainty the point of contact amid so great an inconstancy of the element? Who will distinguish a fixed and sure point in the instability of the fluid nature, when the waves now subside after the manner of valleys, now swell up like mountains? Surely no one.

[Margin: The point observed in the sea cannot stand fixed.]

The geodesists, indeed, in the confine of the horizon and the heaven, will firmly persuade themselves that the visual line touches nothing but a point; but I say that it is so far from being a point that in its breadth it spans and embraces — I will not say a foot or a pace, but many miles. We are deceived by our senses through the inequality of the sea's surface that is taken for a plain; the air mocks us in a thousand ways — so that this whole geodetic contrivance really cannot stand, unless the surface of the sea be round without any inequality, unless the terrestrial plain be continuous with the surface of the sea, unless the aerial medium be everywhere one and the same. And since this matter far exceeds human power and knowledge, so too every effort of human industry is baffled in investigating the quantity of the Earth exactly. These things I write, not that anyone...

[the page breaks off mid-word at "tam laude digno / moli-" — "in so praiseworthy an under[taking]..."]

to detract from a work so worthy of praise, but to set the difficulty of carrying out the task before the eyes of the curious reader.

But I come now to the other source of difficulty. There are those who would summon to the balance not merely the surface of the Earth, but also its solidity and weight. [Margin: The solidity or weight of the Earth cannot be found out by human intellect.] If indeed, granting the value of the Earth's semidiameter, one were to regard the whole body — by hypothesis — only as to how great it is and

how solid, that would not be hard. But there are some who, after deducting the Earth's caverns, would commit the remainder to the scale; and this attempt, in my judgment at least, ought to be reckoned bolder than is fitting, since beyond a useless exercise of calculation it yields us no benefit whatever. This one thing I know: to investigate the weight of the Earth involves difficulties perhaps greater than human industry and labor can overcome. For — as will be shown in what follows — the Earth is bored through with countless tunnels and riddled with vast caverns beyond number, small, smallest, and largest, and is moreover packed full of matter of heterogeneous nature. From this, given so great a discrepancy of mixtures, no one could ever attain the desired aim of weighing it; and to possess a knowledge of all these things would be necessary. Let us therefore conclude with the divine Job: *Gird up your loins like a man; I will question you,*

answer me: where were you, when I laid the foundations of the Earth? Tell me, if you have understanding of it. Who set its measures, if you know? Or who stretched the line upon it? Upon what are its bases founded, or who laid its cornerstone? Have you entered into the depths of the sea, and walked in the lowest parts of the abyss? Have you considered the breadth of the Earth? And Job answered: What can I answer? I will lay my hand upon my mouth. One thing I have spoken, which I wish I had not said, and another, to which I will add nothing further. (Job 38) [Margin: Job, ch. 38; v. 4, 10, 11, etc.]

And these are the things I thought worth saying about the vastness and magnitude of the Geocosm. As for the methods both of measuring and of weighing its whole mass, since I have treated them elsewhere in my works, and since scarcely any geographical work exists in which such a method is not contained, I have deliberately passed over them, lest I should stuff this work full of what others have already handed down. Yet so that the reader may not be cheated of the information he desires, I have decided to excerpt those things which are more to one's taste from the table of authors who have devoted their efforts to measuring the Earth's mass — from which, given so great a discrepancy, [the reader may take what suits him]. Let us conclude, then, with the divine Job: *Gird up your loins like a man; I will question you.*

CAPUT VIII.

Of the Mountains of the Geocosm, and their Necessity.

There is great controversy among authors, especially among the interpreters of Sacred Scripture, whether before the Flood the Earth was made rough with

mountains, or whether on every side it was rounded into a wholly flat surface. Each opinion has its adherents. But just as the former is most true, so the latter is most false and dangerous to the faith. [Margin: The mountains existed before the Flood.] Certainly the Sacred text plainly teaches that the Earth was furnished with mountains from the beginning; for it makes mention of Mount Ararat, and it makes mention of the height of the waters in the Cataclysm rising fifteen cubits above all the mountains in the whole Earth. If, then, the cataclysm of waters covered the mountains, then they already existed before it; and so the adherents of the latter opinion are not to be heard. That the terrestrial globe, then, was made rough with mountains is so certain that whoever stands alone in the contrary opinion will find his match in our most learned Father Riccioli [Giovanni Battista Riccioli], in the *Almagestum Novum*, Volume 1, fol. 62.

What the bones do in the Microcosm, the structure of the mountains does in the Geocosm: they bind the whole mass of the terrestrial globe so tightly that it cannot in the least be dissolved, and in this way it acquires a perfect consistency. [Margin: The bone-frame of the Earth is the framework of the mountains.] For since the Earth does not contain in its womb a clod of a single kind, but is teeming with countless species of diverse things — as with minerals, powders, metallic fluxes, ashes, as will later be reported — these surely could not hold together unless they were contained, by a firm structure within the innermost cavities, by the framework of the mountains, like wine in casks bound by hoops. Secondly, since the sea that flows around the Earth is perpetually agitated, both by its tide in ebb and flow and by the force of the winds, [Margin: The usefulness of the mountains in the terrestrial domain.] surely without the barriers of the mountains the Earth could not endure; for by these the sea is contained within its own bays and channels, as if by levers and barriers, lest it devastate the Earth with an immoderate deluge, according to that saying of Job: *I encompassed it, and set bars and doors to it, and said: Thus far shall you come, and you shall go no further; and here shall you break your swelling waves.* (Job 38) [Margin: Job, ch. 38.]

Thirdly, the mountains were absolutely necessary for the propagation of springs and rivers; [Margin: Mountains necessary for producing springs.] for by these a more sloping Earth provides an easy flow into the sea, which could not have happened had the Earth been wholly flat. But of these things more fully in the treatise *On the Origin of Springs*. The mountains, then, are like certain breasts protruding in the Geocosm, and like certain storehouses and treasuries of nature, established by provident nature both to supply liquid perpetually, and to nourish and enrich the valleys lying beneath the mountains and regions, by the gift of the

beneficial liquid diffused on every side. Fourthly, the mountains contribute marvelously both to checking the fury of the winds, and to producing the variety of herbs, trees, and plants — which would not otherwise come forth without mountains — and to tempering the heat of the Sun and the healthfulness of the air, all of which are obtained only in the higher recesses of the mountains. Hence men and herds, wearied by the summer heat, generally seek out the mountainous regions for the sake of refreshment and the restoration of health. Fifthly, what are the mountains but an inexhaustible storehouse and treasury of metallic bodies? [Margin: Metals.] In whose hollows, through hidden passages, by the power and energy of the subterranean fire — cooked as in some furnace, and brought to the desired maturity — they are produced for the use of mortals. I will not speak here of the pleasantness of the prospect, of the usefulness which their shade affords to the underlying plains and valleys of the fields; I do not recount how great is the importance of the mountains in determining the nature of places. This I will dare to affirm reverently: that the property and quality of diverse regions, provinces, and cities arise solely from the natural constitution of the mountains. But there is one thing which provident nature aims at chiefly in the constitution of the mountains and in the roughening of the terrestrial parts: namely, a proportioned increase of heat, [Margin: That the heat may be tempered.] without which nothing could be rightly arranged. For from this it comes about that the rays of the Sun and of the other stars, tempered within the windings of the mountains and the diverse constitutions of the rocky masses, by their varied reflection strongly intensify the heat, and draw out vapors fit for producing meteorological impressions, from which countless benefits in the economy of the Geocosm must necessarily arise, as will be said in its place.

For to whom is it not established by experience that the plains lying beneath the mountains, as soon as the Sun first enters Aries, when the masses of snow that cover the peaks of the mountains are loosened, marvelously warm the surrounding earth and stir it to bring forth? And lest the earth be intoxicated by too much moisture, by its slope it hinders the stagnation of moisture, and the moisture, continually gathered into the channels of the rivers, it thrusts down into the sea, so that, freed from superfluous moisture, the earth may be made fit for the produce of things. [Margin: Why the surface of the Earth ought not to be flat.] But if the Earth had been spread out with a flat surface, it would doubtless have lacked all the benefits just recounted; for neither would the rivers have continued their flow because of the level surface of the Earth, nor would the melted snows have had any place into which to discharge themselves. And so, by the multitude of stagnant waters diffused into all parts, the earth, together with the offspring of vegetative and sentient nature, would necessarily have perished

from the superfluity of moisture. Add to this the unhealthfulness of the air, which the breath of stagnant waters of the level plains, standing without motion, would have caused. From all of which, weighed by a deeper scrutiny of the mind, the necessity of the mountains plainly appears.

CAPUT IX.

Of the Hidden Constitution of the Mountains.

Those who wish to construct a material sphere first fit together the circles which they call Meridians, in such a disposition that they all intersect one another at the Poles of the World; to these they then apply the Equator and the rest of the parallel circles in order, both for the firmness of the Sphere and to indicate the hidden constitution of the Earth. [Margin: The first ring-like chain of mountains.] If we examine the structure of the Geocosm with a somewhat finer balance, we shall find that nature has constituted it by exactly the same method by which it fits and arranges the terrestrial globe; for the Geocosm itself teaches abundantly that the chains of the mountains are set from Pole to Pole, that is, from North to South. But to show the truth of the matter more clearly:

The first chain of mountains, arranged in a circle, is brought down from the Pole through Iceland, Scotland, England, Germany, by a continued series of mountains and in a straight track all the way to the Alps — which are like a certain knot of the great chain, by which those mountains that, extended in a discontinuous order, had incurred some flaw of connection, are bound and drawn tight to a firmer consistency. From the Alps, the mountains, interlaced as if in a new ring-like order, are joined to the Apennines, by which the central spine of all Italy, just like a certain backbone, with an excellent framing of bones, is continued in series through Sicily and connected to the mountains of Africa, which they call [the Mountains] of the Moon [Mountains of the Moon].

The other limb of the great chain's knot extends all the way to the farthest promontory of the South, named the Cape of Good Hope, and this order — reason itself dictates — is doubtless continued all the way to the opposite Pole of the World. [Margin: The other limb of the connected chains of mountains — which it is.] From this Southern pole, it is extended through the unknown tracts of the Southern Land all the way to the Strait of Magellan, and from there it is joined, through the Andes of South America and the immense tracts of the North, to the Northern pole from which it had flowed. A second chain, intersecting the first at right angles, departing from the Pole and deriving the course of its extension through Tartary, joins to itself the Imaus [Himalaya], which through the middle

of Scythia, the great empire of the Mogor [Mughal Empire], and finally through the backbone of India, runs out into the promontory of Comorin [Cape Comorin]; there, by means of the sea-floor, it is connected to the mountains of the island of Zeilan [Ceylon/Sri Lanka], and from there, beneath the Ocean, it is extended to the Southern pole; and from there at last, through the unknown tracts of lands and Ocean, it is connected to the beginning from which it descended.

But since the perpetual tide and flow of the Ocean from East to West, by its continual dashing, could bring some detriment, provident nature has therefore disposed transverse chains of mountains, by which the whole machine of the Earth's mass might acquire a firmer consistency. [Margin: The transverse chains of mountains — which, and for what?] Hence you see, from East to West, beginning from the farthest region of the Chinese, mountains so joined to mountains that what China propagates crosswise, the Imaus continues beyond China westward to Scythia, India, the Caspian Sea, America, Asia Minor, Macedonia, all the way to the Cottian and Rhaetian Alps, by continued mountains conjoins them; and the Alps, through Dauphiné and all of Narbonese Gaul, commit continuous mountains to the Pyrenean Alps, which thence at last extend, in a marvelous order, to the farthest boundary of the West, until they are restored to their own beginning.

But you will perhaps ask why chains of this kind do not appear continued in the Ocean, but at the farthest promontories of the lands seem to break off, as if cut short and interrupted? [Margin: Why chains of this kind do not appear in the Ocean.] I reply: chains of mountains of this kind are not broken off altogether, but are continued beneath the depth of the Ocean in the same order. That they do not rise up, except through the scattered islands emerging here and there in the Ocean — this you may persuade yourself was certainly done by the most sagacious counsel of nature. For since the Ocean perpetually surrounds the globe of the lands with its flow, the element, being of a fluid nature, required as if by a certain right that its paths be free from every obstacle and barrier, and passable on every side. Hence the chains of mountains are not continued by jutting peaks in the Ocean, lest they set an obstacle to the motion of the Ocean and the seas,

Diagram. A hemisphere of the bone-frame [skeleton] of the terrestrial globe, stripped bare of its waters. The figure shows a circular globe whose surface is entirely covered with engraved mountain ranges and ridges, surrounded by a wavy, hatched border representing the encircling waters that have been drawn away. Labels are placed around and across the disk:

- A (top): one terminus of the north–south mountain chain (Arctic Pole).

- B (left): western point of the transverse latitudinal chain.
- D (right): eastern point of the transverse latitudinal chain.
- E (center): the central knot/crossing of the chains.
- C (bottom): the opposite terminus of the north–south chain (Antarctic Pole).
[Letter at lower edge faint — [?]]

Caption (verbatim): *Hemisphaerium Offaturæ Globi Terreni aquis nudata*
("Hemisphere of the bone-frame of the terrestrial globe, stripped of its waters").

and so that they might have a free field for fertilizing the whole Earth with an abundant influx of waters; which would not have happened if the Ocean had been

obstructed by chains of mountains, and had met with paths not free, but inaccessible to its motions and agitations. But lest by its most free and most impetuous motion it should, by its washing, be a detriment to the shores of the terrestrial regions, nature disposed these chains of mountains, so that the swelling storms of the waves, broken against them, might return to the channels destined for them. And since the Ocean also keeps its own laws of flowing, from North to South and the reverse, at appointed times, against this the transverse orders of the mountains are set, so that in this way, without hindrance, nature might perfect her operations in the economy of the terrestrial world. Yet I would not have anyone here suppose that these chains of mountains are coordinated into perfect circles; rather, as the necessity of the lands required, they are composed from time to time, with the fringes of the chains drawn out into the immense spaces of the surrounding regions on either side. But since we are to speak of these things more fully, God granting, in what follows, let these things, said in general only about the mountains, suffice. See the figure set opposite here. In it, the chain of mountains A B C D shows that framework of mountains which, from the Arctic Pole, through the middle of Europe and through Africa, [runs] to the Antarctic Pole, and thence through the Andes of South America is restored to the Northern Pole from which it had been drawn. [Margin: The boundary of the chains of mountains.] But the chain of mountains A E G extends from the Northern Pole, through the middle of Asia and India, to the Southern Pole C, and thence at last, through an unknown submarine framework, is restored to the Northern Pole A. But the chains of mountains extended in latitude, B E G, and the rest parallel to them, mark the transverse framework of the mountains, for the firmer consistency of the whole, for the ends just described.

CAPUT X.

Of the Mountains in Particular, and of their Hidden Architecture for Human Uses.

§ I.

Of the Storehouses or Water-Reservoirs [hydrophylacia] established in Europe.

That the mountains were constituted on the surface of the globe of the lands by nature, not by chance or at random, but by a most sagacious design, the things we are now about to say will abundantly prove. For from these — besides the moisture which by the agency of the mountains it confers upon the whole Earth — it has countless other uses, which we have recounted above. Let us extend our pen to describing those things which, so far as I know, no one before us has yet noticed. And that this may be done as well as possible:

It must be noted, first, that the terrestrial globe was constituted from Pole to Pole in a certain unequal and irregular framework, so that in the central parts of the terrestrial regions it might show itself most admirable; [Margin: The water-reservoir of the Alps, the Rhaetian, etc., and its rivers.] while it interwove, into the heaping-up of the greatest and most immense mountains, certain knots as it were of great chains, both for the firmer consistency and firmness of the whole structure, and for founding, in the blind bowels of the mountains, immense storehouses of waters — from which, as from storehouses, the rivers gushing forth on every side might water the underlying tracts of valleys and plains with a kindly outflow. And that this may be clear to the eyes of the curious reader, I have thought it right to unfold the matter more fully by an enumeration of its parts. [Margin: The boundary of the chains of mountains.]

Storehouses of this kind of nature, in Europe, are in the first place the offspring of the protruding mountains spread far and wide, which they call the Alps. From these, as from a most rich water-reservoir, most abundant outflows of waters are supplied to all the regions of Europe. And they are distinguished by a threefold name: those which look toward Gaul are called the Cottian; those which surround Switzerland [Helvetia], the Rhaetian, with the adjoined Vosges; those finally which face the Adriatic Sea, the Pennine. From this whole complex of the Alps, as from a fertile womb, pour forth great rivers: the Danube, the Rhine, the Inn [Oenus], blessing Germany; the Rhône [Rhodanus], the Saône [Arar], the Meuse [Mosa], the Moselle [Mosella], blessing Gaul and Belgium; while the Po [Padus], the Adige [Athesis], the Mincio [Mincius], the Ticino [Ticinus] bless Italy; and the Sava [Savus] and the Drava [Davus] bless Illyricum, by their watering. From this

not only rivers, but also great and immense lakes have drawn their origin. In Germany, the lakes Acronius [Lake Constance], Lucerinus [Lake Lucerne], Tigurinus [Lake Zurich]; in the region of Gaul and the Insubrian [Lombard] territory, the Lemanus [Lake Geneva] — to say nothing meanwhile of the countless lakes of lesser order. In Italy, in the Cisalpine region, three lakes, which they call the Major [Lago Maggiore], the Comensis [Lake Como] — to the ancients the Larius — and the de la Garda [Lake Garda]. But whence so great an abundance of waters derives its origin, and how it is contained in the storehouses of the mountains, will be shown in its place and time; for in this place it has seemed right to treat only of the disposition of the storehouses, so that, this being explored, we may gradually come to the hidden and secret causes of such great wonders of nature. But let us follow the thread we have begun.

Having recounted, then, the vaulting of the Alps — since it cannot communicate itself in equal measure of waters to each and every surrounding region, lest nature should seem to have shown herself a stepmother to the needs of mortals — therefore it has annexed to itself other orders of mountains, heaped together on every side, with their fringes, as a kind of auxil-

Diagram. A large double-page engraved map plate, the "Geographical Table displaying the Water-Reservoir [hydrophylacium] of Greater Asia, by which all rivers — whether near or far, through hidden winding channels — receive their origin." The plate spans the two-page spread: the western half covers Arabia, Persia, the Persian Gulf, the Indian subcontinent, and the Arabian Sea; the eastern half covers India beyond the Ganges, Indochina, China, Sumatra, Borneo, Java, the Philippines, and the China Sea. The map's design illustrates Kircher's thesis that all the rivers of Asia issue from interior mountain water-reservoirs (the *hydrophylacia*), shown as mountain masses with rivers radiating from them. A compass rose at center marks the orientation (N at top, with W, O [Ost/East], S). The ornate cartouche at lower left, flanked by putti and reclining figures, carries the title.

The verso pages of the plate are blank show-through; no text.

Readable labels (west half — with positions:

- Top center: "La Mer Caspian Hircanum de Sala ou Bachu" [French/Latin: the Caspian Sea, the Hyrcanian (Sea), of Sala or Baku]
- Upper center: "LA PERSE" [French: Persia]
- Upper center, below: "FARS" [the province of Fārs]
- Center, along a river: "Choralan" [Khorāsān]

- Upper right: "Ieselbas" (a place label near the upper-right mountains)
- Right edge, in a mountain mass: "Hydrophylacium prin[cipale] Asiæ" [the principal Water-Reservoir of Asia] [partly cut at the page-join]
- Left: "Arabia deserta" [the Arabian Desert]
- Center-left, along the gulf: "Sinus Persicus" [the Persian Gulf]
- Center (open sea): "MARE ARABICUM" [the Arabian Sea]
- Lower center, along the south edge (open sea): "MARE INDICUM" [the Indian Sea / Ocean] — spaced caps running along the bottom margin (a separate label from MARE ARABICUM, not a continuation of it) [exact extent [?]]
- Right, along a river to the coast: "Indus flu." [the river Indus]
- Right: "India intra Gangem" [India within the Ganges]
- Right edge: "Indostan" [Hindustan] (vertical label along the right margin)
- Lower right, an island with a small inset: the island label reads "Ceyl[on]"; the inset lists, top-to-bottom, "Iaffna / Candea / Patalao / M.deno [?] / Colombi" [Jaffna / Candy / Patalao / ... / Colombo] (the island of Ceylon, partly at the page-join)
- Lower right margin: "Æquator" [the Equator line]
- Numerous unlabeled mountain-clusters (pictographic hill-symbols) are scattered across Arabia, Persia, and the Indian peninsula representing the mountain reservoirs.

Readable labels (east half — with positions:

- Upper left (continuing from west half): "...um principal." [Hydrophylacium principal — the principal Water-Reservoir] (the great mountain mass at the left edge, source of the rivers; gutter-cut at left)
- Upper left: "Chiamai lac." [Lake Chiamai — the legendary lake source of the Indochinese rivers]
- Left of center: "Tolema"
- Upper center: "Sancy" (twice — a region label "Sancy" and a mountain "Sancy")
- Upper center, large: "CHINA" (spread across the upper region as "C H I N A")
- Center: "Quancy"
- Center: "Quichen" / "Cauchin" [Cochin / Cochinchina]
- Center: "Cantam" [Canton / Guangdong]
- Center: "Quancü"

- Left center: "Bengala" [Bengal]
- Left: "India extra Gangem" [India beyond the Ganges]
- Left, along a river: "Ganges flu." [the river Ganges]
- Left edge: "...oltan" [?] [—stan, partial, at page-join]
- Center, along the peninsula: "Iancoma" [Iangoma]
- Center-south: "Camboia" [Cambodia]
- Center (islands): "Manille" [Manila]; "Lucon" [Luzon]
- Right of Luzon: "Les Philippines" [French: the Philippines]
- Right: "L'Archipelage de S. Lazare" [French: the Archipelago of St. Lazarus — the Philippine archipelago]
- Center: "Mindora" [Mindoro]
- Center: "Calamianas" [the Calamian Islands]
- Center-right: "Mindanao"
- Center: "Borneo"
- Center-right: "Mer de l'Anchidol" [French: the Sea of (the) Anchidol — i.e. the sea of the spice/Banda islands]
- Right: "Cele[bes]" [Celebes / Sulawesi] (split "Cele- / bes")
- Lower center: "Sumatra" (vertical, down the island)
- Lower center: "Iava" [Java]
- Upper right (open sea): "OCEANUS CHINENSIS" [the China Sea / Chinese Ocean] (spread as "O C E A N U S / C H I N E N - / S I S")
- Left edge: "Ceylon" (continuing from west half)
- Left margin: "...quator" [the Equator line, continuing]
- Bottom margin, spaced caps: "MARE INDICUM" running along the south edge (the spaced caps D / I / N... along the bottom; exact extent [?])
- Numerous unlabeled mountain-clusters across Indochina, Sumatra, and Borneo representing the mountain reservoirs feeding the rivers.

[The map is the only content on these four pages; there is no body prose. A few residual labels remain partly cut or too fine to resolve at the engraving/gutter limit and are flagged [?] above: the 4th Ceylon-inset line ("M.deno"), the gutter-cut "...oltan" tail, and the exact extent of the spaced MARE INDICUM caps along the bottom margin.]

[Margin: Auxiliary water-reservoirs.]

some auxiliary stores as well. In Germany, the Noric mountains and those that ring Bohemia — the Hercynian range, which faces the north — and Mount

Cottimelabocum [?]; in Gaul, the Vosges, the Auvergne mountains [Alverni], and the remnants of the Cottian Alps, the Dauphiné [Delphinatus] mountains; in Italy, the great skeleton of the Apennines, packed together with countless peaks like a kind of spine made of the ribs of the back. So it is that in Germany the mountains cited above feed yet another brood of rivers — namely the Main [Moenus], the Elbe [Albis], the Moldau [Moldava], and the Ems [Amasus]; in Gaul the Loire [Ligurim], the Seine [Sequana], the Durance [Druentia], and the Var [Varus]; in Italy the Arno [Arnus], the Tiber [Tyberis], the Aniene [Anien], the Liri [Lyris], and the Volturno [Vulturnus]. By these the whole of Italy, Gaul, and Germany are watered with a fertile outpouring.

And so that the outlying regions of Europe should not be left without the nourishment of moisture owed to them, nature set up new storehouses and reservoirs. Between Spain and Gaul she placed the Alps, that is, the Pyrenees mountains; between Germany on one side and Poland and Hungary on the other, the Carpathian mountains.

[Margin: The Pyrenees mountains.]

[Margin: The Carpathian mountains.]

[Margin: Rivers of Spain.]

[Margin: Rivers of Poland and Hungary.]

From the first of these — that is, from the folds of the Pyrenees, the mountains of Castile — Gaul receives the Garonne [Garumna], while in Spain they pour forth the rivers Ebro [Iberus], Douro [Durius], Tagus [Tagus], Guadalquivir [Betis], and Guadiana [Guadiana]. From the Carpathians, in Poland they yield the Vistula [Vistula], in Hungary the Tisza [Tibiscus], in Germany the Oder [Odera], and countless other rivers besides, with which those regions teem.

Thus, once these three reservoirs of nature have been put in place by the world's Founder, the whole of Europe is blessed with the highest and inexpressible benefits.

Diagram. An engraved geographic map plate occupying the upper part of the page, depicting the central-European water-reservoir within the Rhetian Alps. A cartouche at the upper right carries the title. At center rises a prominent mountain mass (the Rhetian Alps / the principal reservoir), drawn as a great peaked massif from which rivers radiate. The four cardinal regions are labelled, with mountain ranges drawn as rows of small conical hills and rivers as winding lines. The map is bordered top, bottom, and sides; seas are named along the lower

margin. [Several toponyms are small and partly faint — flagged individually below; this plate]

- Cartouche (upper right): "TYPUS HYDROPHYLACY [recte: HYDROPHYLACII] intra Alpes Reticas, quod fundit totius Europae Celeberrima Flumina; uti patet." — "Representation of the principal water-reservoir within the Rhetian Alps, which pours forth the most celebrated rivers of all Europe, as is evident."
- "GALLIA" (upper left): Gaul / France
- "GERMANIA" (upper right area): Germany
- "ITALIA" (lower center): Italy

- "Nizza" (lower center): Nice
- "Mare Gallicum" (lower left): the Gallic Sea (Gulf of Lion)
- "Mare Adriaticum" (lower right): the Adriatic Sea

[The body text resumes below the plate. Note: the opening clause of this column ("...some auxiliary stores as well...") and the marginal "Auxiliary water-reservoirs" are printed *above* the plate at the head of the page; the catalog of mountain ranges continues immediately beneath it.]

§. II.

On the Storehouses of Nature, or Water-reservoirs, established in Asia.

[Margin: The water-reservoirs of Asia.]

Nature proceeded in Asia along the very same plan she had followed in setting up Europe's mountain storehouses; indeed, in laying out the mountains, Nature gave free play to her art. For it is established from the science of geography that the central length of the whole of Asia is spanned by continuous chains of mountains, stretching from the Thracian dawn-star of the West [the Bosphorus] all the way to the farthest boundary of the East, and that these chains, as it were, divide off northern Asia — that is, Scythia or Tartary — from southern India. These mountain masses, according to their varying location, have received various names: some designate them under the names of Taurus and Antitaurus; some under that of Caucasus; others again under those of Imaus [Himalaya] and Paropanisus [the Paropamisus / Hindu Kush]. Be that as it may, our business is not with names but with the things themselves.

It is certain that these mountains, converging in the very midst of all Asia, form an immense mass of the highest mountains, which we accordingly assert to be the principal water-reservoir of all Asia. For from it she belches out vast rivers into every part of Asia: toward the south,

the Indus and the Ganges, by which the whole Indian nation is abundantly watered; toward the east, the many immense rivers of the kingdom of China

[Sinae]; toward the north, the Rha [the Volga] and the Ob [Obin]; and toward the west, finally, the most distinguished rivers — the Oxus [Amu Darya], the Jaxartes [Syr Darya], and the Hydaspes [Jhelum] — besides the countless and enormous lakes which she produces, as the map appended here clearly shows.

But since Asia extends over too long a tract for the central reservoir to reach every region scattered far and wide, it has distributed its wealth through the commerce of the subterranean realms in such a way that no one region can boast of having received more than another. For Taurus and Antitaurus enrich Asia Minor with the most fertile rivers; Greece they water with rivers poured forth from the Acroceraunian mountains, from Athos, Olympus, Pelion, Ossa, and the rest.

[Margin: The more celebrated mountains and rivers of Asia.]

Armenia, Persia, and Babylonia they water with the most famous rivers — the Euphrates [Euphrates], the Tigris [Tigris], the Derbi [?], and the others which for brevity's sake I pass over — fed by the Gordyaeon mountains, or Ararat, and the Caspian mountains. These, linked to Taurus and Caucasus in the west, finally toward the east are grafted, like so many separate branches, into their own common trunk, the heap of mountains just described. In the farthest corner of the north, too, the Hyperborean and Rhiphaean mountains have their own water-reservoirs, from which the vastest rivers — the Borysthenes [Dnieper], the Volga, and the Tanais [Don] — pour out to water Russia and Tartary abundantly. Of these and their noteworthy features I shall treat more fully in their proper place.

§. III.

On the Water-reservoirs, or Storehouses of the Mountains, established in Africa.

Since Africa is for the most part exposed to the heat of the Torrid Zone, and therefore suffers from extreme drought, nature, providing against this evil, set up a vast water-reservoir in the middle of it — the mountains they call the Mountains of the Moon [Montes Lunae]. This is an immense mass of mountains, which pours out countless rivers far and wide on every side, as if from fertile udders.

[Margin: The river Zaire.]

[Margin: The river Niger.]

From these, in the first place, the Nile — the most celebrated of all the rivers of the world — draws its origin; and after long and unknown wanderings, finally hurled down over cataracts, it is discharged, to Egypt's supreme good fortune, into the Mediterranean Sea, weighed down by the greatest mass of water. From this same source the Zaire [Congo] makes for the west, and licking past various regions of as-yet-unexplored extent, it mingles at last with the Atlantic Ocean. Rising not far from it, the Niger, undergoing various turns of fortune — now swallowed up in the gulfs of the earth, now disgorged again — empties at an equal pace into the Ocean just mentioned. From the south it belches out the Cuama [Zambezi] and other rivers transformed into names of a foreign tongue, rivers that for their vastness can be compared with the sea itself; and all of these the Southern Ocean receives.

And lest the deserts of Nubia and Libya should perish from the heat, nature so arranged the mountains of Atlas, chained together toward the east, that — just as moisture is distributed from the head through all the members of the body — so it should be aptly distributed from Atlas through the rest of the mountains' inner parts, to come to the aid of laboring nature.

Now the reservoirs, as it were the casks of these waters, are two lakes: Zambre and Zaire. The latter of these I should not be wrong to call an offspring of the former, the Zambre — each so swollen with such an abundance of water that they seem to belch out not rivers but seas; above all Lake Zambre, which, set as it were at the center and diffused into the broadest rivers, supplies the most abundant outpourings of water to every part of the world, as from a richly endowed vein.

[Margin: The great rivers of Southern Africa.]

To the north it supplies the Nile; to the east the great rivers Cuama [Zambezi] and Coavo [?], the Zeila, and the Manhice or Manhensen [?]; to the south and west, finally, the Zaire — and these rivers, watering the whole western tract of Southern Africa, the kingdoms of Congo, Angola, Monomotapa, Matama, Dagamidri [?], and Agisymba [?], all the way to the Cape of Good Hope, free it from sterility with their fertile silt. Those others water the whole interior region of the Abyssinians, and all those regions which the maritime coast marks off from the mouth of the Red Sea [Mare Erythraeum] to the mouth of the Cuama — which are Melinde, Barnagassus, Quiloa [Kilwa], Mombasa, Mozimba, Mombara, Membaca, Mozambique, and other such prodigies of kingdoms.

But so that we may set down here a noteworthy piece of history, and so that the truth — sought after for so many ages — may at last become known, I shall attempt to reveal who are the true sources of the Nile.

[Margin: The false account of the Nile's origin.]

We said elsewhere that Odoardo Lopez [Duarte Lopes] had, above the rest, devoted himself to the discovery of the Nile's origin, and had striven for this one thing: to assign the Nile's true sources. But neither was Odoardo an inspector of the Nile's true wellspring, nor is his account sufficiently in accord with the facts. Truer things, therefore, must be brought forward by us on so notable a subject. At the very time, then, when this most intricate and exceedingly perplexing business held me fast, Father Francesco Caravaglio [?], procurator of the Indies and Ethiopia, landed here at Rome; and being instructed by him in the truth through the manuscript of Father Pedro Páez [Petrus Paez], I have chosen to set the same down here for posterity, so that the truth may at last, after so many and such great fabrications and futile conjectures of the gravest authors, be restored to its own brightness.

The matter stands thus: The province where the Nile rises is called Agaos [Agaw], near the kingdom of Gojjam [Goiam]. The land in which it rises is called Sahala [Sabala]; it lies on the summit of a mountain, on a plain surrounded on every side by trees.

[Margin: Description of the Nile.]

The diameter of the spring is one and a half feet wide; its bottom cannot be sounded; it does not overflow at the margin, but opens an outlet for itself at the foot of the mountain. There, as soon as it has emerged from the bowels of the mountain, it spreads out into the light; then, swelled by further rivers, it at last empties into a lake thirty leagues in length and fourteen in breadth. From this, when it emerges again, through long...

Diagram. The left-hand (verso) leaf of the double-page Africa water-reservoir map plate. As bound, the printed sheet has come through very faint — most of the engraved detail (coastline, river network, hill ranges) is present only as a pale ghost impression, with the page largely blank. The recto column of this leaf carries running text of the Nile description together with its marginal labels (transcribed above and below). No engraved toponyms are legibly resolvable on this faint verso half. [This faint plate half]

[Margin: 73]

[Margin: Places situated around the source of the Nile.]

[Margin: The course of the Nile from its first origin.]

[Margin: Lake Bed [?], through which it passes.]

[Margin: Between the two rocks, the cataract.]

Diagram. The right-hand (recto) leaf of the double-page Africa water-reservoir map plate. The left third shows the Atlantic coast of west-central Africa, the open ocean inscribed "OCEANUS ÆTHIOPICUS" in large spaced display capitals; the right portion shows the interior, the Mountains of the Moon, the Nile-source lakes, and the radiating river network. An elaborate engraved cartouche at the bottom, framed by cherubs, putti, a reclining river-god, and a globe, carries the title. Several interior labels run off the right edge of this leaf (continuing onto the missing/faint conjoint half).

- Cartouche (bottom): "Hydrophilacium [recte: Hydrophylacium] AFRICAE praecipuum, in Montibus Lunae Situm, Lacus et Flumina praecipua fundens, ubi et nova inventio Originis Nili describitur." — "The principal water-reservoir of Africa, situated in the Mountains of the Moon, pouring forth the chief lakes and rivers; where also the new discovery of the Nile's origin is depicted."
- "OCEANUS" / "ÆTHIOPICUS" (left, large display): the Ethiopic Ocean (South Atlantic)
- "CONGO" (upper center): Congo
- "ANGOLA" (center, vertical along coast): Angola
- "Batta" (upper center): Batta
- "dictae Agisimba" (upper right): "called Agisymba"
- "Zaire flu." (upper center): the Zaire (Congo) river
- "Malemba" (upper right): Malemba
- "Les peuples Bagamidre [Bagamidri]" (upper right) [French label]: "the peoples of Bagamidri"
- "Matama" (upper right): Matama
- "Baiadas" (left center): Baiadas
- "Base Desert" (center): the Lower Desert / Base Desert
- "Lac" (center): lake [Lac]
- "Lac Bea[...] [?]" (center right): lake [name cut at the engraved margin]
- "Origine del Nilo" (center, along a river): "source of the Nile"
- "Hydrophilacium [Hydrophylacium]" (center right): water-reservoir

- "MONOMOTAPA" (right margin, large vertical display capitals dispersed down the leaf edge): Monomotapa

[Several interior toponyms on this plate are small, faint, or cut by the leaf edge — flagged [?] above. This plate]

Diagram. This is the recto (right-hand) half of the double-page engraved map of Africa whose left half appeared on the preceding plate. It shows the southeastern coast of Africa, the western Indian Ocean, and the island of Madagascar, with a wind-rose compass at upper right (N–O–S–W, i.e. North–East–South–West in the Dutch/Latin convention where "O" = *Oost*/East). The far left edge carries over from the verso half the river-and-lake network feeding out of the Mountains of the Moon. The ocean below is lettered in large engraved capitals OCEANUS ORIENTALIS [the Eastern (Indian) Ocean].

Readable labels (left to right, top to bottom):

- Upper left (cartouche text): "Hydrophylacia Æthiopiæ aperta quæ cum alio in montibus Lunæ communicans per subterraneos meatus" [The open water-reservoirs of Ethiopia, which communicate with another in the Mountains of the Moon through subterranean passages]
- Upper right corner: "Tomus I. 72" [Volume I, p. 72 — plate-keyed page reference]
- Far left, upper: "le Lac de Zaire" [the Lake of Zaire — French label]
- Far left, below it: "le Lac de Zembre" [the Lake of Zembre/Zambere — French label]
- Far left: "Sebsan" [?]
- Far left, lower: "Nilus" [the Nile]
- Left of center: "Montes Lunæ" [the Mountains of the Moon]
- Center-left: "Zofala" [Sofala]
- Center: "Mozambique" [Mozambique]
- Center, river label: "S. Spiritus flu." [the Holy Spirit River]
- Center, river label: "Cuama flu." [the Cuama River — i.e. the Zambezi]
- Vertical engraved label down the coast: "CAFRES" [the land of the Kaffirs / Cafraria]
- Lower left, mountain label: "[...]m sub Montibus Lunæ" [?] [(reservoir?) beneath the Mountains of the Moon]
- Lower left: "Buro mina de Oro" [Buro, gold mine — Portuguese]
- Lower left: "Rio del Spirito Santo" [the Holy Spirit River — Spanish]

- Lower left, vertical engraved: "CAFRA[...]" / "...TA" [Cafraria — coast labels, partly off the plate edge]
- Large island at right (unlabeled but clearly Madagascar), surrounded by numerous small islets (the Comoros / Mascarene scatter)
- Large engraved ocean legend: "OCEANUS ORIENTALIS" [the Eastern Ocean]

[Several small interior labels are too faint to resolve at this resolution]

Diagram. This is the verso (back) of the engraved map plate; the page is essentially blank apart from heavy bleed-through of the recto image and a marginal index list set in the left column. The marginal text appears to head a key of "the more celebrated Mountains and Rivers of Asia" [*Montes & Flumina celebriora Asiae*], evidently the legend belonging to a following Asia map, with only fragments of the entries legible through the show-through.

Readable marginal labels:

- "Montes & Flumina celebriora Asiæ" [The more celebrated Mountains and Rivers of Asia — index heading]
- "Fl. Zaire" [the Zaire River]
- "Fl. Niger" [the Niger River]

[The bulk of this column is an index of single initial letters and truncated words obscured by bleed-through and the binding gutter — not recoverable at this resolution.] ...it spirals through the windings of its meanders and comes round again to nearly the same place from which it had set out — that is, back to its spring. Then, its course reversed, it slips straight down over vast precipices and pathless rocks and turns aside into the interior of Ethiopia. All of this is confirmed by the eyewitness testimony of Father Pedro Páez, a priest of our Society, who surveyed this source of the Nile in company with the Emperor of Ethiopia — both of them spurred at once by curiosity and by love of the truth, and escorted by a large army. And since Father Pedro Páez treated with the greatest diligence whatever he observed of this matter, in a vast manuscript work on Ethiopian affairs, I shall set down here his own words translated from the Portuguese into Latin, so that the truth may shine out the more clearly. He speaks thus:

[Margin: An account of the origin of the Nile, by Father Pedro Páez.]

"After we had treated of the fertility of the lands under the dominion of Prester John, I judged it would be worth my while if in this place I were to relate something about the chief rivers and lakes of the territories subject to his empire.

Among these, the first to present itself is that greatest and most celebrated of rivers in all the world, the Nile — which was held in admiration not only among the ancient and the modern authorities, the gravest of writers, but of which Sacred Scripture too makes frequent mention. In Genesis 2 [Gen. 2:13] it is called Gihon, one of the four rivers watering Paradise. Today it is called by the Ethiopians Abawi. It takes its origin in the Kingdom of Gojjam, in a single district called Sahala, whose inhabitants are called the Agaw — and they are Christians, though, the Church having grown wild over the lapse of time, they are steeped in and corrupted by various superstitions, and differ little from the heathen and pagans round about them.

[Margin: A description of the Nile and its origin, newly discovered.]

"The source of the Nile lies in the western part of the Kingdom of Gojjam, on the summit of a single valley which resembles a vast plain, ringed about on every side by mountain ridges. In the year 1618, on the 21st day of the month of April, while I was staying in this kingdom together with the Emperor and his army, I climbed up to this place and surveyed everything carefully. I found first of all two round springs there, each about four palms wide in diameter, and with the utmost delight of my soul I saw what neither Cyrus, King of the Persians, nor Cambyses, nor Alexander the Great, nor that famous Julius Caesar could attain for all their wishing.

[Margin: The site of the place where the Nile rises.]

"The water of this spring is exceedingly clear and exceedingly light, and very pleasant to the taste. Yet one should know that these two eyes of the spring do not have their outlet at the top of the mountain's level surface, but at the mountain's foot. We also sounded the depth of the springs. Into the first we let down a lance, which on going in seemed at about eleven palms to touch certain root-like fibers of nearby trees interwoven with one another.

[Margin: The depth of the spring.]

"The second spring wells up about a stone's throw to the east of the first. Probing its depth, we sent down a lance of twelve palms and found no bottom; and when we had tied together two lances of twenty palms and tried the thing again, not even so could we reach bottom. The local people say the whole mountain is full of water — and they gave this as a sign of it, that the entire plain around the spring was trembling and boiling, a plain proof of the water lurking beneath. For the same reason the water does not well up at the spring itself, but discharges itself at the mountain's foot with the greatest force. The inhabitants affirmed — as did the

Emperor himself, who was present together with his army — that in that year the ground had trembled but little, on account of the great drought of the season, but in other years it trembles and boils so violently that one can scarcely approach without danger. The circuit of the place is like that of a certain round lake, whose breadth a sling could span.

[Margin: Of the places lying about the source of the Nile.]

"Below the peak of this mountain a population lives on the mountainside, about one league distant from the spring, toward the west; the place is called Guix, and the spring seems to be reachable from here. In this place is a settlement of heathens, who sacrifice many cows, and come to the springs on a fixed day of the year together with their priestling, whom they hold for a priest, who there sacrifices one cow beside the spring, and throws the severed head of the cow into the abyss of the spring."

[The narrative now reverts to Páez's original Portuguese for several clauses, which Kircher prints verbatim alongside the Latin:]

[Portuguese, as printed: "...e lago hia prima a qual buo, onde faciam solenne sacrificio matando muitas vaccas, que os gentios, d'hi tracion, & depois se cubria todo como sevo dellas, e se asentava en un Cadeira de ferro, que tinha posta nomo (= em cima) de muita lenha seca, e mandava sem se queimar nem ainda derreter-se o sevo, e algumas vezes etravan (= entravam) depois da fogo aceso, e se asentava à questa gente de maneira, che con estas feiticerias enganava àquella gente de maneira, que o tinham por grande Santo, che davam questo fato queria." — "...and then he would first [enter] the lake, where they performed a solemn sacrifice, killing many cows, which the heathens brought there; and afterward he covered himself all over with the cows' tallow, and seated himself on an iron chair that he had set up on top of a great heap of dry firewood, and gave the order [for it to be lit] — yet without his being burned, nor even the tallow melting; and sometimes they went in afterward, the fire being kindled. And he made himself agreeable to these people in such a way that, by these sorceries, he so deceived that people that they held him for a great saint, who could grant whatever he wished." — Páez's text drifts between Portuguese, Spanish, and Italian forms; the gloss follows the sense.]

[Margin: The field about the source of the Nile.]

"Furthermore, the Field of the Nile's source is on every side difficult of ascent, except on the northern side, where one climbs up easily. Below the mountain, about one Nile-league away [*una leuca Niliacâ*], in a certain very deep valley,

another river emerges from the bowels of the earth, which nonetheless joins itself to the Nile a little later — for which reason they believe it shares the same source-spring with the Nile, but, conducted beneath the earth through hidden channels, first breaks out at this spot. But the stream of the source, which breaks out below the mountain, runs eastward for the space of a musket-shot; then, turning suddenly, it makes for the north, and after about a quarter of a league a second stream offers itself, bubbling up out of rocks and crags. A little later two other streams join it, breaking out from the eastern quarter; and so, as further streams are gathered in one after another, the Nile grows notably.

"After the space of a day's journey it joins a great river called Yama [the Jamma], which then bends westward for about thirty-five leagues from its own first source, and afterward, its course changed, makes again for the east, insinuating itself into one vast lake.

[Margin: It crosses Lake Bed.]

(This lake is situated in the province called Bed, and lies partly under the Kingdom of Gojjam, partly under the Kingdom of Dambea [Dembea / Lake Tana].) The Nile so passes through this lake that its waters show a notable difference from the waters of the lake; and the whole river keeps its own course and current unmingled with the marsh-waters. As soon as it leaves the lake, swerving through various windings toward the south, it waters the land at a place named Alata, five leagues distant from the lake's outlet [*ab epistomio lacus*], where, hurled down over a cliff fourteen cubits high amid an immense roar and crash of falling water — which from a distance looked to me like a mist — it is, a little after the plunge, so swallowed up between two great rocks that it could scarcely be made out with the eyes.

[Margin: Between two rocks. A roofed-over crossing.]

The summits of the said rocks are so [near to one another] that the Emperor several times, with his whole army, has crossed over them by a bridge laid across — at all of which I myself was present.

"After this, on the eastern side, when it had watered far and wide the kingdom of Begemder [Begamidri], Gojjam, and the other intervening kingdoms — Amhara, Olaca [Walaqa?], Xaoa [Shewa], and Damot — it presently returns by its flow to the Kingdom of Gojjam; and when it has watered the territories of Bizan and Gumancanta, it so gradually approaches the Kingdom of Gojjam again that it is found to be no more than a single day's journey from its own source. From here, twisting its course back toward Fazolo and Ombarea — a kingdom of heathens

which in the year 1613 the *Exaz* [Ras] Selachristos [Se'ela Krestos], the Emperor's brother, had subdued with a great army; and being a kingdom hitherto unknown, he called it, on account of its vastness, *Ayzola*, that is, the New World — from here, inclining from east to north, it slips down through countless other regions and the vastest precipices into Egypt, and from there empties itself into the Mediterranean Sea."

And this is the description of the source of the Nile and of its course, which the aforesaid Father Pedro Páez observed with such care, and recorded with such great diligence, with his own eyes, together with the Emperor of the Abyssinians, in the year 1618 on the 21st of April — so that by this so distinguished and eyewitness examination of his he freed the republic of letters from many tangles and doubts. And I should hold that one must henceforth rely on him alone, since now, by the Emperor's approved testimony, the source of the Nile has attained its own infallible certainty. But lest anything seem to be wanting to this work, I have judged that a chorographic map ought to be added here, which you may see in Volume I of the *Oedipus*, in the chapter "On the Origin of the Nile" [*Oedipus Aegyptiacus*, tom. I, "Cap. de Origine Nili"].

Since this account states that two springs appear within ground that trembles on every side, it is likely that once a great part of this field which we have described was held in an open spring, as it were within the crater of a mountain; and that, over the lapse of time, as grasses and shrubbery grew up matted with mud, it drew over itself a kind of skin — of which sort I recall having seen myself in various places of Europe too. If that skin were drawn aside, I should not doubt that the whole trembling plain would soon reveal the face of the primeval spring. But let this suffice concerning the origin of the Nile.

[Margin: A chorography of the source of the Nile.]

§. IV.

Of the water-reservoirs of the mountains of America.

[Margin: The Andes mountains.]

Inasmuch as America lies for the most part under the Torrid Zone, provident Nature, beyond all other regions, willed to endow it with the richest water-reservoirs of mountains — of all the mountains beheld in the whole globe of the Earth, the highest. Of this sort are the mountains they call the Andes, which, by various ranges of other mountains converging into one, make up that most opulent storehouse of waters which they call Narags [Naragua / the Andean

reservoir], hemmed in by innumerable mountains in the middle region between Cuzco, Quito, and Lima. From here, chained together toward the south, the mountains extend through an immense tract of land — which the Spaniards therefore call the *Cordillera* — to the Strait of Magellan, the last bound of the habitable Earth. Toward the north, on the other hand, by the Isthmus of Panama they are joined to the mountains of New Spain, continued on into unknown coasts of the lands.

This reservoir of the Andes, then, pours forth so great a multitude both of lakes and of rivers that, whether you look to their number or to their size, none in the whole world — neither lakes nor rivers — can be compared with them. Of these the first is the Amazon [*Amazonius*], commonly the *Río de las Amazonas*, which, drawing its origin not far from Quito, crosses the whole breadth of America in a straight line, until — swollen by the association of countless other rivers — it discharges into the Northern Sea by a mouth, as it is written, seventy leagues wide.

[Margin: The Río de las Amazonas.]

The second, the Marañón [*Maragnon*], yielding nothing to the first, which is led out from the same already-mentioned reservoir of the Andes, washing countless regions of the unexplored interior of America, is rendered to the Brazilian Sea with such force that it furnishes sailors a supply of fresh water as much as ten leagues out within the Ocean — a rival, in its rise and fall, of the very Nile.

[Margin: The Marañón.]

There succeeds the Januarius [the January River], commonly the *Río de la Plata*, which, swollen from the inmost womb of the Andes by the confluence of rivers, is at last deposited within the Ocean alongside Paraguay and Brazil. Toward the north, on the other hand, it makes fruitful the New Kingdom [of Granada] with great rivers, one of which they name from St. Mary Magdalene [the Magdalena], the other from St. Martha [the Santa Marta].

[Margin: The Río de la Plata. The St. Martha River.]

It supplies also the most vast lake of the whole world, which some call Paraima, others Titicaca, enriched by the accession of twelve rivers. I shall not here recall the rivers beyond number — all of them fit for bearing ships — which, toward the west, it rolls out into the Southern Sea (commonly *del Sur*), along the region both of Lima and of the kingdom of Chile; of the nature and hidden properties of all of which fuller matter for discussion will be given in its own place. Father Alonso

d'Ovalle [Alonso de Ovalle], a Chilean, in his history narrates things scarcely credible about the marvelous constitution of these mountains. For from north to south they extend for fifteen hundred [1500] Spanish leagues; in height and length they far surpass all the mountain-chains in the whole globe of the Earth.

And it is in these that we place that immense water-reservoir which, just as it is perpetually filled — by the alternating motions of the tides — from the surrounding Eastern and Western Oceans by which it is hemmed in, so likewise pours out the mass of waters entrusted to it through the greatest rivers and lakes of the whole world. And in the Kingdom of Chile alone it discharges into the neighboring Pacific Sea, over a space of thirty or forty leagues (the distance of the Andes from the sea), as many as 246 rivers — most of them fit for bearing cargo, some hot like thermal baths, some cold, and various ones tainted with the juices of minerals.

Moreover, among the rest of Nature's prodigies, this surpasses all wonder: that in those same mountains, teeming with so great a mass of waters, Nature has besides [set] 14 volcanic mountains — which all, by their belching of flames and their outpouring of fiery torrents, have more than once laid the Kingdom of Chile in utmost desolation...

(into desolation) — joined them in a kind of unsociable, almost forced, marriage. But I have treated these matters more fully elsewhere. In North America, by contrast, nature played out the same providence: she enclosed other seedbeds of waters within vast mountains, so that the whole expanse of the New World might be watered by its most abundant rivers. From everything that has been brought forward, it is plainly evident that the mountains were established—this being their chief purpose—by nature for the fertilizing of the earth through the streams and the offspring of rivers they put out. But just how these water-reservoirs [hydrophylacia] of nature never fail in their perpetual flow will be explained in its proper place.

CAPUT XI.

On Fire-Belching, or Volcanic, Mountains [De Ignivomis seu Vulcaniis montibus]

We have seen nature's water-reservoirs [hydrophylacia] set in place for the good of the Geocosm. Now let us follow, step for step, the fire-reservoirs [pyrophylacia] —that is, the storehouses of fire.

It is certain that if the moist element alone ruled the Earth, the terrestrial body would perish, overwhelmed by a flood of moisture. It is equally certain that if the fiery element alone, enclosed within the Earth, exercised its power, all things would be reduced to a wasteland. [Margin: The necessity of subterranean fire.] Since nature understood this, she fittingly bound the watery element to the fiery, so that—chained together by the laws of a friendly marriage—neither could carry on its operations without the other. This marvel of nature shines out above all in our Geocosm. Nature had established various storehouses of waters enclosed within the highest mountains, as the preceding chapter showed. But because she could not bring forth her hidden offspring without the midwifing hand of fire and its warmth, she therefore distributed, throughout the whole surface of the globe and within the bowels of the loftiest mountains, various receptacles of fire. By this innate and primal warmth she could more easily bring living animation to the earthy and watery elements and accomplish the generation of things. [Margin: Subterranean water would freeze without fire.] For lest the water hidden within the secret and inaccessible recesses of the mountains should stiffen and freeze, the dissolving action of a friendly warmth was needed—both to raise the necessary vapors and exhalations, and to bring forth the offspring once conceived. But fire, since it cannot subsist without nourishment, lives on no other food than moisture. In this way, within the bowels of the Earth, fire and water strike the bonds of a mutual exchange. And because fire, wonderfully eager for freedom, cannot endure without the free fostering of air, provident nature set the highest mountains as so many boundary points, so that through them, as if through breathing-vents, the air might be drawn in and continually nourish the fire-reservoirs with so welcome a guest; and so that through these mountain chasms the fire might unburden itself, as through a sewer, of its surplus mass of smoke and dregs. [Margin: The flaming mountains are the breathing-vents of the subterranean fire-reservoirs.]

Of such furnaces—besides several others—five in particular are established in Europe. [Margin: The volcanoes of Europe.] Etna in Sicily, the most celebrated in the records of every writer; Vesuvius in Campania; Strongylus [Stromboli] and certain others among the Lipari Islands, especially the one designated by the name of Vulcan—all of which I traversed and examined in the year 1638. In the far north is Mount Hecla in Iceland; in Greece, the Chimaera. [Margin: The volcanoes of Greece.] In Asia, Persia has several volcanic mountains, and there is one on the island of Hormuz [Armuzia]. [Margin: The volcanoes of Persia in Asia.] In the empire of the Mogul, on the island of Ceylon [Zeilanum], there is a mountain marked with the name of Adam; but most of all in the Moluccas and the Philippines, the Banda Islands, the Moluccas, and in both Javas, nature has

established such reservoirs of fire within the bowels of the highest mountains. [Margin: The volcanoes on various islands.] Among these, in the Banda Islands, the foremost is Mount Gourapi [Gunung Api]; Mount Balaluanus [Berapi?] [?] in Sumatra; an exceedingly steep mountain on the island of Ternate, in whose summit there is a crater with a vast opening, which—divided into several greater and lesser circles—presents the form of an amphitheater. In the Mauritius Islands [Mauricis Insulis], Mount Tola; in Tandaia, near the Cape of the Holy Spirit, several are found, as also on the island of Marindica. Moreover, in Japan there is no small number of these mountains near Firando [Hirado] and Tanexuma [Tanegashima], and scattered here and there about the neighboring islands. [Margin: The volcanoes of Japan.] Such volcanic workshops are gazed upon with the greatest wonder by travelers; these, conducting their hidden traffic through subterranean passages in the islands of the Archipelago of St. Lazarus toward New Guinea and the islands they call the Solomon Islands, discharge it through new openings in the mountains, then displayed afterward upon other islands of the Pacific Sea.

Yet no part of the world displays more celebrated volcanic workshops than America. [Margin: Chile abounds in volcanic mountains.] In the kingdom of Chile alone, fourteen are counted in a row; in Peru no fewer, all of which the continuous ridge-summits of the Andes display. In New Spain three are counted, fearsome for their belching of fire. Nor is the farthest northern tract destitute of its fire-storehouses: of these, authors count four in the region of the Tinguise [Tynseorum] in Tartary—to say nothing for now of the volcanoes of Greenland [Grunlandia], and others on the neighboring islands or continents lying about the Pole, which extend even into the land popularly called *del Fuego*, "of Fire," along unknown gulfs—so that many think the Antarctic region inaccessible at the Pole because of the multitude of fire-belching mountains. But of these we shall speak more fully in what follows.

Now as to why the nature of things shut up these fires within the bowels of the highest mountains: the first cause is that from the loftiest places, as through [Margin: Why nature established the flaming mountains.]

certain lofty chimneys, the hidden element might find breathing-vents through which to relieve itself of the surplus burdens of pressing nature. The second is this: were it to discharge such an office of suffering nature in the lower-lying places of the regions, it would bring upon all the surrounding districts—through ashes, smoke, the waste-matter of tufa, and pernicious and deadly exhalations—the utter ruin of the fields and of living creatures. This does not happen on the

inaccessible ridges of the lofty mountains, since the refuse and ashes are either deposited in the precipices of the mountains, or the deadly smoke and vapor is dissolved into the higher air and scattered elsewhere by the winds. And so for no other purpose has nature banished such mountains either to the sea or to islands separated from the continent: lest in the heart of the mainland they should bring inevitable slaughter on all the surrounding peoples.

But perhaps you will ask: why has nature not everywhere joined to her water-reservoirs these mountains, so necessary for the conservation of the waters? I answer: since such mountains are nothing other than breathing-vents through which the fiery element purges itself; and since it draws in through them the air necessary for its own preservation—it does not follow that they should be joined to the water-reservoirs by swelling waters. [Margin: The channels of subterranean fire run throughout the body of the Earth.] For the passages of these mountains, propagated through the whole bowels of the Earth, correspond with nearly all the other mountains through the hidden laws of nature, so that the Earth may nowhere be deprived of so necessary a warmth—as the innumerable boilings-up of hot waters, conspicuous in every region, abundantly and more than sufficiently demonstrate. These would never continue their effect unless the hidden power of the fiery element, stored away in the bowels of the Earth, urged this warmth on in a perpetual flow.

But you will object: two contraries, such as fire and water, cannot subsist in the same place. [Margin: Objection.] I answer: they do not inhere in the same subject, but the fiery store-chambers, separated from the watery ones, act upon one another through the hidden siphons of the Earth and the mountains, fostering each other by a secret bond of friendship, and in this way nature attains the effects she intends. But since we shall, God granting, dispute about these matters most fully in what follows, I have chosen not to be longer here. From all this it is evident that from these elements of water and fire, established within the bowels of the Earth, the generation of all things and of mixed bodies is constituted—as will be set forth in order.

CAPUT XII.

Whether Mountains Decrease over Time, or Grow Again Anew; and on the Marvelous Transformation of the Earth's Parts [Utrum Montes cum tempore decrescant, aut denuo accrescant, & de mira Terrestrium partium transformatione]

Experience of every age teaches that the Earth suffers its own diseases and alterations, arising from the various disorders of its inner economy. [Margin: 1.1. Meteor.] For since—as Aristotle rightly says—the inner parts of the Earth have their youth and old age just as the bodies of animals and plants do, we may rightly conclude that the Globe of the Earth does not persist, either in its inner or its outer parts, in the same state in which it was from the beginning of things. [Margin: Nature suffers its own diseases.] Lactantius, weighing more deeply the condition of fluctuating nature and the instability of this earthly wheel—which, involving all things in countless mishaps, allows nothing under the Sun to be perpetual, nothing lasting—cries out thus: [Margin: Lactantius.] "I could recount how often, shaken by sudden movements, lands have either yawned open or sunk into the abyss; how often, swallowed by the waves, cities and islands have gone down into the deep; how marshes have flooded fruitful fields; how rivers and lakes have dried up; how mountains too have either fallen away in ruin or been leveled to the plains; how many regions also, and many a foundation of mountains, a hidden and devouring fire consumes"—a vicissitude of unstable nature which the loftiest philosophers, in no age, have observed without wonder.

[Margin: Seneca.] "All things," says Seneca, "time the devourer feeds upon, all things it plucks away, all things it stirs from their seat; it suffers nothing to abide for long."

[Margin: Lactantius.] "Rivers fail, the fleeing sea dries up the shores, Mountains subside, and lofty ridges fall."

[Margin: Ovid, *Metamorphoses* I.] "I myself have seen what once was most solid land become sea; I have seen lands made out of ocean. Far from the deep, sea-shells have lain, and an old anchor has been found on the highest mountaintops. What was a plain, a torrent of water made into a valley, and by its flood a mountain has been carried down into the sea; and the marshy ground dries out with parched sands, while what had borne thirst stands now under standing pools."

England [Anglia] once clung to France [Gallia], bound by a friendly union. [Margin: Islands once continents.] Nordstrand [Nordstrandia], a northern island which Cranzius [Krantz] calls Northern Frisia, was once joined to the mainland of Dithmarschen [Thietmarsia]; now, torn from the continent and enrolled in the register of islands, it follows the laws of Amphitrite. The same is testified of the Herculean Strait [Gibraltar] and the Sicilian Strait [Messina] by Valerius Flaccus: [Margin: The Herculean and Sicilian Straits.]

"...for King Aeolus was not yet ruler there, when the stranger Calpe [the Atlantic] broke through into Libya, when the Ocean, weeping, robbed the Sicilian and Oenotrian [Italian] bounds, and the wave entered in from the midst of the mountains."

Rivers change their beds and their accustomed courses; [Margin: Rivers change their beds.] flourishing empires perish—all of which, as they prove a dreadful havoc, so do they argue the divine power,

and lay bare the uncertainty of the human lot, and warn the mortal dwellers of the Geocosm that, since nothing is stable, nothing perpetual—but all things are fleeting, subject to fortune's various chances and to the various and unforeseen stratagems of things—they should raise every effort of the mind, every study, all the powers of a soul that can be satisfied by no created thing, toward the sublime and everlasting possessions of the heavenly goods above; that they should rest on God alone as on a center, in whose hand are all the rights of kingdoms and all the bounds of the Earth.

In various ways, then, the terrestrial body can undergo these metamorphoses. [Margin: The cause of changes in the Earth.] First, mountains are swallowed up by a yawning of the earth, or else are suddenly born where they were not before. Second, mountains, in the succession of ages, worn down by the injuries of the weather, dwindle away, the valleys being correspondingly raised up. Third, lands which the geographers call peninsulas—the Greeks, *Chersonesi* [χερσόνησοι, "peninsulas"]—when that narrow strip of land they call an isthmus is broken by the violence of the waters, become islands which were before part of the continent; or, on the contrary, islands are joined to the mainland by isthmuses formed of immense heaps of sand, which the violence of the sea brings up with its waves. Fourth, the sea, which on one side by its receding leaves behind a terrestrial space, on the other—by I know not what crime of nature—recovers it in a violent invasion, invading the land with its waves by as much as it had left behind in retreating from its former station. [Margin: Various transmutations.] Fifth, new islands sometimes spring up, while others that had stood from time

immemorial are swallowed up. On the contrary, in the heartlands of the Earth, certain regions, devoured by the tyranny of the inner Vulcan, leave lakes behind them; and in certain swallowed-up lakes, mounds of terrestrial parts are left. Sixth, in certain parts, rivers and lakes failing render the land habitable; in others, land rich in cultivation, by a sudden change, turns into a lake. But that all this may be established by historical authority, it has seemed good to treat of each by so many separate paragraphs.

§. I.

On Mountains and Valleys Swallowed Up and Reborn [De Montibus & Vallibus absorptis & renatis]

Pliny relates that in his own time Mount Cybotus [Margin: Pliny, l. 2. c. 91.] [Cibotus], a very high mountain, together with the town of Eurite [Curites?] [?], was so devoured by the earth that no further trace of it could be discerned. [Margin: Mountains swallowed up.] He writes that the same fate befell Mount Sipylus in Magnesia, which the destruction of the city of Tantalus—swallowed up by a gaping of the earth—had preceded as a fearsome omen. A like fate was suffered by Galanis and Ganatus, once most celebrated cities in Phoenicia. Phlegium, a most lofty ridge of Ethiopia, by the violent shock of a single night, appeared no more. We too can add those mountains which in our own times we have seen devoured by the earth. The mountain Picus [the Peak] is one of the Molucca Islands, of such height that, like a column, it appeared to sailors many days' journey off, in the most remote tracts of the sea; this, laid low by the violence of an earthquake, with no trace remaining, gave rise in its place to a lake, whose base is seen level with the periphery of the mountain. [Margin: History.] The same happened in the kingdom of the Chinese [Sinarum], in the year 1556, when an entire mountainous region of China, with all its peoples and cities, was swallowed up and left in its place a huge lake, nothing being rescued except a boy floating on a piece of wood. We have seen also in our own age the dreadful destruction of the city of Plurs [Plurium], situated in the territory of the Swiss [Helvetii], from the fall of an overhanging mountain. The mountains Vesuvius and Strongylus [Stromboli] are seen cut down by half through their volcanic warfare, which formerly seemed to strike heaven with their peaks. I will not speak here of the mountains of Chile, which they call the Andes, some of which have been found to be missing [Margin: The mountains of Chile collapsed.] after that greatest earthquake, memorable to all ages, by which nearly the whole kingdom passed into wasteland, in the year 1646—as the accounts made by our Fathers narrate. We have seen the swallowing-up of mountains; now let us set forth their rebirth. [Margin: The rebirth of mountains.]

Pliny, l. 2, c. 87 and c. 88, sets forth their series in these words: "Lands are born also in another fashion, and suddenly emerge in some sea, as though nature were balancing accounts with herself, restoring in another place what she had swallowed up by a gaping chasm. The islands of Delos and Rhodes are recorded long ago as having come to birth; later, smaller ones—beyond Melos, Anaphe; between Lemnos and the Hellespont, Nea; between Lebadus and Teos, Halone; among the Cyclades, in the 135th Olympiad, Hiera, the same as Automate; and two stadia from it, after 110 years, in our own age, in the consulship of Marcus Junius Silanus and Lucius Balbus, on the fourth day before the Ides of July [12 July], Thia." In the year 1638, at the island of St. Michael [São Miguel] in the Atlantic Sea, with the subterranean fires goading it on, so great a mass of stones was cast up in the midst of the sea that an island, born from stones heaped up into mountains, extended itself to a breadth of five miles. [Margin: A new mountain arose in the territory of Pozzuoli.] Near Pozzuoli [Puteoli], in the Bay of Baiae, about 120 years ago, a new mountain, swelling up out of the sea by the violence of subterranean nature raging in a single night, snatched all into wonder and terror at once; and it persists to this very day, by the name of Monte Nuovo, "triumphing holy" [Mons Sancti, i.e. Monte Nuovo]. The Lipari Volcano [Vulcano], about sixty years ago, is said to have ejected so great a quantity of ashes and rocks that it produced beside itself, in the midst of the sea, what they therefore call *Vulcanello*, "the little Vulcan," as a son begotten by a father; which I myself, while traveling along those shores, found to be true, as is plain from what I noted in the preface to the Reader. Innumerable such events, truly memorable, occur in the records of historians; and since I have judged it superfluous to recount them all, it has seemed good to bring forward here the better-known ones, both to confirm the destruction of certain mountains and the rebirth of new ones. These Pliny in these words

affirms, l. 2. c. 88: "Both near Italy among the Aeolian islands, and again near Crete, an island has emerged from the sea, 2,500 paces in extent, together with hot springs; another in the 163rd Olympiad, in the third year, in Thera, blazing forth; and this with a violent movement; and it is recorded for memory that a great multitude of fish was found floating about it, and that those who immediately ate of them perished. Likewise they say that the Pithecusae [Ischia] arose in the Bay of Campania; and among them Epopon, when a flame suddenly flashed forth from it, was leveled into a flat plain; and in the same place a town was swallowed into the deep, and by another movement a marsh emerged; and with mountains rolled away in yet another, the island Prochyta [Procida] arose."

§. II.

Mountains Fail in the Succession of Time; and Plains and Valleys Are Raised Up
[*Montes successu temporis deficiunt; & plana vallesque attolluntur*]

Experience teaches that the summits of mountains are at last gnawed away and consumed by rains, snow, hail, long-lasting frost, and the other injuries of the air; [Margin: Why mountains fail.] and this has already appeared sufficiently in the preceding paragraph from the failing of the fire-belching mountains. For there are some mountains—as in Lipara, Melita [Malta], and Ilua [Elba]—which the niter-bearing winds, on that side from which the winds pregnant with them blow, so gnaw away that the overhanging crags threaten imminent ruin; and the ruins of crags still surviving in the valleys abundantly testify that they once, when standing erect, finally collapsed. [Margin: The collapse of the foundations of the mountains.] The cataracts of subterranean waters, too, and their headlong fall, so wear away little by little the inner fabric of the mountains that, with their foundations undermined, they totter at the first earthquake—which I would reckon to be one cause of the failing of certain mountains. [Margin: Subterranean fires too dissolve the mountains.] Subterranean fires likewise contribute wonderfully to the failing of mountains, as we hinted above. From the wearing-away of mountains, then, it is necessary that valleys and plains should grow; and so the decrease of the mountains passes into the increase of the surrounding plains and valleys—so that this saying of Job seems verified in these things: [Margin: Job 14.] "By slow alluvion the Earth is consumed." For the waters of rains, rivers, torrents, and melted snows so corrode the sides of the mountains that the foundations of buildings set upon the mountains are mostly seen laid bare; [Margin: Rains, snows corrode the bases of the mountains.] which I have more than once had occasion to observe in the castles of Germany that are set upon ancient crags. Yet nowhere does this catastrophe of nature show itself more for the seeing than at Rome and in the other parts of Latium. I behold almost daily the once high and steep crags of the Palatine and Capitoline mountains so diminished by the injury of time that they seem now nearly to equal the plain—indeed, the foundations of the old Capitol now actually to equal it; and the very laying-bare of the foundations by the cataracts of subterranean waters clearly teaches this. So much so that, of those which authors write to have once been high mountains, now—unless certain traces of the mountains persuaded you—you would scarcely believe that mountains had ever been there, the plain rising up by just as much as the mountains have decreased. The Pantheon teaches this above all: [Margin: The Pantheon.] one once ascended to it by steps, whereas now the descent into it is made by steps. The innumerable half-buried carcasses of

antiquities teach it too—of amphitheaters, circuses, arches, and columns—of all which I shall treat more fully, if God grants me life, in our work *On the Marvels of Latium*. Hence many have judged that it will come to pass that, after many myriads of years, the plains, leveled with the mountains, will in the succession of time open the way to a universal cataclysm. Yet this I would by no means hold to be admitted—not, at any rate, in those great mountain chains mentioned above, but only in those which are worn down either by the daily use and the service of buildings, or are composed of earthy, clayey, and similar friable and tufaceous matter.

§. III.

Peninsulas Are Changed into Islands, and Islands into Peninsulas [Chersonesi sive Peninsulae in Insulas, & Insulae in Chersonesos mutantur]

It is altogether probable that the straits by which now one sea insinuates itself into another through the narrows of the mountains were once joined by an isthmus, [Margin: The metamorphosis of islands and peninsulas.] and were straits, with the sea—by the impetuous tyranny of its flux—gradually eroding the isthmus. In this way, on Pliny's testimony, the sea tore Sicily from Italy, Cyprus from Syria, Asia from Europe by the Propontis and the Thracian Bosphorus [Phosphoro Thracio]; Euboea from Boeotia; Atlas and Macris from Euboea; Besbycus from Bithynia; Africa from Spain, the union of Calpe and Atlas being destroyed. In like manner Leucosia from the promontory of the Sirens; Sumatra from Cambodia [Camboia], Ceylon from India; Greenland [Gronlandia] from America by Davis Strait [Fretum Davits]; Nordstrand [Nordstrandia] from the Baltic-sea island of Dithmarschen [Thrithmarsia], on the testimony of Cranzius [Krantz]; from South America the Land of Fire [Tierra del Fuego], the isthmus being broken through, and by the Strait of Magellan [Fretum Megallanicum] the perpetual battering of the great Eastern and Western Oceans opening for itself the gates to their union. For most isthmuses are like certain bridges, beneath which, through certain hidden passages and the blind recesses of caverns, the seas that wash the isthmuses on either side carry on for the most part their mutual exchanges of water, to and fro; [Margin: Isthmuses are like bridges, beneath which the sea passes.] and when, in the succession of times, their piers are eaten away and the foundations of the bridges shaken by an earthquake, the isthmus must collapse.

But let us come to the other part of this discussion. Seas break through isthmuses, and these same isthmuses are sometimes formed by the alluvion of waters and by the great heaping-up of sands; as the Pharos of Egypt, which once in the midst of

the sea offered its light to those in peril, [Margin: The Pharos of Egypt, once an island.] now...

we see joined to the mainland by an isthmus, formed when the Nile filled the strait with a great quantity of silt.

[Margin: Mount Circeius, once an island.]

Mount Circeius, once separated from the continent, is now attached to it, the strait having been filled up by an accumulation of sand. This commonly happens at narrow and low-lying places between seas, where islands lie between the open sea and the mainland: there, either a violent sea-tide or a great quantity of sand carried down by rivers builds up the gap. So it is in Batavia, Frisia, and Zeeland, throughout all the tracts of the archipelagoes, and along the other sandy and clayey shores that rise gradually from a flat plain into very high mountains.

Thus Pliny [Pliny, *Natural History* II.89] records that Antissa was once joined to Lesbos, Zephyrium to Halicarnassus, Aethusa to Myndus, Dromiscos and Perne to Miletus, and Pithecusa to the promontory of Parthenius. Indeed, he says that Hybanda, once an island of Ionia, afterward lay two hundred stadia inland from the sea; that Syrtis near Ephesus, and Derasides and Sophonia in the interior of Magnesia, were once counted in the register of islands; and finally that Epidaurus and Oricum ceased to be islands. To this point belongs Ovid's line [Ovid, *Metamorphoses* XV]:

A time will come when the Pyramus, once with its rushing waters, will reach into sacred Cyprus, the shoreline having been heaped up.

§. IV.

Whatever the sea loses in one region of the earth, it recovers in another — hence the origins of islands and of new lands.

Daily experience in the course of rivers teaches this abundantly. Suppose a river M N rushes from C into B, and from B into D drives the whole force of its current. It is certain that the clayey banks at B and at D will, over time, be hollowed out by the violence of the flooding; and the river will gradually creep into the interior fields at F and G.

Diagram. A schematic plan-view of a meandering river illustrating the argument that a river erodes one bank while depositing on the other. The river M N winds across the figure in two sweeping bends; hatching along the banks marks where

the channel cuts in ("demit," it carries away) and where it builds up ("addit," it adds).

- M (upper left): river mouth/source label, head of the channel
- C (left bend, inner): point on the channel
- D (right bend): point where the current strikes the bank
- B (center, inner bank): point on the channel
- F (lower left): field into which the river encroaches
- G (upper right): field into which the river encroaches
- "demit" (upper right and lower left, by the outer banks): "it carries away" — where the current erodes
- "addit" (center-left and lower center, by the inner banks): "it deposits" — where silt accumulates

As a result, the water necessarily abandons its station at bank B and lays the land bare — the give-and-take of the two banks, by a kind of commutative justice, sharing out their mutual rights between them.

This natural metamorphosis has been observed in many rivers — the Rhine, the Main, the Moselle, the Rhône — but above all in the Tiber.

[Margin: The Tiber, a river.]

Over a span of just twenty years I have noted the Tiber creeping forward onto the flat of Monte Mario, into the fields and meadows, so that at this time it laps almost the very roots of the hill in several places, while on the other side it leaves heaps of sand behind. But since these things are commonly known, I will not dwell on them.

The same must be supposed to occur in the sea: just as its ebb and flow, and what they call the currents, are more violent, so they likewise work greater transformations on the terrestrial globe. Yet this should be noted: certain rivers — chiefly those that have their source in very high mountains — wash so much eroded material down from the mountains and valleys, scoured from the soil's mixture, that they silt up the lower-lying places. From such a great quantity of sand and mud, gradually heaped into broad mounds, and once the waters have been confined within channels, they establish a new region fit both for human habitation and for cultivation.

[Margin: From the silt carried down, new fields are born.]

The truth of this is plainly evident from the larger rivers — the Rhine, the Danube, the Rhône, the Po, the Euphrates, the Indus, the Ganges,

Diagram. A landscape view of a river delta — the Po (labeled "Padus flu.") descending from mountains on the left and discharging through multiple branching mouths into the Adriatic Sea on the right. The engraving illustrates how alluvial deposits build new land and islands at a river's mouth. Mountains rise at the left and lower foreground; the braided channels split around silt-islands as they reach the sea; a sailing ship rides at lower right.

- D (left, mountain): mountain from which the river descends
- C (lower-center foreground, mountain): mountain from which the river descends
- A (upper center): point on the descending river / plain
- B (lower center, in the plain): the stagnant plain A B where waters once pooled
- E, F, G, H, I (right, among the river mouths): the low-lying tracts and islands formed at the delta by the branching arms of the river
- "Padus flu." (center): "the river Po"
- "Mare Adriaticum" (right): "the Adriatic Sea"

confined within their channels, and at last discharging themselves into the sea through a manifold distribution of mouths. From this we conclude with certainty that those low-lying tracts near the river mouths — E E G H I — together with the islands that the arms of the rivers form, are nothing but the offspring of sand and mud brought down and carried in by these rivers, as the figure shows.

That this is so, the histories teach more than amply. The lower part of Egypt, which they call the Delta, was deposited by the Nile, and is called by Herodotus "the gift of the Nile" — δῶρον Νείλου [Greek: dōron Neilou, "gift of the Nile"].

[Margin: Egypt born from the buildup of silt.]

This is the common opinion of geographers, and we demonstrated it at length in the First Part of our *Oedipus Aegyptiacus*. In just the same way, the district of Holland was built up out of the Rhine and other rivers, as Goropius teaches.

[Margin: Holland from the Rhine and other rivers.]

Likewise a great portion of the territory of Ferrara grew from the floods of the Po. The coastal land of Arles, together with the island of Camargue, is the offspring of the Rhône.

[Margin: The Maeotic marsh; the Tanais.]

By the same reasoning the marshes of Ammon and of Maeotis were once far deeper and able to bear larger ships than they were afterward, when the mud had been deposited — as Aristotle attests. All of Teuthrania and the regions around Ilium are flat: where there was once sea, now there are fields, thanks to the river Maeander.

[Margin: Cities once washed by the sea, now far from it.]

That these things are so, the cities that were once washed by the sea but now lie far from it abundantly prove. Ravenna, once set upon the Adriatic Sea, is now six miles distant from it. Ostia on the Tiber, once placed against the shore of the sea, is now separated from it by 3000 paces, with mounds of sand thrown up between. This has been verified in many places throughout Lower Germany as well. Already in Pliny's time the sea had withdrawn five thousand paces from the harbor of Ambracia toward Athens, though it had at first washed that very spot. Time would fail me if I tried to bring forward all the natural catastrophes of this kind, since there is scarcely a maritime region — especially near the mouths of great rivers — where they are not to be seen.

We have said, then, that the sea, by the deposits brought in by rivers, has in some places left behind habitable land, a supreme gift of nature. Now let us show a new catastrophe of the sea: how, forgetting its former kindness, by some inscrutable wickedness of nature, it presses vast regions of the earth under so harsh a tyranny — some it submerges utterly, others (the more stubborn islands, as it were) it has so overwhelmed that they seem to rise above the water only with their mountain peaks.

[Margin: Submerged cities.]

Near Dordrecht and Dollart in Frisia, castles of no small repute were so submerged by a deadly flood that even now the tips of their towers rise above the water, seeming to want to tell posterity the calamity of the past event.

[Margin: Submerged cities.]

On the Tuscan shore, not far from Livorno, an entire city yielded to the waves, the dwellings of men turned into hiding-places for fish — which, not without horror, I observed with my own eyes in the year 1634. Between Centumcellae, commonly called Civita Vecchia, and Severa, abundant ruins are indeed to be seen in the sea, some of which are still furnished with windows, others with gates and arches — indices of past misfortune. Opposite Pozzuoli, in the very bay of the

city of Baiae, houses together with the layout of their streets — a thing astonishing to relate — show, in a most mournful spectacle, the traces of the ruin, on the sea floor, of a city once most renowned. These things, indeed, I have verified by my own experience — to say nothing of the countless other events with which the records of historians are filled.

[Margin: Archipelagoes once joined to the mainland.]

From all of which we conclude that all those clusters of heaped-up islands which they call archipelagoes were once joined to the mainland, but were broken apart by the violence of the Ocean working back and forth: the softer parts of the continent were gradually eaten away and pierced through, while the rockier crags of the mountains were left standing in that great multitude of islands which the maps show us — sundered by hidden channels, or sometimes also by the fury of subterranean fires through earthquakes.

Certainly Plato teaches that the Atlantic Ocean, where the Canaries and what they call the Terceras now lie, was once inhabited by a vast multitude of people — in that dialogue which he entitles with the name of *Critias*. But let us set down a brief epitome of this history, well suited to weighty reasoning; and so I begin further back.

[Margin: Plato, in the *Cratylus* [recte: *Critias*], on Atlantis.]

Plato, then, in his dialogue called the *Critias*, reports that there was a certain island beyond the Pillars of Hercules in the Atlantic Ocean, much larger than Africa and Asia together. He says that Solon, instructed by the Egyptian priests — who had described in their records the situation of that region, the names of the people living in it, and the history of their deeds — rendered it into Greek law [i.e., into Greek]. From Plato's age back to the age when the Atlantic land was still surviving there had intervened nine thousand years. The earliest heroes of the Athenians waged most valiant wars with that island; yet these wars, worn away by the injury of immense antiquity, left nothing behind but their names and fame, when the whole island, together with its inhabitants, was swallowed up, whether by flood or by earthquakes.

[Margin: The destruction of the island of Atlantis.]

To show that this is a true history, by no means mythical — that is, not subject to fables — he undertakes to prove it from Greek antiquity. He first extends its boundaries to the Isthmus, and from there bounds it on the right toward Epirus and Cithaeron, and on the left to the sea; and he says it was furnished with such

fertility, beauty, and abundance of everything needed to sustain human life that, reckoning by the standards of those times, the condition of the region in his own age, by comparison, could be called nothing but the bones of a body wasted by disease. This degenerate state, compared with that of the ancients, he sets forth in these words: After describing the immense abundance of things flourishing in Greece in the first ages of the world,

[Margin: Plato gives the reason for the degeneration of one region compared with another.]

he then subjoins the causes of so great a degeneration in these words: "Every region," he says, "stretched out at length from the continent like a promontory,

[Margin:...most fertile in Greece.]

lies; and that deep gulf of the sea encircles it on every side. Since, then, many and great floods occurred in the space of nine thousand years (for so many have elapsed from that time down to our present age), no part of the earth, in our times, ever heaped up a mound by flowing down from the higher places into these lower ones (as it does in other places), but always, settling in a circular fashion, it is hidden away in the deep. And therefore, just as in narrow islands, these regions of Attica which are now inhabited — if they are compared with the ancient ones — are like the bones of a body wasted by disease, the soil that was rich and soft having been carried off, so that only the thin and dry body of the earth remained. For when the earth was whole, it had high mountains and hills; and the fields which are now called *Phellei* ['stony'] abounded with rich soil and with copious forest on the mountain ridges, as the traces still manifestly are. Moreover this region drew abundant fruitful rain from Jove, nor — as in this our time — did it flow down from the steep and precipitous place into the sea, but, absorbing it, settling with a certain copious and tenacious firmness, it concealed the water and, drinking it in, sent it down into the inner parts from the higher places; whence everywhere great springs of rivers and of fountains gushed forth, of which even now, at the old fountains, certain sacred memorials appear." Thus far Plato.

In order to show the destruction of the island of Atlantis, he begins from a notable transformation of the terrestrial parts, which the Greeks fable to have occurred in Greece over a span of nine thousand years through a threefold flood. He attributes the cause of this transformation first to the subsidence of the mountains, which he holds were all once clothed with rich and fertile earth (like flesh), and also with forests (like a kind of hair), but are now bald and bare,

stripped of all the adornment of their woods, presenting themselves to view like the bones of a body wasted by disease. He supposes that the subsidence of the mountains — partly through the deluges of rain, partly through the rich earth being scoured and torn away together with the forests — gradually filled up the lowest valleys, the fields, and even the sea itself. Hence the earth, raised up by the heaping of soil, made the mountain summits not only much lower and shorter than in the first ages, but also stripped them of all their flesh, leaving nothing but a kind of bones of the mountains; and he thinks the same happened in the land of Atlantis.

Then he says that in Greece today many rivers and springs are missed, which the records of earlier ages report once watered the whole land. He assigns the cause of this: that the mountains, once clothed in very rich earth, did not allow the rain sent down from Jove to flow off, but soaked it up at once like a sponge; and the absorbed water, insinuated through the hidden meanders of the mountains and collected, fed the most abundant rivers and springs. Yet he says these are not found today because the mountains' meanders, choked with mud and soil, have cut off every entry to the rainwaters, or else, shaken by earthquakes, have brought on that transformation we spoke of. But this opinion of Plato concerning the diminution of mountains and the drying-up of rivers we shall examine more fully elsewhere. For now, let us return to the island of Atlantis.

[Margin: A description of the island of Atlantis.]

As we taught in our *Oedipus*, Plato tries in many ways to show that it is by no means fabulous but truly historical, in that he so carefully describes the situation and quality of that island, the character and disposition of its people, and their political method of administration; in that he recounts that its cities, fortresses, and strongholds were built up not only with an apparatus of wondrous enclosures and moats, but that there was the greatest abundance there of gold, ivory, and precious stones, with which the temples of the gods were wont to be adorned; that at last it collapsed; and that, just as it was swallowed up by the sea, so it has remained obscure in the memory of men down to this very day.

Certainly the Greeks, marvelously swollen with glory, ascribe this Athenian expedition into the Atlantic land — they whom Plato calls the most ancient of all men and αὐτόχθονας [Greek: autochthonas, "sprung from the earth itself"] — first and foremost to their own valor and skill in action, in order to obscure the glory and antiquity of the Egyptians by this so memorable a history; although even Plato himself admits that Solon learned this history from the Egyptians, who had

it described in their sacred records as a monument of antiquity and Egyptian fortitude more lasting than cedar.

[Margin: The expedition of Osiris to the island of Atlantis.]

They relate, as we showed in our *Oedipus*, the sequence of deeds in this way: The Egyptian Hercules, whom they also call Osiris, having entrusted the care of his kingdom to his wife Isis, was traversing the whole world with a strong army he had raised; and when from the East he had subjected to his rule all those regions situated beyond and this side of the Strait of Hercules (so named from his memory), at length, made more certain by a reliable report of a vast island set in the immense Ocean, he directed a maritime expedition there, suddenly invaded the island, subjugated it, and, having made peace with the inhabitants, established a colony, setting over it one of his grandsons named Neptune. These, then, are the things the Egyptians record about the land of Atlantis.

As for Plato's statement that nine thousand years had elapsed up to his own time, by which he proves these things to have happened, this too is an Egyptian invention; for in order to persuade men that they themselves were the most ancient of all, it can scarcely be said with what an extravagance of years they fashioned their own origin in times gone by. But since we have demonstrated all this very fully in the first volume of the *Oedipus*, we refer the reader there. So, omitting those things that do not pertain to our subject, let us return to the island of Atlantis.

[Margin: How the island of Atlantis perished.]

That the island of Atlantis existed within the memory of all the ages has been made clear from what precedes. But how and when it ceased to exist is as unknown as the times in which it flourished are unknown. Moreover, if what the ancients report about it is true, I would say that its situation was no other than that which is comprised by the Canaries, the Azores, the Flemish Islands [Flandricis — the Azores group / "Flemish Islands"], and the other islands surviving in the Atlantic Ocean (as appears from the map set here). Just as these enumerated islands consist of vast and very high mountains, so it is likewise probable that the higher and harder parts of the island of Atlantis survive in them, while the rest — the deeper places lying between, of lesser mountains, valleys, and plains — were swallowed by the motion of the earth, and the Ocean rushed in to take their place.

Diagram. A map showing Kircher's reconstruction of the location of Atlantis as a single great island filling the central Atlantic between the Old World and the New.

A cartouche at the upper left bears the title. Africa and "Hispania" (Spain) form the eastern (right-hand of those two) coast at the left; "America" forms the western coast at the right; the great "Insula Atlantis" occupies the center of the "Oceanus... Atlanticus." A compass rose (north-pointing arrow within a circle) sits at the lower center of the island; a sailing ship rides in the ocean at upper right.

- Cartouche (upper left): "Situs Insulæ Atlantidis, à mari olim obsorptæ, ex mente Ægyptiorum et Platonis descriptio." — "The situation of the island of Atlantis, once swallowed by the sea: a description according to the mind of the Egyptians and of Plato."
- "Africa." (left)
- "Hispania." (lower left): Spain
- "Oceanus... Atlanticus." (center, spanning the ocean): the Atlantic Ocean
- "Insula Atlantis." (center): the island of Atlantis
- "America." (right)
- Compass rose (lower center of the island): north-pointing arrow within a circle

There are some who would have this part of the continental land connected to America on the west; but this is wholly without warrant. For in this case the continent would have been carried on, continuous up to the Strait of Hercules, through more than nearly 90 degrees of the longitude-circle of the terrestrial globe — which would be contrary to the intention of nature, which has so distributed the portions of the terrestrial world that they are always accessible to the surrounding Ocean, both for the production of springs and rivers and for furnishing the other benefits of nature which we mentioned above.

How it perished remains to be told. And as far as could be learned with experience as teacher, its destruction could come about in only two ways. The first is that drawn from earthquakes, whose efficient cause is the breath of subterranean fires, with which the Atlantic sea teems; whence the historians of these times write that it is exceedingly exposed to earthquakes.

[Margin: The height of the Peak of the Canaries.]

For they report that the Peak [Pico] on Tenerife of the Canaries is of such height that from 60 miles away it appears to sailors stationed on the high Ocean like a column. They attest, too, that it sometimes emits smoke from its summit, and has at times vomited forth fires — sulphurous stones, which are carried off from there in great quantity into Spain. In a three-day journey one comes to the summit — a plain conspicuous at its peak, from which all the Canary Islands,

however far apart, offer themselves to view. It also abounds with hot and bituminous springs, which are manifest indications of the latent subterranean fire.

[Margin: A peak on the Azores like the Peak of the Canaries.]

In the Azores Islands a mountain is seen, equal in height to the Peak of the Canaries, called by the inhabitants the Pico de Fayal de São Jorge [Pico of Faial / São Jorge]. From it one has [a view of] the surrounding islands, of which the ones called Terceira and São Miguel are reported once to have belched fire in many places and on cliffs, and are shaken by frequent earthquakes.

[Margin: An account of a fire and earthquake on the island of São Miguel.]

About twenty years ago, these so shook the whole island that nearly the whole of it went into the abyss. But since the matter is worthy of being remembered in this place, it seemed good to add the course of the event from the faithful account of our Fathers:

On the 26th day of June in the year 1638, earthquakes so dreadful, lasting eight days, began to shake the whole island that men, abandoning their cities, towns, and castles, were compelled to live in the open fields — especially in the cultivated land called Vargem, where the earthquakes raged more fiercely than in other places, and much more violently. These earthquakes were followed by the prodigy that follows: A place called La Ferreira, distant six miles from the Peak (commonly Pico delle Camerine), where the fishermen of this island used to betake themselves to fish, especially in the summer season,

especially in the summer season [æstivo]: for in that place, within the span of a single natural day, they would net such an immense quantity of fish of every kind that no skiff returned that was not loaded with 10,000 fish. In this stretch of the Ocean, then, on a Saturday in the month of July of the year 1638, fire erupted with such inexpressible violence — notwithstanding that this part of the Ocean had been sounded by fishermen often before and found to be 120 geometric feet deep — that the Ocean itself was not enough to quench so great a conflagration. [Margin: Vehemence of the subterranean fire.] The space that the boiling fire occupied was about as large as two measures [modii] of grain would cover, and it burst forth with such violence that, notwithstanding the said depth of the Ocean, it rose level with the clouds. Carried up into the highest region of the air, it bore up with it the very water, along with sand, earth, rocks, and other enormous masses, which to those who watched grievously from a distance presented a

spectacle like flocks of cotton; while the molten matter, falling back into the sea, took on the appearance of porridge. Moreover, it must be ascribed to divine providence and kindness that at that time a land wind was blowing from the parts of the island, driving back the fury of the raging fire; for had this not happened, the whole island would beyond doubt have been consumed and destroyed by that fearful blaze.

Then the raging force kept hurling up rocks of immense size to the height of three spears, so that you would have said not rocks but whole mountains were being thrown up. To the horror was added this: that the rocky mountains thrown on high fell back upon other rocky mountains hurled up from the depths of the sea, and with terrible crashing they shattered into a thousand pieces, which, gathered up afterwards by hand, ground into black sand. [Margin: A new island in the Ocean.] Then, from the vast and immense mass of ejected material and the countless heaping-up of rocks, a new island arose in the midst of that deepest Ocean. At first small, only five iugera [acres] in extent, but growing day by day, it swelled so much that within 14 days it occupied a stretch five miles in length. So great a multitude of fish, moreover, perished in this conflagration that eight East Indian cargo ships could scarcely have held them. [Margin: Destruction of the fish.] Lest, scattered far and wide across the island, they should cause some contagion by their rotting, the natives gathered them into very deep pits some 18 miles round about and buried them. The smell of sulphur, meanwhile, was perceived over a span of 24 miles.

From these things it is abundantly clear that what happens in our own times could also have happened of old in the earliest ages, since the nature of the place has always remained the same, given that the storehouses of fire — which nature has set beneath this region, as we shall show in its place — lie immediately underneath. Hence, being always subject to earthquakes, the place has in no age failed to suffer some loss of its islands. [Margin: The destruction of other islands.] To these is added another contrivance of nature which gradually disposed the Atlantic island toward its final ruin: namely, the violent motion of the Ocean from the North, which over time eats away the roots of the cavernous islands lying in its path, so that, when even a slight earthquake arises, the whole mass — its mountain joints giving way — collapses. It is therefore likely, and most highly probable, that this Atlantic island, once of enormous size and worn down by similar afflictions of nature, finally fell — leaving behind only the aforesaid islands (which, being equipped with very high mountains, have thereby obtained a firmer and more durable constitution) as it were the heralds and surviving witnesses left of that past calamity. The same is likely to have happened, through

the tyranny of the Ocean, to the Archipelago of the Philippine Islands — which the Chinese Annals assert were once joined to the continent at the Golden Chersonese [Aurea Chersonesus] — in that what was previously one was in later times broken up into innumerable islands. But we have pointed to these matters more fully above.

COROLLARY

From this discussion — longer, perhaps, than was fitting — it becomes clearer than the noonday light that the Earth has a wholly different constitution in modern times than it had of old, before the universal cataclysm of the world, or even, for unremembered ages, after the Flood. [Margin: The face of the Earth is different today from what it was of old.] There are therefore islands that did not exist before; the land has grown where before the untamed eddies of the waters had their stables. Conversely, we know that tracts of land which once enjoyed rich and fruitful soil have now, with the sea ruling, turned into lairs for fish; mountain ridges have been swallowed up here while new ones rise elsewhere; vast lakes have transferred the jurisdiction of Neptune to the realm of Rhea or Vesta, and the reverse. Rivers, abandoning the native cradles of their channels, have made themselves other outlets from the mountain enclosures. And such transformations of the terrestrial globe, as fearful as they are, lay open both the infinite power of God and the uncertainty of the human lot. They warn the mortal inhabitants of this Geocosm that, since they recognize that nothing is perpetual and stable, but all things are perishable and exposed to the various accidents of fortune and to destruction, they should raise their thoughts, pursuits, spirit, and mind — which can be satisfied by nothing created — to sublime and everlasting goods, and yearn for God alone, in whose hand are all the rights of kingdoms and on whom the bounds of all nature depend.

APPENDIX

On the most celebrated plains of the Globe of the Earth, or Geocosm

We have set out the structure and fabric of the mountains as far as seemed sufficient for our purpose. It now remains for us to discuss, briefly, the famous plains of the Globe of the Earth as well.

[Margin: Division and regions of plains.] Plains may be divided in various ways. For many are suited to cultivation and filled with a variety of woods and forests; others are sandy; others are stony and heath-covered, which are also called deserts; and some of these extend to an enormous breadth. [Margin: Woods.]

Though fruitful, plains nevertheless appear before us chiefly deprived of inhabitants — through the inhabitants' own idleness, or through a lack of farmers — as do Poland, Muscovy [Moscovia], and Russia, clothed with vast recesses of woodland. With sand and heaped-up grit Africa lies squalid above all the regions of the world; Arabia with stony ground; with heath both Germany and the remaining parts of the world. Fruitful plains are divided into fields, gardens, and woods. The variety of woods is great, both by reason of place and by reason of climate. In Germany there are the Hercynian Forest [Sylva Hercinia], the Black Forest [Nigra Sylva], and the Spessart [Sessartus], notable for their plantings of oak, beech, pine, juniper, and likewise fir, larch, and Italian-oak [esculus] and the like. In Gaul [France] and Italy woods of chestnut predominate. Africa abounds in palm groves, and at the Green Promontory [Promontorium Viride — Cape Verde] there is a whole wood of citron-trees; Ceylon [Ceilanus] nourishes woods of cinnamon; the Banda [Bandames] and Molucca Islands have nutmegs, and cedars adorn Lebanon. And — to take in much in a few words — the variety of woods follows the nature of the region in which it grows; and since this is different in every region, there must necessarily be found an innumerable variety of woods differing in their species of trees. But of these more fully in what follows.

[Margin: Deserts and their vastness.] There are also immense tracts of land destitute of all human cultivation and habitation: of this kind are the deserts of Tartary which are called Mongol [Mongul] and Lop. Of these, the latter is thought to be that sandy desert which, not far from the walls of China, extends in the form of a band of as-yet-unexplored length from South to North, and which must be crossed by merchants travelling to and fro from Tartary into China — a place squalid to the terror of all. [Margin: Desert of South America. The Pampas.] There are also in America, both Northern and Southern, vast deserts, of which the one lying between the Kingdom of Paraguay [Paraguavia] and Chile holds the foremost place, called by travellers "Pampas." [Margin: The height of the Andes mountains and the thinness of the air on them.] All, therefore, who travel from the Kingdom of Chile into Paraguay must first cross mountains of incredible height, which they call the Andes [Andes] or Cordillera [Cordilleira], over a journey of 40 leagues. On their summit the air is said to be so thin that men can scarcely stand without danger of suffocation. Hence all must be equipped with sponges soaked in cold water to condense the air; [Margin: The inflammable air.] and the air is so disposed to inflammation that travellers seem to belch out flames, and, set ablaze by an immense flow of sweat, are all on fire — a wonderful spectacle to those unacquainted with the nature of the place. All this I received by word of mouth from Father Alfonso de Ovalle [P. Alphonsus de

Ovalle], a Chilean of our Society and Procurator of that Kingdom, who had made a journey of this kind.

To those descending the mountain, then, after a three-day journey, there appears the city of Mendoza [Mendoza], and then that immense desert which they call the Pampas [Pampas], spread out far and wide like an Ocean, yet by no means infertile — for, without any trace of sand, it is entirely planted by nature with grasses, [Margin: Description of the desert.] inhabited by animals of every kind, and not lacking in rivers and lakes. This they enter, just as one enters the Ocean, equipped with a nautical compass, as if heading for the boundary of the desert, which is called Buenos Aires [los buenos ayeres] — the first city of Paraguay, situated on the River January [flumen Januarium — the Río de la Plata], toward which they steer by a fixed course. They have wooden carts, capable of holding many men, which, while drawn by oxen, at the same time level a path by trampling down the grasses and herbs, and open a route — on which a span of rarely three months, more usually four months, is spent. How far this desert reaches to the South is unexplored; some think it extends all the way to the Strait of Magellan [Fretum Magellanicum]. This much, at least, I have from report: that over a span of nearly two months no higher land or trace of mountains at all appears in this place, and that the horizon is open on every side — you would call it a terrestrial Ocean. See what Father Alfonso de Ovalle relates more fully about these matters in his history of the Kingdom of Chile; and, lest we linger longer over these things, let the reader consult the geographical books, where he will find all that is written at length about the various deserts of the Earth. Our task is to investigate the causes of these deserts.

[Margin: The cause and end of deserts.] It is asked, then, why and to what end nature has produced so many deserts throughout the world, of no use to any human need — and I speak here of sandy and stony deserts, not of the wooded, heathy, and grassy ones, which offer their own advantages. Sandy deserts present themselves above all in Africa and on the northern boundaries of Arabia Felix [Arabia Felix]. And as far as has become clear to me through various exploration of these places, through information given by the natives, and likewise through the reading of various Arabic antiquities, I find that this sandy ocean lying between the Persian Gulf [Sinus Persicus] and the Erythraean [Red] Sea [Sinus Erythraeus] was, before the Flood, a continuous sea; [Margin: The sandy desert between the Persian and Erythraean Gulfs was once sea.] but that the Flood heaped up immense mounds of grit and sand there, and, when the land was raised and the sea drawn back within its own gulfs, left behind this heap of grit which they now experience. This cannot seem impossible to anyone who

observes the nature of the place — low, depressed, without any mountains (except those that the unstable sand, by the agitation of the winds, raises up repeatedly and soon destroys), and level. The same is to be supposed about the sandy desert of Tartary, which on not ill-founded grounds was once the site of an Ocean, joined to the Caspian Sea, as will be seen hereafter. The same of the sandy plains of Libya; for since we said above that the lower part of Egypt was once flooded by the sea, surely this must not be denied of Libya, since the water spread out together with Egypt. As for the end intended by nature...

perhaps this was it: lest, if the said deserts produced fields, they should bring destruction. For if the humid soil of the regions of Babylon near Basra [Balsora], watered by the Euphrates, enjoyed moisture, vapors drawn up by the Sun and resolved into rains would, by their floods, bring final ruin to the fields of the neighboring fruitful regions — such as Egypt, Arabia Felix, and Babylonia. But now, with rains banished forever from these arid places, there is no reason for the neighboring peoples to fear flooding. The same is to be said of the other sandy deserts. But, leaving these matters aside, let us turn our pen elsewhere.

CHAPTER XIII

On the Waters, or the Ocean surrounding the Geocosm, and on the communication of the seas through hidden passages

[Margin: What the Ocean is.] That the Geocosm is formed into one globe out of watery and earthy substance, perhaps only he will deny who is ignorant of hydrography and has not seen the maps drawn by geographical art. The Geocosm, then, is an earth-and-water [terraqueous] globe, founded from the beginning of things by the great and most profound counsel of nature with this diverse mixture of elements; for without Water, neither could Earth, nor could Water without Earth, in any way subsist. It falls to us, therefore, to examine the rationale of so necessary a composition. That I may do this as well as possible, I shall begin first from the division of the Waters, and then go on to bring the causes of each into the light. May God, most wise Architect of the Geocosm, assist our undertakings.

The whole mass of those waters which surrounds the Earthen globe is called the Ocean, in such a way that there is no sea which is not joined to it, either through straits or through hidden passages of the Earth. There is therefore one Ocean, which has obtained different names by reason of the various regions it laps. Thus the Atlantic Ocean, poured between America, Africa, and Europe, is so called either from Mount Atlas [Athlas mons], or from the island of Atlantis [Athlantis

Insula] that once floated upon it, of which we spoke in the preceding sections; and it afterwards obtains particular names too. There are the Hibernian [Hybernicus], Glacial [Arctic], Deucalidonian, Germanic, Aethiopian, and American Oceans. This Ocean, then, branching out from the still-unknown polar regions through its various meeting with islands, surrounds nearly all of Europe from the North and East. Swollen in the West by an immense expansion, it claims for itself the rights of three parts of the world — America, Africa, and Europe. Thus, partly opening an entrance for itself through the narrows of the Magellanic Sea, it mingles in new wedlock with the Southern or Pacific Sea; partly through the Strait of Maire [fretum Mairanum] it wanders, by passages still unexplored, into the farthest subpolar parts of the Southern Land. The Pacific Ocean, commonly called Mar del Zur, the greatest of all the Oceans, on one side bounds with its waters the Western and Northern parts of all America, and on the other all the unknown tracts of the Southern Land; and from the North, indeed, through the Strait of Anian [fretum Anian] — a passage of communication between America and Tartary — it is at length restored, by the Boreal subpolar Ocean from which it had departed, to the Atlantic. From the West, as it were carded apart by an innumerable multitude of islands and stirred up by new narrows of straits, it passes into the Indian Ocean, and, after surveying the immense tracts of China, both Indias, Persia, and Africa, is at length restored at the Cape of Good Hope to the Atlantic Ocean.

[Margin: The connection of the seas.] From this description it is abundantly clear that the Ocean is one, so continuous around the four chief parts of the world that there is no land of the Earth, nor any Ocean or sea, which is not joined to it in some part of the world. Thus the Mediterranean Sea is joined to the Atlantic through the Herculean or Gaditanian Strait [fretum Herculeum seu Gaditanum — Strait of Gibraltar]; and to the Red Sea it is committed through the hidden conjunctions of subterranean channels. The Caspian Sea, by like reasoning, is joined to the Black Sea [Pontus Euxinus], this through the Bosphorus to the Archipelago, and at last is mingled with the Mediterranean Sea. By a not dissimilar reasoning, the Baltic Sea [Mare Balthicum], spread through two gulfs, the Bothnian and the Finnic, into the heart of Scandinavia, is connected through the Cimbrian Strait [fretum Cymbricum] to the Germanic or Deucalidonian Ocean. And these are the seas by which, as by certain arms, the whole mass of the Earth is bound; and these premises being laid down, let us now proceed to a particular description of them through several sections.

§ I.

On the Caspian Sea, the Black Sea [Pontus Euxinus], certain lakes of America, and the Atlantic Sea — things worthy of note

[Margin: Description of the Caspian Sea.] The Caspian Sea has tormented the wits of nearly all natural philosophers, since they cannot grasp how it neither increases by the perennial inflow of immense rivers, nor exhibits any trace of an outflow of its own, nor any trace of continuation with another sea. To me, indeed, the matter does not seem so abstruse that no cause of the hidden effect can be adduced.

[Margin: All seas communicate among themselves through hidden passages.] I say therefore first, and I assume as something confirmed by manifold experience, that all seas — not only at the surface but as...

I intimated above, through hidden and subterranean channels — carry on reciprocal exchanges of waters. I begin with the Caspian Sea, which before the Flood — by probable conjecture — was joined to the Ocean that flooded all the deserts and the flat, sandy places of Tartary, through a strait near the mouth of the Volga: not a few think so with me. [Margin: Tartary was once a sea and marshland.] But by the inundation of the Flood, with the softer parts of the earth scraped away by the huge mountain-chain of the Caucasus, the sea standing there — perhaps not very deep — was filled up. Hence the deeper gulf of the Caspian Sea, with the rest of the diffused sea covered over by a heaping-up of earthy parts, was wholly closed off, like a lake, and has remained so to this very day. Yet since from time immemorial it has received immense inflows of rivers, and has been seen to discharge no river, nor offers any trace of increase or inundation, this is a most evident sign that it secretly plays together with the Ocean, or with the neighboring seas, through hidden passages. But how and where this happens, it is now time for us to disclose.

[Margin: Hidden passages communicate among themselves.] As I intimated above, [Margin: The communication of the Caspian Sea with the Persian Gulf and the Black Sea.] we think it has two such passages, of which the first discharges itself into the Black Sea through the infernal passages lying beneath Georgia and Mingrelia [Megrelia] at A B, so that the whole region lying between the Black Sea and the Caspian could rightly and deservedly be called a kind of bridge of waters gliding underneath. Nor are there lacking indications of this matter. [Margin: First passage.] For first, Paradia Persa [?] relates, in his geographical treatise on the Caspian Sea, drawing on the Trapezuntine [Trebizond] history, that on the maritime shores lapping Mingrelia the Black Sea was sometimes observed to be

seething as if with huge boilings; and he assigns the cause of this in these words: "It has been observed, by long observation, that whenever East winds blow violently in the Caspian Sea, at the same time in the Black Sea boilings of this kind, greater than usual, are seen, with a vast agitation of the whole deep; and conversely, when West winds prevail on the Black Sea, disturbances of this kind are noted in the Caspian Sea." This is surely a clear sign that these seas assail one another with reciprocal motions through hidden and vast passages. [Margin: The proper ejecta of the Caspian Sea.] To confirm this, he adds that various things are from time to time cast up — fragments of ships, trunks of trees — which in no way belong to the Black Sea, but which are proper to the Caspian (such as a certain kind of seaweed and serpent, and "Tatar tablets" [?]), a clear indication of a continuation of seas of this kind through subterranean waters.

Diagram. A regional map showing the postulated subterranean communication of the Caspian Sea with the Persian Gulf and the Black Sea, looking across the Caucasus region. The Caspian Sea (upper left) and the "Mare Persicum" (Persian Gulf, upper right) are linked by a dotted line labelled "Canalis subterraneus" (subterranean channel) running eastward across the upper part of the map through the Kingdom of Persia. Below, the Black Sea (Euxine) is shown with Constantinople at its mouth. Mountains are engraved in ranges across the field; a compass rose sits at right-center. A decorative cartouche at lower right carries the title. Letter labels A–D mark the postulated channel mouths and connecting points.

- Top center–left: "PERSIÆ REGNVM" (Kingdom of Persia)
- Upper left (body of water): "Mare Caspium." (the Caspian Sea)
- Upper right (body of water): "Mare Persicum." (the Persian/Persian Gulf)
- Across upper field (dotted line): "Canalis subterraneus" (subterranean channel)
- Right-center field: "ANATOLIA" (Anatolia) [styled across the map: A-N-A-T-O-L-I-A]
- Center-left region: "Georgia" (Georgia)
- Center region: "Megrelie." (Mingrelia)
- Center, near a peak: "Hapezarde" [?] (a mountain/place name — uncertain reading)
- Left margin (river): "Volga flu." (the Volga River)
- Center (near A, connecting waters): "Canalis [?]" (channel label, partly obscured)
- Center-left: "Caucasus" (the Caucasus)

- Lower center (body of water): "Euxinus mare Nigrum." (the Black Sea)
- Lower center (city): "Constantinopolis." (Constantinople)
- Lower left (river): "Borysthenes flu." (the Dnieper River)
- Lower center (river): "Danubius [?] flu." (the Danube River — reading uncertain)
- Lower left (small water body): "Tanais flu." [?] (the Don River — uncertain reading)
- Point label "A": near the Caspian's southern channel mouth
- Point label "B": near the northern shore of the Black Sea (channel terminus)
- Point label "C": at the right, near the Persian Gulf channel mouth
- Point label "D": near the Caspian, on the dotted subterranean channel
- Cartouche (lower right): "Typus Communicationis maris Caspy, cum Persico et Euxino." (Diagram of the Communication of the Caspian Sea with the Persian and the Euxine)

LIBER II "Geocosmus" — Caput XIII (continued)

[Margin: The same channel.]

There are also clear enough indications, supplied by the Persians themselves, that a second channel of the Caspian Sea is continued through subterranean paths to the Persian Sea, that is, the Persian Gulf. The first of these is the Charybdis, or whirlpool, of the gulf that washes Persia, two days' journey from Balsara [Basra]. There the sea is swallowed down with a marked drop in level, and then, once the waters have been restored to their bed, not even a trace of the whirlpool remains. The explanation of this is none other than a certain correspondence with the Caspian Sea. When the Caspian, stirred up by the violence of the winds, has driven a great part of its water into the Black Sea, it then — to make up the deficit of water — draws water from the Persian Gulf through the said subterranean channels C and D, so that at the said spot C a whirlpool must necessarily arise.

[Margin: Subterranean link of the Red Sea with the Mediterranean.]

But when, in turn, the Black Sea, churned up by the fury of the western winds, restores to the Caspian Sea the deposit of water entrusted to it, the Caspian — having now regained its fullness — gives back to the Persian Gulf the burden of water that had been drawn from it. And so, by this reciprocal circulation — a truly marvelous play of nature — the said seas, kept in agitation, carry on their

subterranean commerce, sustained by the silent communications of their waters. But so that the reader may understand that this is true, I shall bring forward several other seas in which repeated observation has shown that the same thing occurs.

[Margin: A wonderful story.]

That the Mediterranean Sea is connected with the Red Sea through hidden channels is taught by a most famous story which Abulhassen [?] recounts in his work *On the Wonders of Egypt*. When the pasha of the city of Sues [Suez] (which lies at the far end of the Red Sea, and was once called Asiongaber [Ezion-Geber]) was at one time taking part in a celebrated fishing expedition, it happened that, as the fishermen drew their nets to the shore, they found an enormous dolphin trapped in them. They presented it to the pasha as something rare and unusual, both for its great size and for the wonderful appearance of the beast. He, gazing at the creature with admiration, judged that it should not be killed but set free. This was done — but only after a plate of brass [aurichalcum], inscribed in Arabic letters, had first been fastened between the gills of the animal, with this wording: *Ahmed Abdalla, Pasha of Suez, grants you your life together with this gift, in the year of the Hegira 720*. The beast, honored with this gift, was at once released into the sea; and feeling itself weighed down by the burden of this new thing fastened around it, and driven by terror, it plunged into the innermost depths of the sea.

Now it happened that in the same year, fishermen pursuing their catch in the Mediterranean Sea near Damiata [Damietta], besides an extraordinary multitude of fish enclosed in their net, dragged ashore a dolphin of unusual size; and when it was cut into pieces, they found within it that very plate, inscribed in Arabic letters not long before by the aforesaid pasha. When the pasha Ahmed was informed of this, he acknowledged that the inscription was indeed his own. But just how the dolphin had passed from the Red Sea into the Mediterranean Sea sorely vexed the wits of many. Some claimed that it had made its way to this place by swimming around the whole of Africa, through the straits of Gades [Gibraltar]; but this opinion was at once rejected as improbable and incredible. Others, however, more sensible, asserted that the said dolphin had reached its destination through the subterranean channels by which the Mediterranean Sea is joined to the Red Sea. This view was accepted with applause by everyone, and it strongly appealed to me as well; and if what the story relates is true, the matter certainly cannot be otherwise.

[Margin: The Dead Sea.]

To these is added the Asphalt Sea [Mare Asphalticum], which they call the Dead Sea [Mare Mortuum], famous in Palestine. It receives the Jordan into its bosom, yet is furnished with no outlet on its outer surface by which it might discharge itself. Therefore, since the said sea never grows larger from the increase of the river, it is a plain sign that it likewise discharges itself, in equal measure, through subterranean channels along the hidden recesses of its bed into the sea — but into which sea? I shall say what has come to my knowledge from the report of many travelers. On the seacoast of the Red Sea, on that side which washes Arabia Deserta, there is a very famous place called Eltor [El-Tor], as appears on the map, where not far from the shore an enormous quantity of naphtha and bitumen is belched up at all times from the bowels of the sea, to the astonishment of all, who wonder whence so great a quantity of naphtha can come.

When I had been informed of the nature of the place by the report of those who had made their yearly pilgrimage to Mecca, I long puzzled with myself over the origin of this bitumen, and at length concluded that this boiling-up of bitumen comes from nowhere but the bituminous sea of Palestine — which, on account of its sluggishness, is called the Dead Sea — discharging itself through a subterranean passage. For since the Asphalt Sea, so named from its bitumen, generates a very great deal of bitumen, and the shores round about it are seen to be filled with bituminous pits — and since this sea has no outlet by which it might discharge the waters of the Jordan flowing into it — it certainly cannot discharge itself except through a hidden meandering channel of the earth, at this spot, together with the bituminous offspring which it has carried down with it from its source. The boiling-up of bitumen at the said place clearly shows this, if what I learned from the mouth of the man himself [Greek: αὐτόπτης (autoptēs, "an eyewitness")] is true. And that this bitumen wells up from nowhere but the Asphalt Sea is clear from this: that the whole of that shore shows not even a trace of bituminous growth, which it nevertheless ought to show, if it were produced there by nature in the neighboring shore. For there is generally a certain reciprocal communication between seas and the lands they wash, as regards their powers and properties [...] discharges itself in like manner into the sea through the hidden recesses of its bed.

[Margin: A common communication.]

It remains, therefore, that the Dead Sea discharges itself into the Arabian gulf through a channel of 62 leagues (for that is the distance of the Asphalt Sea from the Red Sea).

[Margin: The distance of the Dead Sea from the Red Sea.]

Therefore the Dead Sea is connected with the Red Sea, and through it with the Ocean — which was what had to be shown. The same must be said of all other seas and lakes which receive rivers and emit none: for they have subterranean channels through which they discharge themselves into the Ocean or into neighboring seas. For just as the Lake Zaire in Aethiopia

receives huge rivers and discharges others into the Ocean, by way of beds found on the outer surface of the earth, so the Caspian and Dead Seas receive certain rivers but do not emit them, except through the inmost bowels of the earth, by channels [...] led off into other seas — with this difference, however, that these latter are sometimes salt, the former unsalted, and consequently derived from the storehouses of springs into the cavities destined for them by nature.

Diagram. A bird's-eye landscape map of the eastern Mediterranean coast, showing the supposed subterranean connection of the Mediterranean and the Dead Sea with the Red Sea. A cartouche at the upper right carries the title. At the upper left is a compass rose with an arrow pointing left (toward the viewer's west). Ranges of stylized mountains run along the top and left edges; the open sea fills the lower portion. Two dotted lines labeled "subterranean channel" run from the Dead Sea / interior toward the Red Sea coast.

- Cartouche (upper right): *Communicatio Maris Mediterranei et quod mortuum dicunt cum Mari Rubro* ("The communication of the Mediterranean Sea, and of the one they call the Dead Sea, with the Red Sea")
- Compass rose (upper left): arrow pointing left
- *Ior* (upper center, source of a river): label for the spring/head of the Jordan
- *Dan* (below *Ior*): the other source-spring (Dan)
- *Jor*: (mid-upper, on the river course): Jordan [river]
- *Lacus Genesari*. (lake, center): the Lake of Gennesaret [Sea of Galilee]
- *...danus flu.* (river label, center; reads "[Jor]danus flu.", i.e. the river Jordan): the Jordan River
- *Mare mortuū Asphalticū* (center, the body of water): the Dead Sea / Asphalt Sea
- *Leni* (?) (small label below the Dead Sea): place-name, reading uncertain
- *Montes Idumei* (mountains, upper center-right): the Idumean [Edomite] mountains
- *M. Libanus* (left): Mount Lebanon
- *Tripolis* (town, left coast): Tripoli

- *Carmel* (peak, center-left coast): Mount Carmel
- *PALÆS:… TINA*. (spread across the interior): PALÆSTINA (Palestine)
- *Ierusalem* (town, center): Jerusalem
- *Canalis subterraneus bi[tuminis]* (dotted line, upper, toward Eltor): "subterranean channel [of bitumen]"
- *Canalis subterraneus* (dotted line, lower, toward Suez): "subterranean channel"
- *Eltor* (Red Sea coast, right): El-Tor
- *Mare Rubrum* (right): the Red Sea
- *Sues, Asionga[ber] olim*. (town, lower right): Suez, formerly Ezion-Geber
- *Ægyptus* (lower right): Egypt
- *Nili flu.* (river delta, lower right): the Nile River
- *Alexandria* (town, bottom): Alexandria
- *MARE MEDITERRANEUM* (lower center, spread across the sea): the Mediterranean Sea
- *Cyprus* (island, lower left): Cyprus

[Body heading: CONSECTARIUM I. — p. 88]

COROLLARY I [CONSECTARIUM I]

From these few points the reason is clear how and why some lakes receive rivers and emit none; some emit and receive none; some both receive and emit; and others neither receive nor emit. Of the first kind of lakes enough has already been said. Those which emit rivers and do not receive them necessarily draw the perpetuity of their flow from the hidden water-reservoirs [hydrophylacia] of the neighboring mountains, by which whatever is lost on the one side by outflow is restored to them on the other. As for those which both receive and emit rivers, they have the same explanation as the preceding kind.

Here this too should be noted: that some rivers pass through marshy waters without mingling with them — as the Nile through Lake Bed, that is, Zaire; the Rhine through Lake Acronianum [Lake Constance / Bodensee]; and the Rhône through Lake Lemanus [Lake Geneva]. The reason for this is none other than the lightness and clearness of river waters, purified of all dregs by their perpetual motion and by the force of their cataracts. From this it must follow that marshy water, weighed down by dregs and made, as it were, torpid and heavier by rest and idleness, is rendered heavier — so that the lighter water [the river water] floats upon it; which also [is apparent]

[Margin: The various differences of lakes.]

[continued from p. 88] is apparent at the mouths of great rivers, from which streams, depositing themselves into the sea, continue their flow together with their sweet taste for an interval of many miles — for no other reason than that river water is lighter than seawater. But of these matters in their own place and time.

Finally, lakes which neither receive rivers nor emit them can be considered in two ways. First, some are so constituted that at one moment they greatly increase, at another they suddenly diminish, and from time to time they dry up altogether; and these must be judged to take their origin from no other cause than the increase and decrease of rainfall and melted snows. These are called not so much lakes as standing pools and marshes. Secondly, there are found other lakes which never either increase or decrease, remaining in a perpetual equilibrium. The reason is that, through hidden channels, they are kept perfectly level with the surface of the waters in the water-reservoirs of the mountains, with no difference intervening — except that the hidden water-reservoirs of the mountains are covered, as if by certain arches, over the mountain ridges, whereas these [lakes], lacking lids, lie open beneath the open sky.

As appears in the Figure: imagine a water-reservoir D E covered by the mountain A B C; this, by its waters derived beyond the wall of the mountains, produces on the outer surface of the plains two lakes F F. These lakes will be on the same surface with the waters of the water-reservoir D E, and the external [reservoir] does not differ from the internal, except that the one is covered by a mountain set over it, while these [lakes] appear uncovered. But of all these matters, one and all, fuller treatment will be given in the discourse on the Origin of Springs.

Diagram. A cutaway landscape cross-section illustrating mountain water-reservoirs (*hydrophylacia*) and how they feed plain-lakes. A dotted line traces the original (now cut-away) profile of the opened mountain up to a peak marked A. At the center the mountain is shown "opened and cut" to reveal a large internal cavern-reservoir; to right and left lie lower plains with lakes fed from it. Labeled points and captions:

- A (peak, top): apex of the (cutaway) mountain profile
- B (upper, at the cut): upper edge of the opened reservoir
- C (upper right, at a second cut): upper edge of the right-hand reservoir
- D (mid-left, within the cavern): lower point of the reservoir interior
- E (mid-center, mouth of cavern): outlet point of the reservoir

- F (in the plain, left): label of the plain-lake (*Lacus in planitie*)
- F (in the plain, right): label of the second plain-lake
- *Mons apertus et sectus* (center): "the mountain opened and cut [away]"
- *Hydrophylacium intra viscera montis* (within the mountain): "water-reservoir within the bowels of the mountain"
- *Lacus in planitie* (left foreground): "lake in the plain"
- *Hydrophylacium apertum sive Lacus in planitie* (right foreground): "open water-reservoir, that is, a lake in the plain"

[Body heading: CONSECTARIUM II. — p. 89]

COROLLARY II [CONSECTARIUM II]

From this it is also clear that scarcely any lakes of any name are of that kind which neither receive nor emit rivers and yet are capable of increase and decrease — lakes which, even though they receive no rivers, are nevertheless always increased by an abundance of rivulets and by the inflow of springs. Otherwise, in the height of summer, no trace of them would remain — as happens with marshy and stagnant waters, which for the most part are consumed by the summer sun.

That lakes are therefore both filled and emptied through subterranean channels is evident from many rivers which, in the middle of their course, are in some places entirely swallowed up, and on the other side are born again and burst forth, so that they seem to be wholly new rivers. Thus the river Niger of Aethiopia, flowing from the Lake of the Nile, when in Nu-

[Margin: The Nile and Niger, buried in the earth, burst forth again elsewhere.]

bia, enclosed and hemmed in by huge chains of mountains, finds no place to escape — these barriers being, as it were, broken — is hurled headlong through subterranean meanders, and seeking an outlet for itself on the other, western, side of the mountains, and joined by many other rivers, is increased as though by some interest [on a loan], and rolls down into the Atlantic Ocean.

[Margin: The Tigris.]

In like manner the Tigris, carried across Mesopotamia and meeting Arethusa, when it encounters the resisting Caucasus, withdraws and plunges into a certain very wide cavern; and at length, bursting forth again over an immense expanse of land, it scarcely crosses Lake Thospites [Lake Van] with an unbroken flow when — behold! — struggling far and wide against new barriers of mountains, it

at length cunningly hides itself underground, and bursting out on the other side of the mountain at an interval of 24 miles, continues its flow, and near Babylon mingles with the Euphrates. Aristotle [Aristoteles] writes that there were many streams of this kind (*Meteorology* I.13 [cited: l. 1, c. 11]).

[Margin: The Alpheus, a river of Greece, communicates with the Arethusa of Sicily.]

So too certain Greek writers think that the Alpheus, a river of Achaia, performs its course either beneath the surface of the sea or all the way into Sicily, where, near Syracuse [Syracusas], it emerges as a huge spring which is called Arethusa. They say that the sign of this is that, in the end, near Arethusa and in the middle of the harbor, in a submarine [...] the dung of cattle was discharged at the bottom; for once, every fifth summer — that is, every five years [lustrum] — at the very time when the games of Olympia were being celebrated in Achaia, and the dung of the slaughtered cattle was thrown into the Alpheus, it was carried out by the favorable current and ejected near Arethusa, into the harbor-bay which is to this day on that account called the Alpheus, commonly *l'Occhio*.

[Margin: The Anas, a river of Spain.]

In like manner the Guadiana — which was formerly called the Anas — a river between Lusitania and Boetica [Baetica] and the town of Medilina [Medellín], submerged in subterranean passages, after an interval of 32 miles wells up again; so that the Spaniards boast that their kingdom has a bridge furnished with woods and meadows, on which countless myriads of animals are fed in the richest pastures. I myself have also seen similar plays of nature in many places in Germany. In Westphalia, not far from Lichtenaw, a river is swallowed up and bursts forth beneath the very foundation of the Cathedral Church of Paderborn, and from there is deposited by a threefold stream into the Lippe. I remember having seen a similar one in Eichsfeld, whose name does not now come to me. In America, everywhere, such playful sportings of rivers are to be seen, so that I think it superfluous to describe them at greater length, since in every region of the world, everywhere, such spectacles are to be met with.

CAPUT XIV

[Body heading: CAPUT XIV. — p. 89]

On the Height of Mountains, and the Depth of the Ocean and of the Seas; in which also the height of Mount Caucasus asserted by Aristotle is examined.

[*De Altitudine montium, et profunditate Oceani, mariumque, ubi et Caucasi montis altitudo ab Aristotele asserta discutitur.*]

It was the opinion of certain men, and is still the opinion of very many, that the height of the mountains is as great as the depth of the neighboring seas. Whether this is true, we shall examine in this chapter, [beginning] from the height of the mountains

as we set out to begin the first principles of our reasoning.

Ancient Geography persuaded itself, rather simplistically, that mountains are not raised higher than 15 stadia, and presents as the highest mountains of the whole world: the Caucasus; the Imaus, that is, the Parapanisus [Hindu Kush]; the Alps; the Acroceraunia; in Asia Minor, the Olympus; the Pelion and the Ossa in Macedonia; in Mauritania, the Atlas; in Greece, Athos. Aristotle himself admired the lofty summits of the Caucasus. But since, in the very text of *Meteorology* I.13 [l. 1, c. 4] where he describes it, many things occur which need examination and the touchstone [lydius lapis], we shall now bring this passage — already treated by many others — back to the anvil, so that the truth of the matter may shine forth. He speaks as follows:

[Greek: ὁ δὲ Καύκασος μέγιστον ὄρος τῶν πρὸς τὴν ἔω τὴν θερινήν, δῆλον δὲ καὶ τῷ πλήθει καὶ τῷ ὕψει σημεῖον δ' ἐστὶ· τοῦ μὲν ὕψους, ὅτι ὁρᾶται καὶ ἀπὸ τῶν καλουμένων βαθέων, καὶ εἰς τὴν λίμνην εἰς πλεόντων, ἔτι δὲ ἠλίσσεται τῆς νυκτὸς αὐτοῦ τὰ ἄκρα μέρει τοῦ τρίτου μέρους τῆς ἔω, καὶ πάλιν ἀπὸ τῆς ἐσπέρας. ("The Caucasus is the greatest of the mountains lying toward the summer sunrise, and this is clear both from its extent and from its height. A sign of its height is that it is seen even from the so-called Deeps, and by those sailing into the lake [the Maeotis]; and moreover at night its peaks are lit for a third part of the night before dawn, and again [for a third part] after evening.")] (*Meteorology* I.13 [Met. c. 4])

In Kircher's Latin: *The Caucasus is a mountain among those that lie toward the summer rising of the Sun, the greatest alike in extent and in height; and a sign of its height can be gathered from this — that it is seen both from that place which they call the Deeps of the sea [profunda ponti], and by those who navigate the mouth of the Lake Maeotis. Besides, its highest parts are illuminated by the Sun's rays at night, both at dawn and at evening, for as much as a third part [of the night].*

[Margin: The height of the Caucasus.]

This is the view of Aristotle on the height of the Caucasus, which he set forth in the present text — and over which so sharp and vehement a skirmishing has arisen among the commentators that there is scarcely anyone who has expounded this passage rightly. And, to confess the truth, if in any passage of his writings, then surely here, the Philosopher has suffered no small loss to his reputation, since — according to the tenor of the words — the height of the Caucasus is so great that it seems to overthrow all the principles of Astronomy. But let us set out the matter a little more fully.

[Margin: Exposition of the Aristotelian text.]

First, then, he begins with the places from which it can be seen, which are: the *Deep of the Pontus* — or, what is the same thing, the Black Sea [Pontus Euxinus], on account of its immense depth deservedly called the Black Sea — and a second place, the Lake Maeotis [Sea of Azov], which he also calls a "marsh" [stagnum], and from which he asserts that the Caucasus is seen by those sailing on it. We have seen the places from which a free view of the Caucasus to the eyes lies open; now nothing else seems to be required except that we determine the distance of the Lake Maeotis from the Caucasus. But when we do this, no small difficulty arises: namely, just which one is properly that most famous Mount Caucasus, the one that reaches the sky with its summit, and in what region it is situated.

[Margin: Where the Caucasus is situated.]

For it is certain that it exists in the nature of things, and can be seen from the Maeotis — unless you wish to assert either that other intervening mountains, grown up in the meantime, have taken the summit of the more distant Caucasus from sight, or that the Caucasus has been carried off elsewhere by some gigantic feat; all of which to suppose is, I think, ridiculous and a mark of stupid folly. For my part, to reach some ray of light in such great darkness, I left nothing undone: I approached Armenian merchants, and

[Margin: The Caucasus is manifold.]

[I approached] the missionaries of the Congregation for the Propagation of the Faith, who had dwelt for many years in Caffa [Kaffa / Feodosia], the chief city of the Cimmerian Chersonese [Crimea], and had more than once crossed the Lake Maeotis. I also dealt with the Theatine Fathers, to whom a field for the evangelical sowing has been assigned in Georgia, that is, Colchis, so that they might give me some certain information about the height and situation of the Caucasus. But neither the aforesaid explorers of the Maeotis lake nor the Georgian (Colchian) Theatines — just as the former asserted that they had found nothing of so great a

height of the mountain as I was describing, even though they had continually roamed back and forth from the Euxine to the Caspian and from there to the Euxine — so too the latter had discovered nothing about the Caucasus, celebrated for its prodigious illumination by the Sun.

Indeed, they even testified that Georgia is separated from the Maeotis lake by so great an interval of travel that it cannot possibly be that any mountain, however immense its height, could be seen from such remote shores. There are indeed certain very high mountains proper to Precopian Tartary, which the ancients called the Hippici [the Hippican Mountains], as well as parts of the Corax, which are seen from Caffa; but these can by no means be the Caucasus mountains, since the whole of Geography is against it; nor does any mountain of Asia Minor disclose itself to the eyes of those exploring ever so carefully on this side. Hence they consider the whole account by Aristotle of the height of Mount Caucasus to be fabulous.

[Margin: The Caucasus cannot be seen from the Maeotis.]

These things, therefore, having been duly investigated, I now set about demonstrating that this whole text is utterly false. And first, indeed, I shall show that the Caucasus cannot by any reasoning be seen from the Maeotis. The common opinion of the geographers places the Caucasus in the region of Colchis — which today they call Georgia and Mingrelia [Mengrelia] — at latitude 47 degrees, that is, in the middle of the region lying between the Pontus and the Caspian Sea; so Ptolemy [Ptolomaeus], Strabo, and their commentators.

[Margin: The Caucasus is manifold.]

Nor should anyone persuade himself that the Caucasus is some solitary mountain; rather, it is a chain of mountains stretched out in a threefold order: the first runs from the middle of the region to the West, the second to the East, the third to the South, propagating a numerous offspring of crags linked to the Taurus — whence very many have asserted the Caucasus to be a part of the Taurus. Be that as it may, the Caucasus takes on so many different names that to this very day a dispute hangs among the geographers about the true place and genuine situation of the Caucasus, some confounding it with the Taurus, some with the Corax and the Heniochus, others with the Caspian [range]; nor are there lacking those who would have the Caucasus mountains to be the same as the Imaus and the Parapanisus.

[Margin: The situation of the Caucasus between the Pontus Euxinus and the Caspian Sea.]

The stronger opinion, however — as we said above — places it between the Caspian and the Euxine Pontus, in the intermediate district of Colchis, Albania, that is, Iberia, which embrace Georgia and Mingrelia. For here, with the threefold order of mountains converging into one, it is raised up by a huge peak, near the Albanian Gates [the Caspian Gates / Derbent]; and this mountain,

—or rather a heap of mountains, which to this day they call *Caxes*, a word not far removed from "Caucasus." This we say is the Caucasus, about whose height our dispute with Aristotle is concerned. For since in that whole stretch of the shores of the Black Sea [Pontus Euxinus], or in Colchis [Georgia], no greater mountain than this is found, the origin of the river Phasis from it—which Aristotle himself also notes—confirms this identification.

The first question, then, is this: can the Caucasus be seen from Lake Maeotis, or from Caffa (the ancient Theodosia), where lay what were called the depths of the Black Sea? My answer is that it cannot. For, on the testimony of Ptolemy and of modern geographers, the lake is ten degrees of longitude distant from it. [Margin: The distance of the Caucasus from Lake Maeotis.] Resolved into linear measure, these yield a distance of 600 Italian miles—exactly as great a span as that by which Mount Etna is distant from the Pennine Alps. Therefore, just as it is impossible to see the Alps from Etna, so I say it is impossible to see the Caucasus from Lake Maeotis—unless the mountain were of such height that it raised its summit more than a hundred thousand paces into the air. No one has ever observed such a height in the kingdom of Georgia, frequented though it is; nor is it granted by any cosmographer, for reasons to be demonstrated shortly. [Margin: No mountain can be seen at a distance of 100 miles.] I add further that the mountain, once the curvature of the earth is taken into account, would, at the stated distance of ten degrees, not merely fail to be seen but—as optics teaches—would vanish entirely from the eye. The peaks of the Alps demonstrate this more than amply: their summits, at a distance of 40 German miles, can never be seen, and at 30 German miles only barely—scarcely even that—and then only now and then, in the clearest possible air, faintly visible like a thin bluish cloud, from other very high mountains of Germany.

The same happens with the mountains of islands. For if you stand on the highest ridge of the Apennines and cast your eyes out over the whole horizon, bounded by the surface of the sea, you will find not the slightest trace even of the loftiest mountains of Corsica and Sardinia—which are nevertheless scarcely a hundred miles away—unless now and then (which happens very rarely indeed) by some peculiar effect of refraction, in a perfectly clear state of the air well suited to

refraction, they appear somewhat raised into view. (So much can both the curvature of the earth and the packed density of the layers of air accomplish in hiding the objects of islands and of the most distant mountains.) If, then, objects at so near a distance disappear from sight, how shall the Caucasus, set 600 miles away from Lake Maeotis, lie open to the eye?

From this, unless I am mistaken, it is clearer than the noonday light that Aristotle's text [Margin: The Caucasus cannot be lit along its whole height by the Sun.] cannot at all agree with the facts, and that it cannot come about that the Caucasus should be visible from the places he designates. But I come now to a second difficulty—as much greater as it is entangled in greater complications. Aristotle says, as is evident from the text cited above, that the summit of the Caucasus is lit by the Sun up to a third part of the night, both at dawn toward morning and again toward evening. This passage has wonderfully confounded the ingenuity of all the commentators, since an inexplicable difficulty shines out in the text. Some have extended this illumination *to a third part of the mountain*; others have transferred it *to a third part of the night*. And while they have striven all the more stubbornly, by every possible means, to defend Aristotle's error, they have at one stroke smeared both themselves and Aristotle with the mark of utter ignorance.

Those, then, who transferred the words to the illumination of a third part of the mountain—as though the Sun by night, morning, and evening always lit a third part of the mountain—commit an error so glaring in cosmography that schoolboys could correct it. For from this it would plainly follow that the mountain must reach the borders of the Moon to produce so unusual an effect; and who does not see how ridiculous this is? And so, since they were ashamed of so disgraceful an error, they transferred the words of the text to a third part of the night—that is, so that at a third part of the night, namely four hours (of which the whole night contains twelve) before the rising of the Sun and after its setting, the mountain should begin to be illuminated. But I show by ocular demonstration that this too cannot, and should not, be admitted on any grounds.

First, the light by which he says the Caucasus is lit for four hours before sunrise and as many after sunset can be understood in two ways: either as direct light, or as reflected (secondary) light. If they take it as reflected light—such as appears at the onset of twilight, that is, as doubtful light—they prove nothing. For light of this kind, from the 45th up to the 66th degree of latitude, is continuous on summer nights, and bathes mountains small and very high alike indifferently with the ray of its reflected light. Nor does this seem to have been Aristotle's view,

since by the illumination of the mountain he wished to show its excessive height. Aristotle's words, therefore, are to be understood of the direct light that illuminates the mountain—whatever the interpreters unskilled in astronomical matters may prattle, with useless effort, about reflected light. This being established, I undertake to demonstrate that the mountain must have been of excessive height. And first, with the Sun in Cancer, then in Aries and Libra, and third in Capricorn, I shall show how great a height the mountain must have had in each of these stations in order to be illuminated by direct solar rays at a third part of the night.

I assume, then, from Ptolemy, that the summit of the Caucasus is set at a latitude of 47 or 48 degrees, and that the Sun is in the first degree of Cancer. I assume, second, the third part of the night, at whose beginning the mountain begins to be illuminated.

PROPOSITION I.

The arc of four hours below the horizon, set in the vertical circle, with the Sun placed in Cancer, is 16 degrees 10 minutes at latitude 48 degrees.

Demonstration.

Diagram. A great circle representing the vertical circle of the Caucasus, with its labeled points. The circle is the vertical circle A F D; F is at the top, A at the left, B at the right. Through the center pass the diameters; several intersecting ecliptic and horizon arcs are drawn within. Point D lies just above the center O; C lies just below it; L is at the lower left; d is at the upper right.

- F (top of circle): apex of the vertical circle
- d (upper right): rising point of the ecliptic [recte: D, ecliptic rising point per text]
- D (center, above O): point of the ecliptic culminating in mid-heaven
- A (left): point where the vertical circle meets the horizon
- O (center): center of the Earth
- B (right): point where the vertical circle meets the horizon
- C (below center): occiduous (setting) point of the ecliptic
- L (lower left): position of the Sun at the beginning of the third part of the night

Let the vertical circle of the Caucasus be A F D, the point of the vertical F; the horizon A D B C, and G D L C the ecliptic, with the center of the Earth O. By

hypothesis these are all great circles, whose planes intersect one another at the center of the Earth; and let the diameter of their common section be C O D. Let the Sun be at point L, at the beginning of the third part of the night. The arc A L is sought.

Given, then, the hour of the night and the elevation of the Pole, there is given—by the doctrine of spherical triangles—the point of the ecliptic, rising at D, setting at C, and each both above the horizon at noon and below it at midnight. But given the culminating point in mid-heaven, there is given also, for the stated latitude, the angle of the horizon with the ecliptic at the given point of the ecliptic, which is A C L; and the angle L A C will be right, being that of a vertical to a horizontal. And given the points L and C, the arc L C will also be given. Moreover, in the right triangle A L C, by Problem 2, Proposition 4 of the *Spherical Triangles* of Clavius [Christoph Clavius], the angle A C L will be given, together with the remaining arcs, and consequently the sought arc L A.

Given, then, the right spherical triangle A C L, two sides will be known: namely the side subtending the right angle L A C, which is the arc between the horizon and the lowest point of the heavens, 68 degrees 53 minutes (for this is exactly the interval between the 20th degree of Leo and the eleventh of Gemini, the latter being at the lowest point of midnight, while the Sun is at point L, at the third part of the night). The other side, A L, the arc of the meridian, is likewise established. Since, then, the sine of the angle A C L (which remains after subtracting the declination of the Sun, set in the 11th degree 7 minutes of Gemini, from the complement of the elevation of the Pole)—the angle being 21 degrees 19 minutes—is 36371, and the given arc L C is 50 degrees (which is the difference of degrees between the beginning of Cancer and the 20th degree of Leo, which is on the horizon at the given time)—the sine of these 50 degrees being 76604—it will be: as the whole sine 100000 is to the sine 36371, so 76604 is to a fourth term. Carrying out the operation, the sine 27861 results: the arc L A, to which there correspond in the table of sines 16 degrees 10 minutes.

The arc L A, therefore, with the Sun at the beginning of Cancer, is 16 degrees 10 minutes—which was to be demonstrated.

In this way we find that, with the Sun set in the points of Aries and Libra at the given hour of the night, the arc L A is below the horizon by 35 degrees 25 minutes; and in the first degree of Capricorn, the arc L A is depressed below the horizon by 50 degrees. These being found, let us now show how great the height of Mount Caucasus must be in order to produce the effect of the alleged illumination.

PROPOSITION II.

How great the height of Mount Caucasus must be, when the Sun, set in Cancer, Aries, and Capricorn, illuminates it at the third part of the night.

Diagram. Two concentric circles: an outer circle representing the periphery of the Geocosm (the Earth) and a smaller inner circle. The vertical of the Caucasus is the vertical line through c (top) and H (bottom); A is at the left and B at the right of the horizontal diameter; D is the center; m and n mark the ends of the physical (mountain) horizon; e, f, g lie on the line of the vertical near the summit; i appears at upper left and again as an inner point near D; o lies to the right of D; L is at the upper right; h at the lower right; P at the bottom of the inner circle.

- c (top, outer circle): apex of the vertical of the Caucasus
- i (upper left): point on the line of a solar ray [?]
- L (upper right): the Sun's position
- f (on the vertical, near top): point on the axis of the horizon
- e (on the vertical, above center): point of contact of the rational horizon with the mountain's surface
- g (just right of e/center): point of contact of the solar ray with the Earth
- m (left): end of the physical/mountain horizon
- n (right): end of the physical/mountain horizon
- A (left, outer): end of the rational horizon
- i (inner circle, left of D): point on the inner circle [?]
- D (center): center of the Earth / Geocosm
- o (right of D): point on the horizontal
- B (right, outer): end of the rational horizon
- P (bottom of inner circle): point on the inner circle
- h (lower right): point where the solar ray meets the outer circle
- H (bottom, outer): foot of the vertical

Let the vertical of the Caucasus be A C B; let the periphery of the Geocosm or Earth be e o p q, whose center is D; the physical horizon, or that of the mountain, m n; the rational horizon A B; the line of the vertex, or axis of the horizon, e C; and the height of the mountain e f. Let the line i h be tangent to the surface of the side at point e—at the time when, before sunrise or after sunset, at the beginning or end of the fourth hour of the night, the Sun illuminates the summit of the mountain.

Now since the line $i h$ of the solar ray touches the Earth at point g , and the horizontal $m n$ touches it at point e , let the lines $D g$ and $D e$ be drawn from the center D through the points of contact g and e , of the lines $i h$ and $m n$; these, since on both sides they make right angles with the lines $i h$ and $m n$, and since the semidiameters of the Earth $D e$ and $D g$ are [equal], the vertical arcs $L f$ and C will consequently be equal to one another. Once the common arc $L f$ is removed, the remaining arcs $f h$ and $C L$ will be equal to one another. But the arc $f h$, intercepted between the Sun and the horizon, is already known from the preceding proposition: 16 degrees 10 minutes. Therefore the arc $C L$ equal to it is likewise known. In the angle $D f e$, then—being a right angle—the angle $D f e$ is known. [Margin: The height of the Caucasus is demonstrated by geometric reasoning.] Subtracting, then, the angle $e D g$ from a right angle, the angle $D e g$ will appear. Therefore all the angles of the triangle $e D g$ will be known. Given also the side $D e$, the semidiameter of the Earth, the remaining sides are therefore known by Proposition 2 of Clavius's *Plane Triangles*; and therefore the height of the mountain $e f$ also, in the manner that follows.

With the Sun at the beginning of Cancer, at the beginning or end of the third part of the night, the arc between the Sun and the horizon, $f h$, is, as shown above, 16 degrees 10 minutes, whose complement is 73 degrees 50 minutes, whose sine is 96040 of such parts as the whole sine $D f$, 100000, contains. Moreover, since the semidiameter of the Earth $D e$ is known to be 3036 Italian miles, let it be done thus: as the sine $D e$, 96040, is to 3036, the known semidiameter of the Earth, so is the whole sine 100000 to a fourth term. The operation completed, there results 3161: namely the line $D f$, made up of the semidiameter of the Earth and the height of the mountain $e f$. Therefore, subtracting from 3161 the semidiameter of the Earth, 3036, there will remain 125: the sought height of the mountain. [Margin: 125 Italian miles for the mountain.]

But with the Sun placed at the beginning of Aries and Libra, since the arc $f h$, at the beginning and end—before or after the setting of the Sun—was found by Proposition 1 to be 35 degrees 25 minutes, you will find, by the procedure of the preceding operation, the height of the mountain $e f$ to be 699 miles. Finally, with the Sun in Capricorn, and at the beginning or end of the third part of the night, set at point h below the horizon—which arc $f h$ we found by Proposition 1 to be 50 degrees 17 minutes—if you proceed by the rule of the preceding operations, you will find the height of the mountain $e f$ to be 1715 miles.

Recapitulation of the Calculation.

[Margin: The height of the Caucasus demonstrated by geometric reasoning.]

If the Sun, before or after rising, at the beginning of the third part of the night, begins to illuminate Mount Caucasus, the height of the mountain will be:

	Italian miles
If at the beginning of Cancer, it will be	125
If at the beginning of Aries and Libra, it will be	699
If finally in Capricorn, it will be	1715

Since these things, then, stand firm by the infallible reasoning of calculation, let the Reader now judge whether a mountain of such height can be found in the nature of things—one that would display the illumination alleged by Aristotle. And let the Peripatetics not here take refuge in the light of twilight; for they will accomplish nothing. Since the twilights, with the Sun set in Cancer, last the whole night, and since one and the same twilight is common to flat places and to small, great, and very great mountains alike, the height of the mountain—which Aristotle meant to infer from the Sun's illumination—cannot in any way be gathered from this. He spoke, therefore, of the true and direct illumination by the Sun, as his words plainly teach; nor are his words, since they are perfectly plain, to be twisted into other meanings; rather, we must stand by the words of the Author. For it is not what he conceived in his understanding that falls to us to explain—since of that nothing can be established for us—but what he meant by his writings, and those plain and open ones.

If, then, it is true—as is found most true from his writings—that he said the Caucasus is lit by the direct rays of the Sun at the third part of the night, then necessarily these absurd consequences follow, which we have just demonstrated: namely, that the mountain must be high, with the Sun set in Cancer, 125 [miles]; in Aries or Libra, 889; finally in Capricorn, 1715 Italian miles. And since these are utterly absurd, and wholly unworthy of so great a genius—being repugnant to all the principles of geography—nothing remains for the defense of Aristotle except to say that he asserted these things on the report of others. Yet a man of such authority and renown ought not to have assented to any old tales of old wives' reports, but with the utmost diligence and caution to have looked carefully into whether what was said agreed with the truth, and whether it accorded with the principles of astronomy. Indeed, since he abounded in riches and power, and was not so far distant from Lake Maeotis, he ought to have sent geographers to investigate the matter more thoroughly, sparing no expense, lest by paradoxes and absurdities he entangle both himself and posterity along with him. [Margin:

Caution to be employed in doubtful matters.] But let these things, said in passing about the height of Mount Caucasus, suffice.

Mount Athos—which Mela thinks exceeds the region of rain on account of its height, because of the undisturbed state of the ashes found upon it year after year—was, by an enterprise truly memorable to all the ages, cut through by Xerxes and made passable by a navigable strait. [Margin: Mount Athos in Macedonia, cut through by Xerxes.] Dinocrates is said to have measured it and found it twelve stadia high. (See the account of this measurement in the *Ars Magna Lucis et Umbrae*, where you will find everything treated at length concerning this mountain.) Pliny and Geminus teach that the mountains Pelion and Cyllene were measured by Dicaearchus at the King's expense, and that the former was found to be 1,250 paces high, the latter no less. Pliny says that Mount Coesim in Asia raises its ridge to four thousand paces. Martianus Capella writes that Mount Haemus is 6,000 paces high. Strabo reports the rock of Sisimithra as 15 stadia, and a rocky mountain of the Sogdians as 30 stadia high. But lest I waste time on the description of mountains already carried out by others, I shall here set down a Table of the heights of the principal mountains, so that the Reader, from their known height, may gather what is to be thought about the depth of the sea. [Margin: The height of Mount Athos.]

Table of the heights of the principal mountains.

Mountain	Stadia	German miles (of which 8 make one mile)	Paces
Pelion	10	1 2/8	1250
Catalyrium	14	1 6/8	1680
Cyllenom [Cyllene]	15	1 7/8	1875
Petra Sogdiani [Rock of the Sogdians]	30	3 6/8	3750
Haemus	80	10	10000
Olympus	10 15/125	1 6/8 (nearly)	1269
Petra Sisimythrae [Rock of Sisimithra]	15	1 7/8	1875
Picus Canariarum [Peak of the Canaries, i.e. Teide]	80	10	10000
Aetna	23	4	4000

Mountain	Stadia	German miles (of which 8 make one mile)	Paces
Aetna	40	5	5000
Caucasus	120	15	15000
Caucasus	408	51	51000
Cassius	224	28	28000
Atho [Athos]	160	20	20000
Athlas [Atlas]	210	15	15000
Riphaeorum altissimus <i>Stolp</i> dictus [the highest of the Riphaean mountains, called <i>Stolp</i>]	200	25	25000
Norvegiae Montes [Mountains of Norway]	48	6	6000
Montes Lunae [Mountains of the Moon]	120	15	15000

To these we append a table by which, from a given distance, we determine the height of a mountain, and, from a given height, the distance at which it can be seen.

TABELLA

By which, from a given distance, to find the height of a mountain, or, from a given height, the distance at which it can be seen.

Liber II "Geocosmus" (Technicus) — Caput XIV (continued)

Worked examples. For instance: suppose there is some mountain that lies 10 minutes distant from you, and you wish to know its height. Look in Table 1, in column 2, for 10 minutes; opposite it, in column 1, you will find 21 paces — and that is the height of the mountain. Again, let the mountain recede 50 minutes from you: the 50 minutes found in the second column will give 528 paces in the first column, which is the height of the mountain you sought.

In the same way, if some mountain recedes 4 degrees from you, look in Table 2 in the second column for 4 degrees, and opposite it you will find 12 miles, 209 paces — the height of the mountain you sought. You will proceed no differently in the other cases.

But if instead the height of the mountain is given, you will find in the second column of the Tables the minutes or degrees — that is, the distance from the mountain you sought.

Note, however, that all this is to be understood of the eye of the surveyor situated on the surface of the Earth that is concentric with the sea, not on the mountain's surface.

On the limits of measuring the great mountains. And these are the mountains whose heights mathematicians of keen ingenuity have attempted to explore — or rather to measure out — though not with any very certain measure. Yet if you should wish to compare their lofty peaks with the mountains of the American Andes, then certainly — on the testimony of [José de] Acosta — you would find these mountains [of ours] to be no more than humble cottages set beside palaces; mere cypresses, mere shrubs [viburnum], I say, set beside towering [peaks]. To undertake to measure those [Andean peaks], as also the mountains mentioned above, would indeed be a task most worthy of a mathematical mind — but for one who has duly weighed in the finer balance of his judgment the reefs of the difficulties that arise, he will perhaps, in due proportion, encounter the same difficulty as in measuring the very stars. I am speaking always of those enormous mountains — like the Caucasus, the Paropamisus [Paropamisus / Hindu Kush], the Pico [Pico del Teide, Tenerife], Athos, and countless others mentioned above. And so, in determining these by exact measurement, the true height can scarcely ever be assigned with certainty — only that height which emerges from a given hypothesis can be assigned. For since the root [base] of such mountains usually lies many days' journey away, one must first know that [distance] by exact measurement. Second, there is need of a sure, direct, and infallible incidence of the visual line upon the point of that mountain's summit — which, by the aid of no instrument, can be reliably taken at so great a distance. Third, the full account of refractions must be taken — refractions which, the more uncertain they are amid so great a diversity of the surrounding medium, wrap the task in correspondingly greater difficulties. Fourth: at so great a distance of the surveyor from the mountain's perpendicular, one must have foreknown — and with the utmost precision — the magnitude of the swelling of the terrestrial globe [its curvature]. For since the perpendicular of the mountain and the perpendicular

drawn from the center of the Earth through the surveyor's zenith are by no means parallel to one another, one will necessarily have to know in advance the angle that the perpendiculars from the center of the Earth, of the mountain, and of the surveyor's station make. And this angle simply cannot be had unless the distance between the mountain's apex and the surveyor's station is known; but this, in turn, presupposes

the precise quantity of the terrestrial semidiameter, which is still in question and, amid such great perplexity of disagreeing geographers, has to this day been correctly assigned by no one — since they falsely persuade themselves that the surveying plane on which they stand is continuous with the rest of the level surfaces, or even continuous with the sea beneath a concentric convex surface. I could adduce countless other obstacles and deceptions of sight, but let these suffice to draw out and clearly demonstrate the difficulty. Nevertheless, in mountains that are nearer, and not hampered by such circuitous journeys, [the attempts] will meet with happier success; for in this case no account need be taken of refractions, nor of the visual line, nor of the swelling of the Earth — these being scarcely subject to any perceptible error, provided the geometer's diligence and ingenuity are not lacking in the rest.

The disagreement over Monte Baldo. The difficulty of the work is shown by the recently made measurement of Monte Baldo [Monte Baldo], which rises with a lofty peak in the territory of Verona and is distant 75 miles from Forum Navii [Nave / Forum of Naevius (?)], a measurement made by [Giuseppe] Biancani [Blancanus]: the mountain's height was found to be 860. But [Niccolò] Cabeo [Cabeus], having weighed the matter more deeply, afterwards found its height to be 1190. And here Riccioli [Giovanni Battista Riccioli] was not satisfied: for, having examined everything thoroughly, he assigns the mountain a height double that which Biancani had found — namely 1654 Bolognese paces. Which of these three, then, I should subscribe to, I cannot discern. There will perhaps be another who, by discovering still other difficulties, will assign now a greater, now a lesser [height] — and so the stone of Sisyphus is rolled, the course of doubts never finished. So no faith can be placed in the three measurers of Monte Baldo cited just above, since they diverge from one another by such embarrassing differences. The uncertainty, therefore, that we have found established in the height of Monte Baldo — which is by no means the loftiest of all — we are bound to find, entangled in far greater difficulties, when we come to explore the monstrous height of the mountains mentioned above. This is as certain as the effort of all human ingenuity is uncertain and doubtful in wresting [an answer] from so many knots of difficulty — especially since the precise situation of

mountains of this kind, in degrees, is still unexplored, though the whole undertaking rightly depends upon it.

Kircher's own trial on Monte Albano. Indeed, that I might in some way test this difficulty of orometry, I judged that the business should be attempted in measuring Monte Albano [Monte Albano / the Alban Mount], 20 miles distant from Rome. So, having set up astrolabes in a suitable place, and then a quadrant whose diameter was 4 palms, I ordered just as many practiced observers of hawk-like sight to track, as accurately as possible, the very last extremity of the said mountain's apex in degrees on the quadrants — hoping it would turn out that they would all agree on one and the same degree and minute. But, the labor once begun, everything turned out to the contrary: for when I examined the numbers of degrees they had read off, I found them all, to a man, differing not only in degrees but even in minutes. The same happened when the same observation was repeated three or four times;

the matter was tried anew through individual observers, with the aid of that quadrant which I judged the most accurate. But not even here was agreement reached among them. At last we set about taking the height of a nearby tower: since its apex was closer to us, we likewise reached its point more precisely, and so all agreed in degrees and minutes. It was a most evident sign that the cause of error in the first observation had been nothing other than the excessive distance of the mountain, whose uttermost apex could not be precisely reached. From this experiment you have [proof of] how difficult it is, at a more remote and excessive distance, to investigate with infallible certainty the exact height of any rather distant mountain.

Kircher declines to give a method. The Reader might perhaps wish that here I should set down some method for exploring the height of mountains. But since countless others have handed this down, and the matter is not of such great moment, I judged it superfluous to waste time on a business commonly known — especially if the affair is carried out by a simpler geodesy, according to the rule of trigonometry, with all the above-mentioned observations and required conditions set aside. But if anyone desires such procedures more ardently, let him consult [Christopher] Clavius, [Willebrord] Snellius, [Giovanni Antonio] Magini [Maginus], [Adriaan] Metius, [Adriaan] Van Roomen [Sambecum (?)], and as many as have written on practical geometry. Among the rest, however, let him consult Riccioli, who, in Book 10 of the *New Almagest*, section 4 (*Almagestum Novum*, Lib. X, sect. 4), has treated this subject most fully. As for the arguments which the Author of the *Reformed Geography* [*Geographia Reformata*] adduces in

his recent work against me and my opinion concerning the measurement of mountains — since they are of no weight, they are likewise not to be heeded; for, the dispute that has arisen between us being unknown to no one, and since he [is] an honest hater of quarrels, not seeking (as the saying goes) a knot in a bulrush, [these arguments] could most easily be reconciled.

Return to the main question: do mountain heights match sea depths? But, to return at last to the thread of our purpose: we have introduced the heights of mountains here for no other end than to settle a dispute pending among most celebrated authors. Now the doubt is this: **Whether the depth of the sea, or of the Ocean, corresponds to the heights of the mountains.** [Margin: Whether the heights of mountains correspond to the depth of the sea.] Most commentators on Genesis, as well as the geographers, do not hesitate to embrace the affirmative part, and seem to wish to prove it from that passage of Genesis: *"Let the waters be gathered together into one place, and let the dry land appear,"* etc. So (they argue) in order that the water surrounding the Geocosm might be gathered into one place, there was need of deeper channels [alvei] in the surface of the Earth. The Earth, therefore — by the power of the almighty God and [Margin: The affirmative opinion.] by the efficacy of the divine word — they say was dug out and heaped up into vast mounds, from which the chains of mountains then arose; so that, on this account, the depth of the Ocean is exactly as great as the height of the mountains. This is the opinion of most Interpreters of Sacred Scripture. But whoever scrutinizes their statements more carefully will see clearly that from this an equal quantity of the Ocean's depth and the mountains' height [Margin: The negative opinion.] can by no means be inferred — since experience teaches that the depth of wells, ditches, and the foundations of any structure is always greater than the [height of the] earth heaped up round about into mounds. For in order that the heaped-up earth might equal the depth of some well, one would have to pile up the earth into the form of a cylinder, in exactly the same figure as the well had; and thus the earth heaped on high, being equal to the earth contained in the well, the depth would necessarily correspond to the height. But if you heap the said earth into a cone, you will never reach a height equal to the depth of the well — and the reason is that the parts of earth, since they cannot stay together at the vertex of a cone, run down by perpetual flux into the base and increase it by just as much as the separated heap of earthy material had departed from the vertex. And so in this way the height of earthen cones will never correspond to the depth of the ditches from which they were heaped up. Since, then, we see that mountains are heaped up for the most part not in the form of cylinders but of cones, it is certain that they are much lower than the

channel [bed] of the sea — granting always that the mountains arose from the excavation of the channels, as the above-named authors suppose.

Kircher's own view. But that I may here also set down my own opinion concerning the constitution of mountains: [Margin: The Author's opinion.] I say first, that just as the divine Wisdom has disposed nothing rashly or in a disorderly way in the nature of things, so it established the mountains too, and the Ocean, toward the loftiest and incomprehensible ends — ends hidden, as it were, in the divine Idea — with such providence that there should not be even the least slope which did not have its own uses: both universal ones, in the preservation of the Geocosm, and particular ones in some [given] region.

I say second, that since nothing is so necessary to the Geocosm as a fit distribution of mountains, it is plain that they were established in a certain order, according to the requirement of each region: for from these the whole mass of the earth draws sufficient nourishment, as it were from the breasts of a great mother. Whence I infer that the height of the mountains has nothing to do with [Margin: The height of mountains, or the depth of the Ocean, [need not] correspond to the height of the mountains.] the depth of the sea; nor did the mountains arise from the earthy clods of channels rashly heaped up in the primordial separation of the waters. Rather, as soon as the divine voice sounded forth — *"Let the waters be gathered into one place, that the dry land may appear,"* etc. — straightway also the whole mass of the Earth, according to the law prescribed in the archetype, was arranged into mountains and depressed into channels suited to the Ocean, the seas, the lakes, and the rivers — in a word, [it was disposed by] all [the efficacy] of the Author. [Margin: The efficacy of the divine wisdom and power in fashioning the structure of the world's mountains.]

The organs of the Geocosm, and the workshops of the interior Divine Economy — its storehouses [penuaria], its siphons, its furnaces — were established with exactly that perfection in which we behold them persevering to this very day. For the infinite Wisdom of God is not to be supposed to have founded the Geocosm after the human manner, so as first to dig out channels and then heap the excavated earth rashly into mountains — by no means. Rather, at God's voice, in a moment

all things, both as a whole and singly, came into being furnished with the necessary supports, according to the prototype of the eternal Mind. And that this is true, the constitution of nearly all mountains plainly teaches: for even the highest mountains — such as the Alps, the Pyrenees, the Acroceraunia [Acroceraunian Mountains], the range of the Caucasus and of Imaus [the Imaus /

Himalaya], extending over immense tracts of land — have obtained their God-appointed seat not on the shores of the Ocean, but in the Mediterranean [inland] regions of continents or islands, sundered from the Ocean by a long stretch of land. Most false, therefore, is the doctrine of those who would have the height of the mountains be as great as the depth of the sea.

The sea floor is as uneven as the land. For just as the earthy mass consists in its own unevenness, roughened with mountains and valleys, so too does the floor of the sea. [Margin: The floor of the sea is as uneven as the surface of the Earth.] On the terrestrial surface there are great, small, and middling mountains, the very highest; there are valleys, meadows, woods, pastures, tamarisks: and all these same things exist on the floor of the sea, roughened with countless underwater crags. So you may think that islands are nothing else than underwater mountains of enormous height, [Margin: Underwater mountains.] emerging with their summit alone beyond the Ocean and the seas — yet whose roots and fringes, stretched far and wide across immense tracts of underwater regions, you would then first see, if by divine power, with the waters dried up, they should disclose themselves to view. That there are underwater forests, the Red Sea sufficiently and more than sufficiently teaches, [Margin: Underwater forests.] from whose floor a great abundance of coral trees — scarcely yielding to our cherry-tree [in size] — is from time to time drawn up by fishermen, as I have more than once heard from the Arabs dwelling on the shores of the Red Sea; indeed, they sometimes grow to so great a height that they raise their branches [cornua] beyond the very surface of the deep, not without hindrance and danger to ships — and that not in some one place, or over some small tract, but in many places of the said sea, and over tracts extending for several miles, such underwater forests are found.

Now forests of this kind of coral are found not only in the Erythraean [Red] Sea, but in several others — as in the Sicilian sea near Drepanum [Trapani]; in the Gallic [sea] near Toulon [Tolonem], and on the other shores of the Ligurian sea; and in the Ocean, indeed, in countless places, which for brevity's sake I omit. [Margin: Underwater meadows.] That underwater or submarine meadows also exist, experience has sufficiently and more than sufficiently taught those who travel back and forth between Spain and Portugal and America; where the whole surface of the sea blooms with a submarine herb — which they call *Sargasso* — for the space of many days' [voyage], just as in some most delightful meadow: a herb that cannot keep its place, driven this way and that by the perpetual motion of the sea; the cause of which we shall disclose elsewhere. That there are also meadows luxuriant with submarine flowers, the coast of the New Kingdom

[Nuevo Reino de Granada] clearly demonstrates: [Margin: Submarine flowers.] [flowers] which, plucked by divers from the floor of the sea, as soon as they come up into the air, take on, as it were, the nature of crystalline stone, perfectly expressing the form of flowers — which the Fathers of our Society [the Jesuits] generally employ in adorning the altars of the College of Cartagena: a remarkable work of nature, and unseen in Europe. Submarine [growths] too, of seaweeds of various kinds among pleasant green plots, are lacking to no sea. And not far from Malta [Melita] there is a tract of sea which they call the *Praterias* [the "Meadows"], [Margin: Submarine meadows not far from Malta.] especially renowned for fishing, where, over a great expanse, as on the plateau of some mountain, a meadow remarkable for its greenness and pleasantness — not without the delight of beholders — spreads itself out beneath the waters, hidden about 20 palms deep; in which countless shoals of fish, stabling as it were in a field of full beauty, take their delight, not without great profit to the fishermen. If anyone inspect the boundaries of this meadow more closely, he will see that the sea, beyond the limits of the greenery, is suffused with a certain dark color — either because of its remarkable depth, or because of the very high precipices of crags that bound the meadow. But since we shall treat of these prodigies of nature expressly in their own place, I do not pursue the subject, since it suffices us [to have shown] that the floor of the sea, no less than the land, is rough, uneven, scabrous, filled with mountains, valleys, or impenetrable abysses; and that it abounds also in springs and rivers, [Margin: Submarine springs and rivers.] as was demonstrated in the *Prodromus Subterraneus [Iter Exstaticum / Prodromus]* — so that anyone explores the height of mountains from the depth of the sea with fruitless labor.

This, however, I do say: that just as in the inmost recesses of the terrestrial continents the highest mountains are seen to be heaped up, so in the middle of the Ocean a greater depth is always found, but toward the more level shores an ever lesser and lesser depth. I said "toward the more level shores," because where shores are girt with huge crags, there too a greater depth than at more level shores is found — nothing other than experience itself teaches this, on the rocky shores of Norway, Iceland, the Flemish Islands [Azores? / Flemish Islands], and countless others.

[See the figure description below.] See, in the following figure, a terrestrial mountain whose roots, slipped in at B and C, are carried beneath the waters to D; where it rises again with new crags D, E, and from there is carried on to F, the highest depth of the sea, or abyss; from there, ascending again upward and emerging beyond the surface of the sea, it forms the island G, which is then again

connected with still other crags of submarine mountains; and in this way the whole floor of the Ocean is constituted with a wondrous and incredible unevenness. Submarine plains, however, are reckoned to exist chiefly there where the Ocean or sea is seen to be destitute of all traces of islands — just as plains [are] among valleys; as is shown at I.

Diagram. A wide landscape-format woodcut spanning the column-width at the top of the page, depicting a cross-section profile of land and sea floor to illustrate the unevenness of the submarine terrain described in the text. At the left, a terrestrial mountain mass rises above a horizontal water line; its base descends below the water into a series of jagged underwater peaks and deep troughs (the "abyss"), then rises again to form a small island near the right, before connecting to further submarine crags. The lower portion is filled with horizontal hatching representing the body of water; the sea floor is drawn as an irregular, serrated profile line. The lettered points correspond to those named in the text.

- A (upper left, on the terrestrial mountain): label A
- B (left, at the mountain's base near the waterline): label B
- C (left of center, at the base, descending below water): label C
- D (lower left of center, a deep underwater trough/crag): label D
- E (center, an underwater crag): label E
- F (lower center, the deepest trough — "summa maris profunditas sive abyssus," the highest depth of the sea or abyss): label F
- G (right of center, the emergent island above the waterline): label G
- I (right, on a submarine plain region): label I

Conclusion of Caput XIV. [Margin: Submarine meadows.] [Margin: Submarine springs and rivers.] From the things adduced it is plain how greatly those are mistaken who think that the depth of the sea is everywhere either equal, or [who] suppose that its precise depth can be determined; for that is just as difficult as [to determine] the heights of the mountains diffused over the whole surface of the Earth

by a sure method. So that this [verse] seems to fit here: "*Who has measured the height of the heavens, the breadth of the Earth, the depth of the Sea?*" [cf. Sirach 1:3 / Ecclesiasticus]

CAPUT XV.

De Inæqualitate fundi maris, cui jungitur Historia memorabilis
supradicta confirmans.

**(On the Unevenness of the Sea Floor, to which is joined a Memorable History
confirming what has been said above.)**

I shall add in this place a History which happened in Sicily in the time of King Frederick [Frederick II of Sicily / of Aragon], by which the things hitherto said concerning the unevenness of the sea floor are confirmed. [Margin: A history of Pescecola, a Sicilian diver.] There was in Sicily at that time a certain diver, most renowned for his fame, Nicholas by name, whom from his skill in swimming the common people called *Pescecola* — that is, they named him "Nicholas the fish." From boyhood accustomed to the sea, and excelling in skill at swimming, he occupied himself almost solely with gathering oysters, corals, and the like on the sea floor, by the sale of which he afterward earned his living. And he was so taken with this commerce of the sea that, in his early years, he would linger in the sea for four or five days at a stretch, sustaining his life on raw fish; he went and came repeatedly to Calabria by swimming, performing the office of a letter-carrier; he is said to have reached the Lipari Islands more than once by swimming; he was sometimes found by triremes in the midst of a swelling and stormy gulf of the sea, off the coast of Calabria — the sailors at first sight supposing him to be some marine monster; but, recognized by some, he was taken aboard the trireme. Being asked where he was bound in a sea tossed by so many storms, he answered that he was carrying letters, enclosed in a leather pouch and pulley skillfully fitted out — lest they should be spoiled by the surrounding moisture — to some city or other [coriacea bursa et trochlea]. At last, after long conversation, and being well fed, and bidding the sailors farewell, he finally committed himself once more to the sea. [Margin: A wondrous degeneration of the diver's nature.] They relate, moreover, that from his continual companionship with the waters the said Nicholas had so changed his nature and constitution that he was more like an amphibian than a man: a cartilage having grown between his fingers into the form of a goose's foot, necessary for swimming, and his lung so dilated that it could hold air sufficient for breathing for a whole day.

While, then, the King of Sicily was staying at Messina at a certain time, having heard incredible things commonly told about this diver, he was moved both by curiosity and by a desire of seeing the man, and wished him to present himself to

him; which, after he had long been sought for by land and sea, was at last done. The King had heard certain wondrous things told him about the nature of the nearby Charybdis; and so, having obtained so opportune an occasion, he resolved that the interior constitution of Charybdis should be explored — [Margin: The exploration of Charybdis.] which exploration, indeed, he thought could be done no better than through this Nicholas. So Nicholas was ordered to let himself down into the depths; and since he seemed somewhat reluctant to resist the King's command, on account of the extreme perils (and others known to him alone), the King, to render Nicholas more courageous for the execution of the work, ordered a golden cup to be thrown into that place, promising it should be his if he brought back what had been thrown in. Nicholas, allured by the gold and accepting the condition, soon hurled himself into the deepest whirlpools; where he remained for nearly three quarters of an hour, while the King and the bystanders awaited him with great longing. At last, cast back up with great force from the lowest floor of the vortex, brandishing the recovered cup in his hand in the manner of one triumphing, he was received within the palace, and, somewhat weakened by the excessive labor, and revived by a sumptuous meal, after he had indulged in sleep a little while, he came into the King's presence; and, being questioned about all that he had discovered on the floor [of the sea], he is said to have addressed the King thus: [Margin: The diver's account to the King concerning the perilous state of Charybdis.] "Most clement King, what you commanded I have carried out; I would never have obeyed your commands, had I first known what I have found out — not even for the half of your kingdom promised me: I committed a great rashness, while I deemed it rashness not to obey the King's command." And when the King asked the cause of [his calling it] rashness, he replied: "Know, O King, that there are four things which make this place — I will not say to me and to divers like me, but even to the very fish — impenetrable, [and] too greatly to be feared:

[Continuation of CAPUT XV — the four dangers the diver enumerated, the diver's death, and the close of the chapter.]

[Margin: Vortices terrible within.]

make it so. First, the violent rush of a river boiling up out of the deepest abysses of the sea — a force that a man can scarcely resist, however great his strength and power. I myself could not overcome it, and so I had to descend into the depths by other byways. Second, the multitude of rocks one meets everywhere, whose bottoms I have barely reached without manifest danger to my life and of having my skin torn off. Third, the channels [Euripi], or surges of subterranean

waters, which roll themselves out with enormous force from the innermost bowels of the rocks, and whose contrary flux drives whirlpools so formidable that they can kill a man stunned by sheer terror alone.

[Margin: Enormous octopuses.]

Fourth, the herds of huge octopuses [Polypi], which cling to the sides of the rocks and, with their tentacles stretched out far and wide, struck the greatest horror into me. One of these — if you look at the body's bulk — I saw to be greater than the size of a man; and its tentacles were no less than ten feet [decempeda] in length. Had they gripped me with these, they would have dragged me to themselves in inescapable danger of death and killed me with their embrace alone.

[Margin: Sea-dogs.]

There also lodge, in the nearby lairs of the rocks, fish monstrous in their ferocity, which they call "dogs" [Canes], commonly *pesce Cane*. These have jaws furnished with a triple row of teeth, and in the bulk of their bodies are by no means inferior to dolphins. From their savagery no one can be safe; for whomever they have seized with their teeth, you may hold it for certain that he is finished — since no daggers [machærae], no scimitars [acinaces], can be furnished with so great and so keen an edge as these sea-monsters fail to surpass with the sharpness of their teeth in cutting through whatever you please.

When these things had been set out in order, he was asked how he had managed to find the cast-in cup so quickly. He answered that the cup, owing to the violent flux and reflux of the waters, had by no means descended straight down to the bottom; rather, it had at once been thrown back by the force of the waters — much in the manner, he said, in which he himself was thrown back — and he had found it inside a certain hollow in the rock. Had it descended to the very bottom, it could not have happened that any hope of finding it would have remained, amid so great a boiling of the surges and so violent an onset of the whirlwinds.

[Margin: Channels.]

For the channels [Euripi], by which the subterranean water is now swallowed into the inner depths and now disgorged back again, are stirred with such great turmoil that there is no force which can resist them. He added that the sea in that same place is so deep that it confounds the eyes with an almost Cimmerian darkness. He was also asked about the disposition of the inner part of the strait. He answered that the whole of it is entangled with innumerable rocks, from

whose roots the flux and reflux of the subterranean waters running between them produces — according to the variation of the time — those disturbances at the surface which sailors experience at great peril to their ships.

[Margin: Surges of the subterranean waters violent.]

He was further asked whether he had the heart [animus] to attempt once again the bottom of this Charybdis. He answered: no. Yet, overcome a second time by a purse full of gold coins — with a cup of great value attached and thrown into Charybdis — and enticed by an accursed hunger for gold, he gave himself a second time, headlong, into the gulf. But he never appeared again, perhaps carried off by the force of the channels into the labyrinths of the mountains, or made prey to the very fish he had feared.

I have thought it well to set down here this history — just as it was recorded in the royal records, and communicated to me by the Secretary of the Archive — so that the eddying tracts of the seas might appear more plainly.

[Margin: The author died in the year 1638.]

[The right-hand margin carries several lines of handwritten (manuscript) annotation in a later cursive hand, partly legible: "...plus / ...Alm. Magn... / Gerual. Diary [?] / ...pag. 90 [?] / ...Mart. Ding Canicula [?] / tom. X. colleg. 9. pag. 139". These are a reader's reference jottings, not part of the printed text.]

CAPUT XVI.

Measurement of the Sicilian Strait, made by the Author in the year 1638.

Having long observed the turbulent state of this Mamertine Strait — both from my own experience and from my reading of the historians — and being at that same time on my way back to Italy, waiting near the Pharos for an opportune moment in the course of three days, I did not want to let so notable an occasion for exploring the strait slip away. So I hired sailors skilled in the nature of the place and entered the strait, equipped with a great coil of line for use as a sounding lead [bolis].

[Margin: Unevenness of the bottom of the Sicilian Strait.]

First, at the point where the strait is narrowest — between the bank of Pelorus at the Pharos and the Calabrian promontory called Scyllaeum — I found by geometric measurement that the breadth is 2,783 geometric paces [passuum

Geometricorum]. This done, I steered the boat in a straight line across, undeflected, from the Pharos continuously up to the said promontory, and by continually casting the sounding lead I explored the depth of the sea. In some places I found a bottom now of 30, now of 50, 60, then 100, and again 200 feet; in some places, as it were, certain sheer rocks [scopulos praeruptos]; but — astonishing to say — in others I found the whole bottom of this breadth to be rocky, and a certain ridge running across like a bridge from Calabria into Sicily, with the bottom on either side sinking away into the abyss.

[Margin: Sicily was once joined to Calabria.]

This gave no obscure evidence that Sicily was once joined to Calabria by this rocky tract; and that from time immemorial — whether by an earthquake or by the violence of the Tyrrhenian sea — this Isthmus had been broken apart and had degenerated into a strait, thus turning the peninsula Trinacria into an island. But since I have described this expedition in the *Ars Magnetica* [Kircher, *Ars Magnetica*], I have decided to add here only those things worthy of note which I omitted there.

Three things, therefore, I labored above all to explore with the utmost zeal — the strange effects of which, as we read, have grievously vexed all the greatest philosophers in the assigning of their true cause. The first was the surge of Scylla; the second, Charybdis; the third, the inconstant, varied, and reciprocal motion of the strait —

— whose causes, if (as I hope) I shall have assigned them, I shall certainly have accomplished what in every age has been singularly desired by every philosopher without exception.

First, then, with the utmost zeal I explored the courses of the surging sea — entirely varied: straight, sloping, contrary, and colliding with one another in a kind of perpetual struggle. Moreover, I found that whole stretch of sea between Scylla and Charybdis, nearly five miles in extent, to be most seething, unfathomable by any sounding lead however long, and formidable with its whirlpools.

[Margin: The surge of the strait varied and formidable.]

There, where waves meet contrary waves, they raise savage whirlwinds: now the strait rushes off into a chasm, now — with the force and crash of colliding waves rebounding from the surface of the sea — they produce a vast gulf and an immense whirlpool. By these inundations, in a marvelous way, ships and

whatever else meets them are dragged through gyres and contrary courses — swallowed by the internal force of the spirit — down into the deepest subterranean burrows of the gulf; these reappear, regurgitated, on the Tauromenian shore, by the testimony not only of Sallust [Sallustius] and Strabo [Strabo], but also of the observation of the people of Tauromenium [Taormina].

[Margin: The surge of the strait follows the motion of the Moon.]

And these savage and merciless squalls do not always (as I learned while staying at Messina for the space of a month, on purpose) play out their scenes of ferocity, but most of all when winds — partly from the Ionian, partly from the Tyrrhenian sea — lash the jaws of the narrow strait with contrary waves. At other times, even though as to the surface it may seem calm, it nevertheless by no means ceases from the customary tumults of its inner workings. Rather, it so regulates its flux to the ascent and descent of the Moon that the sailors themselves, accustomed to this strait from boyhood, can predict the behavior of the currents even at the first aspect of the Moon. And when the Moon is hidden by clouds, they recognize its station in the heavens from the flow of the currents — all of which things I found out, to my great wonder and admiration.

Hence this strait, once notorious for shipwrecks, is now crossed as easily as any other, thanks to the skill of these sailors, who are accustomed to steer ships through various windings without any danger — so that, the contrary currents having been avoided, they take advantage of a neighboring one running straight on, until at last they reach their destination. But if anyone, neglecting the guidance of these sailors, enters the strait too rashly, then — as surely as they do not know the hidden reasons of the currents — so too they expose themselves to manifest danger of shipwreck, unless they are quickly freed from the peril by the helping hand of the guides.

[Margin: The force of the contrary surges in holding ships fast.]

There is, in an elevated spot, a house of the Novitiate of our Order [the Society of Jesus] at Messina, from which the whole length of the strait lies open to view. From this I afterwards observed, not without admiration, that even very large freighters [naves ... praegrandes & onerarias], with their sails spread, clung fast for many hours to all their anchors, as if held fixed by cables fastened to beams — yet soon, when the currents changed and by the skill of the guides, they got free and continued the course they had begun.

But to return to the subject we proposed: in the first place, just past the jaws of the strait, there occurs that famous Scylla, of which Virgil [Vergil] writes:

[Margin: Charybdis.]

Scylla guards the right side, implacable Charybdis the left: three times she gulps the vast floods sheer down into the gulf of her chasm, and again hurls them up by turns, and lashes the stars with the wave. (*Virgil, Aeneid III*)

The monuments of all historians and poets are full of the voracity of its hidden nature, entangled with countless fables. If anyone wishes to see these, let him consult Cluverius [Philipp Clüver], *Sicilia Antiqua* I.1, fol. 64. It is not my intention to cite the things of others, but to bring forward the things we have learned by our own experience.

[Margin: Scylla — its surge and properties.]

Scylla, then, lies next to the promontory which was once called Cenys, now Scyllaeum, commonly *Sciglio*. Its nature is such that it is stirred by an immense disturbance of the waters coming and going both ways. When it is agitated by the influx, its violence is so great that a ship entrusted to it, with every hope of escape taken away, is dashed against the walls of the mountains and committed to inevitable shipwreck. Yet it becomes somewhat gentler when the surge has driven it back in the reflux toward the eastern [Ortivam] quarter of the strait. But unless the dangers are properly guarded against, and the turning-points of the flux not observed in good time, it happens from time to time that those who have been swept from the quicksands of Scylla into the eddies of Charybdis find — only then — the very danger they had fled; and so this verse aptly fits them:

He seeks the caverns of Charybdis who wishes to escape Scylla.

And conversely:

He falls into Scylla who wishes to avoid Charybdis.

I said that this Scyllaeon ferocity does not always slacken its reins, but does so at certain blasts of the winds, as will be shown later. So, in order that the reciprocal surges of so prodigious a sea may at last be settled by physical reasoning, I say first that Scylla is nothing else than a subterranean whirlpool [voraginem], continued through hidden meanders into the Tyrrhenian sea, or into some other one. How, then, this approach and recess of the waters occurs must be explained.

[Margin: The cause of the flux and reflux of Scylla.]

It was observed — both by me with the utmost diligence, and by the sailors as confirmed — that in the gulf of Cujatium [?], at the Vatican promontory, within

the hollow of the bay, both on individual days and especially when the east wind [Subsolanus] blows, and most of all when Scylla undergoes its influx, the signs of an almost maximal boiling sea are to be seen. But at the defluxion of Scylla, when the west-by-south wind [Eurus, here "occiduus"] prevails, that water too is stirred as if into certain eddies and whirlwinds. As these things are established by daily experience, so too they point out, as if with a finger, the cause of the flux and reflux of Scylla.

Note, then, that both the Tyrrhenian sea and the Mamertine — that is, Scyllaeen — strait are stirred by a twofold motion: one through the influx entering by the Straits of Gibraltar [fauces ... Gaditanas], by which the inner sea, pressed by an immense mass of water, communicates its impetus to all the other bays and straits —

— that meet it. Hence the bays of the sea, and especially this strait of ours, acquire their greatest increase. But when the Ocean ebbs, then in the same proportion by which the inner sea had previously risen in its bays and straits, it decreases in ebbing — this is also called the "drawing-back" [attractus]. And this motion, as it depends upon the Moon (as will be said in its place), so it also lasts with a stable and perpetual flux and reflux twice by day and by night.

The second motion of the inner sea is ascribed to the winds, and to the dashing of the wind-driven waters against the opposing tracts of land. This motion, being by its own nature unstable and subject to the caprice of the winds, accordingly occurs only at uncertain and indeterminate times.

[Margin: Description of the flux and reflux of Scylla.]

With these things presupposed, let us now begin with Scylla. By perennial experience it undergoes its influx and refluxes on individual days, which happen in this way. As the hidden force of the urging Moon insinuates itself into the Ocean, within the Mediterranean sea, through the Straits of Gibraltar, suddenly that whole length of the sea, stretched out from west to east, driven by the impetus of the Ocean, dashes itself — with a great mass of water, as if in formed battle-line — against the bay of Cujatium [?] directly opposite there. But since in this bay (as experience teaches), at Scylla, the subterranean passage C B has its mouth B, assigned to it by nature in the bottom or side of the inmost sea, it comes about that the bay's narrows, pressed by the great mass of water, find an occasion of escape and flight through the said channel, and so prepare an exit for themselves through Scylla.

Hence Scylla, pressed by the mass of the following waters, directs its flux eastward [in ortum] toward Charybdis D. But when the Ocean ebbs, and thus draws the mass of the inner sea's waters along with it, then the flux of Scylla, by a contrary motion, hides itself within its accustomed whirlpool beneath the Scyllaeen rock, and the water withdrawing from the bay of Cujatium [?] takes its place. This is the cause of the perennial daily motion of the flux and reflux of Scylla; hence sailors, observing the Moon, know by an infallible sign the time of flux and reflux.

[Margin: The danger that here threatens ships.]

And this motion of Scylla is the gentler, the more constant is the recess and access of the sea depending on the Ocean. But where the western winds have roused the sea more violently, then too the passage of Scylla is exacerbated by storms of waves in the bay of Cujatium [?], and stirs up in the Scyllaeen outlet those waves which sailors experience to their great peril. For then the same Tyrrhenian sea, being agitated, not only insinuates itself through the hidden inlets, but also — with open warfare [manifesto Marte] — through the jaws of the strait; and when it dashes more violently against the curved shore of the strait, and is stirred into circles by the reflected course coming from the blasts of the east wind [Subsolanus] on the opposite side, it drives — as if in a joined battle — horrible whirlwinds and motions together with the Scyllaeen flux. This struggle of nature lasts as long as the fury of the winds is found to last; but when the west and east winds are at rest —

Diagram. A large engraved map-plate occupying the lower half of the page, depicting the Strait of Messina (the "Mamertine Strait") with Sicily at the lower left and Calabria at the lower right, shown in oblique relief with mountain ranges. A compass rose with a directional arrow sits at the lower left. The cartouche at the lower right carries the caption.

Labels read on the plate (positions approximate):

- Caption cartouche (lower right): *Tabula Freti Siculi Charybdis et Scyllae, aliorumque aestuum rationes explicans* [Map of the Sicilian Strait, explaining Charybdis and Scylla, and the workings of the other surges]
- Top center / upper band: *SICILIA*
- Upper right: *Mare Thyrrenum sive Siculum* [The Tyrrhenian or Sicilian Sea]
- Upper right (coast): *Mylae* [Milazzo]
- Right (coast): *Pelorum Promont.* [Cape Peloro / Punta del Faro]
- Left: *Syrophœnia* (with a wind-head blowing — a personified wind)

- Left coast: *Mare Africanum* [The African Sea]; below it *Os Canis ex mari Sico* [the "Dog's Mouth" from the Sicilian sea]
- Center: *Messana* [Messina], shown with buildings
- Center channel: *Canalis subterraneus in Charybdis* [Subterranean channel into Charybdis]
- Lower-left mountain: *Promont. Pachynum* [Cape Pachynus / Capo Passero]
- Center-lower: *Canalis ex [A]Etna* [Channel from Etna] (with *Aetna* labelled on a peak, point *M*)
- Center-right (coast of strait): *Charybdis*; nearby *Charybdis Tauromenia*
- Right-center: *Pelorum Promont.* [Cape Peloro / Punta del Faro]
- Right: *Scylla*; with point letters *C, B, E, D* marked near the Scyllaeian shore (matching the C-B passage and point D of the text)
- Right edge: *Claucus Sin.* [= Glaucus Sinus, the Gulf of Glaucus], point *A* (the bay called "Cujatium" in the text)
- Across the lower water: *FRETVM MAMERTINVM* [The Mamertine Strait]
- Lower right (Calabrian coast): *Regium / Rheggio* [Reggio di Calabria]
- Lower band: *CALABRIA*
- Geometric construction points lettered *M, N, A, B, C, D, E* distributed across the channel, keying the subterranean-channel argument of the text.

— at rest, the sea still seethes with whirlwinds and storms. From this it is plain why, when the strait is roused, such great dangers threaten sailors.

This is certain: near the Scyllaeian cavern I have found a bottom unfathomable by any sounding lead. The cause of this, however, I have judged should be ascribed not so much to an abyss as to the flux of the violent water that drags the lead along with it into the hollows of the mountain — which both the resistance of the lead and its persistent leaning toward Scylla seemed sufficiently and more than sufficiently to indicate.

Here, reader, you have the account of the flux and reflux of Scylla. If anyone disapproves of it, let him assign a better one — to which we promise not unwillingly to subscribe — we who here set forth the things we have learned by irrefragable experience.

[Margin: Description of Charybdis.]

Now follows the nature of Charybdis to be explained. Charybdis — which is nothing else than an absorption of the sea — exists in that part of the curving shore of the harbor by which Rhegium [Reggio] is reached, distant only 20 paces

from the part of the Mamertine harbor that faces Calabria. This I crossed twice, by the diligence of the ferryman and on the occasion of an opportune moment. Its nature is such that now, as if a pot set over a fire, it boils perpetually; now it drives whirlpools stirred as if by whirlwinds — which are the more dangerous to sailors the less the boilings expose them to danger; for you may pass over a boiling shoal [Syrтим] with impunity, but not so when it is stirred with whirlpools.

[Margin: When Charybdis rages most.]

It was observed by the long experience of sailors that Charybdis boils most of all when the Syro-Phoenician wind [Syrophoenix], commonly *Scirocco*, dominates the strait. Yet this wind too, according to the common law of the flux and reflux of the strait, also gives daily its not-obscure signs now of regurgitation, now of absorption; but it rages most, as we said, when the Syro-Phoenician blows, and indeed with such a fury of the waters that it seems to belch up deluges of water in the form of a column. The cause of this matter, therefore, is asked.

I am not unaware that many have attributed so unusual an effect to contrary surges of the strait meeting each other, by whose collision the waters, heaped up, are raised on high — as happens in not a few seas. But if this were so, why is there always at one and the same place a sea-boiling of this kind? Why not in any other quarter of the strait? — since, with winds contrary to one another, the sea could cause such an accumulation in any place, as also happens in seas situated at the great mouths of rivers, where, when the winds' blasts check the river's flow, that turbulent and tumultuous struggle is born by which the masses of water, agitated by diverse motions, are raised on high in the manner of a column, to the great peril of ships. And it is well known from frequent experience in the French sea, in the region of the mouth of the river Rhône [Rhodani], which they commonly call *Golfo de Lione* [Gulf of Lion] — so much the more dangerous, the more impetuous the southern winds and the swifter the flow of the Rhône.

Why, I ask, do the failing boilings in the same place soon give way to whirlpools and whirlwinds? You will perhaps say that whirlpools of this kind are made by the mass of subsiding, heaped-up waters. But neither can this be said, since the whirlpools of Charybdis are of such a nature that whatever is cast into them, after many circuits, is at last snatched down toward the center near the bottom, and in far-distant bays —

— is at last vomited out through a subterranean regurgitation. Nature, therefore, uses other instruments for producing effects of this strange kind, and to explain them:

[Margin: Charybdis is a whirlpool.]

I should like you to note that this Charybdis is nothing else than a huge whirlpool or abyss, by which — through the blind bowels of the Earth, as through the vast siphons of the Globe — that mass of water, boiling up, is at a certain time regurgitated. When the cause of the regurgitation ceases, the receding water must necessarily be absorbed again, as if by a kind of drawing-back; and this absorption of the waters is necessarily followed by a whirlpool. It happens, moreover, in this manner.

[Margin: The cause of Charybdis's turmoil.]

It is certain — and proved by almost daily experience, both in the strait and throughout the whole Island — that Sicily is entirely cavernous, so that through hidden subterranean channels the seas play together with one another by a reciprocal commerce of waters. Just as, then, we showed to happen in the surge of Scylla, by the same reasoning we shall here prove that Charybdis rolls out its surges. The whirlpool of Charybdis undoubtedly has its outlet somewhere, through some subterranean passage N M, in the eastern sea — whether this be near Tauromenium [Taormina], as most think, from things cast into Charybdis which afterwards emerged here. For Lucan [Lucanus] mentions a Charybdis of Tauromenium, in *Pharsalia* IV [Lucan, *Pharsalia* IV], in this verse:

Fleeing the destructive Charybdis of Tauromenium.

And in IV.14 [?]:

They behold the Charybdis of Tauromenium from its seat.

These are to be understood not of the Charybdis of the Sicilian strait, but of the Charybdis of that place — namely, on the eastern side of Sicily between the promontories Pachynus [Capo Passero] and Lilybaeum [Capo Boeo / Marsala]. For it has been observed that when the east wind [Subsolanus] or the Syro-Phoenician [Scirocco] blows, then for the first time Charybdis exercises its fury. Therefore, with the sea swelling from the blasts rushing in from the eastern quarter, it happens that the roused sea, pressed by a great mass of water, insinuates itself with great force into the said passage; and then — wave thrusting wave, and the reverberation of the rocky shores aggravating the mass of water —

it at last discharges, through the whirlpool of Charybdis, with that surge which they experience under the said wind.

[Margin: Tauromenian Charybdis.]

Since this whirlpool (as the above-cited *Cola Pesce*, taught by experience, reported) is situated among the depths of the surrounding rocks, it happens too that the mass of expelled waters tends straight upward, and so rises up at the sea's surface in the form of a mound [clivi]. But when the Syro-Phoenician ceases, then too the mass of waters by which Charybdis was burdened soon subsides and hides itself within its whirlpool; and through that same channel M N by which the heap of waves had been rolled out — now restored to its eastern tranquility — the sea is given back its calm. Hence, as the waters recede through the whirlpool, an eddy must necessarily be formed.

From this it is plain that the Mamertine Charybdis D then boils up when the Tauromenian one, P, agitated by whirlpools, absorbs —

boils up. [Margin: The Mamertine Charybdis communicates with the Tauromenian.] Conversely, the Mamertine Charybdis [at Messina] then sets its whirlpools in motion when the Tauromenian one [at Taormina] is stirred by its boilings. And so, by an alternating law of reciprocity, the two carry on the mutual exchanges of their hidden mechanism. As for why the Tauromenian Charybdis is less perceptible, the cause lies in the configuration of the place and of the chasm: it does not vomit out its waters straight up, as the Mamertine one does, but along a sloping channel. [Margin: Etna communicates with the Charybdis through subterranean channels.] There is also the fact that hidden channels drawn from Etna feed into the channel of the Charybdis, and these, charged with fiery vapors and seeking an outlet there, stir the sea with dreadful storms.

As for why the Charybdis also appears to boil up and subside somewhat with the daily tide, I judge this is to be assigned to the flux and reflux of the strait, in much the same way I spoke of Scylla above. For just as the swelling of the sea under the Moon's pressure causes the Charybdis to boil up, so its ebbing causes the Charybdis to suck back in.

It remains, then, to set out the many currents of this strait. For—as is established not only by my own experiment but also by the trial of Pisecola [Piscecola], mentioned above—the floor of this strait is thoroughly rocky and is constantly agitated by vast surges that pass through hidden chasms; and these surges can come from nowhere else than the subterranean channels, drawn partly from the various seas that surround the island and partly from Etna. Since, therefore, the

surrounding sea never exists without the agitation of winds, this strait too always suffers, now in this part and now in that, its own reciprocal surges of the waves, according to the winds blowing in different quarters: now with the waves receding on one side, now advancing on the other, now all rushing together at once—at which times the strait rages most violently.

[Margin: All Sicily is honeycombed with caverns.] That Sicily is full of caverns and pierced through with countless channels is most clearly evident from this: that Etna has its channels spread out through the whole island, and first of all into the Lipari Islands, so that when Etna undergoes its usual eruptions, Strongylus [Stromboli] too suffers its own at the same time, as if by a kind of sympathy. The sulfurous exhalations and the streams of water dispersed through the island likewise then carry out their operations more effectively—which would not happen unless there were a passage to them through the subterranean dealings of Vulcan. But how the burrows that carry fire are distinguished from those that carry water will be explained more fully a little later. And these are the things I judged needed to be said about the Sicilian Strait.

CAPUT XVII.

On the Magnetic Constitution of the Earth, or On the Bony Framework of the Earth [De Magnetica Telluris constitutione sive de Ossatura Telluris].

Just as the work of Nature is the work of an Intelligence, so it cannot be that all things coalesced in a tumultuous and merely random fashion. On the contrary, that all things were arranged from the beginning in the highest order, with distinction and an apportioning of parts—only the man who has never weighed the marvelous play of divine wisdom in the world of the Earth could fail to know this. Divine providence therefore disposed the Earth, or Geocosm, in such an order and position that—since it was to be, as it were, the foundation and final end of all created nature, into which, as into the lap and passive principle of the whole of nature, all the remaining bodies of the world above would pour out their seeds and the energies of their powers—surely of itself and by its own nature it seemed to require rest, stripped of every power of locomotion. For in this way it was the better made subject to the powers of the surrounding stars and impregnated by the mixtures of the seminal principles.

[Margin: The marvelous constitution of the Geocosm.] Now one may rightly ask: by what means, or by what power, is it held fast beneath this immense steadfastness of immobility? Is it balanced by the unfailing equilibrium of its own gravity, or is it held by some superadded power thrown over it like a bridle, so that with utterly imperturbable constancy it forever faces the same quarters? [Margin: By what power the Earth is held immobile in the center.] A simpler antiquity placed the immobility of the Earth in the mere weight of its native gravity alone. Later generations, taught better by the experience of things and probing more deeply, added to gravity a force that holds the Earth in its place with a certain unbending stability—a force they call magnetic. Now, in order to show just how all this is accomplished, it has seemed good to begin a little higher up.

I therefore lay down, first, that the Earth has been so constituted by divine providence (as was said above) that it is naturally borne by an innate and intrinsic appetite toward the heavenly regions as toward the limits of its rest. But since no thing is borne by an inborn appetite toward another unless there is in that toward which it is borne something that affects it well and by whose good it is fostered, surely the Earth would by no means be borne toward the surrounding regions of the world with such unbending constancy unless there were present in the corresponding heavenly regions some power that nourishes and benefits the Earth—whether that be the magnetic power itself, or something analogous to magnetic virtue, or some marvelous sympathy of the heavenly bodies, in accordance with which the Earth disposes itself with unremitting stability. For unless we admitted this power, or this sympathy of universal nature, there would be no reason why the poles of the Earth should face this part of the heaven rather than another. Therefore there must necessarily be granted some power in the heavenly bodies, analogous to the magnetic virtue with which the Earth is imbued, by which the Earth stands firm in its unshaken stability.

[Margin: What that fixing power of the Earth is.] Now, then, the question is: what is that corresponding power in the heavens to which the Earth accommodates itself? A bold undertaking of nature is here set before us,

for the exposition of which nothing less than a bold effort of intellect is required. Let us therefore unravel the mystery, if not with a bold effort, then at least with the effort that the weakness of our intellect allows.

It must be understood, then, that God, the Best and Greatest, by the ineffable disposition of His providence, has so ordered the heavenly bodies toward the immobile Earth in the fluid expanse of the world's atmosphere that—just as those

bodies perpetually wheel from rising to setting [from east to west], all and each by an imperturbable law performing their motions about the Earth within the span of a natural day—so each globe too, or astral body, observes this law: namely, that each of the heavenly bodies revolves about the Earth not with a confused spinning but with that constancy of motion whereby the poles of the individual globes, or astral bodies, correspond to the poles of the Earth by a certain perfect adaptation. [Margin: The axes of the heavenly bodies have a position parallel to the axis of the Earth.] This secret the keenness of the Lyncean observers of our day has disclosed. For we see all the heavenly bodies—the Sun, the Moon, and the rest of the stars—so adapted that the very circles and poles which we imagine for ourselves on the terrestrial globe we see expressed in each and every one of the globes of the stars, with only this difference intervening: that on the immobile Earth they are immobile, whereas on the stars, which are agitated about their own center, they are found to be mobile. But let us look at these matters more closely.

[Margin: The position of the solar globe corresponds to the position of the Earth.] On the solar globe there is the region of the equator and of the torrid zone, boiling with an ineffable surge of heat, exactly corresponding to and equidistant from our own equator and torrid zone—a unique seedbed of spots, which, being rotated together with the solar body about its own center and driven by a south-to-west [noto-zephyrian] motion toward our region [Greek: ἀνὰ λόγος (ana logos, "in proportion")] [?]. We find, moreover, that the points of the solar poles perfectly agree with our points, and that the solar axis is parallel to that of the Earth; nor has it ever been observed, to this day, that the solar body has deviated even in the least from so great a sympathy with the Geocosm—except for a certain nutation of its axis back and forth from the terrestrial poles, for particular ends intended by nature, which we set forth in our *Itinerarium Extaticum*, in the discourse *On the Journey to the Sun*, to which I refer the reader. We have, then, that the solar globe is adapted to the terrestrial globe by an unchangeable position of its parts. For if the solar globe were carried round in a confused spinning and were to change the poles, axis, and regions that match those of the Earth, it is certain that the symmetry of all things below and above would at once be destroyed, the laws of nature thrown into confusion.

[Margin: The adaptation of the lunar globe to the Earth.] But the lunar globe, being nearer to us, also demonstrates more perceptibly its adaptation of its body to the Earth. In it, if you set aside some nutation and oscillation, the whole symmetry of its axis, poles, and circles is found to square perfectly with that of the Earth; and it preserves the position of these parts by so constant a law that, as

a result, the Lyncean astronomers have divided the lunar globe, no differently from the terrestrial, into its circles, points, and axis, exactly corresponding to the terrestrial ones. Hence they have named the spots that occupy the middle region of the globe "equatorial," and those that lie under each pole on the globe—according to the pole's position—now southern polar, now northern polar. This adaptation of its individual parts, and the equidistance of its axis from the terrestrial axis, it preserves by so close a law of likeness that, whether the faces of the lunar phases are changed, or its ascent and descent in its circular path are altered in motion, it never falls away from the perfect adaptation of its axis to the terrestrial axis. Nor has it ever been heard, in any age, that the polar parts of the lunar globe have, with their seats changed, held the equatorial regions by a confused and disordered spinning of their motion.

[Margin: The globes of Venus, Mercury, Mars, Jupiter, and Saturn are adapted to the Earth.] The same must be said of the globes of Venus and Mercury; the same I would have you think of Mars, Jupiter, and Saturn. The clearest sign of this is found in the Jovial globe: that, being agitated about its own center, it always describes its belts—revealed by the optical tube [telescope] not long ago—parallel to the equator. This is a most luminous sign that the whole mass of the globe, together with its axis and the apparatus of the remaining lines conceived in it, being perfectly adapted to the terrestrial axis, perpetually and constantly strives to maintain a [Greek: παραλληλισμόν (parallēlismōn, "parallelism")] with the terrestrial globe by motions however much differing. That the same happens in the globe of Saturn, the attendants surrounding it sufficiently and more than sufficiently demonstrate. [Margin: The globes of the fixed stars are adapted to the Earth.] And what we have said of the planets must, by the same analogy, be thought of the fixed stars as well. But since we have treated of these and similar matters at length in the *Itinerarium Extaticum*, fol. 273, I refer the reader there; and so that the curious reader may see my meaning more luminously, I here append a figure.

Thus all the globular bodies of the world always hold a perfect south-northern position [noto-borean], that is, from south to north, in accordance with the position of the Geocosm; and this disposition, implanted in them by nature, is taught by any material globes whatsoever, constituted of whatever matter: if you let them run on a level surface, you will observe that they unfold their motion not with a confused and disordered spinning, but with their poles perpetually facing the same, and the same opposite, quarters. And so that this may be more luminously evident, let any two opposite places on the globe be marked with some color; and if you cast the globe, thus marked with its points, with its axis

parallel to the horizon, you will see the globe, by an unchanging law, continue its motion always with the position of its axis parallel to the horizon. Since, then, this happens in globes that are otherwise indifferent, when they are furnished with a symmetry of axis, poles, and lines, how much more shall we suppose this symmetry of parts toward the Earth to be present in those vast bodies of the world?

I conclude, therefore, first, that all the bodies of the world have a certain hidden property, which

we call directive, given them by nature, by which they are perpetually extended from south to north along their axis; for in this way they will the better conspire to preserve their union in the universe, [Margin: The final cause of this directive virtue.] and the more perfectly adapt themselves to the Earth, to be made fruitful by their influent rays, for whose sake they were created. For since they perpetually revolve about the immobile Earth from east to west,

Diagram. A large circular schematic titled *Magnetismus Globorum Astralium* ("The Magnetism of the Astral Globes"), oriented by the four cardinal points printed outside the rim. At the center is the terrestrial globe, with a vertical axis (pole-to-pole) running the full height of the figure. Arranged along this central axis and within a series of concentric rings are the planetary globes (marked by their astronomical glyphs), and the surrounding rings are studded with numerous small star-globes (each drawn as a tiny sphere with its own equator and axis-lines, all parallel to the Earth's axis), interspersed with asterisk symbols marking fixed stars. The arrangement illustrates Kircher's thesis that every celestial globe's axis lies parallel to the Earth's.

- (top, outside rim): **Septentrio** — "North"
- (bottom, outside rim): **Meridies** — "South"
- (left, outside rim): **Occasus** — "West"
- (right, outside rim): **Ortus** — "East"
- (upper region of central axis): ♄ — Saturn
- (mid-upper, central axis): ♃ — Jupiter
- (right of center): ♂ — Mars
- (left of center, near Earth): ☾ — Moon
- (lower region of central axis): planetary glyph [?] — a lower planet (Venus or Mercury) [?]
- (center): terrestrial globe (Earth), shown with surface features and axis

- (throughout the concentric rings): numerous small star-globes, each with equator and parallel axis-lines, alternating with asterisk (*) symbols marking fixed stars

certainly it seemed to be required by a kind of necessity of nature that the poles and axes of the individual upper globes should, step by step, correspond perfectly to the disposition and position of the terrestrial globe. For by the eternal providence of Divine Wisdom the motions of the heavenly globes are so constituted that, by a certain perfect symmetry of position and analogy of motions, they perpetually regard one another, and under this position—not under another—they foster, animate, and preserve one another. For if their position were changed by some random rolling and disordered spinning, then the bodies too, being as it were forced into a violent state, would withdraw from their operations—by which, with a certain reciprocal and inborn appetite for influence, they fostered one another—and would presently fail, lapsing into an unaccustomed and unsuitable position, together with the ruin and final destruction of the world that would follow. For just as, if the Earth, by Divine power, with its poles turned toward the Equator, were to be twisted away [from its position]... [the sentence breaks across the column]

the dictate of the Divine Archetype, by an unchangeable law established, demanded that, with the seats of their axes unchanged, they should describe their motions about the Earth by this their directive south-northern [Notoborean] faculty.

I conclude, secondly, that this directive

[Margin: The Notoborean magnetic virtue is common to all the bodies of the world, implanted in them from the first cradles of the world.] virtue is the Notoborean Magnetic virtue, and that it is common to all the bodies of the world, implanted in them by the first cradles of the world—being, namely, that without which they could not be preserved in a perfect adaptation of position, both to the rest of the stars and most especially to the Earth. For, with the starry globes wheeling through the empty spaces of the great expanse, nothing would be easier for them than, by a confused direction of their axis, to deflect now into this, now into that quarter of the ethereal path—unless they were held in check toward some determined aspect by this faculty as by a kind of bridle, or were moved under this position by a moving Intelligence according to the laws prescribed by the Author of nature.

COROLLARY I [Consectarium I].

Hence it is clear why the Earth extends itself, by its poles, in the Notoborean position by an inviolable law—so much so that, if for any cause its poles were moved from their native points, then at once, left to its own discretion, it would by natural force adapt itself to the position from which it had been drawn away. For under this position, and not under another, the heavenly bodies foster, strengthen, and animate one another by reciprocal influxes, ordained both for their own preservation and for that of the universe. The Earth, then, accommodates itself to the heavenly bodies under this position, because the heavenly bodies likewise have their parts extended under the same position; [Margin:...the adaptation of the globes to the Earth.] so that neither the Earth, nor the other heavenly bodies, could have a better position for performing the operations prescribed by nature. For under this position—the best in which they can be—they exist, in order that they may be that for which they are.

COROLLARY II [Consectarium II].

Hence it is also clear why nature willed the heavenly globes to be conformed, by this directive Notoborean faculty, to the position of the Earth. Namely, in order that the surface of the Earth, under this Notoborean extension, by the most wise counsel of nature, might receive the heat of the Sun, the Moon, and the stars [Greek: ἀστέρων (asterōn, "of the stars")] with a great difference of degrees of intensity, and might obtain its alternations of nights and days. [Margin: The effect of the stars upon the Earth.] For under the torrid zone there is a perpetual equalization of days and nights; just as the stars rouse the highest heat by their perpendicular incidence, so the sub-polar regions obtained a day of six months from the most oblique aspect of the Sun—so that by the perpendicular efficacy of the Sun under the torrid zone, the heat caused in twelve hours might be compensated by the six months' lingering of the Sun above the horizon. Secondly, in order that the Sun, rolled by its annual motion through the oblique band of the Zodiac, by surveying the whole globe—with the stations of the four seasons (Spring, Summer, Autumn, and Winter) established—might advance the generations and productions of things; which would by no means come about if the Earth, deprived of this directive Notoborean virtue, were to fluctuate this way and that in uncertain wavering. [Margin: The whole annual variation depends on this position of the Earth.] Upon this position of the Earth, then, and upon the annual motion of the Sun, depends the whole...

[Column break — text continues at top of facing column:]

for itself suffice to stabilize so great a mass by its own power, we will explain in this place. I say, then, that this virtue is nothing else than a certain directive Notoborean virtue, by which both the other bodies and—most especially—the Earth extend themselves along their axis from south and north by an inviolable law. Hence the Earth is not unfittingly called a Magnetic body, and its framing together from pole to pole luminously teaches this, as we have demonstrated most fully, and by a frequency both of various experiments and of observations, in the *Ars Magnetica*, book 1, p. 2 [*Arte Magnetica* lib. 1. p. 2]—which, lest I repeat it here, I refer the reader to.

Since, then, the Earth, by this virtue, is of itself indifferent to any position, and since indifference of this kind could cause irremediable defects in nature, it stood in need of a certain directive virtue by which it might remain within the due limits of nature—a virtue we call Magnetism; and lest the Geocosm, by nodding and fluctuating into uncertainty, should involve all things in confusion, it stood in need of this as of a bridle. But nutation and the inconstancy of staggering may, in the course of time, come about from the various internal turmoil of the terrestrial body—from frequent deluges, inundations, earthquakes, the swallowings-up of islands and regions, and the prodigies of similar events, of which the records of historians are full—by which, since the center of gravity of the Earth is marvelously altered and twisted away from its genuine position,

Mundus Subterraneus — Liber II "Geocosmus"

Caput XVII (continued): The Magnetic Constitution of the Earth

[...so that it could not] be steadied. This virtue was certainly indispensable for holding the Earth fixed in the middle and protecting it from every danger of change and unsteadiness. But you will object that the gravity innate in the terrestrial body could have accomplished this, so that this added faculty would seem superfluous.

[Margin: The Earth endowed with a twofold quality: gravity and magnetism.]

I answer, then, that nature has endowed the Earth with two qualities especially necessary for its preservation: namely, gravity and magnetic directiveness [verticitas]. The office of gravity is to hold the Earth fixed in the center; that of magnetism is to hold the same Earth pointed in a polar direction so as to prevent any wandering — what we call its directiveness [verticitas]. This directiveness is

nothing other than a certain motive faculty or quality by which a peculiar magnetic motion, and likewise rest, is produced. Now since the Earth, in its greater part, is a homogeneous body, and is simple as to its rocky structure and composed of similar parts, it was necessary that it possess this quality uniformly diffused throughout the whole body.

[Margin: The office of the magnetic virtue.]

Moreover, since the Earth must extend not in a confused way but in a fixed and determinate orientation, from south to north, it deserved precisely that quality which would dispose it into two termini — so that the quality, otherwise simple, might nonetheless at its termini exercise distinct prerogatives, as though under a divided command. Who does not see that this was most wisely established by nature? For if the force and power toward one and the same pole were equal at each terrestrial pole, there would be no reason why the southern pole of the Earth, for instance, should be subordinated to the Arctic rather than to the Antarctic, and conversely why the northern pole should be subordinated to the latter rather than to the former. The Earth would then have been poorly provided for, since its wandering could in no way be checked by that force; and it would often happen that, when one pole of the Earth was turned toward its pole, the other would stray here and there at random, as is clear from what has been said.

Therefore, so that this very great inconvenience might be avoided, the Earth was owed a quality of this kind: one that would both possess distinct termini and yet, divided as it was through the whole, exercise the power of dominion. By this quality the Earth was endowed with a twofold virtue, so that a fixed pole would unceasingly and necessarily seek out and love a fixed pole agreeable and suited to it, but would stubbornly shun the other — set, as it were, outside the limits of its jurisdiction — fleeing it with oars and sails as contrary and unsuited to its nature. So then, while each region strives to defend the rights of its own zone, the whole globe — its entire quality straining toward opposite parts, leaning toward each pole — stands fixed in the middle, undeviating, with both poles pressing inward: the Geocosm.

By this reasoning, then, the Earth, in its frame established from pole to pole, possesses magnetic force and directiveness, by which it disposes itself toward the poles and preserves itself so disposed. And it has this directiveness not in itself alone, but also in all other proportionate and similar bodies, provided they are placed within the sphere of its magnetic quality.

[Margin: The magnet shares in the forces of the Earth.]

Furthermore, it is well known that in homogeneous substances the parts are not merely assimilated to the whole, but are altogether of the same essence and nature as the whole, so that each property and accident belonging to the whole necessarily belongs to the parts as well. Since, then, the magnet is a true and homogeneous part of the whole homogeneous body — indeed a genuine son of the Earth, sprung, so to speak, from the true and natural seed of the Earth, entirely like and proportioned to it — it follows that it shares in the affections of the whole. Hence, conveyed in an aerial carriage and fittingly affected by that magnetic outflow with which the Earth disseminates its forces in every direction, the magnet too, in conforming itself to the whole, takes on for itself that very relation of position and motion which its parent Earth pursues, and exerts the vigor conceived from the Earth not in itself alone, but in all other capable and proportionate bodies. Just as the Earth, then, is directed toward the poles of the world, so the magnet too is directed toward the poles of the Earth, because it thus flows together with the Earth and is so disposed by the form of the whole globe as the entire substance of the Earth demands. Since, therefore, the position of the whole Earth is situated in an arrangement ordered toward the poles, this homogeneous part of it likewise agrees with the whole, and so eagerly strives to express in itself all the virtues of its Mother.

But why are metals and the other heavy bodies not disposed in this way? The cause is that they are not primordial, genuine, and true parts of the Earth, but altered ones, corrupted by certain spurious materials. Again, since every being is naturally and necessarily carried toward its own internal good and preservation, and since the good of the magnet is the conformation of itself to the orientation and position of the Earth — of the whole, that is, by which it is perpetually fostered and preserved — it is therefore directed toward the poles for the sake of its internal good and convenient preservation: namely, that by accommodating itself to the orientation and position of the Earth, it may be aided and strengthened by it.

[Margin: The inclination of each thing toward its proper orientation.]

For this same reason light things are carried upward and heavy things downward, as toward the place in which they may conveniently exist together with the whole; and so the parts of water are gathered into drops, so that, defending themselves by the union of their parts against hostile dryness, they may exist more conveniently, and may by their innate force more fully conform to the whole element, which seeks a circular surface. For this cause all vegetables, or germinating things, are carried upward, because such is their orientation,

which they naturally seek for their good. Therefore the magnet too loves the said orientation because in this way it is fostered and preserved, and not otherwise. For if the magnet were not found in the orientation which the Earth has, it would remain contrary to its natural inclination. So then, lest it should suffer violence from this contrariety, it conforms itself by turning toward the orientation of the magnet — and thus, on account of the harmony of the world, and the analogy of the perfect and homogeneous parts of the world to the whole, and the mutual agreement of their chief forces, it strives toward the continuation, position, direction, and unity of the terrestrial [O 3]

globe's poles. By that radical force of its own and by formal efficiency the magnet is disposed, so that the remote principle of this directiveness is the very form or essence of the magnet, while the proximate and immediate principle is that δίμορφον [Greek: dimorphon, "two-formed"], or biform quality, which strains toward opposite parts and strives to dispose the body into an orientation agreeable to the whole. Let us therefore lay it down. From which it is also clear that this directiveness comes not from any external agent altering the magnet, but through an internal principle and the magnet's own proper form — which should be well noted.

CAPUT XVIII

[Body heading, p. 108:]

The Geocosm, or the terrestrial body, is by no means of homogeneous but of heterogeneous nature. And concerning the wonderful variety and panspermia of things of which the terrestrial body consists, and what is the true and proper element of the Earth.

There are certain philosophers who hold that the Geocosm is heterogeneous only as to its outer surface, and by no means as to its interior — those deeper bowels of the Earth, where they suppose that pure element of Earth lies hidden. But just as such men, destitute of all experience of things, are detained by mere contemplations abstracted from all matter, so too there can be no doubt — to anyone who knows more deeply the hidden miracles of nature — that they slip into countless and most absurd errors.

[Margin: The world is fond of variety in things.]

It must therefore be understood that the Geocosm, or terrestrial world, by this very fact — that it possesses the name of "world" — necessarily rejoices in variety, no differently than the greater and lesser world, which the Greeks call

Megacosm [Megacosmus] and Microcosm [Microcosmus]. For it belongs to the essence of a world to be strong in an innumerable variety of things, both for the adornment and benefit of the universe and for displaying the infinite wisdom of its Creator. If, then, the world were always to produce one and the same thing in itself, neither the whole nor the parts could subsist, nor could they conspire into the union of the whole. Rather, this whole conspiracy consists in nothing but the variety of things and in the wondrous laws of the agreement and disagreement of natural things prescribed by nature — whereby, while each thing procures its own good, it at once removes from itself by innate appetite whatever is harmful and pernicious to it, with all its effort. And while all things are bound together by the open bonds of discord and friendship, the universe, together with its parts, is preserved in perfect union and in a most absolute harmony forged from consonant and dissonant elements, as we demonstrated in our *Musurgia*.

[Margin: The Geocosm is wholly constituted of heterogeneous things.]

The Geocosm, therefore, constructed on the analogy of the greater world, ought by no means to be reckoned as coagulated from some homogeneous substance — as common philosophers of simpler wit suppose — but is strong with a panspermia [panspermia, "all-seed"] of innumerable things, implanted in it from the very origins of things, for the producing of that variety of things which, taught by daily experience, we behold not without wonder. For, as we showed in our *Itinerarium Exstaticum*, there are as many different virtues of things implanted in the substances of the terrestrial globe as there are diverse virtues and properties in the greater world among the stars and innumerable luminaries — all of which pour out the emanation of their forces into the Earth, either immediately, as the lower stars, or by means of other intermediaries, as the higher ones.

[Margin: The spirit of the world.]

But to come a little closer to our proposed aim: the bony frame, or structure, of the Geocosm is a certain magnetic and rocky framework from pole to pole, which nonetheless must by no means be reckoned to be of homogeneous nature after the manner of a pure magnet, but consists, beyond its magnetic fibers, of an innumerable mixture of bodies of most diverse natural endowment.

[Margin: Of what sort is the bony frame of the Earth.]

In some places there are metallic and mineral bodies, yet not of one kind, but distributed here and there with great providence, so that — just as not every land

bears all things — in one place it produces gold, in another silver, in some iron or copper, in others only lead, tin, or quicksilver.

[Margin: Different places yield different things.]

Thus some parts of the earth display diverse precious stones, others diverse species of herbs, plants, and aromatics; others diverse kinds of marble, others diverse species of animals proper to themselves — all of which derive their origin from the diverse temperament of the terrestrial portions. In the terrestrial globe there are innumerable veins of the most diverse things, diffused throughout the whole body of the Earth: some of which produce an earthy and muddy substance, others a clayey or pumice-like or tufaceous one, others one full of metallic juices, others one filled with powders and sandy masses.

[Margin: Subterranean veins of diverse kinds.]

What shall I say of the diversity of substances which are extracted from the bottom of the sea and offer themselves to view? I would venture truly to affirm that scarcely a few miles of access lie open in which we do not see the Earth imbued with one and another property of the terrestrial portions. But since we have reserved all these matters for the following treatises, we have judged that we should refrain from being longer here. Whether, however, this panspermia of things and this utmost variety was created together in the Earth from the very origins of things, or whether it was imbued with this virtue by the Sun and stars in the course of time — that remains to be explained.

The divine Wisdom, destining from eternity a dwelling for the human race — a dwelling which, unfolded from the point of eternity in the fullness of time...

the Creator established with such great artifice that whatever is rare and exceptional in the whole universe, whatever of forces and properties exists in the celestial globes — of which there is no number — may seem to have flowed down into this Geocosm.

[Margin: The Creator implanted the seeds of all things in the Geocosm.]

For since the globe of the Earth, divided into various climates, had a varying aspect toward the Sun, Moon, and stars, from this so manifold relation and aspect of the celestial bodies there necessarily followed a great and incredible variety and multitude of things — whether of mineral, vegetable, or sentient nature (consider the economy of nature). For the diverse aspect of the globes of the Sun, Moon, and stars, impregnated with the various and reciprocal influxes of the

other globes, now directed toward this region of the Earth, now slanting and sharp toward that, now obtuse — what, I ask, could it not effect upon the Earth?

There is this besides: that the whole mass of the Earth already beforehand, according to the need of each climate, had created in it the seeds proper to each thing; which, made fruitful and animated by the virtue of the warmth that plays the midwife, emerged into the offspring of innumerable things. That seeds of things were created in the Earth, sacred Genesis plainly teaches in chapters 1 and 2:

[Margin: Genesis 1:11]

And He said: *Let the earth bring forth the green herb, and such as may bear seed, and the fruit tree yielding fruit after its kind, whose seed is in itself upon the earth. And it was so.* [Gen. 1:11]

[Margin: What is panspermia?]

Truly, therefore, panspermia, or the spermatic commingling of all things, was created together. But since this panspermia was not yet brought from potency into act before the separation of the waters and the uncovering of the dry land, but needed a virtue from on high, by whose influxes, being preserved, it might bring forth the seeds of things into shoots, leaves, flowers, and fruits — hence Genesis at once subjoined the production of the Sun, Moon, and stars, according to whose influxes and luminous, active emissions it so disposed the Earth that thereafter, for a fixed constitution of times and climates, an infallible effect of vegetables might follow. And thus the active principle, joined to the passive — with God as the matchmaker — then first continued the propagation of the whole vegetable nature. God, therefore, in His ineffable wisdom, first, according to the need of each region, co-produced in the body of the Earth seeds suited for producing diverse species of plants; but afterward, in the course of time, the influxes of the celestial bodies brought those forth into living and vegetative soul for the perennial propagation of the species. For without warmth and light, all things lay torpid and dead.

[Margin: The generation of aquatic and flying animals.]

But of what sort these seeds were, and from what principles they coalesced, will be taught in what follows. In like manner, after the production of the Sun, Moon, and stars, Genesis immediately subjoined the production of aquatic and flying animals. For at the voice of God sounding forth, the Earth straightway, according to the nature and property of the waters, rivers, and seas, brought forth the

various kinds of swimming creatures proper to each place, perfect in their own kind; which afterward, with the influx of the heavens cooperating, propagated by generation, filled all the parts of the Geocosm. And so, just as not all seas produce the same animals and the same fish, but — according to the nature and temperament of the water of the region — produce diverse ones in diverse rivers, lakes, and seas, so too on the sixth day, by a like analogy, the Earth did not bring forth the same production of terrestrial animals in every part.

[Margin: The wonderful diversity of regions provided the subject from which animals were formed.]

Hence the Indian land furnished elephants, rhinoceroses, and other animals unknown to us; the Asiatic land camels, lions, tigers; Africa ostriches, dragons, apes; America all things differing from the rest; Europe horses, asses, oxen, sheep, and so on — animals agreeable to its own temperament.

[Margin: Why Indian, Asiatic, and African animals adapt to the European climate with such difficulty.]

From this it is clear why Indian, Asiatic, African, and American animals so reluctantly grow accustomed to the European sky, and conversely European animals to the other parts of the world: because they make use of a foreign sky, in no way agreeable to their nature; and because only their native soil, from which they drew their origin, suits them well and provides nourishment fitting to their nature. If they are torn away from it, then — as exiles from their native soil, when they cannot bear the disproportionate and foreign region of sky, air, and earth — they soon perish; or if they last for a while, they nonetheless so depart from their native temperament that they put on an entirely different form and character. Whatever has been said of animals is to be understood, by a like reasoning, of the offspring of vegetable nature, as will be more fully confirmed in its proper place by an induction of particulars, where also other ends of so great a metamorphosis will be indicated.

From the orientation, then, and from the disposition and diverse nature of the terrestrial climates, depends the diverse nature of animals and vegetables; which is indeed so confirmed that there is scarcely a region which does not produce something differing from another, whether in nature or in qualities. All of which draws its origin from the commingling of the primordial seed with which the terrestrial world was imbued — things which were so adapted by the supreme Architect to time, place, and sky that from them that incredible variety of produced things which we marvel at necessarily resulted.

[Margin: Why minerals are found nearly everywhere.]

Minerals, however, since they emanated from the immediate seeds of the principles of nature and of the elements, dispersed through nearly the whole mass of the Earth, were also allotted an indifferent location; hence it comes about that, since they regard no particular climate, having become a possession of common right among all nations, by their happy yield they bless no region — some more, some less.

Furthermore, one doubt still remains to be explained, which is the following. If the Earth consists of so great a diversity of terrestrial parts, it may rightly be asked: what and where is the true, proper, and homogeneous element of the Earth? To resolve this — [O 3]

I suppose first.

[Margin: Whether there is a true and proper element of the Earth.]

Terrestrial substance can be considered in two ways here: first, insofar as it is a pure substance, most purged of all the turbid commingling of most diverse things; second, insofar as it is taken for an impure substance, variously compacted by the confluence of heterogeneous matter. In the former way, the element — one of the four — is constituted by us; and we say it is nothing other than the substance of Salt, like a kind of soul and form of the Earth, the fourth and last element of all things.

[Margin: The Salt of the Earth is its element.]

For this element, which we have called pure and necessary to all the things of the world — that usual salt of ours, or saltpeter, or vitriol, or some similar saline sensible body of this sort — is what we maintain it to be.

[Margin: That the pure element is salt.]

For bodies of this kind are nothing other than the excrement and covering, as it were, of the terrestrial element, by which the form of the element, like a soul wrapped in its own body, perfects its wonderful operations.

[Margin: The covering of the Earth.]

But we say that this is a certain spirit — incorporeal, although corporeal; insensible, yet incorruptible — residing in the center of the saline body, from which, by the diffused rays of its virtue, it furnishes to each species of mixed bodies that coagulation, and produces a hard, dense body, suited to subsisting; in

such a way, indeed, that no mixed body is found in the whole economy of the Geocosm which does not receive from it its firmness of solidity.

[Margin: The wonderful force of Salt.]

All of which we shall confirm by chemical experiments in the course of this work, God granting. But the impure portions of the Earth can by no means be called an element, but rather a kind of excrement and menstruum of the pure element, which nature uses chiefly for constituting the grossness and thickness of earthly bodies. And since such excrementitious parts of the Earth are not so perfectly and firmly united to the elements, hence too the dissolution of the union of parts necessarily destines them to destruction. But the more firmly some things are united to the confluence of the elements, the more remote they are from corruption, taking on a certain character of incorruptible substance, as is evident in gold.

I said above that the pure substance of the Earth, which we called Salt, constitutes the true and proper terrestrial element — not that the element of Salt is so pure as to have absolutely nothing heterogeneous mixed in; for in this way no element is found in the nature of things.

[Margin: No pure element is given.]

The element of the Earth, then, is properly nothing other than the purest substance of Salt diffused throughout the whole body of the Earth — the subsistence, cause, and foundation of all the virtues which shine forth in the Geocosm, and of mixed bodies.

Nor would I have you suppose, Reader, that that terrestrial element which we have called pure — [the salt itself]...

[Margin: What the proper element of the Earth is, why it is said to be Salt.]

furnishes those advantages, which are most necessary for the firm and fixed subsistence of the mixed body, by virtue of this element's own property (with the remaining elements nonetheless accompanying). For there lurks in this, no otherwise than in the seed and in its plastic faculty, I know not what divine craftsman, who works in the inmost recess of the body without any instrument and without tumult.

[Margin: The wonderful force of Salt.]

And it produces works most worthy of admiration, replete with an incredible variety of most dissimilar things — and all of this from the rude and (so far as

sense goes) formless covering of a material substance, in which, as no dissimilarity, so no variety presents itself to the senses. And since these saline bodies are wanting to no place on earth — indeed, are hidden away in concealed lairs and are brought into the light only by the spagyric [chemical] art — that a certain saline material body is rightly constituted by us as the terrestrial element is evident even from this:

[Margin: Salt is in all things.]

that, just as it is most necessary for the composition of mixed bodies, so nature has willed it, diffused through the body of the whole Geocosm into the fibers of its innermost parts, to be wanting nowhere. Let no one, therefore, seek in the center of the Earth I know not what Earth constitutive of the true terrestrial element; let no one seek a certain kind of chalk, clay, or gypsum; let no one seek I know not what sands or other terrestrial substances annexed: that the saline body is the one and only constitutive of the terrestrial element, that divine study of the Empyric art [chemistry] has long since taught us abundantly and more than enough. But of these things, expressly, in what follows.

CAPUT XIX

[Body heading, p. 110:]

Concerning the interior constitution of the Geocosm, its workshops, and its analogy to the members of the human body.

I judge that there is no philosopher of so simple a wit as to persuade himself that the terrestrial globe coalesced by some tumultuary heaping-up of mud, and stood firm with perfect solidity, with no cavities left behind. For that would be a notion unworthy of a philosopher. Nay rather, let it be certain and beyond doubt to all that the eternal Wisdom of God — κοσμοτεχνίτη [Greek: kosmotechnitē, "world-craftsman"] — just as it constituted nothing tumultuary, nothing confused, undistinguished, and ἄτακτον [Greek: atakton, "disordered"] in the nature of things, so likewise constituted the Geocosm, the last end of the works of the Creator, with the highest wisdom, with eternal counsel, with ineffable order, and with a certain plan incomprehensible to the human mind.

For it would be ridiculous — not to say stupid — that some king's vast palace, adorned only as to its outward ornament, its paintings, moldings [Cimatia], carved figures [Zooglypha], rows of windows, and similar μηχανήματα [Greek: mēchanēmata, "contrivances"] of beauty and magnificence on the outside, I say — that so great...

[Margin: The vast variety of the Geocosm's things and parts.]

to consider only [the outward surface], while supposing that the remaining apparatus of the interior furnishings — the breadth of the chambers, the depths of the foundations, the layout of the halls, the orderly arrangement of workrooms necessary for the proper management of a household — either does not exist or serves no purpose.

Divine Wisdom built this house, destined for the human race, and equipped it with such an abundance and richness of all things necessary to human life that, just as on its outer surface it was furnished with an innumerable variety of things, so too it ordered the internal economy of this house with such supports that the external face of things could not have subsisted at all if it had not furnished the hidden body of the inner house with an equal apparatus.

[Margin: The Geocosm is like the Microcosm with respect to its internal structure.]

For just as God adorned the Microcosm — that is, the external body of man — with a wonderful variety of members, so He did not fail to embellish the internal body of man with a still greater interlinking of members. In this body you see the principal members — the heart, liver, lungs, stomach, brain, kidneys, spleen — as so many workshops, in which the four humors are variously processed and, through countless channels of veins, through the manifold fibers of the muscles and cartilage, the members are able to be of mutual aid to one another by the reciprocal communication of the processed humors — so that, if one member fails, the whole is not destroyed.

[Margin: The wonderful structure of the human body.]

You see how the stomach, by digesting the nourishment taken in from outside, processes it and converts the digested matter into chyle, and through the mesaraic veins transmits it to the liver, the workshop of the blood, for further refinement there; and how the liver, in turn, to be imbued with the spirits of life, directs part of it to the furnace of the heart, so that, once actuated there and carried through the complete *pericyclosis* — that is, the circulation by systole and diastole — and diffused into all the veins of the body, it may replenish the whole of life with the vital spirits and motions that it communicates to the muscles and cartilage. You see how the kidneys claim for themselves what is serous in the blood, and the spleen what is excrementitious, while the thick and excrementitious dregs discharge themselves through the winding folds of the intestines by way of the bowels.

And since the body needed air to be blown through it — both for respiration and for tempering the heat of the heart and of the blood that surges up from it — God in His supreme providence set the lungs beside the storehouse of the heart, so that by their continuous motion, both inhaling and exhaling, the intention of nature is fulfilled. And since the body needed a certain universal moisture, lest the organs of the inner members, parched by the heat, should be deprived of their spirits, behold: both the stomach and the rest of the members, through hidden passages, seek out the brain — like a kind of vault — by evaporation, where, dissolved by its native coldness back into humors, they water all the members, as by a beneficial irrigation, with the moisture necessary for the right performance of their functions.

We have seen, so far as suffices for the purpose of our argument, the internal constitution of the Microcosm; we have surveyed its workshops and set out the offices of each of its members. Now let us see how, by exactly the same analogy, the architectonic Mind of God constituted the Geocosm.

[Margin: The structure of the Geocosm parallel to the Microcosm.]

We know that the Microcosm is preserved in its being by two principles, the external and the internal. The external is the Heaven — the influence of the Sun, Moon, and stars; the internal is the vital members, so bound to the external principle that, if either is taken away, the whole is rightly judged to be destroyed. The Geocosm, or Terrestrial World, enjoys these very same principles, and if either of them is removed, the whole must necessarily fail in its operations. The Heaven, as we shall show in its proper place, supplies the most abundant nourishment, which the Earth, having received it within her bowels, actuates, digests, processes, and distributes — once digested — to the rest of the interior members through hidden little channels: both for the necessary generation of metals and for blessing the household of the outer economy with a plentiful yield.

But this distribution of nourishment could by no means take place if the Geocosm were destitute of workshops fitted for digesting, processing, and distributing, and of hidden channels branching off into each part — as we taught at length in the *Iter Exstaticum* II [*Iter Exstaticum II, sive Mundus Subterraneus*]. Now it is time for me to disclose what these are; and so that it may be done *methodically* [Greek: εὐμεθόδως (eumethodōs, "in well-ordered fashion")], I shall fulfill the part of a good anatomist in setting them out by paragraphs in order.

§ I.

On the constitution of the subterranean reservoirs and workshops.

Just as in the Microcosm some workshops or reservoirs — such as the brain, the liver, the bladder — overflow with moisture; certain ones seethe with the heat of vital fire, like the heart; some swell with airy breath, like the lungs; and certain ones, like the kidneys and spleen, are filled with dregs-laden matter — in just the same way, in the Geocosm, reservoirs of moisture and of water have been aptly constituted by provident nature. And since these could not be preserved without heat, there are attached to them other storehouses of fire, by which the brood of waters might in some measure be enlivened. And because not even the Vulcanian workshops of fire could subsist without air, the wise Craftsman of nature, by the ineffable arrangement of His providence, disposed yet other airy reservoirs to foster both, so that by the hidden commerce of their passages they might preserve the fire lest it be extinguished, and the water lest it putrefy or freeze, for the continuation of perpetual motion.

[Margin: Air-reservoirs.]

And since this distribution of elemental reservoirs would be in vain unless there were something upon which they might act, hence other terrestrial ones were constituted — storehouses of nature imbued with a medley of seminal principles of every kind, in which, by a certain hidden working of the waters and fires, the continually-operating workshops might bring forth an innumerable brood of things.

We have set out the workshops; now the order of our plan demands that we review each of the enumerated workshops in turn, confirming them both by reasoning and by authority. But so that we may have appropriate names for these workshops, we have judged that the reservoirs of water should rightly be called *Hydrophylacia*; those of fire, *Pyrophylacia*; those of air, *Aerophylacia*; and the storehouses of the terrestrial medley, *Geophylacia* — as the guardhouses [custodias], so to speak, of water, fire, air, and earth. With these preliminaries set down, now to our aim.

§ II.

On the hydrophylacia of the Geocosm, or Terrestrial World.

That hydrophylacia have been constituted within the bowels of the highest mountains for the production of springs, rivers, and lakes, we have shown amply

enough above in Chapter 6, and in the *Iter Exstaticum* II in the *Mundus Subterraneus* — in which place we likewise reviewed all the more notable rivers and lakes, with which the Geocosm is clothed as with a kind of fringe, and which draw their origin from the enumerated recesses of the mountains. It now remains to speak of those hydrophylacia which men call *abysses* [abyssos] — not those near the horizontal surface, but those founded by nature, for excellent ends, within the blind bowels of the deeper Earth.

[Margin: What an abyss is.]

That there are such abysses of water among the bowels of the Geocosm is so certain that even Sacred Scripture itself, in the Psalmist, hints at them in plain words. Psalm 41[:8]: *Deep calls to deep at the voice of thy cataracts* [Abyssus abyssum invocat in voce cataractarum tuarum]. Here, although most interpreters refer the abysses to mystical, tropological, and anagogical senses, yet those who hold to the literal sense call an Abyss, in the sacred writings, a most profound whirlpool of waters whose bottom cannot be explored, situated in the innermost parts of the earth — concerning which see Lorinus on the cited passage of the Psalm. And the following verse of the Psalm clearly explains its depth in these words: *all thy high waves* — and, according to the Chaldee paraphrase, *all thy springs and thy floods have passed over me* [omnes fontes tui et fluctus tui super me transierunt]. Here, by "high waves" is connoted the height of the lands and mountains from which he had been drawn up from the abyss, and by "the floods of the sea," the monstrous vastness of the waters by which he is covered.

[Margin: Chaldee.]

And so the Psalmist, in another place, cries out — carried down into the abyss, and by divine mercy led back out of it: *and thou hast brought me up again from the abysses of the Earth* [de abyssis Terrae iterum reduxisti me]. Sacred Scripture, then, makes mention of abysses in many places; and from these — as horrid and inaccessible whirlpools — its Commentators took occasion to twist them toward a moral and mystical sense. For into these, the sea, hurled down through the immense precipices of the inner crags, stirs up huge roarings and fearful crashings — which the words of the cited verse also intimate, *at the voice of thy cataracts*.

[Margin: That there are abysses in the bowels of the Earth.]

And that there are very many such abysses enclosed within the inmost bowels of the Earth, we deduce from effects shining forth in certain places of lakes, seas, and the Ocean so deep that they reject any sounding-line, however immense.

Among these are also numbered gulfs or whirlpools and *Euripi* [tidal straits]; some of which I shall here adduce in confirmation of the abysses. Of these, the foremost, most celebrated, and greatest is seen in the Northern Ocean, off that part of Norway which is divided from Lapland.

[Margin: The Norwegian whirlpool, an abyss.]

For, by the testimony of nearly all geographers, it has thirteen miles in circuit; its center is occupied by a rock called *Muske* by the natives, whose force is of so devouring a nature that, in the space of six hours, it swallows up all things — which, agitated by chance in the perpetual whirling, slip into the crater of the whirlpool as soon as they have touched even the outermost edge of the circumference — vast heaps of water, whales, cargo ships, and other things, spun about as if in a vertigo; and in just as many hours it spews out again what it had gulped down, belching it forth with great force and an incredible crash and roar, which is heard not without dread by listeners in the most remote places. Its cause I shall, God willing, disclose in the following book.

[Margin: A whirlpool of the Persian Sea.]

In the gulf of the Persian Sea a similar whirlpool is seen, off the Promontory of Mossendam [Musandam], whose hidden power, because it is most worthy of consideration, I shall here append in the words of an eyewitness as recounted in his *Eastern Itinerary*:

[Margin: *Itinerary into India* of Fr. George of Jesus and Mary, fol. 138.]

"There is a place," he says, "in the Persian Gulf most perilous and ordinarily agitated by storms. For on the promontory of Mossendam there are several crags which they call *Salemas*. Among these, one juts out so far toward the promontory that it scarcely leaves the sea a stone's throw of passage. There the sea, even while it is calm elsewhere, continually boils, and produces such great whirlpools that in the midst of them — especially while the sea is agitated — a large stone can for some space be let down without its touching the water; and for that reason the passage there is dangerous and perilous for sailors, and no one crosses when the sea is rough; but when it is quiet, they run through it with oars, for they are carried along by a most rapid force of the waters, and so approach the promontory that they almost touch it in passing. For they fear lest they be snatched against the crag itself and into the whirlpools." Others say that this whirlpool communicates with the opposite Caspian Sea through a subterranean passage. From their report, I, made more certain, found the truth in the book of the Persian Paradise [*Paradisus Persicus*], the Describer of both Seas, who asserts

the same — namely, that with the inflow of the Persian Sea, driven through its straits by the Ocean, the Caspian Sea at the same time rolls up vast tides on its southern shores, upon the ceasing of which the whirlpools follow.

[Margin: A whirlpool between England and Normandy.]

Between Normandy and England a not dissimilar whirlpool is observed in the Ocean, toward which ships are violently dragged with wonderful speed — not so much by their straining as by the fierceness of the tide. Yet this too is a wonder to behold: that with the same swiftness by which they were drawn from afar, by the same — when they are now near the gulf — they are driven back. Of the Euripus of Chalcis

of Chalcis there is nothing for me to mention, since it is celebrated in the records of all historians. The Indian History in Peter Martyr [Pietro Martire d'Anghiera] relates that, at the entrance of the Strait of Magellan, the Ocean is stormy with utterly fearful tides and of unexplorable depth — so much so, indeed, that many have judged that the sea here descends into the innermost bowels of the Earth.

[Margin: An abyss at the Magellanic Sea.]

The Caspian Sea too has its own whirlpools, according to the report of Fr. Riccardi, a priest of our Society, who crossed it, and who on account of its unexplored depth thinks that this whole sea is an abyss penetrating into the innermost bowels of the Earth.

[Margin: The Caspian Sea is an abyss.]

Similar ones are found at the entrance of the bay of Aynam [Hainan] near Sumatra and Cambodia.

[Margin: A whirlpool at the African shore.]

In an African gulf, which they call Ferdinand Po's [Fernando Pó], the water is snatched into the subterranean passages with such violence that no ship, once it has run into that current, is given the power of retreating; rather, for the space of many months — as if fastened with beam-spikes — those crossing remain fixed, at the utmost peril to their ships, doubtless about to perish, unless they are rescued from the straits by the winds that grow strong in those places.

I could here point out countless such abysses, both in rivers, lakes, and the Ocean; but since I have partly intimated them in what precedes, let it suffice for the moment to have explained them here, and to have noted them on the universal map — namely, that all places of the Ocean, of the seas, and of the lakes that are

of unexplorable depth, as well as Whirlpools, Euripi, gulfs, and abysses, are hidden in the innermost and deepest bowels of the Earth. But for what purpose nature destined them, and how they communicate with the rest of the waters, and with what probable depth they stand, together with the causes of the reciprocal ebb and flow, I shall disclose in the following Book.

[Margin: Wonders concerning a Tartary cave.]

That the Earth, then, is full of such hydrophylactic abysses, various histories narrate. Haithon [Hayton of Corycus], speaking of the affairs of Tartary, says that a cave is found among the Caspian mountains, passable by a journey of many days, in which men say they have everywhere found vast cataracts of water and the most spacious subterranean places. Of similar caves Fr. Martino Martini treats at length in his *Atlas Sinicus* [*Novus Atlas Sinensis*].

§ III.

On the pyrophylacia of the Geocosm, or fiery Abysses.

That huge abysses, hidden away in the bowels of the Earth and full of fires, are found, the Volcanic mountains demonstrate amply enough. These you should by no means suppose — as the common crowd persuades itself — to lie in the bottom of the mountains, but they have their workshops in the deepest bowels of the Earth, of which the mountains are only certain breathing-holes for discharging the superfluous soot and the violence of the conceived heat, lest they continually shake the Earth with intolerable convulsions.

[Margin: The fire of hell is true and elemental.]

So that, accordingly, the holy Fathers have not incongruously placed the greatest of all the pyrophylactic abysses in the Center of the Earth — the eternal prison destined for the punishment of the wicked.

[Margin: Why hell is in the Center of the Earth.]

And lest perhaps some suppose that the infernal fire is of a nature other than elemental fire, let them know that, just as God uses the element of water — elevated, by an obediential power (as the theologians speak), to confer grace in baptism — so too He torments the wicked by a truly and properly elemental fire, but one so elevated by the immensity of His power, by a supernatural force, that with an efficacy infinitely greater than that of elemental fire it afflicts the guilty with eternal damnation, the rigor of divine justice so requiring.

[Margin: The central abyss is destined for the reprobate.]

Therefore we shall say nothing absurd if we assert that this abyss is appointed at once, for the time being, both to the necessity of nature, and to souls only [for now]; but after the universal [judgment], to the bodies and souls of the damned together, to be tormented eternally — the lot of the reprobate equally [decreed].

[Margin: The mouths of the central abyss.]

The same, I think, is to be held concerning purgatory, which perhaps — by a conjecture not improbable — obtains in the innermost receptacles of the Earth, in one or more of the pyrophylacia. For just as it was altogether fitting to the Divine power to make use, from time to time, of the natural element of water, both for physical and for supernatural effects — as most of the holy Fathers and Theologians hold — so too it was in the highest degree fitting to Nature to decree in the Center of the Earth a place [of] fire, so that from this, as from a central pyrophylacium, it might communicate the efficacy of its power to other, higher pyrophylacia, and this to others and others still, through subterranean channels, all the way to the very surface of the Earth; since it is proper to this element always to tend from the lowest to the highest.

[Margin: Why fire is in the Center of the Earth.]

[Margin: How fire endures perpetually.]

But how these pyrophylacia endure with perpetual heat, and how, not consumed by so long a duration of exhalations, they are preserved in perpetual vigor — this ought to seem by no means a wonder to anyone who has more deeply contemplated the perennial works of nature and their efficient *cause* [Greek: αἰτίαν (aitian, "cause")]. For since the Geocosm is a terraqueous globe, surely, just as fire receives life from air and its necessary nourishment from water, so fire communicates strength and life to the watery element and to the airy, by reciprocal commerce — inasmuch as neither could subsist without the other. The terrestrial substance, in turn, when one fuel fails, supplies fresh fuel to the fire through subterranean paths, so that in this manner all things, each and every one, are preserved in their being perpetually.

[Margin: A comparison from rain.]

Just as you see happen on the outermost surface: the Sun draws up the moisture from rivers, lakes, and seas by means of vapors; the vapors, dissolved by the coldness of the airy region into waters, rains, snows, and hails, at length restore

to the hydrophylacia all that had been drawn up by the Sun. And the exhalations, drawn up from the earthy portions,

[Margin: The circulation of nature.]

are transmuted into fiery phantasms; these, by the impulse of the encountering cold, taking on the nature of the neighboring air, are changed into air, and this into water, the water into Earth — and by a wondrous metamorphosis of nature at last return again; and where they cease, there they soon lay the foundations of new efforts of the *pericyclosis* [cyclical revolution]. In the same way, the Sea, forced through hidden burrows by the secret contrivance of urging nature into the vastest caverns of the mountains, at length bursting out from there into springs, rivers, and lakes, returns by right of postliminy to where it had departed from, to be revolved anew. And the water, gliding through the blind bowels of the Earth, substituting along with itself both the moisture and the medley of terrestrial portions it has carried down as nourishment and fuel for the pyrophylacia — these, in turn, swelling with hot spirits, by the heat raised through the siphons proper to them, foster and animate the hydrophylacia and the other reservoirs, for promoting the generation both of minerals and of vegetables through exhalations. And so, by a perennial and cyclic motion, all things that are observed in the nature of things exist and are preserved. But how these are carried out by nature, I shall, as I said, declare in the following Book.

§ IV.

On the subterranean aerophylacia of the Geocosm.

Just as fire and water cannot subsist without air, so certain Aerophylacia were necessary to the Geocosm, from which both elements, Water and Fire, might draw the necessary respiration, as from certain lungs of nature; and the air enclosed in them might in turn receive increase from the water, and the strength of fecund heat from the fire.

[Margin: What the Aerophylacia are.]

These Aerophylacia, then, are huge recesses of caverns, filled with the airy element, disposed to this end: that the air, channeled through countless siphons of hidden passages into other reservoirs — whether hydrophylacia or fire-receptacles — may in the former urge on the mass of water, raised through appropriate little channels into other reservoirs, into springs and rivers; and in the latter may perpetually foster the latent kindling of fire, and, by the arcane art of chemical sublimation, dispose the Earth toward further ends. But the manner

in which each performs its operations, I shall set out, as I have said, in the following Book. That there are such caverns, we know to have been proven by countless examples, some of which we shall here append.

[Margin: A wonder concerning a subterranean passage in China.]

Fr. Martino Martini relates, in his excellent work which he calls the *Atlas Sinicus*, that in the middle of the Kingdom of the Chinese there is a vast mountain stretched out by its skirts into the most remote regions on every side; which, since on account of its rugged roughness it can be crossed only with difficulty, nature — to provide for this inconvenience — so perforated the whole mountain with vast caverns that a way out is given from one side clear through to the opposite one. And this winding course of blind passages extends to such an amplitude that one cannot traverse it in less than the space of six months; and there have been found not a few who completed this subterranean journey, who reported things wondrous and altogether paradoxical concerning the admirable constitution of the subterranean parts. For they say that waters are found there in great quantity; in some places also huge lakes abounding in fish; in many places rivers, which spread themselves out, with a great diffusion of waters, into vast plains; that grasses and herbs, and a great number of subterranean animals of foreign species, are found; and that light, though dim, is nonetheless admitted through the open summits of the mountains and the fissures of the crags, as through a kind of chimney. From which description it is amply clear that what happens in these subterranean places is also found in all other subterranean regions similar to these.

[Margin: The aerophylacia of Asia.]

That the bowels of the inner Earth are full of air, all the books of the Geographers abundantly testify, since there is scarcely any nation that does not display the breathing-holes of aerophylacia. I shall speak first of the prodigious effects of such Aerophylacia in Asia, Africa, and America, and then I shall speak of those that are found in Europe. In the Mountains of Tibet, where the Ganges rises — as is established from the report of Fr. Balthasar de Andrada — certain mountains emit winds through all their fissures with a horrible sound and roar. The same is found in the report of Fr. Pais [Páez], concerning certain mountains of Ethiopia; and in America, that the same happens in the mountains they call the Andes, José de Acosta narrates. The cause of these is none other than either subterranean cataracts, or fiery subterranean spirits agitating the air, or other causes which we shall disclose below; for by these the circulating air, rushing wherever a door is

given, prepares its exit through the fissures of the mountains with the utmost force, and not with less of a crash.

[Margin: Airy breathing-holes in Bothnia.]

Olaus Magnus reports that in the Northern region there are found mountains, at whose roots are caverns, from which so great a crash of bursting-out winds is perceived that, by sudden terror, it either kills outright those who approach, or for very many days leaves most of them stupefied, [robbed] of the vigor of their senses by a pain of the head.

[Margin: A breathing-hole of the Earth.]

Furthermore, between Marseille and the mouth of the Rhône, as Strabo reports, there is a plain of a hundred stadia, a place most thickly strewn with flints no smaller than a man's fist, where from the very soil of that plain a wind blows of its own accord, to which the name *Metemborium* has been given, whose force is so great that it lifts up those same flints, like a whirlwind of hail, and lays men low — and even throws them from their carriages, and strips them of their weapons and clothes.

[Margin: The plain called la Crau.]

This plain I take to be the one which the Gauls call *la Crau*. And I

[This opening is dominated by a large fold-out double-page engraved plate. The two text pages flanking it (the verso preceding the plate and the recto following it) are nearly blank, carrying only faint show-through and degraded printed marginalia in the side margin; their main text columns did not print on these leaves or are illegible at this resolution. The legible content of this opening is the engraving and its engraved captions and legend.]

Verso preceding the plate

[Main text column not legible — faint show-through only; transcribe what the margin and the inset legend show.]

[Margin (right margin, fragmentary): "...[con]cussione fluvium ma[ris], ventus ... cavernas mon[tium] excitatur." — "...by the shaking of the river of the sea, the wind ... is stirred up [in] the caverns of the mountains." The full marginal note is abraded; the legible tail concerns wind stirred up in mountain caverns by the agitation of the sea.]

[An inset legend-strip from the engraved plate is reproduced at the right edge of this page, showing a vertical column of small pictographic symbols (a river/stream, hills, waves, a cartouche, etc.) with tiny engraved labels. The labels are too faint to resolve at this resolution. [?]]

[Margin fragment lower right: "...i fluvii, ...go alla ...rmora," — illegible/abraded. [?]]

Diagram. A large double-page engraved plate — Kircher's famous "Ideal System" of the Earth's interior water-circulation, here spread across the two facing pages (the left half the right half The plate shows the terrestrial globe in cutaway. At its center is a blazing star-burst representing the **central fire** (labeled **A**); from it radiate branching channels — the *pyragogi* (fire-conducting ducts) and *hydragogi* (water-conducting ducts) — that thread out through the body of the Earth like a vascular network, terminating in reservoir-pockets within the mountains (the *hydrophylacia*). The globe is encircled by a thick band of stylized rock/sediment layers. Surrounding the whole are dense banks of cloud, in the four corners and edges of which are set engraved **wind-heads** — putto/cherub faces blowing streams of air (the winds), with two small flying *putti* near the top holding the title-cartouche. The sea is shown washing the outer surface, with waves driven by the wind-heads' blasts.

The engraved caption, set in the upper cartouche and reading across both halves of the plate:

**Systema Ideale, QVO EXPRIMITVR, AQVARVM per Canales
hydragogos subterraneos ex mari et in montium hydrophylacia
derivatio, aquarumque subterrestrium per pyragogos canales
concoctus.**

— "An Ideal System, by which is set forth the derivation of the WATERS from the sea, through the subterranean water-conducting channels [*canales hydragogi*], into the water-reservoirs [*hydrophylacia*] of the mountains; and the cooking/concoction [*concoctus*] of the subterranean waters through the fire-conducting channels [*canales pyragogi*]."

Readable labels:

- **A** (center of the globe): *Ignis centralis* — "the central fire."
- (top, held by two flying *putti*): the title cartouche, transcribed above.

- (four corners and along the edges): wind-heads / blowing cherub-faces — the winds. No individual wind-names are legibly engraved beside them at this resolution. [?]

The long engraved legend at the foot of the plate (running across both halves) reads:

Ignis centralis A, undique et undique per pyragogos canales exhalationes spiritusque igneos qui concavorum antrorum fornicibus illisi, frigore loci condensati in aquas denique resoluti derivati in metallica corpora coalescunt, aut in novam combustibilis materiæ sæturam vel æstuum motum, aquas per subterraneos cuniculos in altissima montium hydrophylacia [eff]fundit; hos hydrophylacijs impactos, partim in thermas disponit, partim in vapores attenuat; fontes rivosque generat; partim in alijs diversorum mineralium succis fœtas matrices ad ignis nutrimentum destinantur. Vides hic quoque quomodo Mare ventis et aëris pressura, [in subterraneum orbem se?] ejaculetur. Sed Figura te melius docebit omnia, quam ego fusioribus verbis non explicarim, uti schema docet. Reliqua exactius ex ipsa operis descriptione et ratiocinio patebunt...

— "The central fire **A** sends out, on every side and in every direction, through the fire-conducting channels [*pyragogi*], fiery exhalations and spirits. These, dashed against the vaultings of the hollow caverns and condensed by the cold of the place, are at last dissolved into waters; conducted into metallic bodies, they coalesce [into metals], or [serve] for a fresh saturation of combustible matter, or for the motion of the heat-surges. [Thus the fire] pours the waters, through subterranean tunnels [*cuniculi*], into the loftiest water-reservoirs [*hydrophylacia*] of the mountains. These waters, once driven into the water-reservoirs, it [the fire] disposes partly into hot springs [*thermæ*], partly thins into vapors; it generates springs and rivers; and partly, in the juices of various minerals elsewhere, the pregnant matrices [so produced] are destined for the nourishment of the fire. You see here too how the Sea, by the winds and by the pressure of the air, hurls itself [into the subterranean globe?]. But the Figure will teach you everything better than I could in fuller words, as the diagram shows. The rest will appear more exactly from the description and reasoning of the work itself..."

fundit"; "[in subterraneum orbem se?] ejaculetur") are reconstructed from sense and flagged. The legend continues beyond the plate's foot edge ("patebunt...") into the body text. The smaller engraved labels scattered along the inner rock-band and the inset symbol-strip are too faint to resolve and are flagged as a]

Recto following the plate

[Main text column not legible — faint show-through only; transcribe what the margin shows.]

[Margin (left margin, three printed side-notes, fragmentary):]

[Margin: "Circula[tio] naturæ" — "The circulation of nature."]

[Margin: "Quid sint Aëroph[y]lacia." — "What the air-reservoirs [aerophylacia] are."]

[Margin: "Mira de subterraneo meatu in Chin[a]" — "Marvels concerning the subterranean passage[way] in China." (Cf. the China cavern-system reported from Martino Martini's *Atlas Sinicus* in the preceding discussion of the aerophylacia.)]

[The main prose of this recto — evidently continuing §IV *De Aërophylaciis* / opening a new subdivision on the "circulation of nature" — did not print legibly on this leaf at this resolution and could not be transcribed. Flagged as a]

[Margin: Sown with stones, between Arles and Marseille.]

in the year 1633. I crossed this plain, lying some four French leagues from Arles, and found it so thickly sown with stones that one can scarcely set a foot down anywhere. From this, some spin the tale that a battle of the gods took place there. Yet whether the passages have over the long course of ages become blocked, or buried under dust mixed with rain, or whether the blustering channels have found their outlet elsewhere, or finally whether they have ceased for some other cause — I have not been able to discover so violent a wind as Strabo describes, though I investigated with the utmost diligence. Nor did the inhabitants, whom I questioned with the greatest care, ever testify that they had observed this so prodigious effect. Still, the layout of the place teaches above all that what is reported could indeed have happened. For since this plain extends all the way to the mouths of the Rhône, where the great commotion and conflict occurs as the rushing river collides with the resisting thrust of the sea, it could easily have come about that air, set in motion within the passages running through the mainland, somewhere in this plain prepared an outlet for itself with the violence recounted.

[Margin: From the collision of the river's flow with the sea, the wind arises that issues from the mountain caverns.]

For — as reports of the Ocean likewise relate — at nearly all the promontories, wherever there is a great collision of the waves driven by the sea's tide, a most violent wind is usually seen bursting out from the clefts of the mountains.

I will say nothing here of the Windy Mountain [Mons Ventosus, i.e. Mont Ventoux] in the County of Venaissin [Comitatus Venusinus], overlooking Carpentras [Carpentoractum], from whose caverns violent blasts of wind erupt — a thing better known than it need be told. I pass over countless other effects of the aerophylacia, found everywhere in Europe. I will add only what I have learned by my own experience in Italy.

Marvellous waterfall at Terni [Catadupa mirabilis Interamnensis].

[Margin: Mount Aeolius of the Caesii and its description.]

In the year 1658, when I was visiting the house of the Mother of God at Loreto [Lauretana Deipara domus] out of devotion, and observing along the way many wonders of nature met with there — wonders well known to everyone yet unknown to most — among the rest I learned much about the Aeolian Mountain of the Caesii [Aeolius Mons Caesiorum]. I thought it would be worth my while to investigate its hidden causes, held by common opinion to be impenetrable. Setting out from Terni [Interamnina], therefore, I first visited the nearby waterfall [Catadupa] most famous in all Italy,

[Margin: The great waterfall of the Velino [Velinus] river, vulgarly *alla marmora* [le Marmore].]

which the river Velino, hurled down over the highest cliffs, forms in the deepest valley of the mountain below. So, to find out whether it held any hidden commerce with the Aeolian mountain, I undertook to explore it. For there the river, rushing with the greatest force in the shape of an arch, plunges into a deep chasm about 300 feet in depth — as became clear from my measurement of the cliff — with so dreadful a din, crash, and violence of roaring,

Diagram. A wide engraved landscape panorama showing the valley of the Velino river with the Marmore waterfall, the Aeolian (Windy) Mountain of the Caesii, and the surrounding towns. The view is a bird's-eye prospect over rolling hills dotted with stylized trees and village clusters; the river winds from the upper right down through the center, with the cataract plunging at the cliff face. A large oval scrollwork cartouche at lower right carries the title. Readable labels (with positions):

- *Piedeluco* (upper right, on a hilltop town): Piediluco

- *Piedeluco Lacus* (right of center, the lake): Lake of Piediluco
- *Velinus flu.* (far right, the inflowing river): Velino river
- *Pons Regula:torius* (center, at a bridge): the regulating bridge [Pons Regulatorius]
- *Catadupa Velini* (center, at the cliff/cataract): waterfall of the Velino
- *De Vinus flu* (center, along a watercourse below the cataract): [?] river — likely the channel below the cataract (reading uncertain)
- *Aqua sparta* (left of center, a town): Acquasparta
- *Mons Æolius sive Ventosus* (left-center, along a mountain ridge): Mount Aeolius, or the Windy Mountain
- *Cæsis* (lower left, a hilltop town, drawn with wind-blasts streaming from caverns): Cesi
- *Nar flu.* (center, the river coursing downward): Nera river [Nar]
- *Termini* (center-right, a town): Terni [Interamnia]
- *Narni* (lower center, a walled town): Narni
- Cartouche title: "TABULA CATADUPAM Velini Fluminis et montem Æolium Cæsianorum situmque circum adjacentium locorum exhibens." — "A map exhibiting the Waterfall of the Velino River, and Mount Aeolius of the Caesii, together with the situation of the surrounding places."

which, even if it did not strike the bystanders senseless, would at least, by the assault on the sense of hearing, render them deaf, just as at the cataracts of the Nile. It is an utterly horrendous spectacle — you would call it a hell — fearful with its foaming whirlpools and the confused recoil of the surging waves, with so great a bellowing of the falling waters that it can easily be heard even at Terni, a space of five miles distant, in the silence of the night.

[Margin: Wonderful spectacles.]

From the fall of the water, ground among the jagged teeth of the rocks, the water is so pulverized that you would swear you stood in a perpetual cloud, and you cannot leave the place without being thoroughly drenched. This too is worth noting: when the sun shines, there appears there a perpetual rainbow — not the dewy sprinkling of leaping fountains, but, as it were, a rainbow in the sky of the sun's own magnitude. Having therefore examined all the circumstances of the waterfall relevant to my purpose, I returned to Terni, and the next day set out for the Aeolian mountain, so that I might explore as an eyewitness [αὐτόπτης — Greek: *autoptēs*, "as an eyewitness, with my own eyes"] the marvels I had heard of it, and render the causes of each particular effect. Received at Cesi [Caesii] with

the greatest kindness by the leading men of the place, I learned the constitution of the whole mountain — partly explored by my own effort, partly through the instruction of the inhabitants.

[Margin: Situation of the windy mountain of the Caesii.]

The situation of this mountain is between the Castle of San Gemini [Castellum S. Gemini] and Terni — in the vernacular *Terzi* — stretching from east to west in a long chain of mountains eight miles in length, as is plain from the map appended here. The whole mountain is of rock, so composed by nature that you may see boulders of enormous mass set one upon another and compacted with the wondrous craft and industry of nature. On the ridge of the mountain sits a town, named Cesi, founded — as they say — by the dukes of the ancient house of Caesia. I judged that this mountain should rightly and deservedly be called the Aeolian mountain, on account of the whirlwinds it spins forth at a fixed season. For in summertime it breathes out the most violent winds through all its fissures and crevices, so that in the adjacent town the inhabitants, with a certain remarkable ingenuity, dispose channels for the winds here and there within their grottoes and cellars — just as in a city the conduits of an aqueduct —

[Margin: The leading-out of the winds through channels.]

both to imbue their wine and water, and their fruits of every kind, with a most welcome coolness; and thus they turn the force of savage nature into the sweetest delights. In the houses of the nobility one sees channels so aptly arranged, and fitted with stopcocks [epistomia] so skilfully, that they can temper the force of the winds at will — with the further addition of little doors and small hatches, within which whatever is stored, whether drink or food, by the utmost violence of the cold is all but turned to ice.

But before I gird myself for the scrutiny of the causes, I will first set out all the circumstances of the effects, which are as follows:

[Margin: The marvellous effects of this mountain.]

First. The exhalations of the winds are found not on just any day of the year, nor at just any hour of the day, but only in the summer months — for four hours before noon and as many after; and once these are past, the blasts of the wind gradually and little by little slacken and fail. By night, scarcely any trace of wind appears; so that, according to the greater or lesser violence of the daytime heat, the agitation and out-blowing of the enclosed spirits is felt now more, now less.

Second. In the winter months the vents [spiracula] obtain effects opposite to those of summer. For if anyone applies a little kerchief, or some such thing, to the mouths of the channels, it is — wonderful to say — no longer thrust out by the wind breathing forth, but is drawn inward by some hidden force I cannot name, and indeed the more forcefully, the more intense the cold has been.

Third. The quality of the out-blown air is such that, despite the rawness of the wind, it in no way drives men who tarry in grottoes of this kind into feverish disorders, as usually happens in other places. Rather, just as it delights in an unsullied dryness, so it conduces wonderfully to men's health and the prolongation of life. These, then, are the circumstances I judged should be set down in advance, so that, relying on them, we may at last hunt out the true causes of effects so prodigious.

[Margin: The diverse opinions to be rejected, and the true cause of the wind.]

It can scarcely be said how much the investigators of natural things have sweated in exploring the nature of this mountain, and how diverse the dogmas they have hammered out — yet none of them attaining the true and genuine cause. Some thought the cause to be cataracts of water hidden in the bowels of the mountain, by which the interior air, agitated, rushes out wherever a gate is given. But that this can in no way be asserted is plain from this: that then the wind would have to last continually, both by day and by night, which is contrary to experience. Others supposed the winds to proceed from the tunnels of the neighboring mountains, into which winds blowing from outside have insinuated themselves through various caverns, and being carried within this mountain, at last burst forth. But neither can this stand on any ground; for it would follow that in winter, when winds chiefly prevail, the winds of this mountain would rage more than at any other time — which is likewise contrary to experience. Nor were there lacking those who asserted that winds of this kind draw their origin from the tide of the nearby sea: that air stabled in subterranean passages is, by the dashing of the sea's waves, thrust into this mountain, and there, compressed, is at last violently forced out through the crevices. But this too lacks solid foundation; for it would follow that the winds last perpetually, matching the perpetual motion of the sea, or at least continue in a confused and interrupted manner — which is again contrary to experience. These are the chief points by which the natural philosophers establish their opinions about the nature of this mountain. It remains, therefore, that we too test the powers of our own wit in so intricate a matter. I say, then, that there is no other cause of effects so prodigious in this

mountain than the rarefaction and condensation of air — which I demonstrate as follows.

And first I suppose that this whole moun-

[Margin: The mountain is hollow.]

tain is hollow — which both the inhabitants, taught by long experience, hold for certain, and which I myself have ascertained by indubitable experience. For when you have advanced some way through the hidden passages, then horrid precipices first overhang, stretching down into the abyss of the mountain; and if you throw down a stone, after a long time an echoing sound is roused, as in wells and cisterns — than which no greater indication of the mountain's cavity could be given.

[Margin: Pierced all over with countless crevices.]

Second. The whole surface of the rocky mountain is filled with holes, crevices, and fissures — not only on the side facing Cesi, but also on the opposite side, facing the town of Acquasparta; where I found the same effects as at Cesi.

[Margin: The violence of the heat among the mountain ledges.]

Third. This chain of rocky mountain masses, stripped of all earthy substance, in summertime, through the various reflections of the sun among the ledges and hollows of the mountains, conceives so immoderate a violence of heat that you might say you stood in the Torrid Zone — nor is there anyone who could bear the heat around midday, with men and animals shut up within their houses and stables.

Resting on these foundations, I say: as soon as the air outside, among the rocky mountains, is by the manifold reflection of the sun reduced to a most tenuous substance and, rarefied, expands, it comes about that — seeking a larger place — it insinuates itself with the greatest force through the fissures and crevices of the mountain into its inner bowels. But since it cannot coexist with the air stabled within, the air driven in, like a stranger and newcomer, pressed and constricted, seeking an escape anew through the wider passages of the mountain, after long struggles is at last expelled with the utmost violence. And in this way that prodigious wind of which we speak is born in summertime at fixed hours. But when the external heat ceases, the wind too must necessarily cease again. All of which is shown by the beautiful experiment of the Aeolian balls [pilae Aeoliae].

[Margin: An experiment.]

Let a ball be made, fashioned of the most solid bronze, with a very narrow neck, in which there is likewise a hole as narrow as the point of a needle. Let this ball, filled to the middle with water, be cast into the fire and left until it has conceived the highest heat. Once this is conceived, you will at once cast it into cold water and hold it submerged a while; and you will see the air lurking there, reduced to a most tenuous substance, gradually condense and be driven back; and since no other body is supplied to fill the place of the failing air, it draws the water with great force into itself, and

[Margin: The cause why the mountain perpetually blows.]

I do that same thing daily in the summer months in my Museum [Musaeum] — which, by a hidden passage, extends into the domestic garden enclosed by the four very high walls of the temple and college. It happens, then, that as soon as the air in the garden is kindled by the heat of the midday sun and by the various reflection of the rays striking the walls, that air, dilated by excessive rarefaction, while it seeks an escape, rushing through the passage with great force, gladdens the Museum with a most welcome breeze — and this happens only in the afternoon hours and the summer months; but at the remaining time of day, or in the winter months, nothing of effects of this sort is perceived. This I would hold — saving the judgment of others — to be the true and genuine cause of the winds bursting from Mount Cesi [Mons Caesianus] with such force in the summer months.

[Margin: Why the mountain draws inward in winter.]

Now as for the fact that in the winter months the external air, together with the kerchiefs, paper, and similar things of lighter substance placed at the mouths of the passages, is snatched into the inner bowels by the opposite course of the way — I say its cause is this: that in winter the air, condensed by dread of a vacuum, always draws other and yet other air inward from outside. The cause of each effect — namely repulsion and attraction — I demonstrate by this experiment.

[Margin: An experiment.]

Let a vessel be made of any rather solid material — glass, bronze, tin — of the kind the figure A B shows; from whose bottom let a tube B A C be led out, and let the orifice D E be so blocked that the air can nowhere escape; and the instrument will be complete.

Diagram. A schematic woodcut of a pneumatic apparatus standing on a footed pedestal: a large spherical (bulb-shaped) vessel from whose top a slender curved

tube rises and bends over to one side, terminating in an open nozzle. Readable labels (with positions):

- C (right end of the curved tube, at its open nozzle): the outlet orifice of the tube
- D (upper neck of the vessel, right of the tube base): one terminus of the closable orifice D–E
- E (upper neck of the vessel, left of the tube base): the other terminus of the orifice D–E
- A (center of the spherical vessel): the vessel A, midpoint of the tube path B–A–C
- B (bottom of the spherical vessel, where the tube exits): the base of the vessel and start of tube B–A–C

Placed in the sun or by a fire, as soon as the air within boils up, that air, dilated by rarefaction, will prepare an outlet for itself through the tube B A C, and consequently will exhibit at the orifice of the tube C a notable wind, which will become apparent when a feather is set before it. But if you drench the vessel A B with cold water, you will feel — to your astonishment — the air A B, now condensed, drawing in the external air to supply the place of the failing interior air; which will appear from a feather set before the orifice C. In this way the vessel of the ball will be filled, as much as is enough; and if you then set lit coals beneath it again, it will soon resolve the rarefied water within into vapor. The enclosed vapor, since it finds no escape except through that narrowest hole, will burst out through it with the greatest hissing and violence of impetus; but when the external heat fails, the water, restored to its natural state, will emit neither vapors nor winds any longer.

[Margin: The cause of the perpetual wind, which some mountains breathe out.]

And from this experiment the cause of each effect in the said mountain is beautifully made plain. As for those winds which are blown out perpetually from some other passage of the mountain, they without doubt derive their origin either from subterranean cataracts, or from the inflow of the sea agitating the air in the subterranean passages — as is noted in some places of Etna [Aetna] — or from the melting of snows, as in Mount

Auvergne [Mons Alverniae], and concerning the cavern in Etruria near Volterra [Volaterrae], from which — Leandro Alberti [Leandro Alberti] being witness — a spirit and wind sometimes erupts so violently that it casts down whatever is in its

path, and even the trees themselves. But enough now of the Caves and Veins of the earth.

CAPUT XX.

Of Caves, Chasms, and the countless passages of the Earth. [De Antris, Hiaticibus, & innumeris Terrae meatibus.]

[Margin: Division of caves.]

Jacques Gaffarel [Jacobus Gaffarellus], in his *Subterranean World* [*Mundus subterraneus*], divides the Caves of the terraqueous Globe into five classes: Divine, Human, Brutal, Natural, and Artificial.

1. He divides the Divine again into various species, and they are the following: Angelic Caves, or Caverns, are those in which an apparition of angels occurred — such as the cave on Mount Gargano [Mons Garganus], most famous for the apparition of St. Michael.

[Margin: Ecclesiastical.]

Ecclesiastical: temples cut within the rocks, as they recount of the Mountain of the Pagodas [Mons Pagodum] in India.

[Margin: Catacombs.]

Catacombs, or cemeteries, which are visited here and there in the Roman countryside with the greatest celebrity — of which *Roma subterranea* [the *Subterranean Rome*, by Antonio Bosio] treats most copiously.

[Margin: Diabolical.]

Diabolical, or Infernal, in the inmost recesses of the Earth.

[Margin: Purgative.]

Purgative, that is Purgatory, Limbo, and the like, which are held by faith.

[Margin: Caves of the Magi.]

To these are referred the Caves of the Magi, in which, with countless superstitions, they performed magical operations — met with everywhere in all places.

[Margin: Of heroes.]

Likewise the Caves of Heroes, Idolaters, and Casters of Lots, and those in which oracles were given — of which kind were the Delphic and the Ammonian caverns.

[Margin: Fabulous caves of the poets.]

To these are referred the fabulous caves of the Poets — of Fauns, Dryads, Nymphs, Tritons, Sirens, and the other gods and goddesses.

[Margin: Caves of giants.]

2. Human Caves, to which are referred first the Caves of Giants, of the kind shown in the Palatinate [Palatina], Sicily, and other places.

[Margin: Of the Sibyls.]

The Caves of the Muses and Sibyls are still seen in many places — as at Naples in the Cumaeen countryside [Cumanus Ager], which we shall describe in what follows.

[Margin: Of hermits.]

To these may conveniently be referred the Caves of the Holy Hermits — as in Egypt and the Thebaid [Thebais], where countless caves of Saints Antony, Paul, Hilarion, and others are seen. In Malta [Melite], the cave of St. Paul the Apostle; in Sicily, that of St. Rosalia on Mount Pellegrino [Mons Peregrinus]; at Subiaco [Sublacum], that of St. Benedict; in France, that of Blessed Mary Magdalene, vulgarly *la Sainte Baume*; near Arles [Arelatum], that of St. Giles [S. Aegidius] — and so of the rest. To these too may be referred the subterranean Cities, and others of which we shall speak in what follows.

[Margin: Brutal caves.]

3. Brutal Caves, to which are referred the dens of Lions, Tigers, Wolves, Foxes, Bears, Serpents, and Dragons, and the other lairs of subterrestrial animals, and the hiding-places of birds that love cavernous spots.

[Margin: Caves endowed with marvellous powers.]

4. The Natural Caves, of which there are countless species, according to the natural powers implanted in them. Some are endowed with medicinal virtue.

[Margin: Mineral.]

Certain ones gush with metallic vapors, exhalations, and waters. There are also glacial ones, full of snow and crystal — as I remember to have seen on Mount Sorano [Mons Soranus]. There are also Aeolian ones, which emit continuous blasts of wind.

[Margin: Of other marvellous powers.]

There are not lacking those endowed with resolute, restrictive, and congealing virtue — of which in their own place and time.

[Margin: Artificial.]

5. Artificial Caves are those prepared for human uses or delights. Likewise subterranean passages made by art — as at Naples the Grotto excavated beneath Posillipo [Pausilippus]; at Syracuse the subterranean Labyrinths. To these are referred domestic grottoes, hydraulic ones, and subterranean temples. Likewise quarries and the other mineral-workings, of which expressly in what follows.

And this is the division of Caves — of which, however, apart from the Natural ones, we shall consider no others in this work.

[Margin: Natural.]

Now we call Natural those which Divine Wisdom established in the inmost chambers of the earth for the necessary uses of Natural things; of which some open an entrance on the outermost surface of the Earth, while others, inaccessible to men, are hidden in the inmost recesses of the Geocosm — distinguished into three species, and they are: Hydrophylacia, Pyrophylacia, and Aerophylacia, of which we have already spoken in the preceding, and which we shall pursue more copiously in what follows. But the external ones open an entrance to the immense vastness of caverns and the abysses of chasms, some of which we shall now adduce.

If, then, so great is the multitude and variety of Caves on the surface of the terrestrial globe, how great a multitude of them shall we believe there will be in the internal bowels of the Earth? This is certain: that all Caves possessing some notable virtue obtain their powers only from some inmost and enormous cavern — whether it be a Hydrophylacium or a Pyrophylacium — derived through far-extended passages, in proportion to the complexion of the earthy substance through which the said passages are conducted.

[Margin: Petrifying caves.]

Hence some caverns, by a petrifying juice proper to the condition of the place, turn everything into stone; others recreate wonderfully with an aromatic odor; certain ones imbue with a prophetic spirit, while some are wrongly perceived.

[Margin: The various virtues of natural caves.]

There are not lacking those which conduce to chastity, and on the contrary others which conduce to lust —

they are said to incite lust. Some, by a certain narcotic power, induce sleep; others, by contrast, induce wakefulness. Many gush with oil, with bloody liquor, with bitumen, with salt, with vitriol, with naphtha, and the like. The explanations of all these we shall assign in the Sixth Book of this work, for upon them depends the whole composition of sensible, vegetable, and inanimate things. Now, for this concurrence of causes to produce effects befitting nature, it accomplishes this in no other way than by distributing them aptly, each to each according to the condition of the earthly substance, through the countless channels and receptacles with which the earthly body is bored through, as if through certain fibers and vessels of the Megacosm.

But let us look at the marvels that Mela [Pomponius Mela] (I.6), Solinus (c. 39), Pliny [the Elder] (*Natural History* 31), and Strabo (XIV) report concerning the Corycian Cave [specus Corycium] — matters that bear greatly on our purpose. Not far from Pompeiopolis, they say, lies the town of Corycium, above which there is reported to be a cave called by the name of Conthyos, and above that one which can scarcely be described, so remarkable is it. For with a vast gaping mouth it opens a mountain set against the shore, steep enough on a slope of ten stadia, right from the summit; and with an ever wider and wider descent it grows green with shady groves blooming on every side, embracing itself wholly in a circle with its wooded flank, with such beauty that at first sight it astounds the minds of those who approach — yet for those who have lingered in contemplation, it does not pall. There is but one descent into it, narrow and rough, of fifteen hundred paces, through pleasant shades and the open spaces of a wood that re-echoes with something wild, with streams flowing here and there. When one has reached the bottom, another cave opens up again. It terrifies those who enter; then for a while it is bright; soon, as those who have gone in descend deeper, it grows ever darker the further one goes, and admits one as if down a deep tunnel.

[Margin: A marvelous cave.]

There a huge river, raising itself with a foaming front, just shows itself; and where it has drawn a great rush of water along a short bed, it is again plunged under and cut off. Within there is a space too great for anyone to advance into — terrible, and therefore unknown. Pliny adds that the dripping drops of this cave at once harden into stone.

Not unlike this is the one which Aelian [Claudius Aelianus] describes (*De Natura Animalium* XVI.16): "Among the Arrians there is a chasm called the Chasm of Pluto, in whose depths lie hidden caverns and immense recesses unknown to men. How it was sunk to so great a depth, not even the Indians can explain. Some three thousand and more diverse animals — sheep, goats, oxen — the Indians drive there, and out of superstition they cast many animals headlong into the depth of that pit, from which there is no exit, nor can they ever be seen again. Yet the lowing of oxen, the bleating of sheep, the voice of goats, and the neighing of horses are heard; and if anyone puts his ears to its jaws, he will hear sounds of this kind for a very long while, for the confused noise does not cease to resound, since beasts are continually driven headlong there."

[Margin: A chasm terrible among the Arrians.]

[Asclepiodorus, however, reports] (he says) [another cave, not far from this one], into which Philip [of Macedon] sent down very many men to explore an ancient treasure long ago appointed [for the purpose], to learn what its abundance was, what its condition, and whether the old greed had left anything for those to come. They descended, he says, with much light, and labored for many days; then, wearied by the long road, they saw huge rivers and vast masses of water gathered there — pools the equal of monsters — not indeed pressed in by the overhanging earth, but seen at large in their free expanse, not without horror. Whence, from so compendious a narration of marvelous things, he wisely concludes at last: "Not the whole earth," he says, "is compacted of solid matter all the way down to one [center], but in many parts it is hollow and suspended over hidden lairs; it has voids without moisture."

And again (*Natural Questions* III.16) he says: "There are beneath the earth rights of nature less known to us, but no less certain. Believe that below is whatever you see above; for there too are vast caverns, mighty recesses and empty spaces, with mountains hanging on this side and that, and chasms broken off into the boundless deep, which have often swallowed up cities that slid into them and buried a vast ruin in the depths." And (chapter 8) he has it thus: "Just as in the outer part of the lands vast marshes lie, and great navigable lakes, just as the seas are spread over a vast expanse of land, poured into its valleys, so the interior of

the lands abounds in fresh waters, and these stand in pools no less than the Ocean and its gulfs do among us — indeed more broadly, the more the land opens out into the deep." These words of Seneca [Seneca the Younger] can serve as a kind of recapitulation [anacephalaeosis] of all that has been said up to this point.

[Margin: Seneca's view.]

The forms of subterranean caves, then, are various, made either by chance or by nature. For some lie open, broadly excavated; some contain a very deep cavity; some are stretched out lengthwise, sunk profoundly to the bottom; some have manifold entrances and recesses. Yet all of them were founded by the Author of nature with that craftsmanship, endowed with those properties which the condition of the places seemed above all to demand, as it were by their own right.

[Margin: Variety of other caves.]

At Metaurus in Sicily there is a cave, horrible to behold, through which a huge river, running for a long while and over a long course along its subterranean bed, at last rolls out into the open plain.

[Margin: Cave-river.] [Margin: Strabo VI.]

On the same authority [Strabo XVII], another is reported to be in the Emporic Gulf of Mauritania, so hollowed out toward the sea that it admits the ebb and flow inward for seven stadia. Another is at Hierapolis and Laodicea, concerning which you may consult Strabo. And (book XIII) near Andira there is said to be a cave of such dimensions that it leads all the way to Palea — that is, to 130 stadia — and this became evident from the fact that when a he-goat fell into the chasm, it was found by a shepherd on the other side of it on the following day.

[Margin: A subterranean river. Strabo XVII.]

I shall not speak here of the vast and immense caverns of Ethiopia, which Father Páez [Pedro Páez] describes at length, through which the Nile and the Niger — huge rivers — roll down through subterranean passages of inexplicable length and incredible depth, plunged below. Nor shall I speak here of the caves and caverns of Mount Taurus or of Jamaí, surpassing all human belief, concerning which see Ramusio [Giovanni Battista Ramusio] (vol. 1).

[Margin: A cave in the Andes.]

Marvelous are the things that American history relates of the Mountains of the Andes, in whose bowels — more than can be told — it asserts that horrid receptacles of caves of such great capacity are found that they do not yield to

whole regions on the earth's surface. In these too there are mighty cataracts of mighty rivers, which hurl down their waters with such a roar and such a diversity of sounds that the diggers testify they have heard nothing more terrible in the world. Among other things worth recording: a small boat was found there, and from where and how it had been carried into this innermost receptacle of the earth, no one could conjecture. Yet it was afterward ascertained that this river finds its outlet from the opposite side of the mountain, nearly a hundred and forty leagues away, in a very deep valley. But since the river bursts forth here through huge precipices, I do not see how this little boat could have been driven by sailors against nature through subterranean groves into that inaccessible subterranean region. It is more likely that the boat was swallowed by the whirlpools [vortices] of the Pacific or Atlantic Ocean, transported here by a continuous flow of waters through subterranean passages, and cast out onto a subterranean shore.

But concerning marvels of this kind — the recesses of the Andes, their rivers, cataracts, and the rest of nature's wonders — let the reader consult Father Alfonso de Ovalle [Alonso de Ovalle], writer of a *History of Chile*, who treats of them fully and curiously, and from whom I received much by word of mouth here in Rome, to be brought forward elsewhere. Let him also see and marvel at what Olaus Magnus relates in his *History of the Northern Peoples* [*Historia de Gentibus Septentrionalibus*] about similar subterranean caverns, or rather regions. I could adduce countless other instances in this place; but lest the work swell beyond measure, I have thought it best to stay my pen here, intending to bring forward more in the course of this work, in their own proper places and at more opportune times.

MUNDI SUBTERRANEI LIBER TERTIUS HYDROGRAPHICUS

SIVE DE OCEANI NATURA, [OR, ON THE NATURE OF THE OCEAN]

Its origin and motions, both external and internal; likewise on its perpetual circulation [pericyclosis], and on the rest of nature's marvelous effects in the world.

SECTIO I. [Section I]

On the Nature of the Watery Element, or on the Sea, and on the continual motions by which it is agitated at every moment, and on the marvelous effects which it produces in the Subterranean World.

It is said in this Section to what end Nature established these marine motions about the earthly Globe. Likewise, [we treat] of the variety and change of the sea's tide [aestus maris] which occurs in various Regions, Rivers, Islands, and Straits; of the causes of each and all; of the marvelous constitution of the Ocean's floor; of the Circulation of the Ocean through each pole of the Earthly Globe; and of the marvelous constitution and intercommunication of all the seas through the hidden meanders of the Earth.

CAPUT I. [Chapter I]

On the diversity of Motions by which the Sea is agitated at every moment.

SUPPOSITIONES. [Suppositions]

Although in our *Ars Magnetica* [*Magnes, sive de Arte Magnetica*] we have set forth at length that most celebrated work of Nature — I mean the Approach and Recession of the Sea, which they also call the Swelling [intumescencia] and Subsiding [detumescencia] of the sea — nevertheless, since this is one of the greatest secrets of the Subterranean World, by whose power all things are preserved and sustained, I have therefore thought it best, so far as can be done, to describe it here in this one place as exactly as possible, as the most apt instrument of nature, by means of which all things (as I said) in the Subterranean World are uniquely disposed for the perfecting of the generations of things — as if in a certain womb and seed-bearing [panspermatic] storehouse of Nature — as will become clear from the discussion.

I suppose, then, first, that the Ocean — which is the one common receptacle of all sublunary waters — has one natural motion, by which all its parts, each and every one, compose themselves into a spherical surface (imperceptibly to us, though perceptibly into a plane surface), and once this is accomplished they come to rest. This is established by experiment: for if a wind makes some lake fluctuate this way and that, it is well known that when the wind ceases the water returns to its equilibrium beneath the level surface of the lake. For since it is a fluid element, it cannot happen that one part should stand higher or deeper than another; therefore it is necessary that it tend toward equilibrium, for this is the

end of this element's appetite. But if you consider the whole Ocean in its natural state, it doubtless composes itself into a spherical surface, so that all its parts are equidistant from the Center of the Earth — and Archimedes proves this beautifully in his book *On Floating Bodies* [*De iis quae vehuntur in aqua*].

[Margin: The Ocean's motion is one and natural to it.]

[Margin: The water of the Ocean composes itself into a sphere.]

I suppose, second: that when one part of the Ocean is moved by a more vehement impulse, the whole Ocean is necessarily moved in succession. For since it is a continuous body, the moved part A will at once raise the following part E into B, and

Diagram. A horizontal wavy line representing the successive propagation of motion across the Ocean's surface, marked with paired letters. The pairs A, B, C, D label the crests/positions, with the moved part A raising the following parts in succession.

- A: the initially moved part (at left)
- B (above): the position into which the following part E is raised
- C (above): the position into which part F is raised
- D (above): the position into which part G is raised

B will raise part F into C; and C will raise part G into D; and so on in succession, in a circle, until it is restored to its starting point. Yet you may judge that the motions are always weaker the further they are from the starting point. Let all this be understood of the motion of the sea with no blasts of wind (which everywhere hold sway), and with the obstructing impediments of shores and promontories removed; for by these the motion is not merely impeded but necessarily destroyed.

[Margin: When one part of the Ocean is moved, the whole is moved in succession.]

From this it is clear that if any canal whatever, of whatever length, is filled with water and closed at both ends with cork stoppers, then — the stopper being removed, or the water being even lightly pressed with a pestle — at the very same moment of time at the other end it will excite a motion just as great as the space the pressed water had left within the canal.

[the motion is] either straight, or a whirling [vortex], or a shaking [concussion].

I suppose, third: that all the surface parts of the water naturally press the waters set beneath them, all the way to the bottom, perpendicularly; but accidentally — that is, through a violent impulse — they press obliquely. Let there be some vessel L M N O filled with water.

Diagram. A cylindrical vessel shown in perspective, filled with water, used to demonstrate that surface water presses perpendicularly on the water beneath. The rectangular body of the cylinder is bounded at the top corners by L (left) and N (right), and at the bottom corners by O (left) and M (right). Along the top rim are the points D, A, C; along the bottom rim are the points C [recte: see note], B, I. Dashed lines descend from the top points toward the bottom, illustrating the lines of perpendicular and oblique pressure.

- L (top-left corner): upper-left edge of vessel
- N (top-right corner): upper-right edge of vessel
- O (bottom-left corner): lower-left edge of vessel
- M (bottom-right corner): lower-right edge of vessel
- D (top rim, left): a surface point
- A (top rim, center): the surface part whose perpendicular pressure follows line A–B
- C (top rim, right): a surface point
- B (bottom rim, center): the point directly beneath A
- I (bottom rim, right): a bottom point referenced for oblique pressure

I say that the parts of the water A at the surface press the waters set beneath them not obliquely toward M or O, but perpendicularly upon the waters placed directly below, along the line A B. But the parts C or D press not obliquely toward B, but straight down into E or I. And this is clear from what Archimedes demonstrates by subtle reasoning in the book cited, to which I refer the reader. It is also clear by experiment: for if you bore a hole in the bottom of the vessel at B, the water will descend straight down, not at D or C, but at the point A perpendicular to B, with a little whirl formed. The same is to be understood of any opened place in the bottom of the vessel: for example, let the bottom be opened at E or I, and you will soon find that the water descends through little whirls perpendicularly to D or C, and empties out through E or I.

[Margin: Water always presses perpendicularly.]

I suppose, fourth: that the motion of the sea is either straight, or a whirling, or a shaking. The straight motion of the sea is when it is driven toward some region by an impulse from without. The whirling motion of the sea is when the sea is

driven into a gyre; and this happens for the most part either naturally or accidentally. Naturally — when the water is absorbed into an abyss hidden in the floor of the sea (of which more fully in its proper place). Accidentally it is moved into a gyre when, by contrary winds, the sea is driven into whirlpools.

Furthermore, the universal straight motion is twofold: the first constant and perpetual; the other indeed perpetual, but compounded of contrary motions. The perpetual and universal straight motion is that by which the sea or Ocean is perpetually driven, following the motion of the Sun, from East to West. The other general motion, compounded of contrary motions, is properly that which we call flux and reflux (ebb and flow), others approach and recession, and some the Swelling and Subsiding of the Sea; and it occurs by the Motion of the Moon from her Rising to her Setting.

There are found in the sea also certain other motions, proper and singular, and others contingent. The proper and singular motions — which we call special or proper — are those by which only some parts of the Ocean are moved; and these again are twofold: perpetual, and anniversary [annual], which never cease to make the sea boil. The anniversary are those which are detected in some sea at fixed months or days of the year. But contemplate the division of all these in the following resolutive Table.

[Margin: Division of the sea's motion.]

The motion of the Ocean (the one receptacle of all sublunary waters) is either:

Straight

Constant and perpetual, and is from East to West, and depends on the Sun.

Compounded of contrary motions, and is called the flux and reflux of the sea, and depends on the Moon.

Reflected, and is either by

The general motion, by which the sea is driven

to the shores of
opposite Regions.

Of the sea toward
opposite shores
by the reflection
of the force of the
winds, made into
another quarter
— which they call
Currents.

**Proper and
special**, or
peculiar to some
particular sea,
and is either:

Perpetual, and
this again either
by

From the
absorption of the
sea's water, as
happens in
whirlpools, and
they are called
circular motions.

From the
vehement
irruption of some
subterranean
river into the
underwater
regions, by which
the sea
continually boils
up to some point
here.

From the impetus
of huge rivers and
streams
discharging
themselves into
the sea, by which
the sea is either
driven straight to
some point, or

agitated into whirlpools, or the sea is driven into inconstant tides.

Anniversary,
which are

Those which are detected at fixed months or days of the year in some sea: to these is referred the motion of the Ocean from South to North, or from North to South.

Contingent
motions of the sea, by which the sea is never free, and which arise either:

From the Winds, of which there is an innumerable variety in the sea, by which the sea is perpetually harassed by their mutual agitations, now into these, now into those parts; and it depends on the sudden commotion of the air (as will be said concerning the origin of the winds); and without any fixed order they now cease, now begin, and are as it were unending [non-

finite].
Or from
subterranean
spirits and
exhalations
disturbing the sea,
which now and
then burst forth
from the floor of
the sea, and stand
in no fixed order,
nor last for any
fixed and definite
time.

Circulatory,
[which is]

General

That is the motion
by which the
Ocean perpetually
circulates from
the Arctic pole,
through the
Antarctic pole,
through the
bowels of the
Terrestrial Globe.

Special

By which all the
communicating
seas, through
subterranean
passages, carry on
the reciprocal
commerce of their
mutual
interchange.

Particular

By which the sea,
through
subterranean
passages,

discharges itself
within the
receptacles of the
mountains; and
this circulation
accomplished, it is
restored to its
origin.

CAPUT II.

On the general motion of the Sea, which is from East to West.

[De Motu generali Maris, qui est ex Oriente in Occidentem.]

The general motion of the Ocean is from East to West, as has become known through long experience to those who, undertaking a voyage across the immense expanses of the Ocean to the New World, have sailed back and forth across it. Those who set out from India toward the western Cape of Good Hope [Bonae Spei promontorium], or who sail from Portugal [Lusitania] or Spain to Mexico, complete a voyage of that kind in a far shorter span of time than one would sailing from Portugal to India, or from Mexico to Spain.

[Margin: Why the voyage from Portugal is shorter, and the return from India longer.]

Moreover, those who customarily sail from the port of Acapulco in New Spain to the Philippine Islands run, from that port — where there is an almost perpetual calm [malacia] — up to the tenth degree of northern latitude, and then sail westward along the parallel of that tenth degree so favorably that, with sails unaltered, they cover a distance of 3000 miles in the space of 85 days. They do not change sail until they reach the islands they call the Ladrones [Ladrones, the Mariana Islands], where, leaving the tenth parallel, they steer the ship to the thirteenth, so as to enter directly the "mouth of the islands" (which they call *la bocca de las Islas*). In this way, with the dangers avoided, they at last safely reach the port of Manila. And so they cover a third part of the terrestrial globe in no more than seven months by this easterly wind, which never fails the sailors.

By contrast, from the Moluccas they cannot make for New Spain under the tenth parallel, since the wind and the sea are always against them there. Hence it is

necessary for those who intend to sail from the Philippine Islands to New Spain to make for the fortieth degree of northern latitude, for under this parallel, driven by the northerly winds that reign perpetually along that coast of North America, they reach the port of California [Caliphornia] in a short time. So Father Simon Cotta [Simon Cotta] and Father Diego Bobadilla [Diego Bobadilla], procurators of the Philippine Islands, who had by then twice crossed that sea, told me by word of mouth.

[Margin: How the voyage from the Philippine Islands to Mexico is laid out.]

This motion is also observed in the Strait of Magellan [Fretum Magellanicum], where the Ocean, rushing from the East into the very narrow jaws of this strait, throws everything into turmoil with vast boilings of its swells [aestuum ebullitionibus], until it finds itself a passage into the Pacific Sea. So too through the Strait of Manila [fretum Manilanum] and the Gangetic Ocean [Oceanus Gangeticus] it is carried from East to West with a most rapid motion through the channel of Cape Comorin [Promontorium Comorinum]. At the Gulf of Paria [Sinus Pariae] it is swept with such violence from the East that the place has been called the "Mouth of the Dragon" [os Draconis, *Boca del Drago*]. This motion is also observed by those who sail from Europe toward Canada. The Tartarian Ocean [Oceanus Tartaricus] likewise is carried with the utmost force through the Strait of Vaigach [fretum Weigats], which is evident both from the motion itself and from the abundant ice that the said Ocean rolls out into that strait.

[Margin: Everywhere the strong easterly motion of the Ocean is noted.]

In the Pacific Sea, too, the sea moves toward the Strait of Anian [fretum Anian]; from Japan it is driven toward China; and in the same way it is set in motion in the strait at Java. In a word, that a motion of this kind from East to West is observed everywhere throughout the whole Ocean is as certain as is the unanimous, consistently confirmed experience, over many years, of all the sailors who have very often plied that Ocean.

The cause, then, of so plain an effect is inquired into. The Peripatetics, in their usual manner, at once take refuge in the sweep of the *primum mobile* [the Prime Mover] — whether or not it exists in the nature of things is not yet settled. Others imagine a magnetic power in the Sun, by which the sea is drawn. Others, intent on metaphysical speculations, are so far from assigning the cause of so great an effect that they rather obscure it. Setting aside those most remote speculations, we proceed to the nearer and more proximate causes.

[Margin: Various opinions about this motion.]

We shall therefore philosophize better if we say that the cause of this marine motion is the Sun's revolution from East to West. For since the greatest part of the Ocean lies beneath the torrid zone [zona torrida], and the Sun almost perpetually strikes some part of this region with its rays at the perpendicular, and thus daily draws up and rarefies an immense mass of water by its rays, converting it either into air or into vapors and clouds — it is necessary that, in place of the consumed and drawn-up waters, others be substituted from the East or from either side. And since this drawing-up of the waters is always continued, no one fails to see that this effect of the sea's flux toward the West will likewise endure.

[Margin: The true cause is set forth.]

That a great and incredible quantity of water is drawn out of the Ocean by the power of the Sun is abundantly attested by the daily and most copious rains in those regions where the Sun stands at the vertical [verticalis]. It is established from the report of Our Fathers who dwell in the Colleges situated beneath the torrid zone: when the Sun is set at their zenith, such daily deluges of rain pour down around noon that the level plains of the fields seem to stand in pools, and the harbors and shores are filled with sand worn down from the mountains, along with clay-like matter and other refuse. In this way, by a kind of restoration [postliminio], the sea is given back what had been taken from it by the Sun.

[Margin: Most copious rains in those places where the Sun is at the vertical.]

But why, at the fortieth degree of latitude, the winds are for the most part northerly and prevail along the shores of the Pacific Sea — the cause is the rarefaction of the vapors, which, raised up beneath the torrid zone and diffused far and wide into the northern region, are driven back by the cold that comes over them and by the air thus condensed, and so produce the said winds. And why the wind in the Pacific Sea is perpetually easterly — the cause is that, as the Sun rises, the vapors hanging over the Ocean, compressed by the nocturnal cold, are rarefied by the ensuing heat of the Sun

[Margin: The cause why, under the fortieth degree of latitude in the Pacific Sea, northerly winds prevail.]

and degenerate into winds. Since they continually disturb the forward paths of the Ocean, it is no wonder that, the same cause persisting, the sea's motion from East to West is likewise perpetuated in accordance with the Sun's motion. To this is added that the vapors driven back from the North and the South [ex Borea & Austro] continually force the waters on both sides into the Euro-Zephyr Current

[Euro-Zephyreum Currentem] within the Ocean. And this motion is the more violent in proportion as the Sun stands more nearly perpendicular to the Ocean.

[Margin: This Euro-Zephyr motion exerts itself most of all beneath the torrid zone.]

Hence, in the Ocean lying beneath the temperate zone [zona temperata], the Sun exerts its force only to a degree; yet because it strikes so great a surface of the sea with its rays obliquely, the sea's motion from East to West is by no means observed here to be so violent as in the torrid zone or in places near to it.

[Margin: It exerts its force most of all in the Euro-Zephyr.]

Finally, that the Moon too greatly promotes this Euro-Zephyr motion of the Ocean is clear from the fact that, at the conjunction or opposition of the Sun and Moon, this Euro-Zephyr motion is found by sailors to be much swifter and more violent. For at conjunction it powerfully presses upon the paths of the Ocean emptied by the Sun, and from this pressure the sea is always driven forward, in accordance with the motion of the Moon and Sun — as will be demonstrated more fully below. At opposition, however, the Moon by night likewise presses toward the West, and so, wave thrusting wave, there arises continually a certain undulation of the Ocean from East to West, by which the deficiency of the waters drawn up by the Sun is made good through the subsequent surges of the waters compressed by the Moon. But at the quadratures, since the Moon does not face the sea perfectly, it accordingly contributes a lesser force of compression as well. And experience teaches that this motion is almost always exceedingly feeble in the Moon's quarters.

[Margin: The Moon promotes this motion most of all.]

Now from this general Euro-Zephyr motion two other motions of the Ocean arise: one is from South to North, the other from North to South. For it is established that the Ocean bursts out from the northern corner of the world with a certain violent force toward the southern region in the Atlantic Ocean [Oceano Atlantico]. Hence those who make for the Cape of Good Hope from Portugal, or from the islands they call the Azores, accomplish it more quickly than the reverse. And the force and efficacy of this flux lasts for nearly the space of half a year — from North to South, that is, and the reverse. How this comes about, I shall now explain.

[Margin: From this universal motion of the Ocean two other motions arise, one from North to South, the other from South to North, and the reverse.]

Since the Sun, as I said above, perpetually overhangs the torrid zone and draws an immense mass of water out of the Ocean lying beneath it, it comes about that this tract of the Ocean, with its waters drained off, is rendered as it were lower-lying [decliviores]. But the northern Ocean, since it is set outside the perpendicular rays of the Sun, by its most humid temperament for the most part receives a continual increase of water — converting the surrounding air into itself — and substitutes itself in place of the drawn-off waters, Nature, the provident dispenser of things, ordering matters in this way. Thus it comes about that the northern Ocean, by its own increase, comes to the aid of the Ocean beneath the torrid zone, which is laboring under a deficiency of waters — as a rich man helps a poor one, all the parts conspiring toward the preservation of the whole.

[Margin: The cause of these motions.]

The same is to be said of the southern Ocean, opposite to the northern. Hence to the parched and lean [Ocean] there is always allotted, alternately each half-year out of the storehouse [penuario] of whichever of the two Oceans is the richer, as it were a certain provision [annona] by provident nature — lest the [Ocean] be deficient in necessities — for supplying the deficiency of the one out of the excess of the other. I confirm this by the following experiment.

[Experiment:]

If above a certain oblong vessel filled with water you draw an iron ball, previously made white-hot by fire and gripped with tongs, gently from A to B, in such a way, however, that the waters

Diagram. A small woodcut illustrating the experiment. An oblong rectangular trough (shown in perspective, with its near and far long walls drawn) holds water; a white-hot iron ball gripped in a pair of tongs is suspended just above the water's surface near the left end, with the operator's hand on the tong handles at the right. The ball is to be drawn slowly from one end of the trough to the other.

- A (left interior end of the trough): the starting point of the ball's motion
- B (right interior end of the trough): the endpoint of the ball's motion

[Note: only "A" is legibly inked at the left end of the trough; the "B" referenced in the text would lie at the right end where the hand and tongs are, but is not separately legible.]

do not touch its surface [i.e., the ball does not touch the water]: you will find what I said — that the water, about to follow the motion of the ball, is left in the middle

as in a kind of channel. And if you have first marked the boundaries of the water and the vessel, you will see, once the motion of the ball ceases and it has cooled, that the water has plainly subsided in the vessel, having been dissolved into vapors by the ball's heat. Let this suffice concerning the general Euro-Zephyr — or Noto-Boreal [Noto-boreo] — motion.

CAPUT III.

On the motions which they call Currents, whether repercussed or reflected.

[De Motibus, quos Currentes vocant, sive repercussos, aut reflexos.]

This motion arises in manifold ways: either from the general Euro-Zephyr motion driven against the overhanging shores of the regions and thence reflected back — which the sailors call a Current [Currentem]; or from the blowing of the winds; or, finally, from the motion of the flux and reflux, caused by the power of the Moon.

[Margin: Currents reflected by the power of the Moon.]

Those who sail from the Canary Islands to Mexico are for the greatest part carried by the Currents of the Ocean, which, between Cuba and Hispaniola [Hispaniola] and the mainland of New Spain, are so violent that they seem to reproduce the rush of a river. Once ships have been cast into jaws of this kind, no means of retreating is given them. Indeed, those who are to sail from the Gulf of Mexico [Mexicano sinu] to Spain must keep to the shores of Virginia and Florida, so that the ship may hold its course. The reason for this is none other than that the Ocean, rushing partly from North to South with the greatest violence, at the Cape or White Promontory [Promontorio Candido] (which they call *Cabo Blanco*)

[Margin: The Currents of the sea between the Canaries and Hispaniola.]

Diagram. A large fold-out engraved world map: the "**Geographico-Hydrographic Table indicating the Motion [of the Sea] throughout the whole World, ☉ [the Sun-symbol] marks [...]**." This is a double-hemisphere ocean-current chart; the leaf shown in this batch is the **left (western) sheet** of the plate, the fold to the right being cut off at the page edge (the right sheet, carrying the Old World and the legend continuation, falls outside this image). The visible sheet is bounded by graduated borders: a horizontal scale of longitude running along top and bottom from **180** through **190, 200, 210 ... 350**, and at the right edge "**Sep: 360**" (top) / "**Meri: 360**" (bottom) — i.e., the meridian count; and a vertical scale of

latitude on the left and right inner frames numbered **90, 80, 70, 60, 50, 40, 30, 20, 10** down to the equator and back to **90**, with "**Occidens**" (West) marked at the left margin near the equator.

The engraving shows the Americas and the surrounding oceans, with hatched current-bands (the parallel engraved lines) sweeping westward across the sea. Sun-symbols (☉) are scattered over the torrid-zone ocean, marking where the Sun draws up water (per the legend convention).

Readable labels (with positions; geographic forms modernized in brackets):

- **AMERICA SEPTENTRIONALIS** (across the upper landmass): North America
- **AMERICA AUSTRALIS** (across the lower-right landmass): South America
- **MARE AUSTRALE** (central ocean, upper portion): the Southern Sea — i.e., the Pacific
- **DEL ZUR** (central ocean, lower portion): *Mar del Sur*, the South Sea (Pacific)
- **MARE DES NORD** (right side, upper ocean): *Mar del Norte*, the North Sea (the Atlantic / Caribbean side)
- **TERRA AUSTRALIS** (across the bottom): the Southern Land (the conjectured southern continent)
- **Nova Guinea** (island, left-center): New Guinea
- **Nova Granata** [recte: Nova Granada] (mainland, right-center): New Granada
- **Nova Hispania** (right-center landmass): New Spain (Mexico)
- **PERU** (right landmass): Peru
- **Brasilia** (far right landmass, partly at the fold): Brazil
- **Magellan[icum]** [?] (lower right, near the southern tip): the Strait of Magellan region
- **sive** ("or" — connective in the sea-name legend, lower-center): linking *Mare Australe* with *Del Zur*
- Several small unlabeled or barely-legible river-mouth and place annotations along the South American coast (e.g., near Peru a short label "**Por[t]...**" [?], and "**Rio...**" [?] annotations) — not resolvable at this resolution.

[The full caption's final clause after "NOTAT" runs off the right edge of this sheet and is not legible here; the companion right sheet of the fold-out is required to read it.]

Diagram. This is the large fold-out engraved world map of the Old World hemisphere (the eastern sheet of Kircher's two-sheet current map), here showing Europe, Africa, and Asia with the ocean currents, abysses (whirlpools/swallow-holes), and fire-belching mountains marked. The plate spans the full opening; is the blank verso of the engraving. The engraved upper-right corner bears the volume/page reference *Tomus I. 124.*

Engraved title banner (top): "OCEANI, CURRENTES, ABYSSOS, MONTES IGNIVOMOS" [The currents, abysses, and fire-belching mountains of the Ocean], with a second line: "HÆC FIG[URA] ABYSSOS [followed by a small engraved volcano vignette] MONTES VULCANIOS" [This figure (shows) the abysses (and) the volcanic mountains]. The little erupting-mountain icon in the banner is the legend-key for the volcano symbol used across the map.

The frame carries a graduated border of longitude (top and bottom, running 10°–180°) and latitude (right margin, 90°–90° through the equator, marked "Oriens" [East] near the equatorial line). Continental labels engraved across the sheet: EUROPA [Europe], ASIA MAJOR [Greater Asia], AFRICA [Africa], OCEANUS ÆTHIOPICUS [the Ethiopic Ocean — i.e. the South Atlantic], and across the southern margin in large scroll letters "[TERRA] INCOGNITA" [the Unknown Land — the conjectured southern continent].

Numerous small point-letters are engraved across the oceans and coasts as keys to the current-and-abyss discussion in the text. The legible labels, with approximate position:

- D (South Atlantic, off SW Africa)
- I (South Atlantic, off SW Africa, near D)
- H (off the southern tip of Africa / Cape region)
- A (interior of southern Africa, "C·A" — part of a continental label)
- G (Indian Ocean, mid-sheet, south of Asia)
- G (a second G further east in the Indian Ocean)
- E (south-central Asia, near the equatorial line)
- S (south-central Asia, near E)
- F (Indian Ocean / Arabian Sea region)
- R (Indian Ocean, off the SE Asian coast)
- M (Indian Ocean, off the SE Asian coast, near R)
- P (eastern Indian Ocean, near the East Indies)
- O (eastern Indian Ocean, near P)
- B (far SE, off the NW promontory of the southern continent)

- C (eastern Indian Ocean, mid-sheet)
- G (a third G, far SE Indian Ocean)
- Z (far east, off the East Indies / "Z" in the right ocean)
- I (far east margin)
- X (NE Asia)
- K (NE Asia, far right)
- Y (NE Asia, right margin)
- V (NE Asia, right margin)
- S (far south, southern-continent coast)
- X (far south, southern-continent coast)
- Q (far south, southern-continent coast, mid-bottom)

Small erupting-volcano vignettes are engraved at numerous points (Iceland/N Atlantic, the Mediterranean — Vesuvius/Etna region, central Africa, NE Asia, and the East Indies), and a dotted line is drawn through the Mediterranean and across to the Persian Gulf / Red Sea region marking a chain of abysses. [Many of the single point-letters sit in densely hatched ocean and are at the resolution floor; positions are given as best read for label verification.]

[The blank verso of the engraving carries no text.]

(...Cabo Blanco) it is poured out by ebb and flow, and from there once again, carried by the general east-to-west motion, it directs its course toward the islands of Cuba and Hispaniola. There, hemmed in and constricted between the narrows, it stirs up violent surgings of the waves. But when it has run on as far as the Gulf of Mexico, and is forbidden to exit there, it wheels its course round toward the shores of Virginia and Florida, and there at last, with the utmost force, is restored to the open Ocean to circulate once more — a motion that, as I said, the general motion of the sea greatly assists. For since the current suffers this violence beneath the torrid zone, and cannot in every quarter break through the agitated sea, it therefore seeks an outlet by a reflected current, and, circulating within the said regions, [returns] to its beginning. But of these matters fuller scope for discussion will be given in what follows.

Caput IV.

On the general motion of the Sea, and its effects around the terrestrial globe.

[Margin: The bottom of the Ocean is uneven, which is a cause of the swiftness or slowness of the sea-flows.]

The reader must first understand this: just as rivers produce different effects on the outermost surface of the land, so too in the sea. For in its tides, currents, sandbanks, and in the sea's swallowing and regurgitation, rivers shut in between mountain walls and made to wind through long detours acquire — as experience teaches — a swifter motion than the rest, and indeed a motion the swifter, the steeper the channels they have. By contrast, where they spread out diffused over broadly open plains and unfold their full breadth, they advance with a motion the slower, the more level their beds. And the bottom of the whole Ocean, no less than the surface of the Earth, is utterly uneven. At one point it is girt with vast chains of mountains and a multitude of crags, and has very deep valleys and gorges; at another it spreads out its waves over the level expanses of immense regions; then again, channelled into hidden and secret chasms, it draws off a mass of water along with itself; and sometimes, regurgitated out of the blind abysses of the Earth, it whips up savage tempests.

These things being so, I cannot but marvel at the ignorance of certain people who say that the sea, as regards its motion, always behaves in the same way, and is not agitated faster in one place than in another. Since this is contrary to experience, I judge it to be rash to assert it — as will shortly be shown by the demonstration of the universal motion of the sea.

[Margin: The motion of the sea, both its flux and its total reflux, sets the whole mass and bulk of the Ocean in motion.]

It is certain that the Ocean is set in motion by a general motion from east to west, by the power of the Sun and Moon. Moreover, it is established from what was brought forward above that the tide — that is, the swelling and subsiding of the Ocean stirred up by the lunar power — moves not merely at the surface, but the whole mass and bulk of the Ocean, from the bottom right up to the surface. And I myself can be an ear-witness to all of this: for while I was investigating the marvels of the Sicilian strait [the Strait of Messina], more than once, at the height of the sea's swelling, I heard a tremendous din. And when I asked the sailors what sort of sound this was, they answered that this sound is always perceived when

the sea is at the highest degree of its tide; and that this sound and crashing noise arises from the collision of the pebbles, shells, and similar things clinging to the bottom, which, agitated by the rapidity of the sea and repeatedly dashed against one another, produce this din.

[Margin: Experience.]

From this I gathered, first, that not only the surface of the sea but the whole mass of water is moved by the lunar power. For if this power makes the shellfish clinging to the very bottom — crustaceans and soft-bodied creatures of every kind — grow at both the new and the full moon, then surely the moving force of the Moon will act with no less power upon the little bodies composed of niter, salt, alum, vitriol, and bitumen, with which the whole sea is filled, than upon other things. For indeed, when the seas are rarefied and thinned by the lunar power, and all the parts at once seek a larger place, and the following parts urge on others, and these still others, violently — that from this a great commotion and swelling of the innermost sea too is born, no one but someone ignorant of these matters could deny. And this is the first point.

The other opinion is that of those who hold that the sea moves no faster along the slopes of the submarine valleys than over the submarine plains — which plainly conflicts with experience.

[Margin: The slope of the sea-bottom is a cause of the rapidity of the currents.]

For since it has now been shown that the whole mass of the Ocean moves together, it is certain that on the slopes of the valleys it rushes with greater force than on level bottoms; and the various perpetual currents of the Ocean, rushing now into this region, now into that, with their speed sweep away with them, even against their will, ships laden with cargo despite a favorable wind. This would not happen unless the said slopes existed in the sea; for by these the bulk of the Ocean, enclosed and constricted and made diverse, drives its course forward just like rivers between mountains, until on the more level places it is restored to repose.

[Margin: Objection.]

But you will say: every day there occur in the Ocean and the seas various and differing currents, which nevertheless do not last but are temporary. Reply: such currents arise not immediately from the lunar power, nor from the disposition of the sea-bottom, but from the winds, which agitate the waters superficially now in this direction, now in that. Hence they are not made perpetual, but when the

wind ceases the sea attains tranquility — whereas the currents (whether the sea [is calm]...

) be tranquil and free from all agitation, nevertheless they always endure. If, therefore, the sea were not moved by these motions we have spoken of — both the general and the special — but always stood still, then it would also be true that the sea always behaves in the same way, whether its bottom be level or sloping. But since the sea is perpetually agitated — now from east to west, now from north to south, and conversely; now within the submarine valleys by its own currents — it is impossible for it to behave always in the same way. But now let us confirm all this by an apodictic and geographical demonstration.

Spread out before you the geographical map, which we have drawn up expressly so that whatever serves our purpose may shine forth from it more clearly than the noonday light. We said in the preceding pages that the general motion of the sea is from east to west; yet I would not have this so understood as if the sea were always borne straight from east to the opposite quarter in a continuous flux, but rather that it is set in motion sometimes by an oblique reflux, sometimes circular, and at times by a motion of flux and reflux according to the configuration of the obstacles it meets.

And so, when the Sun is in the vastest of all the oceans — exerting the power of the luminaries especially, as in the most ample field — the Ocean, struck along the motion of the heavenly bodies, spreads itself far and wide, and most of all through the East Indian Archipelago, swelling and turgid among (as they report) 11,000 islands.

[Margin: Why the tide is so savage in the East Indian Archipelago.]

It has therefore been observed that the sea, in so great a throng of islands, is, as it were, carded [combed] — and on account of the various rebounds and assaults against the islands lying in its path, it stirs up altogether unaccustomed tides. Three places, however, are especially singled out, in which such sportings of the sea are particularly observed. The first is between Japan and China; the second in the strait between Malacca and Sumatra; the third between Java, the Celebes, Borneo, and the Southern Land [Terra Australis].

[Margin: The dreadful tempests between Japan and China, and their cause.]

Between Japan and China the sea, going now from west to east, now turning into a circle, causes such savage tempests that — as the nautical histories relate — ships caught up in it can scarcely extricate themselves. For the force of the sea in

those places is so great that, from the clash of opposing waves, it even lifts the ships themselves up into the air, carried far from the surface of the sea; and especially when a northwesterly wind [ventus Caecias] comes on, it dashes them through the air against the neighboring crags and shatters them into a thousand pieces. On these matters see Father Furnerius [Georges Fournier] in his *Hydrographia*, book 6, chapter 8.

The cause of this is the following. Because the Southern Sea [Mare Australe], driven back with the utmost force against the shores of China, and rebounding from west to east, holds its course for some distance; and with ever-new accumulations of waters K (see the map) pressing upon the sea, when these cannot overcome the rebounding waves, then — along the shores of China X Y V, as pressure builds up against the shores of Japan — the sea must necessarily turn into a circle. And from the other side of Japan, the southern sea coming up with its waves, when they meet the sea circling round from the northern quarter, savage whirlwinds and huge tumults of storms arise there — whence the destruction of ships and men.

Furthermore, as the sea's flux is continued from east to west, when it works its way somewhat more deeply between the Philippine Islands and the shores of Cochin China into the Strait of Malacca, in such narrows, M, it stirs up such unaccustomed tempests and tides as the sailors have often experienced, to the ruin of everything. Nor is it any wonder, since when the sea works its way through the said channel of Cochin China — as through a very deep valley — into the narrows, M, of the strait, there, powerless to sustain so great a mass of waters, it drives part into circles and reverberates part back against the shores of Sumatra. Hence the sea must necessarily counterfeit motions contrary to the general motion.

The same is said to happen between the straits of Java, Borneo, and the Southern Land. For the sea, set in motion from the southern ocean E, both on account of the innumerable encounters and collisions with the islands, takes on an appearance of tides similar to those described above, until — freed from the vexations of the islands — it pursues its free course westward.

[Margin: The currents in the straits of the surrounding islands.]

Therefore, from the mouths of the straits O and P, gliding with the utmost force, the sea first directs its course toward the promontory B of the Southern Land, where it directs its reflected current northward toward the Gulf of Cambodia R,

with such force that — as the nautical itineraries report — the rapidity of a river might be seen and reckoned in it.

[Margin: The immense flux and reflux of the sea on the shores of Cambodia.]

On the Gangetic shore, however, the flux and reflux of this torrent is borne so swift and impetuous that for 30 miles it now covers the shore, now uncovers it, with such speed that scarcely could a horseman at full gallop on the strongest horse escape it.

The cause of this is sought. Reply: when the sea, by means of the current P Q, is driven back against the shore of the Southern Land, Q, its flux is continued for some distance — for example, to C — where the current, encountering once again the supervening currents that rush down from the straits of the surrounding islands, is directed together with them into the farthest edge of the gulf, P. And the cause of the rapidity of the sea in this place I declare to be the steep slope of the submarine valley, through which the sea, rushing with the utmost force, produces on the shore the effects described a little before. But since the sea is found in this place to be so full of whirlpools that the sailors can scarcely overcome them, the cause I declare to be this: that the sea in this place R discharges itself through some passage of a subterranean chasm into the innermost hydrophylacia [water-reservoirs] of the Imaus and Paropanisus mountains, to constitute the sources of springs and rivers. And that this is so, the fact that the depth of the sea in this place can be sounded by no plumb-line sufficiently attests — and it was set out at length in the *Itinerarium*.

Furthermore, when the sea ebbs back from this place with the same force with which it flowed in, it comes about that, leaving its former current to its prior current (being, as it were, contrary to it), partly toward G, and partly through the channel F, set between Ceylon [Zeilanum] and the Cape Comorin promontory [promontorium Camorinum]...

directs its course there with no less force than the currents we described in the straits above. There, finding new encounters with the currents driven back from the Southern Land [Terra Australis] by the Indian sea, it directs part of its flow into the Gulf of Cambay [Sinus Cambaiz], and part toward the Maldiv Islands. [Margin: The currents in the Indian sea described.] Forestalled there by a firm anchorage and by manifold defenses of weapons, it sounds the retreat: seeking safety in flight toward the shores of India, it is swept, as though circling round, into the interior of the Indian Gulf. Here, meeting with the earlier current, it stirs

up equally great floods and ebbs, and the swell rises in that shoreline to five — or, as others say, seven — fathoms [orgyas].

But at one of the mouths of the Indus, the flux and reflux of the sea draws the admiration of all others: so great is the size and the speed of the advancing and retreating sea that many suppose Alexander the Great [Alexander Magnus], once terrified by these prodigious surges, gave up his expedition further on. I think the cause is the same as the one we described in the Gulf of Cambay — namely, the steep declivity of the sea floor, a kind of abyss through which the sea unburdens itself into the interior of the mountains to form lakes and rivers. This submarine valley, I judge, branches in two: on one side toward the mouths of the Indus, where it joins the land valley of that river — for it is too well known to need saying that the Indus runs through the deepest valleys among the sheer crags of the mountains. On the other side, as the map shows, it withdraws from G to E as far as the Persian Gulf [Sinus Persicus], which is also evident from the perpetual flow of the sea into those regions. [Margin: The Persian Gulf described.] We showed at length in the Third Book that the Persian Gulf is filled with abysses and corresponds, through a subterranean channel near the promontory of Loffanda [?], with the Caspian Sea [Mare Caspium].

It is certain that the Indian Ocean, just as it rushes into this sea with violent motion, so too stirs up the most savage and unavoidable storms out of the inconstancy of its waves and the varied circulation of currents driven back now here, now there — to which the almost daily shipwrecks bear ample witness, as both our Fathers and others who have more than once plowed this sea have told me by word of mouth. With one voice they say that this sea ought to be called an abyss rather than a sea, both for its unfathomable depth and, on account of the whirlpools it continually churns, for being filled with subterranean channels. [Margin: The Tigris and Euphrates.] Added to these are the immense rivers Tigris and Euphrates [Tigris et Euphrates], which, joined near Babylon in friendly confluence, cannot but rouse vast commotions when they empty themselves into this gulf near Basra [Bassora] through many mouths at the highest swell of their waters. But of this sea I will say more elsewhere in this work. So let us return to the thread of our undertaking.

[Margin: The currents of the African Ocean.] Next, two new currents are met with in this Indian Ocean. One, rebounding from the Gulf of Cambay [recte: angle of Cambay — "ex Cambaiz angulo"], directs its course toward the shores of Africa, where, like a torrent, it flows part into the Red Sea [Mare Rubrum] and part along the African shores in a continuous stream through the channel set between

Africa and the island of St. Lawrence [Insula S. Laurentii — Madagascar]. Falling, as it were, from a mountain into a deep valley, it stirs up there both surges and storms such as the sailors have at times experienced to their no small loss; for this region, tangled with reefs and shoals [syrtibus], has won itself no slight infamy by the frequency of its shipwrecks — truly the terror of sailors. The other current, rushing out of the Gulf of Cambay toward the Southern Land, is carried with such force that a ship following this current has scarcely been seen to return — a clear sign that there too is a fresh declivity of the sea, carrying the sea off into who knows what subterranean channels of the Southern Land.

[Margin: The Cape of Good Hope.] Further on, at the Cape of Good Hope [Promontorium Bonæ Spei], the former current, joining forces with the latter, raises new storms with the greatest swelling of the surge. Hence, restored to a wider space and spread far and wide into the immense regions of the Western — that is, the African — Ocean, they seem to assail America with a twofold flow: one part of the Ocean running from S to D, and from there checked by the currents of the Boreal Ocean coming up against it, it is deflected into the narrows of the Isthmus and into the most intricate byways of the Gulf of Mexico [Mexicani Sinus]. There it excites those boilings and effects of the waves which we will describe below in the seventh Disquisition. The other part, rushing upon the shores of South America [Americæ Australis] and reflected by the waves of the Ocean coming up from R, is constricted within the narrows of the Strait of Magellan [Magellanicum fretum]. [Margin: The storms in the Strait of Magellan.] There, when the currents from the Southern Ocean meet it and the most stubborn battle is fought over the passage between the two oceans, the water is heaped up into mountainous piles and tossed every which way — were not the Moon, arbiter of the seas, by its decrease and ebb establishing peace and a brief truce between the one sea and the other for a while. See Father José de Acosta [P. Iosephus Acosta], who described the storms and perils of this place most exactly, and asserts in express words that the Ocean rushes in at full force as though from a high mountain into a gorge, as into a narrow valley most tangled with reefs and rocks — and that the same happens in the Southern Sea, when the surge is driven into those narrows by its swelling.

And so the sea, at last struggling free from such straitened passages of the strait, as though triumphing in victory, spread far and wide over the immense Southern Ocean — of a vastness still unexplored — proceeds quietly and peacefully under the common guidance of the general motion, until it is restored to the boundary from which we began this account. Since these things are shown most clearly in the map, I have not thought it necessary to explain them at greater length.

COROLLARY I. [CONSECTARIUM I.]

From this it follows, first, that the surface waters of the sea, unless hindered by the winds, always take their course

from East to West; while in the submarine valleys they are drawn off, according to the configuration of those valleys, now to these shores, now to those. Second, that the course of the sea — both the surface course and the one running within the valleys — is hindered wherever it strikes the shores and promontories of the land regions. Hence, from these points rightly understood, the whole diversity of tides occurring in one region and another depends.

COROLLARY II. [CONSECTARIUM II.]

From these things it also follows that the recounted effects of both the currents and the tides are not everywhere the same in those places, but vary according to the position of the luminaries in the Zodiac. For they undergo certain changes when the Moon is in the tropics, others when it stands at the equinoxes, and still others — the smallest — at the conjunction and opposition of the Light [the Sun], as we shall teach at length in what follows. With these matters settled, let us now turn our pen to explaining the proximate causes of these effects.

SECTION II. [SECTIO II.]

CHAPTER I. [CAPUT I.]

On the second general motion of the sea, composed of two contrary motions, which they call the Tide of the Sea, or Flux and Reflux, also Approach and Recession, or the Swelling and Subsiding of the Sea. [De secundo Motu Maris generali, ex duobus contrariis Motibus composito, & quem Æstum Maris, sive Fluxum & Refluxum, Accessum quoque & Recessum, aut Intumescentiam & Detumescentiam Maris vocant.]

Though nothing is everywhere better known than the tide of the sea [aestus maris], nothing until now has been more unknown — even to the philosophers themselves — than its cause; the many and great monstrosities of opinion that have arisen from it abundantly attest this. [Margin: Various opinions about the flux and reflux of the Ocean.] Some indeed, by a truly laughable fiction, ascribe this motion to the breathing of some land animal — I know not which. Others, with the labor of Sisyphus, devise the daily motion of the Earth about the immovable Sun; certain others, subterranean motions of the Earth; not a few make the Moon a magnet, now attracting, now repelling the sea. Time would fail

me if I wished to recount the follies of all here. Whoever desires more, let him consult the *Meteorology* of Fromondus [Libert Froidmont] and the *Hydrographia* of Fournier, the Coimbrans [Conimbricenses], Cabeo [Niccolò Cabeo], *On Meteors*, book I, Rheita [Anton Maria Schyrleus de Rheita] in his *Oculus*, Enoch and Elijah [?] — where he will find these views refuted at length.

[Margin: The true view of the flux and reflux is established.] Most of the better-regarded philosophers, however, agree on this: that the tide of the sea can come from nowhere else than from the Moon. But even these fence among themselves remarkably with unequal arguments. We, setting aside their opinions, shall set forth our own view on this marvelous motion of the seas — and the more exactly so, the greater the advantages we trust will flow to us from it in the inmost Anatomy of the Terrestrial Globe, and the greater the weight of reasons. And since a tide of this kind is one of those secrets of nature in penetrating which the wisest of men confess themselves to grope blindly, we have resolved to imitate the very jurists, who first agree on the fact before they dispute about the law — since among the Doctors of the Law the law arises only out of the fact itself. In this way, so that the cause of so prodigious an effect may stand the more clearly before us, we must first hold the effect — the thing itself — plainly attested and certain; for to inquire into the cause of a thing by philosophizing, before it is certain to us that the thing truly is so, would be ridiculous, not to say foolish and contrary to reason.

We therefore assert that the principal cause of the marine tide — which we call the influx and outflow [affluxus et defluxus] — is none other than the Moon together with the concurrence of the Sun, without which it would be impossible for the Moon to act; for since the Sun perpetually illuminates the Moon with its rays, it rouses the effective power of the Moon, and so at last the effect we are treating of infallibly follows. [Margin: The Sun and Moon the cause of the flux and reflux of the Ocean.] We say, then, that the Moon is the proximate and efficient cause of this motion, the Sun the remote and dispositive cause; both luminaries together are the adequate cause of all these motions; while the material cause is the Ocean itself, together with the varied configuration of the mountains, shores, regions, and islands that lie in its way. We will speak first of the proximate cause, then of the formal and material cause, and finally of the final cause.

That the Moon is proximately and principally the cause of the marine tide, I show thus. That is properly called the proximate and efficient cause of some effect which flows into the effect through an influence formally defectible in itself, so

that there is a certain essential connection between cause and effect. But that this connection is found between the Moon and the Ocean is too well known to need saying. Therefore — [Margin: A twofold motion of the sea, diurnal and monthly.] To make this evident, it must be noted that a twofold motion of the sea can be considered here: one diurnal, whereby the motion of the sea follows the Moon from East to West, all the way to the place from which it was moved, in the space of about 25 hours. The other is the monthly motion of the sea, in that the sea's outflow and influx follow the Moon's proper motion against the succession of the signs, through an entire lunar month — by which the sea, gradually increasing, reaches its highest rise in the space of about eight days, and twice suffers its decrease over the same number of days. But let us first set out the diurnal motion of the sea.

By irrefragable experience it has become known that each day, at the rising of the Moon, the increase of the sea begins, and after a space of six hours

[Margin: The tide increases for 6 hours and decreases for 6, in opposite quadrants.] is run out, the sea attains its greatest rise; which for the most part happens when the Sun is at the vertical or meridian. When the Moon declines from the meridian, the waters decrease through the same six hours, so that in opposite quadrants the waters always either rise or fall over six hours — as we shall afterward demonstrate to the eye by our instrument. In the monthly motion the tide stands thus. At the time of the new moon the sea swells and boils most of all, up to about the fourth day of the lunar age inclusive; for from the fourth to the seventh the waters begin to decrease noticeably, so that about the eighth day from the new moon they are lowest, up to the eleventh; and from this to the seventeenth they resume their increase; from the seventeenth to the twenty-second they decrease, down to the twenty-fifth; and thence to the time of conjunction they again take up continual increases — this alternating succession of increases and decreases lasting perpetually.

And this is the first argument for the Moon's agreement with the sea. [Margin: An argument from the position of the Moon.] A second argument is drawn from the position of the Moon: for when the Moon is set at the equator [Æquinoctiali], it acts upon the sea with the most powerful influence of all, since it stands at right angles to it — but not so when it is set at the solstices. Thus, just as in the Moon's diurnal motion the sea acquires its greatest increase where the Moon reaches the meridian, so in the monthly motion the sea rightly and deservedly acquires its greatest increase of waters where the Moon arrives at the equator [Margin: Why the sea acquires a greater rise at the equinox], the cause of which will be assigned

afterward. This too is the greatest and most powerful of all when both luminaries, at the time of either conjunction or opposition, stand at the equator. And each of these two motions of the sea, just expounded, in agreement with the Moon, would always behave in the same way, if it were not diverted from its course by external impediments — of which afterward. But let us now proceed to unfold the true and genuine cause.

CHAPTER II. [CAPUT II.]

DISQUISITION I. [DISQUISITIO I.]

By what power or quality the Moon moves the sea. [Quanam virtute aut qualitate Luna mare moveat.]

We said in the preceding that the Moon is the proximate cause of the marine tide, which countless other writers, along with me, assign. The only difficulty, then, seems to consist in this: by what power or quality, precisely, it produces such marvelous effects — which, as no one until now has rightly explained, I have reckoned it my part to demonstrate as clearly as may be.

[Margin: The sympathy of the Moon with the terraqueous globe.] I suppose, then, first: that there is between the Moon and the terraqueous globe a certain wonderful agreement and reciprocal sympathy, arising from a certain likeness and proportion of temperament in the two globes — since it is too well known to need saying that sympathy is born of likeness. For just as there is no substance within the whole range of natural things that does not exercise the quarrels and disputes of agreement and disagreement of sympathy and antipathy with some other, so it is known that the lunar body, beyond the other heavenly bodies, exercises wondrous laws of agreement with the moist part of the terraqueous globe — and this not only in inanimate things, but in vegetable and sensitive substances, and even in the very humors existing in the human body, which are marvelously altered at the increase of the Moon. [Margin: The Moon moves the mass of humors.] Lunatics rage, the gout-ridden are racked more than usual, those prone to catarrh are filled with rheums. Among inanimate things, there are lunar species, such as various stones and minerals; among vegetables, the herbs called "lunar" from the wondrous agreement they have with the Moon; among sensitive creatures, the animals subject to the Moon's dominion experience marvelous

[Note: both this page and the preceding recto carry the page number 129; the running header on the recto verso of this opening repeats. Recorded verbatim — see report.]

vicissitudes of their humors, with which the records of the natural philosophers are so full that I have judged it superfluous to dwell longer on recounting them — that even from this the admirable agreement of the Moon in sublunary things may be plain.

[Margin: The Moon's power that moves the sea is a specific element.] I suppose, second: that this influxive power of the Moon is a specific quality emanating from the whole likeness of the lunar substance — most subtle, and (even when any obstacles whatever are placed in the way) marvelously penetrative. For shellfish on the sea floor amply and abundantly attest the lunar power by their own increase; those prone to catarrh, even shut up within the thickest walls; and certain waters, most tightly enclosed in glass vessels, are so stirred at the increase of the Moon that they seem to boil.

I suppose, third: that the lunar body, by a certain analogy and proportion, consists of the same temperament as our terraqueous globe. But that the latter, together with the whole Ocean, consists for the most part of saline bodies — for example, salt, niter, alum, vitriol, and bituminous springs — is agreed by those who have skill in chemistry, [Margin: All things full of minerals.] who attest that they observe all these things in the distillation of seawater, as in the body from which the origin of all other minerals is observed; since there is scarcely any body in this sublunary world that does not swell with saline, nitrous, vitriolic, and aluminous spirits, with salts both fixed and volatile — and the fixed salts, which remain in the final consummation of the chemical Mastery [Magisterium], abundantly show that all things are full of salt and niter. And that the lunar body is of such a constitution,

[Margin: By what means the Moon moves the sea.] we assert, convinced only by experience. It is likewise agreed that saline bodies are imbued with this power: that, whether on account of the aerial spirits enclosed in them, or their own innate spirits, as soon as the sea is touched by the lunar light endowed with a like power, it presently — by the flatulent quality in which it abounds — rarefies, swells, and marvelously dilates it on every side.

Hence we conclude that the sole cause of the sea's swelling and subsiding is a certain flatulent quality, nitrous or saline by analogy to the body of the Earth, created together with the lunar body from the beginning of things, and so tempered by the warmth of the lunar light that, as soon as it has touched the sea with its rays, it agitates, swells, and dilates it far and wide on account of the likeness of nature and the most proportionate temperament — as something connatural and akin [συγγενές, syngenes, "kindred"] to itself. Hence the nitrous

spirits enclosed in the watery corpuscles, dissolved by the lunar warmth, when they seek a larger space, necessarily push the neighboring waves, and these the others following, and so on in succession, until the Moon arrives at the place near the zenith [vertex], where the water, no longer sustaining its weight, releases in the first quadrant of its ascent the waters it had heaped up. There, in the second quadrant, it is about to accumulate a new increase of waters; whence, for as many hours as in the prior quadrant they had gradually risen through the coming of the flow, for that same number of hours in succession they fall away, until they are restored to their former rest. This specific quality, then, poured out and diffused from the Moon's body, has obtained this gift beyond the other stars: that it alters not only the elemental humor, but especially the nitrous and saline bodies of mixed things — inanimate, vegetable, and sensitive alike — by its nitrous and brackish faculty. But that the matter may stand plainly before the eye, I will here adduce a few experiments, which will so establish our opinion that no one but a senseless person could contradict them.

EXPERIMENT I. [EXPERIMENTUM I.]

[Margin: Saline water and nitrous water is moved by the Moon.] Take a basin, or a rather wide bowl, which you shall fill with nitrous water mixed together with common salt. Then, if you expose this basin in an open place to the Moon's rays on clear nights, you will see with wonder that the water at once begins to boil and to throw up bubbles — and so much the more violently, the nearer the luminaries are, both at the time of opposition and of conjunction,

Diagram. A woodcut showing the apparatus for Experiment I, set out in a perspectival interior. At upper right the Moon (L), drawn with a human face, shines down and casts a fan of rays. A large hinged panel or lid (G) — the open cover of the box — stands at the right, ruled with cross-hatching to suggest a flat board, with a wavy-grained surface. Below and to the left sits the experimental vessel: an oval basin (the large coiled/looped ring shown at center, region B, resting in the box), into which a long graduated rod or measuring scale rises at H, marked with the numerals O (top), 6, 5, 4, 3, 2, 1 descending to the base. The basin/bowl is lettered A at its lower edge, with V marking the rim near the rod. The whole apparatus stands within a box or chamber whose floor and side panels (M, N) are rendered in heavy parallel hatching. The Moon's rays (B region) strike across the open lid into the basin.

- L (upper right): the Moon, drawn with a face, source of the rays
- G (right panel): the open hinged lid/cover of the box

- B (center, between Moon and basin): the field crossed by the Moon's rays / the basin region
- H (left of basin): the graduated measuring rod
- O, 6, 5, 4, 3, 2, 1 (along rod H): scale divisions, O at top down to 1 at the base
- A (lower edge of basin): the basin or bowl of nitrous-saline water
- V (rim near rod): mark on the rim of the vessel
- M (lower-left floor panel): the box floor
- N (lower-right floor panel): the box floor / side panel

which you will not find if the waters lack pure spring water; and although you fill the bowl repeatedly with the same mixture, because they are sufficient in salt and niter, yet — choked by the predominance of the fresh water —

—suppressed, they show no commotion at all. From this it likewise follows that those who are subject to salty, nitrous, and tartareous defluxions feel the power of the Moon above all others — gout sufferers, the arthritic, the moonstruck [lunatici], and the hypochondriac.

We therefore refer the reader to where he will find certain wonderful secrets — much to our purpose — set out, both as to stones and as to plants and animals.

Now that we have explained the lunar quality by which the Moon produces those remarkable effects of ebb and flow in the sea, it is time to demonstrate how the Moon, in pressing upon the sea, accomplishes the said increases and decreases.

Let there be an astronomical horizon, as in the figure. Let X H be the meridian or vertical line. Let the globular surface of the water be T A V O — the quadrants of the Earth A V and O T being the eastern ones (the former nocturnal, the latter diurnal), while the western quadrants are A O and T V. Now let the Moon, at the point X of the index, strike the surface of the terraqueous globe at any hour whatever. I assert that the maritime surface E Q V Y will pass into the oval figure E Q V Y, and consequently that flux will follow in the fixed quadrants of the Earth A V and O T, and reflux in the quadrants V T and A O.

For once the lunar rays are sent down upon the sea-surface Q E Y, the Moon at once — by its saline-nitrous quality, joined with its faculty of thinning and dilating — will swell and extend that surface in every direction during the time of moonlight. Just as when a stone is dropped onto the still surface of water it spreads out in widening circles, so too this pressed surface, seeking a larger place and not finding it, with wave driving on wave, and with the nitrous corpuscles released by the lunar warmth, produces a violent extension and swelling of the

sea toward Y and Q. The sea, then, pressed by the Moon's rays imbued with that nitrous and saline quality, will swell toward the points Q and Y the more violently the more powerful the aspect with which the Moon has struck it.

But once the water has been heaped up at the points Q and Y, of necessity the waters at E will diminish and decrease — because the water, now emptied by its own outflow, has withdrawn into the swellings Q and Y. So too the water drawn together at V will likewise be deficient, opposite to the point E. This is because the water, partly being (through the absence of lunar light) more remote from the Moon's swelling power and so condensed, and partly being drawn off and diminished by the Sun's rays, has returned to its natural state; and thus, just as at the point T, it appears scantier and smaller. And as these two opposite points perpetually follow the Moon's course, so too of necessity the two swellings of the waters around the globular surface of the sea will succeed one another and follow perpetually.

Hence, that the manner of the Moon's stirring up of the sea may appear more exactly, we have marked the terraqueous globe by the innermost circle A O T V, motionless and fixed; but the oval figure E Y V Q, which displays the swellings of the sea, we have set out on a little arm N attached to the Moon X. If you rotate this, you will see, by a kind of ocular demonstration, how in different regions the sea gradually rises and gradually falls in the opposite places. It likewise appears how the swellings of the water Q & Y follow the Moon's motion around the—

EXPERIMENTUM II.

[Margin: A wonderful experiment.]

Make a glass ring A I B V of whatever size, somewhat wider at the opposite places A and B. Then in this wider stretch make a little channel A O, open at the top, as appears in the region marked in the figure. Fill this ring through the hole S with mercury and likewise with sea-water; and once the hole has been tightly closed, set the ring up in a horizontal position, resting on the finest supports, and expose it to the Moon's rays at the time of full moon — in such a way that the middle part I A V is inside a wall or window, while the rest, I B V, lies exposed to the Moon's rays outside the wall or window. You will then see the mercurial liquor, struck by the Moon's rays, move little by little from B toward A, where, finding no exit, it discharges itself through the channel A O, and thus shows in the channel itself the portions of increase and decrease. You will find the same with water extracted from bismuth and from olive shoots cut at the time of full moon. But of these more fully in their proper place.

EXPERIMENTUM III.

[Margin: The hairs of the sea-wolf's hide rise at the tide's increase.]

This experiment Gonzalo Fernández de Oviedo [Gonzalo Fernández de Oviedo y Valdés] writes that he himself performed, and reports that it has very often been observed by others, in his *General History of the Indies* (book 13, chapter 6). If anyone exposes the hide of the sea-wolf — that is, of the seal [phoca] — to the Moon's rays, he will see the hairs of this animal stand up at the increase of the tide, and, what is more, perfectly keep the laws of the flux and reflux of the sea. But that I may not seem to have added anything of my own, I will cite his very words here. For he says, in the passage cited:

"And besides, I will now relate something most worthy of note concerning the sea-wolf (which Pliny [Pliny the Elder] names the seal or sea-calf), and it is thus: the skin of this animal — as well as the belts, straps, and pouches made from it — have this virtue implanted in them, that when the sea is calm and without increase, the hairs of this animal are likewise entirely flat; and when the sea is at its very highest increase, the hairs of this animal also stand straight up again. This is a matter known to me by frequent experiment, and is observed in the said skin on every single day, so that whatever changes the sea undergoes in its flux and reflux, these too the hairy hide of this animal undergoes."

The same is confirmed by Olaus Magnus in book 16 [recte: 6] of his *History of the Northern Peoples*, chapter 6, "On the Sea-Wolf or Seal." Similar examples, in the various eyes of animals which grow and shrink at the increase or decrease of the Moon, are produced by various authors. Since I have treated of all these very fully in Book III of *De Arte Magnetica*, Part V, chapter 4, I refer—

—the reader there, where the reader will find certain wonderful secrets, much to our purpose, set out both in stones and in plants and animals.

—they may follow the terraqueous globe. These things are so clear that they need no further explanation. Yet, for the reader's sake, let us illustrate it by one example and another.

The innermost circle, representing the Earth, is always to remain immobile. In it, if at a given hour you apply the meridian of the sea passing through the Roman clime as the Moon comes beneath the horizon, the index X T, advanced through the following hours, will show that in the quadrant Q E the waters continually rise with respect to the Roman meridian, and likewise in the opposite quadrant V Y; while in the two remaining opposite quadrants E Y and Q V they continually

decrease in those places that the names of the meridians indicate. But after six hours, the water that was in the opposite quadrants will take on its increase for the same number of hours. You see, then, that in the space of 24 hours the waters flow in twice and ebb away twice. And let this suffice as to the diurnal motion of the Moon.

Diagram. A large circle (the terraqueous globe / clock-dial) graduated around its circumference with the hours **1** through **12**, used to demonstrate the diurnal tidal cycle. Two perpendicular diameters divide it into quadrants. The hour-numbers run clockwise around the rim from **12** at the top down through **1, 2, 3, 4, 5, 6** (right side, at the 3-o'clock position) and continue **7, 8, 9, 10, 11** back up to **12**. Interior letter-labels mark the cardinal points of the inner (Earth) circle:

- **X** — at the top (12-o'clock position), the index point where the Moon's meridian-arm is applied.
- **M** — at the right (3-o'clock position), coinciding with the rim's hour **6**.
- **I** — at the left (9-o'clock position), coinciding with the rim's hour **6** [the left "6"].
- **H** — at the bottom (6-o'clock / 12-on-the-inner-scale position).

The two diameters are X–H (vertical) and I–M (horizontal). [The inner hour-counting runs opposite to the outer rim, so that the rim's "12" (X) faces the inner "6," consistent with the text's index X T advancing through successive hours.]

CAPUT III.

DISQUISITIO II.

Why the Sea exerts its power chiefly at the time of New Moon and Full Moon.

[Margin: The inequality of the Moon's motion hinders the tide.]

Irrefutable experience has taught that the sea is agitated with its most powerful motions both when the Moon is in opposition to the Sun or in conjunction with it — but not so when it is set in quadrature. The cause of this is now asked. But before we proceed to the explanation itself, we will first show from various observations of various authors that the matter is indeed so.

Let the reader know, then, that the true motion of the Moon in the Zodiac is exceedingly anomalous, that is, irregular — so much so that here we are forced to assume a mean motion, which nevertheless is not so uniform that the appointed time does not sometimes fall short of it. For the Moon, when set in its perigee, recedes from the Sun much more quickly (as is plain from the *Theorica*) than

when it is in its apogee; and then the highest increase is drawn out longer than six hours and 12 minutes. All of which is to be carefully considered.

[Margin: The inequality of the lunar months.]

To these is added the inequality of the lunar months, some of which exceed 30 days, others are less than 29, and others are middling, namely of—

—that nitrous quality of the Moon — which we said above is the cause of the sea's tide — once roused, beats upon the sea the more efficaciously, the greater the quantity of light it has struck the sea with; for that light is, as it were, a kind of vehicle of the said quality. Since, therefore, the Moon around the full, with the light communicated to it from the Sun, strikes more powerfully with more direct rays, a more vehement motion must necessarily follow from this. Which I demonstrate as follows.

Let Y be the surface of the sea, or of the terraqueous globe; let A B C D be the eccentric oval circle of the Moon — for the Moon describes this figure each month, being placed twice in apogee and twice in perigee, as is plain from the *Theorica*; and although we have not drawn it out here, the reader will be able to imagine it for himself. Now let the Moon, at the time of [its passage through] its body through the lunar phases A O D C F G, etc. — which mark the lunar ages of the 29 days of a single lunar month (here we have set down only the phases, those lines which represent the rays falling upon the surface of the lunar body) — and from these points of the Moon let lines be drawn to the Center of the Earth: A I, S I, T I, V I, etc., which will designate the rays of the Sun (imbued, in the lunar warmth, with the nitrous quality) reflected from the Moon onto the Earth.

These things laid down, I assert that the radiant quality will obtain by its reflection an effect the more powerful, the more closely the reflected rays approach the direct ray (as is plain from the *Catoptrics* [Greek-derived: science of reflection]) — that is, the more nearly the reflection approaches the perpendicular. Since, therefore, the solar rays, the closer they have been to the diametral opposition A B of the Moon, the—

Diagram. [This is the engraved **volvelle** flagged in the catalog, near printed p. 133.] A large rotating disc carrying, on its circumference, a ring of wedge-shaped sectors, each labelled with a *Meridianus* (meridian) of a named region. At the center is a small irregular island/landmass figure (a stylized terrestrial outline). The sector-ring is read as a circle of world meridians; outer letters **A** (top), **B** (right), **C** (bottom), **D** (left) mark the four cardinal divisions. The sector labels, read clockwise from the top (each prefixed "Meridianus,"):

- **A (top):** *Romanus Meridianus per Oceanum* — Roman meridian, through the Ocean.
- *Meridianus Hispaniae & Oceani Aethiopici* — of Spain and the Ethiopic [South Atlantic] Ocean.
- *Meridianus Insularum Caribum [?] per Oceanum* — of the Caribbean Islands, through the Ocean. [label partly cramped]
- *Meridianus Mozambicae per propr[ium]* — of Mozambique.
- *Meridianus Confluentiae per propr[ium]* — of the Confluence.
- *Meridianus Syriae, Sinus Arabicus* — of Syria, the Arabian Gulf.
- *Meridianus Armeniae* — of Armenia.
- **B (right):** *Meridianus Sinus Persici* — of the Persian Gulf.
- *Meridianus Indiae intra Gangem* — of India within the Ganges.
- *Meridianus Indiae extra Gangem* — of India beyond the Ganges.
- *Meridianus Malacae Insulae & Iaphet [?]* — of the island of Malacca.
- *Meridianus Chinae per pro[prium]* — of China.
- *Meridianus Iaponiae per* — of Japan.
- *Meridianus Insulae Salomonis Zur* — of the Solomon Islands (del Sur).
- **C (bottom):** *Meridianus Insulae Latronum Zur* — of the Islands of Thieves (Ladrones / Marianas, del Sur).
- *Meridianus Iohn [?] per mar del Zur* — [Iohn] by the Southern Sea.
- *Meridianus Quivirae per Zur* — of Quivira, by the Southern Sea.
- *Meridianus Totonteac del Zur* — of Totonteac, del Sur.
- **D (left):** *Meridianus Californiae del Zur* — of California, del Sur.
- *Meridianus Mexicanus, p[er] mar Zur* — Mexican meridian, by the Southern Sea.
- *Meridianus Peruv[iae], Fret[um] Magall[anicum]* — of Peru, the Strait of Magellan.
- *Meridianus Brasiliae mar[is] propr[ii]* — of Brazil, of its own sea.
- *Meridianus Insularum Hesperidum* — of the Hesperides Islands (Cape Verde).
- *Meridianus Canariae Insulae Fortunatae* — of the Canary / Fortunate Isles.

Diagram. Below the volvelle, the tidal-mechanism schematic: a radiant **Sun/Moon-face** (a small engraved disc with a human face surrounded by rays) at the top, labelled **X**. From it a straight rod (the "little arm," brachiolum) descends, its midpoint marked **N**, to a large set of concentric **oval rings** (the swollen sea-surface) below. The oval is labelled at four points:

- E — top of the oval (where the rod meets it).
- Q — left of the oval.
- Y — right of the oval.
- V — bottom of the oval.

A small dot/center mark sits at the middle of the oval. To the lower right is a separate small **inset circle** (the terraqueous globe in plan) containing a stylized irregular landmass, with cardinal letters A (top), O (right), V (left), T (bottom) and a cross of two perpendicular diameters A–T and V–O. A manuscript annotation in brown ink at lower right reads "fol. 152" (followed by "tom. primus").

[The verso of this leaf is largely blank apart from the running material and the lower-margin start of Caput III / Disquisitio II, which repeats the same text already given on the facing page; this is the back of the engraved volvelle leaf.]

—Terraqueous Globe they may follow. [duplicate of the p. 132 column-top, on the blank verso of the plate.]

Why the Sea exerts its power chiefly at the time of New Moon and Full Moon.

[Margin: The inequality of the Moon's motion hinders the tide.]

Irrefutable experience has taught that the sea is agitated with its most powerful motions both when the Moon is in opposition to the Sun or in conjunction with it — but not so when it is set in quadrature. The cause of this is asked. But before we proceed to the explanation itself, we will first show from various observations of various authors that the matter is indeed so.

Let the reader know, then, that the true motion of the Moon in the Zodiac is exceedingly anomalous, that is, irregular — so much so that here we are forced to assume a mean motion, which nevertheless is not so uniform that the appointed time does not sometimes fall short of it. For the Moon, when set in its perigee, recedes from the Sun much more quickly (as is plain from the *Theorica*) than when it is in its apogee; and then the highest increase is drawn out longer than six hours and 12 minutes. All of which is to be carefully considered.

[Margin: The inequality of the lunar months.]

To these is added the inequality of the lunar months, some of which exceed 30 [recte: 30; one column-setting prints "20"] days, others are less than 29, and others are middling, namely of—

of 29 days, 12 hours, 44 minutes. In any case, in a matter of physical mathematics no great precision need be sought: whether the new moon or full moon comes half an hour earlier or later, I say, we need not worry, since it is enough for us [to know] that the sea's agitation occurs for some days before and after the conjunction or opposition of the luminaries, but that its greatest swelling and rise happens at the very new moon or full moon. It is the cause of this that we are seeking.

Note, then, that although the Moon is by its own nature of a cold and moist temperament, it nonetheless happens — through the rays shared to it by the Sun — that this very moistness and coldness is so tempered that it is steeped neither in excessive cold nor in excessive heat, but rather in a certain warmth. And from that warmth that nitrous quality of the Moon, which we said above is the cause of the sea's tides, is roused up, and acts upon the sea the more effectively the greater the abundance of light — which is as it were the vehicle of that quality — with which it strikes the sea. Therefore, since the Moon around the full moon, with the light shared to it by the Sun, strikes more powerfully with more direct rays, a more violent motion must necessarily follow from this. This I demonstrate as follows.

Let the surface of the sea, that is, of the terraqueous globe, be the eccentric oval-shaped circle of the Moon ABCD; for the Moon traces out this figure in single months, being twice set in apogee and twice in perigee, as is clear from the lunar theory [*Theoricae*] — which, although we have not drawn it here, the reader can imagine for himself.

Now let the Moon at the time of conjunction be at point A; at the time of opposition at point B; and at the time of the quadrature configuration [quadrature] at points D and C. I say that at points C and D the Moon moves the sea by the least possible degree, but at points A and B by the greatest. Let lines be drawn from the center of the solar body through the phases of the Moon A O D C F G, etc. — which mark the lunar ages of the 29 days of one lunar month. Here we have set down only those phases whose lines render the rays falling upon the surface of the lunar body. And from these points of the Moon let lines be drawn to the center of the Earth: A L, S L, T I, V I, etc., which designate the rays of the Sun — steeped in the lunar warmth and nitrous quality, and reflected from the Moon onto the Earth.

These things being set down, I say that the radiant quality gains a more powerful effect by its reflection the more the reflected rays — as is clear from catoptrics [the science of reflection] — approach the direct line, that is, the more the

reflection draws near to the perpendicular. Therefore, since the solar rays, the nearer they are to the diametral opposition of the Moon A B,

Diagram. A large schematic showing the Moon's eccentric oval orbit traced around the terraqueous globe, with the Sun above and rays drawn from the Sun through the successive lunar phases down to the Earth at center. The Sun (A) is at the top, depicted as a radiant face. The Moon's phases are arranged around an oval ring; rays run from the Sun through each phase and converge on a small central globe (the Earth/terraqeous globe). The figure illustrates how the angle of the reflected rays varies from conjunction (top) to opposition (bottom) and quadrature (sides).

- A (top): the Sun (radiant face)
- *Conjunctio Lunae* (upper center): "Conjunction of the Moon"
- A (upper-center phase): the Moon at conjunction (new moon)
- O (upper-right phase, labeled *3 diebus post* — "3 days after"): lunar phase 3 days after conjunction
- S (right of conjunction phase): intermediate phase point
- D (right side, upper): lunar phase / quadrature region
- T (right side): lunar phase point
- V (right side): lunar phase point
- C (right side, labeled *Quadratum* — "Quadrature"): the Moon at quadrature
- F (right side, lower): lunar phase point
- N (right side, lower): lunar phase point
- M (lower-left of opposition): lunar phase point
- B (bottom center, *Oppositio Lunae* — "Opposition of the Moon"): the Moon at opposition (full moon)
- D (left side, labeled *Quadratum* — "Quadrature"): the Moon at quadrature
- *3 diebus ante* (upper-left phase): "3 days before"
- *3 diebus post* (lower-left): "3 days after"
- *3 diebus ante* (lower-right): "3 days before"
- (center): the small terraqueous globe to which all rays converge

the more they likewise produce a more normal [perpendicular] reflected ray, and therefore a more powerful commotion of the sea must necessarily be brought about by this. For when the sea is struck by direct rays, and when the whole lunar face is turned perpendicularly toward the sea, then the individual projections of the lunar face — that is, of the radiant lunar disc — pregnant with the nitrous quality, will be active; which happens nowhere except at opposition

and at the points near to it. For in the lunar quadratures the solar rays, besides striking the lunar disc at a most oblique position, also strike a Moon that turns only half of its face toward the Earth. Thus, just as the swelling-producing power of the Moon, scattered this way and that by the solar rays into different regions, does not flow whole into the Earth, so too the motion of the sea — falling short because of the inconvenient aspect of the Moon — seems, as it were, to set up a kind of truce with it, remaining motionless. To this is added the further point: that since the Moon at the time of the dichotomy [half-moon] is set in apogee — that is, in the most remote point of its eccentric from the Earth — with its lunar power as it were languishing, it cannot produce the desired effect upon the sea. The Moon, on the contrary, when set in perigee — that is, at the point nearest and closest to the Earth, which is the case at c and f [the half-moon points] — will necessarily, from this nearness, produce by its power a most lively effect upon the sea.

From these things it is clear why the sea at the time of full moon is more turbulent than at other times, and swells more. See what we have written most fully on the nature of the reflected ray in the *Ars Magna Lucis et Umbrae* [Great Art of Light and Shadow], at the end of the first volume.

EXPERIMENT [EXPERIMENTUM]

Let an oblong cylindrical tube A B be made. At its mouth B let fragrant materials be placed,

But let us now examine the second part of the difficulty: namely, how — at the time of the new moon, when the Moon, turned entirely away from the Earth with its whole face, neither looks upon the terraqueous globe nor can share any light with it — it can nonetheless produce the effect of so great a commotion in the sea. Note, then, that just as the Sun at the time of the Moon's conjunction is nearer [to the Moon], so, with its rays sent straight onto the lunar face, it is wholly steeped in that lunar swelling-producing quality of the sea which the body of the Moon perpetually exhales — no differently than solar radiation passing through colored glass, falling upon objects in its path, and so, with the whole intervening space, conveys that color which the glass has, and steeps the walls with red if the glass was red, with green if green, with crimson if crimson. So, I say, the solar rays at the time of conjunction, striking the Moon immediately set beneath them, are steeped in the same quality with which the Moon is affected. For since at this point of the syzygy [conjunction] — that is, of the interlunium [new moon] — the face of the Moon is turned directly toward the Sun, and at no other place of its eccentric is it nearer to the Sun, surely there must then occur both a great

intensification of the lunar light and a great stirring-up of the nitrous quality; and as soon as the solar rays touch this quality, diffused everywhere, they are tinged with the Moon's native vigor and as it were impregnated, and so, made fertile by the intermediate power of the diffused quality, when they fall upon the surface of the sea, they — as certain deputies [vicars] of the Moon — produce in the terraqueous globe the same effect that the Moon does, and indeed with multiplied interest. And this I show by experiment.

Diagram. A woodcut showing the experimental apparatus described in the text: an oblong cylindrical tube angled toward a radiant Sun (depicted as a face) at the upper right, with the mouth B (decorated, holding the fragrant material) facing the Sun and the other end A directed downward into a room. The tube is ornamented along its length.

- A (lower end of tube): the end directed into the chamber
- B (upper mouth of tube, decorated): the mouth holding the fragrant materials, turned toward the Sun
- (upper right): the Sun, radiant face

not packed densely, but as loosely compacted as can be done. Direct this tube inside some chamber, so that the mouth filled with fragrant materials

is turned directly toward the Sun, while the other end A points into the said chamber. You will find that, as soon as the tube has been set directly opposite the Sun, the rays of the Sun passing through the fragrant material B will excite a most pleasant odor in the chamber — a rosy one if of roses, a lily-scent if of lilies, a violet-scent if of violets — which does not happen when the Sun is not illuminating the fragrant material. For the Sun by its heat excites the power lying hidden in the flowers, and its ray, as it were tinged and strained through with the fragrant quality, in this way draws that quality out beyond the mouth of the tube and into the chamber. From this experiment it is clear how the Sun, at the time of the interlunium [new moon], tinged with the sea's swelling-producing quality, and as it were strained through the lunar effluvium, is steeped in the said quality.

And since the whole lunar body is steeped in the said power, it follows that the darker part of the Moon — the part averted from the Sun, which faces the Earth — when it is somehow excited and rarefied by the surrounding solar rays, being joined to the rest of the outflow, must necessarily redouble the effect to some extent. And this I would judge to be the cause why the sea is so greatly stirred up when the Sun is conjoined with the Moon.

Let the Sun be A, the body of the Moon B, and the atmosphere of the lunar quality c c c diffused all around. You see, then, that the luminous outflow of the Sun, strained, sifted, and carded through the atmosphere of the lunar power C, is tinged with an abundant offspring; and that the conceived tincture D is at length drawn down into the sea by means of the luminous radiant outflow as its vehicle. From which it must necessarily be most powerfully stirred up for three reasons. First, because the Sun, steeped in the lunar quality, operates more strongly and effectively than the Moon itself. Second, because the Sun is more penetrating, and strikes the sea with its rays more sharply than the Moon does. Third, because the solar rays steeped in this quality graze a larger portion of the globular sea's surface than the lunar rays do, as is clear from the lunar theory [*Theoricae*]; and consequently, just as they raise a larger mass of waters, so too they bring about a more effective motion. To this is added the fact that, when the Sun's ray reflected from the Moon strikes the sea at the time of new moon, the action becomes most effective of all in the perpendicular [normal] direction. But when the Moon is set at the remaining points, the solar rays are always more or less

Diagram. A large schematic showing the Sun (A) at the top, the body of the Moon (B) below it surrounded by its radiant atmosphere of the lunar quality (c c c), and the Earth (*Terra*) at the bottom. The Sun's luminous outflow forms a broad pear-shaped (teardrop) cone of rays descending past the Moon and converging on the Earth; the tincture imparted by passing through the lunar atmosphere is marked D. Lateral points x (left) and H (right) flank the Earth on the horizontal; points M, F, N are at the base beneath the Earth.

- A (top): the Sun (radiant face)
- B (upper-middle): the body of the Moon, surrounded by its radiant atmosphere
- C C C (around B): the atmosphere of the lunar quality, diffused all around
- D (below the Moon): the conceived tincture carried in the radiant outflow
- Terra (center): the Earth (terraqueous globe, showing a map)
- X (left, on the horizontal): lateral point flanking the Earth
- H (right, on the horizontal): lateral point flanking the Earth
- M (base, left): point beneath the Earth
- F (base, center): point beneath the Earth
- N (base, right): point beneath the Earth

steeped [in that quality]; the result is that the sea, struck by the solar rays acting as deputies of the Moon, takes on the greater increase the nearer the Moon is to

point A, and takes on the greater decrease the nearer it is to points x and H. For at these points, because of the most oblique position of all, the terraqueous globe partakes least of all in the lunar power, for the reasons hinted at above.

The Sun begins to be tinged [with the lunar quality] three days before the conjunction, at point L, from which the sea also begins to grow, up to the point of conjunction B, where the increase is greatest; and from there it gradually decreases over three further days, until the Sun, set at point R outside the rays of the lunar outflow, restores its deputy service to the Moon. The Moon then, just as it thereafter strikes the sea with a feeble light, so too stirs it up least of all, until, emerging gradually from quadrature, it produces day by day a greater and greater increase, in proportion to the magnitude of the light with which it strikes the sea.

COROLLARY [COROLLARIUM]

From this it is clear that for three or four days nearly before the new moon the sea is agitated only by solar light — though tinged with the lunar power — but that for the same number of days before or after the full moon the Moon stirs up the sea immediately by its own proper power, so much more powerfully the nearer it is to the point of opposition B. On the remaining days, before or after quadrature, the sea seems as it were to rest, because of the slenderness of the communicated lunar power. In this way the Moon, having advanced from H [along the path] M N to point V, acquires its forces three days before opposition, [forces that grow] greater up to the point of opposition T, where it presses most strongly; and from this point, gradually diminished in vigor, up to point S, three days after opposition, it there begins to fail, up to point X, where it has the least vigor in stirring up the waters.

CAPUT IV.

DISQUISITIO III.

Why the Sea does not always flow or ebb every six hours in different parts of the World, and whence so irregular motions of the Sea arise.

[Cur Mare non semper sex horis fluat aut refluat in diversis Orbis Terrae partibus, & unde tam irregulares Maris motus proveniant.]

SUPPOSITIONS [SUPPOSITIONES]

Drawn from observations. [Ex observationibus factae.]

I suppose, First: If the whole terrestrial globe were covered with water — as in the universal Deluge [Cataclysm] — then no flux or reflux caused by the Moon's power would appear; rather, the whole fluctuation of the sea would, without doubt, be ascribed to the blasts of the winds driving the sea into this or that region,

with an ever constant and invariable law of order, [following] the Moon's power moved from East to West. And the reason is plain: because the ratio of the flux and reflux is not perceived on the high sea, but only on the shores, where alone the approach and recession of the sea is noted.

I suppose, Second: If there existed only a single island in the Ocean, set under the equinoctial line — for example, the island of São Tomé [*Insula S. Thomae*] — I say that the flux and reflux of the sea toward an island of this kind will behave [as follows]; and if there should be any diversity of motion, it should rather be attributed to the winds than to the Moon,

Diagram. A schematic world-band figure showing a single island set on the equinoctial line, with the Moon depicted in its various positions (as small globes bearing zodiac signs) around the left and right margins, casting rays (solid and dashed) toward labeled points on the island's coast. The horizontal center line is labeled *aequinocialis* (the equinoctial); the top and bottom horizontal lines are each labeled *Tropicus* (Tropic). The left vertical edge is labeled *Meridianus* (meridian); the right vertical edge is labeled *Luna ascendens* (the ascending Moon). The island in the center shows mountains and trees.

- *Tropicus* (top line): the Tropic
- *Tropicus* (bottom line): the Tropic
- *aequi. Anoctialis* [*aequinocialis*] (center line): the equinoctial line
- *Meridianus* (left vertical edge): the meridian
- *Luna ascendens* (right vertical edge): the ascending Moon
- O (far left, upper, with ♑ Capricorn sign): the Moon position
- (far left, middle): the Moon position
- N (far left, lower, with ♋ Cancer sign): the Moon position
- L (far right, upper, with ♑ Capricorn sign): the Moon position
- X (far right, middle): the Moon position
- (far right, lower, with ♋ Cancer sign): the Moon position
- G (island coast, upper left): coastal point
- B (island coast, upper): coastal point
- C (island coast): coastal point

- D (island coast, center): coastal point
- E (island coast): coastal point
- F (island coast, lower): coastal point
- Y (island coast, upper right): coastal point
- Z (island coast, center right, on equinoctial): coastal point

Diagram. A large fold-out double-page engraved map of the Americas, oriented with north at the top, showing the directions of tidal flux and reflux along the American coasts. The map occupies two facing plate-halves: carries the Pacific (western) half and the cartouche; carries the Atlantic (eastern) half and bears the plate/volume number at upper right, *Tomus I. 144*. The two halves join along the central meridian to form one continuous map. Engraved hatching across both oceans renders the tidal current-lines that are the subject of the figure.

Decorative scrollwork cartouche at lower left (on the Pacific half) carries the engraved title:

Mappa fluxus et refluxus rationes in Isthmo Americano in freto Magellanico, ceterisque Americae litoribus exhibens.

[A map exhibiting the patterns of flux and reflux at the American Isthmus, in the Strait of Magellan, and along the rest of the American coasts.] ("refluxus" so spelled in the engraving, for *refluxus*.)

Readable engraved labels, with positions and translations:

- Top center-left (p. 198): AMERICA SEPTEN- / TRIONALIS — North America (the legend split across two banner lines).
- Upper left (p. 198): California — California (here the peninsula/gulf region).
- Upper center (p. 198): Mexico — Mexico.
- Center-right (p. 198): Sinus Mexicanus — the Gulf of Mexico.
- Center-right (p. 198): Cuba — Cuba.
- Center (p. 198): Nova Granata — New Granada (Spanish colonial Nueva Granada, NW South America).
- Right edge (p. 198): Peru — Peru.
- Right edge, lower (p. 198): Chili — Chile.
- Right edge near several coastal points: FR (repeated) — abbreviation marking points of *fluxus*/reflux (flux) along the coast.
- Center (p. 198): large decorative ocean legend MAR DES ZUR — the South Sea (Spanish/Dutch "Mar del Sur," the Pacific).

- Center-left mid-page (p. 198): Circulus beside a horizontal rule — a circle/parallel line (the engraved boundary, here a latitude circle; cf. the equinoctial labelled on the facing half).
- Lower right corner (p. 198): Terra del Fuego — Tierra del Fuego.
- Coastal point near the Isthmus (p. 198, right): Thomas Segá [?] / Panama [?] — labels in the Isthmus-of-Panama region, partly cut at the plate join and hard to resolve [?].
- Top center (p. 199): large decorative ocean legend MAR DES NORD — the North Sea (Spanish/Dutch "Mar del Norte," the Atlantic).
- Upper left (p. 199): Hispaniola — Hispaniola.
- Left (p. 199): Nova Spagna — New Spain.
- Left-center (p. 199): Lacus — a lake.
- Left-center (p. 199): Rio de las Amazonas — the Amazon River.
- Center (p. 199): BRASILIA — Brazil.
- Center, large decorative legend down the body of the continent (p. 199): AMERICA AUSTRALIS — South America.
- Center (p. 199): Paraquay — Paraguay.
- Lower center (p. 199): R. dla Plata / Rio de la Plata — the Río de la Plata.
- Right of center, along the central join (p. 199): Aequinoctialis — the equinoctial (the equator line), running horizontally across the map.
- Several coastal points (p. 199): FR (repeated) — flux markers, as on the Pacific half.
- Lower right and along both coasts: small letters c and d at points on the current-lines — keyed reference letters for the tidal-flow construction (correspond to the lettered points discussed in the surrounding text); a few are faint at this resolution [?].
- Three ships under sail are engraved in the open ocean (one in the Pacific, two in the Atlantic) as decorative staffage.

[The facing leaves are otherwise blank: (the verso preceding the plate) and (the verso following it) carry no text, only show-through from the engraving.]

[This continues the text of **Liber III "Hydrographicus," Sectio II, Caput IV, Disquisitio III** — on the irregularity of tides worldwide. The opening of the page is the conclusion of a sentence begun on the previous page.]

would have to be attributed to the winds, which at one moment hold back the inflow or outflow of the sea, and at another tear it off into one region or another.

Let an island A be situated under the equator, alone in the universe; and let the Moon be in Aries [♈] or in Libra [♎], normally pressing down the surface of the sea beneath it. That surface, heaped up everywhere into swells, spreads out — exactly as a stone thrown into some pool drives out ever-larger and larger diffusions of waves all the way to the shores B, C, D, E, F — and the water, striking shore D head-on, would show an increase over six hours. Striking shores C and E obliquely, it would make the same increase there over the same number of hours; but at the concave shores B and F, striking most obliquely, it would make circular reflections. In the same way the Moon, set in the tropics O and N, would cause one impact of the water after another at the shores, along the lines O G, O C, O D, O E, O F, which mark the course of the waves. Likewise, with the Sun set in tropic N F, at the said shores E, F, D, C, B it would produce one impact after another. This must be understood of all the parallels of the torrid zone individually, in whichever the Moon happens to be at a given time. Again, with the Moon set at point X, the intervening sea, driven against the shores Y, Z, Q opposite the former ones, would there show a fresh increase, while in the opposite quarter it would work a decrease — and this always over the space of six hours, by a constant and unchangeable law of nature, unless it were hindered by the blowing of the winds, as I have said. For if the north wind [Boreas] blows, the currents of the sea stirred up by the Moon would be driven off toward the south; and conversely, with the south wind [Auster] blowing, toward the north. With the Moon set at L and S toward the shores Y, Z, Q, it will prepare new surges of rising water, and in whatever proportion the sea rises here, by the same it will fall at the opposite shores. You see, then, in this figure, that the waters spread themselves out to the pressure of the Moon — according to the wind-points [Rhombi] arranged on the magnetic compass, and according to the bearing they have toward the shores — and the figure set here demonstrates this clearly.

[The figure referred to here is the equatorial-island diagram described on the previous page; no new figure appears on p. 137.]

Fourth. From the winds, which at no time fail to drive the sea by their gusts, now into this quarter, now into that.

[Margin: A constant tide, since the cause of the tide is similar of itself.]

CONSECTARIUM II.

The quantity of flux and reflux is, of itself and by its own nature, inconstant in any given place, and different on different days, and on that account greater or less according as the Moon stands farther from, or nearer to, that place. For since

the Moon changes its position in the zodiac every day, and so on different days becomes vertical at different places, it is consequently farther from any given place, or nearer to it.

This established, we conclude that on different days, in the same place, the quantity of flux and reflux is different — whether that quantity be perceptible or imperceptible. Therefore, the fact that the ratio of flux and reflux is so unequal at different shores is to be ascribed not so much to the Moon — which never stands fixed at a certain place — as to the differing proximity of continents, as we shall show later.

[Margin: Why the ratio of the tide is unequal at different shores: because the Moon is never fixed at a definite place.]

For it has been observed, by the irrefutable experience of all those who dwell along the shores of the Ocean or of the other seas: **First**, that the greatest swelling of the sea first occurs when the Moon occupies the highest or lowest point of the meridian of that place; but in many other places the swelling has been observed to occur at another position of the Moon.

Second. It has been observed that at most shores the sea flows in for six hours and twelve minutes, and ebbs over the same number of hours; in some places, however, it flows in over more hours and ebbs over fewer, as will be said later — yet in such a way that the time of flux and reflux together, that is, from one maximum swelling to the next, makes up twelve hours and twenty-four minutes, or, as others would have it, nearly twenty-five hours. And so the swelling of the sea occurs each day nearly a full hour later, because the Moon returns to the same meridian or vertical nearly a full hour — that is, 48 minutes — later each day.

[Margin: The excess of the flux and ebb each day amounts to nearly 24 minutes.]

Third. It has been observed that in some places the inflow is very great and very violent; in some, very small; in certain places none at all, or scarcely perceptible. The reason for all these variations is therefore sought. So that it may be set forth as clearly as possible, we have decided to attach these hydrographic figures here, so that through them, as in an archetype, the explanation of each of the observations adduced so far may appear more clearly.

[Margin: The cause of the sea's tide.]

CONSECTARIUM I.

[Margin: The flux and reflux of the sea is always similar of itself.]

From these things it is plain that the inflow and outflow of the Ocean is, of itself and by its own nature, always similar, but is hindered and retarded by various causes: **first**, by the differing and varied configuration of continents, promontories, islands lying in the way, and gulfs; **secondly**, by the differing disposition of the Ocean floor, whose unevenness is so great that the sea is stirred up by it in differing ways; **thirdly**, by the underground passages — partly the huge masses of water that they discharge (like rivers) not only from the bottom but also from the underwater sides, and partly the violent eruption of underground spirits, by which the general motion of the sea is hindered in a remarkable way.

[Margin: The cause of the sea's tide, of itself and by its own nature.]

QUAESTIO I.

Why in some places the greatest swelling of the sea occurs when the Moon is at the meridian, while in certain other places it occurs when the Moon holds the middle position between the cardinal points.

I answer. In all those places of the Ocean where no impediment inter-

—venes, it has been observed that the flux lasts six hours and the reflux the same number of hours while the Moon holds the meridian — as happens in the Strait of Magellan; in the channel lying between Africa and the island of St. Lawrence [Madagascar]; in the Strait of Manila, Java, and Malacca. For in these places the sea, as if combed out, holds its motion straight and steadily toward the West, as is plain from the map — provided it is not hindered or disturbed by the winds and currents of the sea, of which more will be said later, as commonly happens; and on this point no one disputes.

The crux of the difficulty turns on this: why in some places the greatest swelling of the sea occurs *before* the Moon reaches the meridian — that is, at the time of new moon or full moon — and then the sea takes on its greatest strength and increase when the Moon has stood in the south-westerly [Auster–Zephyrus] or east-northerly [Eurus–Boreas] quarter. At London, for instance, the sea shows itself most anomalous; for the water is then highest when the Moon reaches the quarter B or A.

[Margin: The tide at London varies.]

Diagram. A simple circle, divided by a vertical and a horizontal diameter into four quadrants, representing a compass / wind-rose with the four cardinal winds named at the rim. Two points marked A and B lie off the axes within the rim.

- Top (rim): Auster (south wind)
- Bottom (rim): Boreas (north wind)
- Left (rim): Eurus (east/south-east wind)
- Right (rim): Zephyrus (west wind)
- A: upper-right quadrant, on the rim (the south-westerly position, "plaga Austro-Zephyrea")
- B: lower-left quadrant, on the rim (the east-northerly position, "plaga Euro-borea")

[In China, in the port of the city of Macao, as Fr. Martino Martini [Martino Martini] reports in his *Atlas* [*Novus Atlas Sinensis*], the water obtains its increase at different times under a different position of the Moon.] Around the twentieth day of September, at new moon, it takes its greatest increase about an hour and three-quarters before noon, the Moon being still three hours distant from the meridian. On the third day of February, the third day after new moon, the greatest inflow of the sea occurs after twelve o'clock; from which it is gathered that on the first day of February the highest, or greatest, inflow of the water was after ten o'clock by forty minutes. Then on 16 February, on the very day of full moon, the greatest increase of the sea was observed to be nearly about noon. On the second of June, the fourth day after new moon, the greatest height of the sea was likewise nearly about twelve o'clock; from which it is gathered that on the first day of the new moon the highest increase was about three hours before noon. He adds the observation that the times and hours of greatest height and of the ebb of the water do not agree with those hours computed from the Moon's motion, except for five days before and after the new moon; the inflow, however, in this region lasts for the most part only nine hours, the outflow only three — so that, as said, the times of flux and reflux taken together always make up about twelve hours and twenty-four minutes, as we said above.

[Margin: In China the tide is anomalous.]

[Margin: The excess of the flux and ebb in a uniform tide; the increase, then the decrease, together exactly equal the whole tide of twelve hours and twenty-four minutes.]

But that we may philosophize more clearly about the diversity of the individual motions, the observations must first be adduced.

In Belgium, France, England, and Holland, the sea at the shores of these said regions, at the time of new moon and full moon, has been observed by perpetual experience to behave as follows.

Observations of the Tide of the Sea in Belgium, England, France, and Holland, collected from various sources.

[Margin: Observations of the tide in Belgium.]

Time (after 12, full moon or new moon)	Location
At 12 o'clock at full or new moon	The sea begins to swell to its highest at the shores of Flanders, Enkhuizen [Enchusa] in Holland; in Friesland, Zeeland; Dover [Dorobernia] in England.
45 minutes after twelve	Flushing [Vlissingen] in Zeeland.
At 1½ after twelve	On the western side of the Isle of Wight; Calais; at the mouth of the river Thames [Tamesis] in England; at the shores of Zeeland at the mouths of the Scheldt [Scaldis].
At 2¼ after 12	Before the mouths of the Scheldt and the Meuse [Mosa].
At 3 after 12	Amsterdam, Rotterdam, Dordrecht, Newcastle [Novum Castrum] in England, before the Sandbanks [Pulvini] of Flanders, at the mouth of the Garonne [Garumna] on the shores of Brittany, France, and Spain; on the western shore of Ireland up to Holland.
At 3¾ after 12	Rouen [Rhotomagum] in France, at La Chapelle [Cupella], on the river Garonne, and at the rest of the limits of the Spanish, Portuguese [Lusitanic], and Galician shore.
At 4½ after 12	From Texel [Texelia] to the southern shores of Ireland.

Time (after 12, full moon or new moon)	Location
At 5½ after 12	In all parts of the southern shore of Ireland [Hibernia], and at Plymouth in England.
At 6 after 12	Before Hamburg on the Elbe [Albis]; in the Channel between England and Brabant.
At 6¾ after 12	Between Bavick and Walcheren [Vaelmuya].
At 7½ after 12	At the ship-station ([Dutch: op de reede, "in the roadstead"]) at Texel, off Kildwin [Kilduina].
At 8¼ after 12	Near the Isle of Wight, as far as Beachy [Bevesier].
At 9 after 12	Before the mouths of the river Ems [Amisis] in Friesland, and at all its shores.
At 10½ after 12	Before the mouths of the river Thames in England, at the shores of Normandy and Picardy.
At 11¼	In the river Thames, and other places in England.

Observations made by sailors in the Western Ocean concerning the tide of the sea, at new moons.

Location	Hours (after midnight)
In the Strait of Gibraltar [Fretum Gaditanum], at new moon, the water is full after midnight by	1¼
At the same time, in the port of Calais [Calessi], and in that whole maritime tract from Tarifa and Sanlúcar [S. Luca].	—
From the Cape of La Roche [Promontorium Rutae] up to Cape St. Mary [Caput S. Mariae], the sea is full	2¼

Location	Hours (after midnight)
after midnight	

Location	Hours
From Cape St. Mary up to Cape St. Vincent [Caput S. Vincentii], and from there up to Cape Finisterre [Caput Finis Terrae], and from there along the shores of Biscay and France in some places — except the mouth of the Garonne and certain other places, which they call <i>Boglienas</i> and <i>la Ollona</i> — the sea is full after midnight.	3
At the said excepted places, however, it is full after midnight.	2¼
On the shores of France at Pontaven [Pondavid], Coradum, Blancabum, and the one they call Furnum [Le Four].	3¾
From Le Four [Forno] up to the island of Houat [Hebas], the sea is full.	4½
From the island of Houat, and those they call <i>Caschettas</i> , up to Carnesul at the shore.	5¼
On the mainland of France that faces the said islands.	6¾
In Normandy and Picardy, Calais, Newport [Neoporti].	9
In the middle of the Channel, between France and England.	12
From Calais up to Newport, in the sea 13 miles distant from the shore.	2¼
From Calais up to Gravelines [Gravelinga], in the sea distant from the shore.	1½
From Gravelines, along the whole shore of Flanders and Zeeland.	3
And in the sea distant from the shores.	3¾

Why such great diversity occurs at the places cited above, and why the sea's commotion does not happen uniformly — for this, several partial reasons or causes concur.

[Margin: The causes of the variety of the tide.]

The first and root cause is the general motion of the sea, stirred up by the Moon, which is set in one or another of the zodiac's twelve signs [Dodecamoria]. The second reason is the differing arrival and recoil of the Ocean against the shores of America, from which manifold reflection toward shores of disparate

configuration there arises the greatest diversity of the sea, both as to time and as to its increase. The third is the differing disposition of the sea floor; for let no one imagine it everywhere equal — but, as we showed in the *Iter Exstaticum Submarinum* [*Subterranean Ecstatic Journey*], it is of most disparate condition.

[Margin: The sea floor is unequal, just as the earth's surface is.]

For just as on the terrestrial globe huge mountain peaks rise up everywhere, and the deepest valleys, distinguished into one valley after another, are drawn out over the longest stretches into countless regions; and rivers, unrolled from the mountains and swelled by countless others, wind in sinuous coils through the immense windings of the lands — I would have you persuade yourself that the same thing happens within the sea. In it you may suppose that islands, with their lofty summits, are very high mountains — indeed, mountains rooted in the sea floor; and you may know that the spaces of sea between island and island, and the narrows of the submarine straits, are the deepest valleys; nor should you suppose that submarine rivers are lacking, by which the general flux, whether direct or reflected, is from time to time hindered in a remarkable way.

[Margin: The sea floor is roughened with mountains and valleys.]

Again, just as experience teaches that rivers constricted between mountains are always swifter than those which flow into the sea with a slow pace in level places — they are rolled along and move more swiftly amid the narrows of both mountains and plains — so rivers move more swiftly in the middle than at the banks, unless the bed and current of the river, weighed down by a great mass of water, rush against the land — which cannot happen without the eating-away and corrosion of the shores it meets. The same happens on the sea floor. For when the whole watery mass of the Ocean is stirred by the power of the Moon all the way to the bottom, and at the bottom there occur everywhere countless immense ridges [literally "combs"] of rocks and the deepest valleys stretched out far and wide into submarine regions — hence this mass of water, towering above such valleys or depths, is stirred by the power of the Moon in the general motion of the sea from East to West. But the waters enclosed amid the hollows of the highest mountains, islands, and shores follow the impulse along the run of the valleys, and these we call natural currents.

[Margin: The motion of the sea follows the hollows of the submarine valleys.]

For when these currents strike the obstacle of land — of mountains and islands — then, behold, repelled, they harass the shores with their assaults: the water now into opposite quarters, now into oblique directions, now by a kind of *pericyclosis*,

that is, by one circulation after another, as we demonstrated above. And since these things do not happen at the same time, but earlier or later according to the varied concourse of the sea's waves — now direct, now reflected in this and that direction by currents and by the stretches of the shores — it is certainly plain even from what has been said that the general tide of the sea does not occur at the same time in those places.

There is the further fact that these currents change and vary in various ways according to the varied position of the Moon in the zodiac. For with the Moon set in the southern tropic [Capricorn ♐] and far distant from our zenith, it stirs the sea in one way; differently when in the equinoctial; differently in the tropic nearer to us [Cancer ♋]; differently when joined to the Sun; differently when opposite it; differently again when set in the quadratures.

[Margin: The sea varies its tide according to the varied position of the Moon.]

The fourth reason is the diversity of the winds, which most of all dominate the surface of the sea; by these the currents of the sea, whether direct or reflected, are very much either retarded or stirred up more swiftly.

[Margin: The winds hinder the tide.]

The fifth reason is the discharge of huge rivers into the Ocean, where, from the continual conflict of the waves, the natural tide of the sea is wonderfully hindered, and the force of the river is overcome only at last by the immense weight of the in-rushing Ocean. And so the inflow occurs more slowly, the outflow more quickly — as may be seen at the mouth of the Gallic river Garonne, and in the African river they call the Senegal [Senega], as will be taught later.

[Margin: The discharge of rivers into the sea hinders the tide of the sea.]

The sixth reason. Since the sea floor, as we showed in the cited *Iter Exstaticum Submarinum*, is bored through by countless channels, it happens that from the underground estuaries at no time fail to be breathed out huge exhalations, by which the sea is rendered swollen in a remarkable way, and by these the general motion of the sea is not a little disturbed.

[Margin: Submarine winds hinder the tide.]

And from this clustering-together of causes...

all the effects of the heteroclite, surging sea are dissolved; in producing which, now one cause, now several, and then all together concur. But order now

requires that we resolve some of the proposed cases by means of the premises set out above.

CAPUT V.

DISQUISITIO IV.

Why at London, in the river Thames, the greatest swelling of the sea then occurs when the Moon has been set in the south-westerly [Auster-Zephyrus] quadrant; whereas, with the Moon set in the northern signs and in the east-northerly [Euro-borea] quarter, the greatest swelling does not then occur — namely three hours before it reaches the meridian of London.

I say, then. When the Moon, set in the southern signs, has reached the German Ocean [North Sea], being too remote to touch it with its rays — hence it comes about that it accomplishes by roundabout ways what it cannot do by direct or oblique rays. For as soon as the Moon reaches the meridian of London, then at the same time the sea at London in the Thames begins to rise. This beginning of the increase, however, does not come immediately from the lunar power by which the German Sea is pressed, but through a certain reverberation of the Ocean made from the shores, as follows. For with the Moon set as it passes through the meridian over London, while by its own proper power it normally presses down the Indian Ocean subject to it, this Ocean — pressed and gradually swelling, and spread far and wide through the Aethiopic Ocean — when it finds no exit at the shores of North America, is soon repelled from there and opens itself an approach into the German Ocean by a double route: first, from West to East through the sea set between England and France; second, circling through the Northern Ocean around Scotland, where, driven against and repelled from the shores of Norway, it more violently insinuates itself into the German Sea. Meanwhile the earlier part of the Ocean, rushing in through the English or British Sea and the Ictian narrows [Strait of Dover], when it is repelled by the shores C and H lying in its way, and is forced impetuously into the German Sea D — when at V it meets the current X Y, as if it were powerless and insufficient to resist it — drives it partly into the neighboring shores of England, partly into the shores of Flanders and Denmark, and most of all into the opposing mouth X of the Thames. From there the greatest increase occurs, three hours after the Moon has departed from the meridian of London; for at that time, as is plain from our wheel of the marine tide, the said circulation of the sea lasts from the shores of America up to the established place.

But let us now proceed to the other part of the difficulty, where it was said that the Moon, set in the northern signs or in the tropic of Cancer [☿], then first causes the greatest increase of the waters at London when it has been set in the opposite east-northerly quarter. We say, then, that this happens for this reason: that the Moon, being then nearest to the said sea, since it stands over it, accordingly strikes it more powerfully by its own force. Hence, with the Moon rising, the sea D, gradually pressed, soon begins to swell; and while it finds no free exit in the narrows X, hence the water, heaped together at the mouth of the river X, produces the greatest swelling of the sea within three hours — which otherwise, if it found a free exit in the open sea, would occur within the space of six hours, as at the other shores of England.

[Margin: The cause is shown of the irregularity of the tide.]

The Moon, therefore, set in the east-northerly quarter, on account of the said causes, anticipates the increase by three hours. Meanwhile the Atlantic Ocean, driven against and back from America — rushing, as it does, through the British Sea — finds the mouth of the Thames turned away from itself; and so, passing it by, diffused either into the northern or into the eastern tracts of the sea, it seizes and carries off with itself the swollen waters lingering in the said mouth, whence the decrease occurs, from the ninth hour up to twelve and beyond.

But the figure will teach you all this better. In it, at the shores of America A, there is an arrival of the Ocean stirred up by the Moon; here, repelled from A, it circulates partly into C and D, partly into F, and, dashed against and repelled from the islands M, L, it begins its current afresh either through O or through P, which anticipates the increase by three hours. Meanwhile the Atlantic Ocean, driven against and back from America — rushing, as through the British Sea — finds the mouth of the Thames turned away from itself, and so, passing it by, diffused either into the northern or into the eastern tracts of the sea, seizes and carries off with itself the swollen waters lingering in the said mouth, whence the decrease occurs from the ninth hour up to twelve and beyond.

[The figure referred to in this Disquisitio — showing the shores of America (A), the points C, D, F, the islands M and L, and the currents O and P — is not engraved on these pages; it is one of the hydrographic figures promised earlier. If a separate engraved plate or volvelle belongs here, it does not appear within this opening.]

CONSECTARIUM I.

From these things it is plain that, whenever a current of the sea has a gulf or a shore lying directly in its way, it exerts its force most strongly upon that too — as happens at the shores Z of Ireland, of Scotland, and at the islands M, L. But on the contrary, if some shore...

[Margin: The propagation of the sea's flux according to the situation of the shores.]

strikes only obliquely, or has that shore turned entirely away from it, then likewise no increase occurs there — as on the shores of the British Sea marked **B B** — unless the current finds some obstacle, whether an island or a promontory, lying beyond that shore. For the sea's current, dashing against such an obstacle, is at last reflected back; and so, after some interval of time, it produces the increase in the very place it had at first passed over. And this is the reason why, on different shores, the timing of the swelling is so inconsistent: because the sea, first passing that shore in a direct course while it is reflected toward another shore, then driven back upon the place it had abandoned, finally returns in a reflected course to do what it had at first neglected. Much, too, contributes to this irregularity of timing the swelling waters produced by the general motion stirred up by the Moon — for either the sea rises in the eastern quadrant and falls in the western, or, on the contrary, it falls in the eastern and rises in the western;

Diagram. A large engraved map filling the page, showing the North Atlantic and the seas around the British Isles, with the schematics of currents that drive the tidal behavior discussed in the text. The cartouche at lower left bears the title: "A chart exhibiting the patterns of flux and reflux in the English Sea and the other adjacent shores." The top edge is labeled **AMERICÆ PARS** ("Part of America"). The ocean basin between Europe and the islands to the northeast is labeled **Oceanus Decalidonus** [recte: Deucalidonus — the Deucaledonian/North Atlantic Sea]. A compass rose with the cardinal directions sits at the right edge.

Geographic labels (with modern forms):

- **AMERICÆ PARS** (top): "Part of America"
- **Hispania** (left): Spain
- **Gallia** (lower left): France [Gaul]
- **Sinus Cantabricus** (off the Iberian/French coast): the Bay of Biscay [Cantabrian Gulf]
- **Os Garumnæ** (French coast): the mouth of the Garonne

- Mare Britannicum (the channel waters): the British Sea
- Hibernia: Ireland
- Scotia: Scotland
- Anglia: England
- Cales (S. English coast): Calais
- Flandria: Flanders
- Oceanus Germanicus (the North Sea): the German Ocean [North Sea]
- Norvegia: Norway
- Dania: Denmark
- Suecia: Sweden
- Finmarck [Finmarchia]: Finnmark
- Lappia: Lapland
- Nova Zembla (right edge): Novaya Zemlya
- Frisland (island, upper right): the (mythical) island Frisland
- Islandia: Iceland
- Orcades (north of Scotland): the Orkneys
- Charybdis (off Norway): the whirlpool Charybdis [the Maelstrom]
- Weigatz [or Vaygats], near Nova Zembla: the Vaygach strait

Point-letters marking the current scheme (positions approximate, read from the engraving):

- A (over the American coast at top): current origin point [?]
- F (top, right of A): current point
- M (island, upper right): island M (labeled "Frisland")
- E (mid-ocean): current point
- L (island, right — Iceland region): island L
- Z (off Ireland): point Z
- B (off Spain/Biscay): point B
- K (between Ireland and Scotland): point K
- O (mid-North Sea, toward the open ocean): point O
- P (right edge, lower): point P
- V (off the English/Flemish coast): point V
- D (off Flanders): point D
- I (near Flanders/Norway): point I
- H (off SW Norway): point H
- G (off southern Norway/Denmark): point G

- W (in the Sinus Gallici / French gulf region near the Garonne): point W
- X (a promontory marked with the planetary/astronomical sign ♂-like glyph in the text — see below): promontory X

or finally it rises in both, or falls in both. From this combination arises a great variation in the timing of the marine tide. For it happens that the sea falls on the eastern side of some promontory while it rises on the western, and the reverse — as occurs in the gulf of the French sea marked with the letter **W**. There, on the western shore of promontory **X**, the water rises as the tide of the British Sea rises, because of the collision against the promontory mentioned [Margin: ...against the promontory.]; but on the opposite, eastern side it falls, while the sea's water generally passes by and ebbs away. Yet some hours later the water here on the **X** shores begins to rise, because the ebbing sea, driven into the curved shore of the sea near the throat **X**, drives its waters back upon the opposite shore — while in the meantime, on the opposite western side of the promontory, the water is falling. What we say of this one case, you may understand to be said of all the others.

[Margin: The reason for the variety of flux and reflux.]

I could at this point describe all the anomalous [*heteroclitos*] effects of the sea on the various shores of regions and islands, and give the reason for each; but...

[Margin: Why on the northernmost island, Vaygach, the tide runs from east to west.]

whoever has more deeply grasped what has been said up to now will find no difficulty in resolving cases of this sort, since the exotic tide of the sea can always be referred to one, or several, or even all of the concurrent reasons and causes mentioned above.

CONSECTARIUM II.

It is likewise clear why, in the Strait of Vaygach [Freto Weigatz], the tide of the sea runs from west to east. I say it happens for this reason: that the Ocean, dashed against the shores of America at **E**, leads its current through **E O & P**, from west to east — as the map shows — and there, between the islands of Novaya Zembla and Vaygach and the continent of Finnmark [Finmarchia] and Bjarmia [Biarmia], confined into a narrow space, it discharges itself with the greatest force into the Eastern Ocean. And since the sea falls along **E O P**, the tide too must necessarily return from east to west.

It is likewise clear why such unusual sea-motions are observed between England and Ireland. We say the cause is the circulation of the currents reflected from the Deucaledonian Sea **E** and the British Sea **B** into **K**, where the sea — broken among the various windings of the gulfs and islands, divided, and thrown into confusion by the diverse, straight, oblique, and sinuous repercussion of its waves — produces anomalous tidal effects; and there is nothing to wonder at in this. Added to these is the eruption of the subterranean channels of both islands, which take up the waters back and forth; and with all these things concurring, you may promise yourself nothing stable in the marine tide. The same cause is assigned to the inconstancy of the sea in the Hebrides Islands.

CONSECTARIUM III.

[Margin: Why on the western shores of Norway the tide is imperceptible.]

Why on the western shores **H** of Norway is the flux and reflux never noticeably observed? I answer: since the sea's current **E O P**, driven back from the glacial sea and from the shore of Finnmark, bends its way toward **H** and **V**, into the German Ocean, and therefore cannot strike the said shores **H** directly but flows off from **H** toward **V**, no notable increase is observed there either. There is the further point that the other current **E M H**, passing through **L** by the islands that lie in its way — both the Hebrides and the Orkneys, and the islands adjacent to **H** in Norway — is as it were combed out, and loses its force as the tide gradually grows faint.

CAPUT VI.

DISQUISITIO V.

Why at the mouth of the Garonne [Garumnæ], a river of France [Gaul], the water rises for seven hours but falls for only three; whereas, on the contrary, in the Senegal [Senega], a river of Africa, the sea-water rises for four hours and falls for eight.

[Margin: The cause why the tide in the river Garonne rises for 7 hours and ebbs for 5.]

I answer to the first point. Since the Ocean, driven back from the shores of America, enters the Cantabrian Gulf **C** directly, and has the mouth of the Garonne directly facing it, it happens that the currents grazing the shores **β** and **γ** and converging at **C** struggle with the river's great resistance, and so block up the mouth **C** of the Garonne. Yet since the direct flux **A A C** makes straight for the mouth, it happens that the earlier resisting currents, broken by the force of the

current **A A C**, all penetrate the mouth together at once. But here a new struggle of the waters arises, the Garonne's own waves opposing themselves to the sea's flux; and when the river cannot resist the more powerful sea-current, in time the sea at last prevails. It completes its increase one hour later than the general motion of the sea requires — namely in seven hours — on account of the labor it must exhaust in overcoming the river's waves. But when the sea's flux subsides, the river, restored as it were to freer air, completes its decrease more easily and in a shorter time, namely in five hours. In this way the time of flux and reflux — which nature has fixed at 12 hours — is balanced: just as the sea spent seven hours in the laborious inflow, so it makes up the difference in the outflow by brevity of time, namely in five hours.

[Margin: The river Senegal of Africa.]

As for the Senegal river — which geographers also call the Niger [*Nigrum*] — concerning the question why its water flows in for four hours and ebbs for eight: [Margin: The reason for the Senegal's tide.] we say this happens because the general motion of the Moon, stirred up in the Indian Sea and diffused far and wide through the Ethiopic Ocean, when it first strikes the Islands of the Hesperides [the Cape Verde Islands] that lie in its way, is so reflected toward the mouth of the river Senegal — which otherwise is slow and sluggish — that on entering it, it begins its increase gradually. But meanwhile, since the Ocean, driven against and driven back from the shores of Brazil [*Brasiliæ*], makes straight for the said mouth, and over a span of four hours increases it remarkably, it happens that meanwhile another current of the sea from the north breaks the force of the prior current and turns it aside. Hence, when the tide has subsided at the mouth of the river, the sea — which had crept into the inner, calm, and tranquil winding folds of the river — gradually flowing back together with the sluggishness of the river, when at last its own current (which had checked the river's flux) subsides, is restored to its channel after eight hours.

CONSECTARIUM.

Hence it is clear that, other things being equal, the sea takes so much more time in the inflow and increase of any river, and the outflow occurs so much more easily, the more rapid and steeply-sloping the mouths the rivers enter through are;

[Margin: The reasons for the tide at the mouths of rivers explained.]

and, on the contrary, the sea labors so much less in the inflow into rivers, and labors more in the outflow, the more level, quiet, and tranquil the rivers are. For when the sea rushes in, these are easily filled; whereas in more steeply-sloping rivers the sea labors greatly to overcome their waves. It is likewise clear that the currents impede one another, and so cut short the natural motion of the inflow in such a way that the increase which the sea ought to have produced by its inflow over a six-hour span, it produces in no more than four hours, or even fewer, on account of the anticipation or postponement of the other intervening current's force — as is clear from what has been said. And this I would suppose to be the cause in the differing tides of rivers.

CAPUT VII.

DISQUISITIO VI.

Not long ago the most illustrious and noble lord **A. de Moray** [Sir Robert Moray], a Scottish knight, proposed a remarkable doubt concerning the exotic constitution of the marine tide, which he writes he had observed in the Orkneys and the Hebrides. Having set it before many other learned men in vain, he at last had recourse to me, hoping I might render the cause of so unsearchable an effect and bring some light to so impenetrable a difficulty. The words of the said knight, as excerpted from his letters sent to me, are as follows:

"For the science of navigation," he says, "it would be very useful to compose a proper history of the sea's tides, fully explaining all the motions — both regular and anomalous — that occur anywhere. Whatever I have so far happened to see on this subject I think defective. It would be a task truly worthy of you to undertake this service. [Margin: A wonderful tide.] Wonderful are the alternations of flux and reflux in certain places. Here I shall relate what I observed in the Hebrides Islands, partly with my own eyes, partly learned from trustworthy inhabitants. [Margin: The marvelous variety of the tide in the Hebrides islands.] There is a place in the strait — strewn with smaller islands, rocks, and frequent sandbars — among the larger ones commonly called Eust [Uist] and Herres [Harris]. At the highest tides, that is, at the time of the conjunction and opposition of the Sun and Moon, when full sea [plemmyra] occurs at the sixth hour, the tides proceed in an orderly fashion: the flux from east to west over a span of six hours, and likewise the reflux from west to east, is completed. This holds always for two days before the full moon and its opposite [the new moon], and as many days after. But on the third day, and thereafter, it is far otherwise; for during the whole daytime, whether it floods or ebbs, the current of the water is always directed toward the west, while at night it

turns toward the east. This I myself observed; but the natives report, moreover, that something even more wonderful happens here. Namely, throughout the whole day, while the Sun traverses the northern signs, the said currents of the water tend westward; but throughout the whole winter, the contrary — whose cause it was not granted me to penetrate." Thus far the words of the knight cited above.

Three things, therefore, are to be considered in this proposed doubt. First, why for two days before and after the conjunction and opposition of the Sun and Moon the sea always floods and ebbs over six hours; and this tide, since it arises from the general motion of the sea stirred up by the Moon's force — as was fully shown above — needs no further explanation. The second presents a greater difficulty:

[Margin: The exposition of the doubt.]

it asks: why, on the third day from the new or full moon, does the sea always flow westward by day, but eastward by night? The third is: why, when the Sun is passing through the northern signs, does the sea always run westward, but in the southern signs — that is, in winter — always eastward? But since the said observation is not expressed in all its particulars according to all circumstances, I have judged it not fair to interpose my own judgment in this matter too rashly. For I do not know whether, after the third day from the conjunction and opposition, the sea undergoes so exotic a change, or whether it does so on the other following days of the waxing or waning Moon as well — a point not made explicit in the doubt. The second consideration suffers a still greater difficulty: namely, that the sea is said to run always westward in summer, but always eastward in winter — which equally cannot be conceived, since it would seem to contradict the preceding observation. Everything ought therefore to have been specified as carefully as possible: namely, whether — excepting the new and full moons — the sea ran westward only in summer, or eastward only in winter. And if it happens so, it will necessarily follow that the sea makes for the west during one half-year and for the east during the other half-year — which is absurd, since it has already been observed that outside the time of conjunction and opposition the sea makes for the east only by night and for the west only by day. Hence, since nothing in this doubt has been determined, but it has been written down in a confused manner, so likewise to pass judgment on these matters too hastily would be the act not of a prudent man but of a fool. Therefore, in order that the genuine cause of such great changes may be drawn out as exactly as possible, careful observations must first be made by skilled men — namely, who and whether there is that exotic motion on the third day before and after the

conjunction and opposition of the Sun and Moon; whether it lasts on that day only, or on the following days as well, when the Moon is at points more remote from those said places; then at what time the sea begins to run westward by night, and at what time eastward by day; whether such contrary fluxes are precisely comprehended within the number of twelve hours;

then how this flux lasts for a half-year span [*semestri*] toward the west in summertime, and how it lasts toward the east in wintertime; whether this is to be understood of all the days of the half-year span, or only of the days lying outside the new and full moons; again, whether it occurs at any position of the Moon in the Zodiac; finally, the situation of the shores and islands would have to be rightly described, the depth of the sea explored, and similar circumstances — without combining all of which we cannot reach our intended aim and purpose.

[Margin: To observe the tide in the open sea is difficult.]

For it can scarcely be said how the eyes from time to time deceive us — I will not say the inexperienced, but those trained to the science of navigation from youth — when they think the sea is running in this or that direction, while in fact nothing exists but a certain fluctuation of the sea by which we are deceived. So, just as we said above, nothing is more difficult than to observe the flux and reflux of the sea in the open sea; in places tangled with a multitude of islands, where the sea is now driven against this island, now against that, by manifold reverberation and the perpetual circulation of the waves, I judge it most difficult of all to observe a constant motion of the sea toward the east or the west. But let us proceed to other cases, with more exact observations and with the daily experience known to all who frequent shores of this kind.

CAPUT VIII.

DISQUISITIO VII.

Why the Southern Sea — commonly called *del Zur* [the South Sea, the Pacific] — near Panama produces such unusual and incredible fluxes and refluxes. Whereas, on the contrary, in the Northern Sea — commonly called *del Nord* [the North Sea, here the Caribbean/Atlantic] — near the port of Nombre de Dios and along the other shores of the American continent, it causes scarcely a perceptible tide.

Francisco González de Oviedo [Gonzalo Fernández de Oviedo] treats this question in his *General History of the Indies* (Book 2, chapter 10). He says that he set these prodigious effects of the sea before all the philosophers and learned men, but that

there was none who gave any satisfaction in assigning the cause; and so, confessing their own ignorance, they left this question as if insoluble, and he thinks it cannot be that the cause of this matter can be given except by a man divinely enlightened. We, however, hold that not so much native genius is required, but that by the natural light alone such marvelous effects can be penetrated — if not intimately, at least to some degree. And so that we might not seem to have neglected so signal an occasion for exercising the intellect, having first duly examined all the circumstances of both seas' effects, and having explored the dispositions and properties of the terrain of both seas, we have at last — God granting — arrived at the true cause of such exotic motions, which I shall then expound, once I have first described the effects which the said sea undergoes in its inflow and outflow. The matter stands thus.

[Margin: The flux and reflux of the sea *del Zur* at Panama.]

Since the Southern Sea is distant from the Northern — or the Western from the Eastern, if you measure a straight line — by no more than 12 leagues, namely with the Isthmus interposed between Panama and Nombre de Dios bounding both seas: all wonder, and seem unable to grasp, why in so small a space of intervening land so great a difference of marine motions should be found. For on the shores near Panama the sea seems to fail in so excessive a recession that it cannot be touched at all by the eyes of those standing on the shore, and seems to have vanished entirely; whereas in the inflow and increase, it is carried against the shores with such force that it first covers with its waves all the islands lying in the way in the Gulf of St. Michael, and then overwhelms the very houses on the shore together with the trees in its path. But in the opposite Eastern or Northern Sea, commonly *del Nord*, at the very same time scarcely a perceptible motion of the sea is found.

[Margin: Why the Atlantic sea at the American isthmus makes only a slight and scarcely perceptible tide.]

To assign the reason for this exotic effect, then:

I suppose, first, that the sea-currents in the Atlantic toward the shores of America — and especially between the throats of the New Kingdom [Nuevo Reino de Granada] and the islands of Cuba and Hispaniola, as we have shown elsewhere — are most powerful, and insinuate themselves with so great a mass of waters within the said straits that ships there seem not so much to be carried as to rush headlong, just as in a most rapid river or down the slope of some mountain. And so for those setting out from Mexico or Peru to Europe, it is impossible to

overcome this force of the sea; instead one must hold a course by various circuits toward the shores of Virginia and Florida, so that by the circulation which the sea there makes around the said islands one may at last reach the desired port of Europe.

I suppose, second, from the observation of sailors, that in the said strait the sea is of unsearchable depth — a clear sign that the sea's bottom there terminates in some hidden abyss.

I suppose, third, from my *Ecstatic Terrestrial Journey* [*Itinerarium Terrestrae Exstaticum*], Section 2, "On the Submarine Itinerary," that there is there an immense subterranean passage by which the Northern Sea communicates with the Southern — as the common opinion of the natives holds, and as the hidden dealings of commerce in both seas sufficiently make plain. But of this passage...

that this passage [meatus] is, as it were, a kind of bridge under the isthmus, beneath which the current of the northern sea rushes through with the greatest force. With these things supposed, then, I make my claim.

When the Moon strikes the Atlantic with its rays, I hold that this sea, stirred by the Moon's power, rushes with the greatest force (as I said) into the said channel; and since it finds no exit there, it works its way into the windings of the isthmus with a great heaping-up of waves. Now since it finds no exit except in the southern sea at Panama, it discharges itself there into that sea, draining off at the very same time as the tide there is falling. From this the sea is driven back from the shores—especially at the time when the Moon declines from its meridian and the swell of the sea in the southern ocean fails, as I said—and this is the source of that very ebb of the sea which the aforementioned Gonzalo de Oviedo [Gonzalo Fernández de Oviedo] could not account for.

When, however, the Moon grows for six hours and falls for as many, and reaches the opposite quadrant, then behold: the southern sea, swelling, rolls its waves toward the western shores of America. And as these earlier waves meet others coming against them—spreading far and wide both from the isthmian passage and from the Strait of Magellan [Freto Magellánico]—an immense tumult of waves arises. So the earlier waves, immense as the sea is, are overpowered by the following swell, and burst out through whatever opening is given: partly toward the shores, partly driven back into the isthmian passage, and there they stir up on the shores of the Gulf of Panama [Sinus Panamicus] those vast, storming inundations we have described. For so great is the violence of the sea at that time that it levels with the sea even the islands lying in its path—lands that are

therefore uninhabitable, by no means flat, but set with rocky slopes and trees—all of them at once buried under the water, and it fills the shores and the city of Panama itself with water, with a certain dreadful subterranean bellowing and also with an earthquake (which I believe is produced by that great violence with which the waters, packed tight, force their way into the said passage).

[Margin: Huge swell and surge of the sea at Panama.]

[Margin: Bellowing of the sea, with trembling of the earth.]

For from the opposite shore of the northern sea, at the port of Nombre de Dios, at the same time the sea—surging in a marvelous manner with the same terrifying sound—directs its onset toward the Gulf of Mexico [Sinum Mexicanum] and the neighboring shores of northern America. This our Fathers, who came here to Rome as procurators, have often related, and the said Gonzalo de Oviedo describes it skillfully indeed in his history, on fol. 87. The cause of this can be no other than the vehement regurgitation of the southern sea out of that passage.

But why in this northern sea no tide, or only a very slight one, is noticed from so great an agitation of the waters—I say the cause of this is the same as the one by which the water entering the passage carries off with it the falling waters of the sea from the shores of Panama. So too the water rushing back through the passage, casting its course into the Gulf of Mexico, likewise carries off the waters from the shores along with it, so that it can produce only a slight impulse upon them.

[Margin: Objection.]

But you will say: this reasoning may hold for a falling sea, but why—

—does it undergo the same alternations even in a rising sea? Because the general motion of the sea, stirred by the Moon, partly hurls the Ethiopian Ocean [Oceanum Æthiopicum] with the greatest violence toward the jaws of the isthmus of Panama, and partly discharges it into the Gulf of Mexico; and so it happens that, finding no exit there, it communicates the tide through the subterranean passage to the said marshes—a thing that has hitherto seemed marvelous and paradoxical to those who do not know the hidden dealings of nature.

[Margin: Why the marshes of Mexico undergo the tide's ebb and flow.]

Imagine for yourself the Gulf of Mexico A, in which the Ethiopian Ocean, surging...

Diagram. A vertical schematic of the chain of Mexican waters and the subterranean passages connecting them to the Gulf of Mexico, drawn as a top-to-bottom column. At the top is the city of Mexico, set within a body of water; below it a series of lakes connected by dotted-line subterranean channels descends to the sea at the bottom of the page. Mountains and stands of trees flank the channels on either side. The running label "Subterraneus" ("Subterranean") is written along the connecting passages.

- Mexico (top, within a body of water): "Mexico" — the city of Mexico, on its island
- Aqua dulcis (just below Mexico): "Fresh water" — the freshwater lake around the city
- G (at the foot of the freshwater lake): junction point of the channel descending from the Mexico lake
- F (mid-passage, on the dotted channel below G): the subterranean channel connecting the freshwater lake to the salt lake (corresponds to passage F in the text)
- Subterraneus (along the dotted channels): "Subterranean (passage)"
- Lacus salsus (middle, large lake): "Salt lake" — the salt lake below
- C (beneath the salt lake's name): label for the salt lake
- E (between the salt lake and the gulf below): the subterranean passage leading down to the Gulf of Mexico
- B (lower, at the head of the gulf): junction where the passage meets the gulf
- Sinus Mexicanus (bottom, within the radiating sea): "Gulf of Mexico"
- A (within the Gulf of Mexico): label for the gulf

surging, since it finds no exit, discharges itself through the subterranean passage B E into the salt marsh C; and this in turn discharges itself through the subterranean passage F into another marsh, G, welling up with fresh water, above which the city of Mexico itself is founded. Most people also wonder why this last lake, though it receives countless rivers, never overflows. But if they understood the arrangement of this subterranean traffic, they would by no means doubt about so manifest a matter. For it does not overflow, because the lake is drained of its water out of D, through the passage E into C, and from there through the passage E B it is carried down into the sea while the tide is falling—only to return, as soon as the sea swells again, to the place from which it had flowed out.

CONSECTARIUM II. [Corollary II.]

From this it is also clear why, in the Hudson Sea [mari Hudson], the water rises by 15 feet, yet in another neighboring gulf of the same sea by only two feet. The reason is that the sea, rushing from east to west, enters the said sea directly, and so it is no wonder that, where it strikes the opposite shore, it should be raised to 15 feet. But in the other gulf the water either does not reach the said shores, or, if it does touch them, it is carried off through a subterranean passage either into other surrounding lakes or into neighboring seas.

[Margin: The Hudson Sea.]

CAPUT IX. [Chapter IX.]

DISQUISITIO VIII. [Inquiry VIII.]

There is a place beside the coast of Guinea, one degree distant from the equator, in a bay which they call Fernando del Po [Ferdinando Pool], in a corner where Guinea, stretching along a great tract of coast from west to east, finally bends to the south. Here the motion of the sea is altogether contrary to the general motion that runs perpetually from east to west; and it is so vehement that whatever ships put in at this place are seized by a certain hidden force, so that by no power of their own can they drive themselves back—unless aided by Ecnephias-squalls [Ecnephiis] and the most violent chronic winds. The place is fatal to vessels, full of dreadful whirlpools.

[Margin: An abyss in the bay which they call Fernando del Po.]

It is astonishing, moreover, that no one has hitherto given the cause of this matter, although so many cosmographers have already wearied their brains in studying that place. We say the cause of this is the subterranean passage through which the sea discharges itself amid the destruction of ships and men—the waves being heaped up in that corner of the ocean and discharging themselves through that subterranean passage. And the explanation is plain: because the rapidity of a current of this kind, besides being perpetual, lasts only to a distance of 14 miles.

[Margin: A subterranean passage in Africa.]

As for the view of some that this current arises from the recoil of the ocean against the shores of Brazil, made toward the east—that cannot stand. For since recoils of the seas of this kind are directed by the rising of the Moon, that recoil would doubtless cease when the Moon reached the opposite quadrant; whereas this current, whether the sea is rising or falling, always and forever behaves in the same way. This is indeed a most luminous sign that the sea, headlong as if through some river, pours in a continuous current into the blind bowels of the

earth through this submarine gulf, draining off into a lake of inland Africa which some call Tigri [Tigrai], others the Niger [Nigrum]. My reasons I now assign.

For Pigafetta, in his African *Itinerary*, says that this lake is by its nature a salt lake, with which the Niger, flowing through it, does not mix; that fragments of ships are very often found in it, and many other things which clearly show that it has some commerce or other with the neighboring ocean. From this I infer that it can communicate with no other place of the ocean than with the place we have just described—where the water, with a most vehement current and also with a remarkable...

[Margin: A place infamous for shipwrecks.]

destruction of ships and men, after such [havoc], discharges itself into that lake. Before this lake was known, the *Nautical History* relates that very many ships were either swallowed up there, or driven against the shores by a violent motion, and left behind only the planks, the relics of a sad and dismal shipwreck. And if any, by skill in the nautical art, escaped this Scylla, these were held back for many months by violence, and—their supplies of all the necessities of life consumed, when they could not overcome the tide—at last miserably perished of hunger and thirst.

CAPUT X. [Chapter X.]

DISQUISITIO IX. [Inquiry IX.]

On the marvelous whirlpool of Norway, the most celebrated and greatest of the whole world.

[Margin: Description of the whirlpool.]

There is a whirlpool and tidal race [Euripus] in the adjacent Norwegian sea, the Northern Ocean, conspicuous beyond all to the great terror of all sailors. It is said to be thirteen miles in circuit; by the inhabitants it is called the Maelstrom [Meelstrom]. A rock occupies the middle of the whirlpool, which the natives call Musken [Muske]; beneath this is a huge chasm which, over six hours, swallows up everything brought within...

the circumference of its crater: cargo ships, the smallest and the largest, water, whales, and other things. And over an equal number of hours it belches and vomits all those things out again, with great violence, with a roar, and with a fearful churning of the dizzying sea. So testifies Olaus Magnus; so report the natives of this coast, and the navigators of the Danes and the Dutch. The effects

we have seen, approved by the testimony of all the northern peoples. It remains for us to assign the cause of effects so prodigious—especially since no one hitherto has given their genuine explanation.

[Margin: Investigation of the cause.]

First, then, it is to be noted, on the testimony of Olaus Magnus, who reports that the whole region of Scandinavia is full of caverns and of passages hitherto undiscovered in their length, and confirms this from the horrible roar both of the Bothnian [Bodnici] and Finnic seas, and of the lakes which they call Vänern and Vättern [Venner & Vetter], and finally from the dreadful roar of the mountains—a roar which can be produced in no way except from subterranean waters that, derived from the neighboring seas and gulfs into other places along channels stretched far and wide, [reverberate] with the varied reverberation of waves in the steep and winding passages or cataracts [catadupis] of the earth. He writes that in many places this roar is so great that men approaching too near are rendered deaf and, as it were, thunderstruck and stupefied, and from time to time even lifeless, unless they timely remove themselves from those deadly caverns of Charon.

[Margin: Dreadful sounds at the shores of Bothnia.]

To be noted, second: not only the lakes of Norway, but also those of Sweden, which they call Vättern and Vänern [Vetter & Venner], are of unfathomable depth, the same Olaus writes—so that ropes which would load a whole ship do not suffice to reach the bottom. The Hollanders experienced the same on the said Norwegian shores, who with a sounding-lead of 130 fathoms [orgiarum] could not find the bottom, as they report in their *Voyage to the Arctic*. These unheard-of depths argue nothing else than subterranean abysses of immense extent.

[Margin: The unfathomable depth of the lakes.]

To be noted, third: from so great an abundance of subterranean passages we can readily infer the mutual and hidden correspondence of the surrounding seas with the ocean that washes Norway. Olaus shows this too by various examples, when he describes the aforesaid vast and very deep lakes Vättern and Vänern [Vetter & Venner], which he openly asserts to be derived from the Bothnian sea; and that the Bothnian Gulf has a hidden correspondence with the White Sea [Mari Albo], which is a gulf of the Tartaric Ocean; and the White Sea with the Finnic Gulf [Sinu Finnico] through a lake which they call the White [Album]—this, together with the Bothnian, communicating with the Norwegian Ocean.

[Margin: Charybdis.]

With these premises laid down, let us now gird ourselves to assign the genuine cause of the Norwegian Charybdis, which flows in for six hours and flows out for as many.

Since, then, the said Charybdis or whirlpool—as is shown by irrefragable experience—so powerfully swallows the neighboring water of Norway, together with the things thrown into it, for six hours, and over an equal number of hours gradually vomits them out, it is certain that this flow and reflux—this swallowing and disgorging, which happens in the space of twelve hours—has no other cause than the general motion of the ocean, stirred by the Moon's power. But how all this can come about, we shall try to show in this place, if not by demonstrative reasons, at least by ones in the highest degree probable.

[Margin: The whirlpool of Norway flows and reflows for six hours.]

We showed in Inquiry IV that the Deucalidonian Sea [Mare Deucalidonium], circulated through the northern region, discharges itself into the Tartaric Ocean through the Strait of Vaigach [Fretum Weigatz] with the inflow of the tide, and that through the same strait, abandoned by the outflow of the sea, it seeks the ocean again over the space of six hours. There too we showed why, on the Norwegian coast, the ebbing water leaves scarcely any perceptible trace of the tide in those regions.

I say, then, that the inflow or swallowing in the said Charybdis happens in this way. When the Deucalidonian Sea, stirred by the general motion and by the Moon's power, directs its currents toward the Strait of Vaigach, it happens that in such great narrows of the strait the waves, heaped up in a marvelous manner and hindered by the obstacles of the glacial sea, cannot penetrate it all at once. So a great portion of the sea, blocked, turns its course back toward the shores of Finmark [Finmarchiæ] and Norway, where—raging amid countless reefs with the swell and increase of the waves—it finally falls, through so many windings and unwindings of caverns and islands, into the crater of the whirlpool. There, no longer enduring the gluttony of hidden nature, it is swallowed up together with all those things then cast into it, whether by chance or by the rapidity of the sea through the reckless haste of sailors. And this voracity lasts as long as the inflow or swell of the circulated ocean lasts. We have the cause of the swallowing carried out over six hours.

[Margin: The whirlpool swallows everything.]

It remains to explain how, in the space of six hours, it vomits up again what had earlier been swallowed—a thing that has rightly seemed to many, unschooled in the secrets of nature, to exceed the capacity of the human mind.

[Margin: How the same whirlpool vomits up everything it swallowed.]

In the third Notandum proposed just above, it was shown that the Tartaric Sea, stirred by the greatest force, by the power of the sea's swell with the Moon in the opposite quadrant, retreats over six hours, [carrying] its currents partly through the Strait of Vaigach, partly through the Tartaric Gulf, by the six-hour outflow. But since the greatest packing of waves and ice meeting at the mouth of the eastern strait obstructs the Tartaric Ocean, its course is therefore deflected elsewhere, and it is forced to work its way into the White Sea, which they call Petzorche [Pertzerche [?]]. Now this sea, because it has a hidden correspondence with the Bothnian and Finnic Gulfs—and these gulfs likewise communicate with the whirlpool of Norway, through the things we showed in the first Notabile, by means of hidden subterranean passages—the point intended is clear. Indeed Olaus (*Septentrional History* II.6) expressly...

states that the Bothnian Gulf is intricate with countless reefs and surrounded by very high mountains covered with perpetual snow, within whose roots the sea is now swallowed up, now vomited out again through immense whirlpools, with a horrible and intolerable sound—all of which has been set forth more fully a little earlier, and in the preceding Book.

[Margin: The whirlpool of the Bothnian Gulf.]

With these things laid down, then, I say: in those six hours in which the Norwegian sea grows to its greatest increase, the Tartaric Ocean—gradually swelling after about 4 hours, according to the reckoning of the Moon's position—on the one side pours its mass of water into the White Sea, and this through subterranean passages into the Bothnian Gulf; while on the other side the German Ocean [Germanicus Oceanus], through the Cimbric Chersonese [Chersonesum Cymbricam] with great windings of the shores and the most constricted narrows, working its way through the Baltic Sea [Mare Balthicum] into both the Bothnian and Finnic Gulfs, meets the Tartaric waters and stirs up great collisions. So the sea, confined within the narrows of the Bothnian Gulf, is restored through hidden whirlpools and passages to the Norwegian sea, by the [route] which we described as Charybdis. For the Tartaric and German Ocean take more time to keep up their swelling through so many winding tracts of country than the swelling of the Norwegian sea requires. For when the water

swells at our Charybdis, the water in the said gulfs is falling, and on the contrary, when these are falling, Charybdis seems to disgorge what it has drunk.

[Margin: The whirlpool of the Bothnian Gulf.]

But that I may not seem to have said this by mere conjecture, I will bring forward the author of my assertion, Levinus Algotius [Levinus Algoth], printed at Antwerp, who in his *History of the Northern Regions*, where he treats of the nature and prodigious things of the said regions, makes express mention of the whirlpool of Norway, and of another in the Bothnian Gulf. He says it was noted by sailors that when the Norwegian one swallows the waters, the Bothnian one, after the space of some hours, returns them with its own impulse, and vice versa. His words are:

[Margin: Levinus Algotius, in his description of the Northern Regions.]

"It has been observed, moreover, by men skilled in those parts and travelling back and forth, that after the Norwegian whirlpool has swallowed the waters, the other whirlpool in the Bothnian sea in turn compels them—through the subterranean Norwegian gulf—to vomit out again the waters which it had swallowed; and the reverse."

Thus far the cited author—whose words indeed so agree with our project that he seems to have overcome almost every difficulty in assigning the cause of the whirlpool. But perhaps someone will object: the hidden commerce of the ocean with the Bothnian Gulf is not difficult to conceive, but how the whirlpool of Norway does not carry off elsewhere what it has swallowed, but vomits it up again within six hours—this indeed seems inconceivable.

[Margin: How the whirlpool of Norway vomits up everything again after six hours.]

I reply that this whole prodigious action is to be referred back to the natural constitution of the subterranean whirlpool. But let us show it by the following diagram, in which C is the whirlpool; the rock B; the orifice of the whirlpool A; the canal of the gulf, drawn down vertically into the inner bowels of the earth, D, beneath which is a vast water-reservoir [hydrophylacium] E; the subterranean passage F H I; while the whirlpool of the Bothnian Gulf is K, the mountain within which G is enclosed.

Diagram. A cutaway landscape view of the Norwegian Maelstrom and its subterranean connection to the Bothnian Gulf. At upper left, the Norwegian Sea (Mare Norvegiae) opens into a conical whirlpool with a central rock; a vertical

shaft descends from it through the earth into a great underground reservoir, from which a winding subterranean passage runs across the page to the right, connecting (via an inland mountain holding a spring) to the Bothnian Gulf at far right. Mountains, trees, and figures of sea-monsters fill the surrounding terrain.

- Mare Norvegiae (top left): "The Norwegian Sea"
- C... C (flanking the rim of the whirlpool's funnel): the whirlpool [vortex]
- B (at the center of the whirlpool): the rock (Musken)
- A (just below B, at the throat of the funnel): the orifice of the whirlpool
- D (within the vertical shaft beneath the whirlpool): the canal of the gulf, drawn down vertically
- E (the bulbous chamber at the foot of the vertical shaft): the vast subterranean water-reservoir [hydrophylacium]
- Subterraneus (running along the horizontal passage): "Subterranean (passage)"
- Meatus (along the horizontal passage): "Passage"
- F (at the near end of the horizontal subterranean passage, beside E): part of the subterranean passage F H I
- H (along the horizontal subterranean passage): part of the passage F H I
- I (continuing the passage toward the right): part of the passage F H I [I not separately legible at the passage's far end on the page; named in the text as F H I]
- G (within the inland mountain at right-center): the spring/water enclosed within mountain K
- K (the crater-like basin on the mountain at right): the whirlpool of the Bothnian Gulf
- Sinus Bothnicus (far right, the large bay): "The Bothnian Gulf"

So I say: as the Norwegian sea swells, the waters, gradually heaped up in a marvelous manner, with the greatest...

force [rush] into the whirlpool C; through the orifice A they discharge themselves into that immense well D, and from this into the subterranean reservoir E. But the sea, over the space of six hours, continually pours greater and greater waves into it; whence the waters in the reservoir E, beyond measure...

and grow [augmented]. Since these waters can find no outlet, they are driven with the greatest force through the subterranean passage F-H-I and discharge themselves into K, the Bothnian whirlpool [vortex/gurges] — which is then at the very bottom of its level. But once the Bothnian sea rises again, the waters held

back in K are stirred up by the swelling of the sea and are driven once more, with the utmost violence, against the orifice K of that whirlpool. (This is the source of the terrible roar that all the historians cited above attest is heard there.) Repelled through the passage I-H-F, they are restored through the orifice F to the reservoir E.

But since the sea in the Bothnian Gulf [Sinus Bothnicus] swells ever more and more, the water in reservoir E — pressed by the waves coming over through the passage I-H-F — gradually raises the water together with the things it has swallowed and held back within reservoir E. And when the Norwegian sea is now subsiding, it disgorges the things it had absorbed. This whole process, experience shows, happens in alternating turns.

You see, then, that the things absorbed within the cavities of reservoir E — when they cannot flow out through the passage F-H-I, whether because of the siphon (which Hero [Hero of Alexandria] calls a *diabetes* [Greek: διαβήτης (diabētēs, "siphon")]), set there in the rocks by nature, or because of the narrowness of the cracks and orifices — are held there until little by little they are lifted up and at last cast back up again. So now you have the cause of the workings of the Norwegian Charybdis [Charybdis Norvegici] at last laid bare. And so that the layout of these whirlpools may be displayed more clearly to the curious reader, I have thought it right to add here a Map.

Diagram. A large engraved map of northern Europe and Scandinavia, showing the Norwegian and Bothnian whirlpools and the supposed subterranean channel connecting them. The cartouche at lower right is framed by an ornamental scroll. The map is oriented with north toward the upper right. A compass-rose roundel sits at the right-center. Readable labels, by position:

- Cartouche (lower right): "Descriptio Vorticis NORVEGIÆ et BODNIÆ eorumq; mirabilium effectuum, quos in fluxu et refluxu operantur." [Description of the whirlpool of Norway and of Bothnia, and of their marvelous effects, which they produce in the ebb and flow.]
- Upper left (off the coast): "Norweg[i]anus Vortex" [Norwegian whirlpool], drawn as a spiral
- Below it: "Muscke dict[us]" [called Musken — i.e., the rock Moskenes], with a depth-sounding figure "1000" beside it
- Center: "Vortex Bodnicus" [Bothnian whirlpool], drawn as a spiral
- Connecting the two whirlpools: a dotted line labelled "Meatus subterraneus" [subterranean passage]

- Right of the Bothnian whirlpool: "Album Mare" [the White Sea]
- Right-center: "Ladoga lacus" [Lake Ladoga]
- Center, gulf: "Bothnicus Sinus" [Bothnian Gulf]
- Below: "Finland[i]a" [Finland]
- Below Finland: "Sinus Finnicus" [Gulf of Finland]
- Left-center (peninsula): "Norvegia" [Norway]
- Town label center-left: "Opland" [Oppland]
- Center: "MARE B[ALT]ICUM" [the Baltic Sea]
- Lower center-left: "Dania" [Denmark], with "Selandia" [Zealand] on an island
- Far left: "Oceanus Germanicus" [the German Ocean — the North Sea]
- Left edge (Britain): "Anglia" [England]
- Lower left: "Westphalia" [Westphalia]

COROLLARY I [CONSECTARIUM I.]

From this it is clear why the Euripus of Chalcis [Euripus Chalcidicus] in Euboea — famous for the fabled death of Aristotle there — has no other principle governing its ebb and flow than the one already discussed. As the waters flow back through the passage I-H-F, it has its seven ebbs and floods; for Pliny [the Elder] records that it flows and ebbs seven times by day and by night. Even though other, later geographers attest that it floods six times and ebbs as many — following the general motion of the marine tide — Pliny can still be explained in this way:

in this way [explained], as though he meant that the Euripus floods and ebbs seven times by day and seven times by night. This difference may be ascribed to the varying circulation of the sea — its ebbing and flooding cycle [pericyclōsis] amid so great a crowd of surrounding islands — and to the now swifter, now slower inflow and outflow of the subterranean passages.

COROLLARY II [CONSECTARIUM II.]

From this it is likewise clear why certain whirlpools always swallow water and never spew it back, as was shown above concerning the African Euripus [Euripus Africanus]. Of this kind too is the whirlpool of the Danube [Vortex Danubii], which deposits the waters it absorbs — by a subterranean passage — into a lake in Hungary near Kanizsa [Caniffam — Nagykanizsa], as is reported. There are besides whirlpools that both swallow and spew back, like the one we explained a little earlier, and like the Charybdis in the Sicilian Strait [Charybdis in Freto Siculo], whose nature and properties we described at length in Book Three. There

are, finally, those that never swallow, but always erupt violently like a column on the surface both of seas and especially of sulphurous lakes; of which kind there is almost an infinite number everywhere, as will be told in its place.

DISQUISITION X [DISQUISITIO X.]

On the Nature of the Mediterranean Sea, its Currents, Ebb and Flow, and the other memorable things observed in it.

The Mediterranean Sea — enclosed, as in a kind of harbor, between the shores of Europe, Africa, and Asia — holds many marvels of Nature: marvels as unknown until now as they are most worthy of consideration. It seemed extraordinary not only to Aristotle but also to other investigators of Natural Philosophy how it is that a sea closed in on every side, with no passage to the Ocean except through the most constricted strait of the district of Cadiz [Gaditanus — Gibraltar], does not overflow — even after such mighty rivers as the Baetis [Guadalquivir], the Iberus [Ebro], the Rhône, the Var, the Tiber, the Po, and the Nile pour themselves into it, to say nothing of countless lesser ones. [Margin: The Mediterranean Sea receives very many rivers.] To these is added the perpetual and constant inflow of the Black Sea [Mare Euxinum], through the Propontis [Sea of Marmara] into the Archipelago [the Aegean], and from there into the Mediterranean. For it is established by everyone's experience that the said sea, fed and driven by the most powerful and most famous rivers of all Europe — the Danube, the Borysthenes [Dnieper], and the Tanais [Don] — pours itself perpetually through the straits of Byzantium [the Bosphorus] with no hope of return. It might therefore seem a paradox: a sea increased by a sea, yet — though it would appear incapable of holding so great a burden of waters without any discharge — nowhere overflowing along its shores; and this especially at the time when the swelling Atlantic Ocean also enriches it with a great increase of waters, discharging into it with the greatest force. [Margin: Why it does not overflow despite so many rivers (the Ocean excepted).] For this is the very thing no one has been able to grasp. We see, in fact, that rivers...

or marshes, swollen now by melted snows and now by rainwaters, immediately — because of their excessive rise — cause floods, to the great damage of the fields. How then does the sea, with whole seas together with the vastest rivers received into its bosom, not overflow? This must be examined; for without doubt something hidden lies here, an argument most worthy of scrutiny.

We said, both in the preceding Book and in the *Submarine Itinerary* [*Itinerarium Submarinum*], that all lakes are so constituted by nature that, when they are swollen by the rivers received into them and cannot discharge themselves through open mouths, they accomplish this through certain hidden, subterranean passages — just as above, in Book 3, regarding the Caspian Sea [Mare Caspium]. [Margin: It discharges itself through subterranean passages.] That sea, though it receives countless rivers, yet seems to send out none; and since it does not appear to be increased by the multitude of rivers depositing themselves into it, this is a most luminous argument that, through certain hidden passages, it discharges into other neighboring seas in the same proportion in which it receives the multitude of waters. This seemed right to Aristotle too (*Meteorologica* IV [l. 4. met.]), and we demonstrated it apodictically in the cited submarine navigation of the *Iter Extaticum* [*Itinerarium Exstaticum*]. [Margin: The Caspian Sea communicates with the Persian Gulf and the Black Sea.] There, too, from the communication of the seas, we explained that the Caspian Sea trades back and forth, by hidden paths, with the Persian Gulf [Sinus Persicus] and with the Black Sea. Since this is so, I say the same of the Mediterranean Sea, on account of the correspondence it maintains, through a subterranean passage, with the Red Sea [Mare Rubrum]. [Margin: It communicates with the Red Sea.] Since we have set these things out at length, with various examples adduced, both in the preceding Book and in the cited *Itinerary*, I have thought it best not to repeat them here. But to the matter at hand.

Why, then, does the Mediterranean Sea experience such varied motions, wholly contrary to those of the Ocean? [Margin: Explanation of the various currents.] For now it rolls from south to north and back again; now from east to west, and again from west to east, in a reciprocal motion — and then with motions wholly contrary and anomalous. Often it passes from a straight motion into circles and gyres; sometimes, unwound from its spirals, it directs the surge of its currents into one region after another. In certain places it rises and falls at fixed hours, just like the Ocean; on certain other shores you will find not even a trace of tide. Those who sail from Sicily toward the Archipelago are seized by some hidden current and violently wrenched toward the Adriatic Gulf. By contrast, those setting out from Drepanum [Trapani] toward the promontory commonly called *Bon Andrea* [Cape Bon, Tunisia], sailing under the Euronotus wind [Rhombus Euromotius] — which is commonly called *Scirocco* [the sirocco] — feel themselves carried off sideways toward Tripoli of Bizerte [Tripolim Bisertinam]. Those who sail from Cyprus toward Alexandria, even though they try with all effort to hold the line directed by their compass-rhumb, are nonetheless seized by the force of the current and carried 60 leagues below Alexandria, to Damietta

[Damiata]. Those, on the contrary, departing from Alexandria toward Cyprus are wrenched by the current and driven to the shores of Pamphylia. Those who sail through the Archipelago toward Constantinople feel a manifest and palpable resistance of the sea.

Diagram. A large fold-out engraved map of the Mediterranean Sea (this leaf is the left/western half of the double-page plate), showing the western basin from the Strait of Gibraltar to Sicily and the Adriatic. The decorative cartouche at upper left is supported by two winged putti. Readable labels, by position:

- Cartouche (upper left): "Mappa Maris MEDITERRANEI Fluxus currentes et Naturam Motionum explicans." [Map of the Mediterranean Sea, explaining the flows, currents, and the Nature of its motions.]
- Upper right: "GERMANIA" [Germany]
- Center-top mountain range: "Alpes" [the Alps]
- Below the Alps: "GALLIA" [Gaul / France]
- River entering from Gaul: "Rhodanus flu[vius]" [the Rhône river]
- Left-center: "HISPANIA" [Spain]
- Upper-right coast: "Venetia" [Venice]; "Sinus Adriaticus" [the Adriatic Gulf]; "ITALIA" [Italy]; "ILLYRIC[UM]" [Illyria]
- Right: "Calabria" [Calabria]
- Islands center: "Corsica" [Corsica]; "Sardinia" [Sardinia]; small island labelled "Majori[ca]" [?] [Majorca]
- Far left: "OCEANUS ATLANTICUS" [the Atlantic Ocean]; "C. d. S. Vincente" [Cape St. Vincent]
- Strait at left-center: "Fretum Gaditanum" [the Strait of Gibraltar]
- Center sea body: "MARE" [Sea] (i.e., MARE MEDITERRANEUM, continued on the right leaf)
- Right edge: "B. Derpa no" [?] / "SICILIA" [Sicily]; "Malta" [Malta]; "MED[ITERRANEUM]" continuing off the right edge
- Lower center: "BARBARIA" [Barbary — the North African coast]
- Bottom: "AFRICA" [Africa]
- Far right edge (fragment): "Bise[rta]" [?] [Bizerte]

Diagram. Engraved map of the eastern Mediterranean and the Black Sea region — the right (eastern) half of the two-leaf Mediterranean map whose western half appeared on the preceding leaf. The plate is signed at upper right *Tomus I. 152*. It shows the eastern basin of the Mediterranean Sea, the Aegean (Archipelago), the Black Sea (Pontus Euxinus) and Sea of Azov, Asia Minor, the Levant, Egypt and

the Red Sea. The engraving illustrates the argument of the surrounding text: a dotted "subterranean passage" links the eastern Black Sea to the Caspian, and a second labeled subterranean passage (points A, B) links the Red Sea to the Mediterranean near the Nile delta. Readable labels, with positions:

- *Tanais flu.* (upper, river entering the Sea of Azov from the northeast): the Tanais River [Don].
- *Mæotis palus* (upper center): the Maeotian Marsh [Sea of Azov].
- *Borysthenes flu.* (upper left, river): the Borysthenes River [Dnieper].
- *Danubius flu.* (left, river): the Danube River [Danube].
- *Chersonesus Taurica* (center, peninsula): the Tauric Chersonese [Crimea].
- *Pontus Euxinus* (center, the sea): the Black Sea.
- *Subterraneus Meatus* (right of center, along a dotted line between mountains): "Subterranean Passage" — the hypothesized underground channel.
- *Mare Caspii pars* (far right edge): "part of the Caspian Sea."
- *THRACIA* (left): Thrace.
- *MACEDONIA* (left): Macedonia.
- *...ICUM* (far left edge, partly off-leaf): the [Adriatic]ic [Sea] / [Ion]ic [?].
- *GRÆCIA* (lower left): Greece.
- *PELOPONESVS sive Morea* (lower left): the Peloponnese, or the Morea.
- *ANATOLIA; ASJA MINOR* (center): Anatolia; Asia Minor.
- *Archipelagus* (center, in the Aegean): the Archipelago [Aegean Sea], with numerous engraved islets.
- *Creta* (lower center, island): Crete.
- *Rhodus* (center, island): Rhodes.
- *PAMPHILIA* (center right): Pamphylia.
- *Cyprus* (center right, island): Cyprus.
- *PALESTINA* (right): Palestine.
- *Alexandria* (lower right): Alexandria.
- *MEDITERRANEUM* (lower center, spanning the sea): the Mediterranean [Sea].
- *LYBIA* (lower center): Libya.
- *ÆGYPTUS* (lower right, over the Nile delta): Egypt.
- *Nilus flu.* (lower right, river): the Nile River.
- *MARE RVBRVM* (lower right): the Red Sea.
- *Biserta* (lower left edge): Bizerte.

- **B, A** (lower right, marking the ends of the subterranean passage between the Red Sea and the Mediterranean near the Nile delta): the passage points A and B referenced in the text.
- *Damiata* (engraved on the cross-isthmus channel between A and B): Damietta.
- **Q** (lower right, just NW of the Nile delta, below Alexandria): a delta-coast point referenced in the text.
- **M** (far left edge, on the European/Adriatic shore below the ...*ICUM* sea-label, above *GRÆCIA*): the M of segment M X — the European/Adriatic terminus of the segment spanning the breadth of the Mediterranean (X being the African promontory).
- **X** (lower left, at the African promontory near Bizerte): the point X (the African promontory), terminus of segment M X.

[The plate corresponds to the "Map of the Mediterranean Sea" that the text instructs the reader to consult.]

[Resuming the main text from the foot of the preceding column.]

Those sailing in the opposite direction, from Constantinople into the Archipelago, are likewise carried along as if by a following wind, with no resistance from the sea — except for whatever resistance contrary winds create. We have now seen the currents; let us next seek the causes of so much inconstancy.

[Margin: The threefold cause of this sea's inconstancy.]

I trace all motions of this kind back to a threefold cause. The first and principal efficient cause is the Moon, working together with the Sun as the universal cause, as was shown in the preceding sections. The second cause is formal: the Moon's specific power to swell the sea, by which it acts upon the sea — and indeed upon all moist bodies — through its nitrous-saline quality. The third cause is material: the jutting-out of mountains and promontories; the situation of the islands scattered here and there; the arrangement of bays suited to catching the winds; and likewise the varied and uneven irregularity of the sea floor, or basin. To all of these is added the discharge of rivers into the sea.

First question. Why does the Mediterranean Sea move now from east to west, now from west to east? I answer that this happens through the general motion of the sea, in the reciprocation of its advance and retreat. I will demonstrate the matter as follows; and so that you may understand it more thoroughly, you should examine carefully the *Map of the Mediterranean Sea* set out opposite here.

When the Moon strikes the Indian Ocean with its rays, that ocean, suddenly swollen, works its way through the Strait of Aden into the Red Sea, heaping up its waves as far as the tip of the Red Sea's tongue. There, after the great influx that it produces against the shore, it rolls itself, all at once, through the subterranean passage A B into the Mediterranean Sea. The Mediterranean, driven by these foreign incoming waters and then gradually swollen by the very power of the rising Moon, is in turn urged from east to west; through the Strait of Gibraltar it yields to the Atlantic Ocean — until, as the Moon passes the meridian, the waves subside. Once this happens, the Atlantic Ocean, soon swelling proudly with a fresh tumor, enters the Strait of Gibraltar with the greatest force. The Mediterranean Sea, compelled to give way, resumes its course from west to east; and lest it overwhelm everything by an excessive surge against the shores of Palestine, it is restored — through that same subterranean passage B C, by which it had earlier made its entry — to the Red Sea, and at last through the Red Sea to the Ocean. Thus, as the lunar tide diminishes, the sea is driven from west to east; and as the tide increases, from east to west. There, then, you have the cause of the question proposed.

[Margin: The causes of the currents explained.]

Second question. Why are those sailing from Cyprus to Alexandria for the most part carried to Damietta, 60 miles below Alexandria, and sometimes driven above Alexandria — while, conversely, those setting out from Alexandria are sometimes carried up toward Cyprus and Pamphylia, occasionally as far as Tripoli of Syria? I answer: because when the Red Sea is belched up through the subterranean passage, the sea's current then runs from east to west. Consequently those leaving Cyprus along this current, when they reach the stretch of the Libyan or Cyrenaican shore, must of necessity be carried by the sea's flow above Alexandria. But those leaving Alexandria toward Cyprus are, by the same current, twisted from their straight path and carried to the shores of Pamphylia. When, on the other hand, the Ocean enters through the Strait of Hercules [Strait of Gibraltar], the sea moves from west to east; and soon, as the sea insinuates itself through the subterranean passage, the current is driven toward the shores of Palestine. Consequently those setting out from Cyprus to Alexandria, deflected by the sea's current, must necessarily put in below Alexandria, at Damietta — that is, Pelusium. Conversely, those going from Alexandria to Cyprus, carried off this flow of the sea from the straight rhumb-line, are driven to Tripoli of Syria. This is why the more experienced sailors, on either voyage, are accustomed to begin their journey not along the straight rhumb-line but with one rhumb taken above or below the midline, so that they may reach the harbor they desire.

[Margin: Why the Nile, when it discharges into the sea, does not impede the current of this sea.]

All of this is greatly furthered by the discharge of the Nile, for it is well known that the Nile's waters, once deposited in the sea, are turned back along the currents just described. From this it is also clear why the current of the Mediterranean Sea — running from east to west and back again — is not impeded by the immense mass of water that the Nile pours into that sea through its seven mouths. The reason is that the waters of the Nile, being fresh, are always lighter than the salt waters, and so they occupy only the surface of the sea; whereas the water belched up through the subterranean passage penetrates the whole midst of the sea and stirs it without any hindrance from the rivers.

[Margin: Why in the Adriatic Gulf the flow and ebb are perceptible, but in other shores not perceptible.]

Third question. Why does the Mediterranean Sea produce a flow and ebb that is scarcely perceptible on the shores of France and Italy, and on certain shores of Africa, while in the Adriatic Gulf, the Sicilian Strait [Strait of Messina], the harbor of La Goletta [Goletta, near Tunis], and certain other shores, it produces a very great one? I answer that this happens for three reasons. First, because the Mediterranean Sea is very narrow and crowded with islands, and moreover stretches in a straight line from east to west along the limits of its length. From this it follows that the swelling Ocean, rushing violently into the mouth at Cadiz, directs its course straight toward Corsica, Sardinia, and Sicily. Hence the inward-curving shores of Spain and France — with the water flowing away — cannot share in the increase of the tide. But the tide that slips in within the jaws of the Sicilian Strait rolls up those surges which we shall describe a little further on. The remaining current, continued on between Sicily and Africa, is carried straight to the promontory of Africa, X. There, as its impulse gradually grows faint, the sea, circling round along the shores of Libya, just as it does not strike those shores, so it imprints no tide upon them either — nor upon the shores of Palestine, since its flow, somewhat weakened by the superadded spreading of the Nile's waters, is altogether extinguished there. And toward the shores of Asia Minor it cannot continue the force of the current, since it is interrupted by the violent flow of the Archipelago.

[Margin: Plurim[a] / fluvios / cipit M[are] / Medite[rra]/neum. — "The Mediterranean Sea receives very many rivers."]

[Margin: Cur tot / flumini[bus] / exceptis / non ex[un]/det. — "Why, despite receiving so many rivers, it does not overflow."]

It cannot — — because, since the Mediterranean Sea is very narrow and crowded with islands [the column break in the source repeats the argument; I render the continuous sense].

What of Corsica and Sardinia, where it rolls up some tides, while at Majorca it does not? This becomes sufficiently clear at once from the current of the sea driven straight into those shores out of the Strait of Cadiz. Since Corsica and Sardinia sustain the impulse of the sea, the shores of Italy are accordingly not disturbed by any tide either — being shielded and defended, as it were, by those islands acting as a kind of outer rampart. But the sea, going round in a circle along the shores of France, Liguria, and Italy, slips into the jaws of the Sicilian Strait. There, repelled, and turned back into the harbor of Tunis which they call La Goletta, it produces no small tide.

[Margin: How the tide arises in the harbor of Tunis.]

You see, then, that the tide is scarcely perceptible along the shores of the sea, on account of the varied arrangement of the sea and of the islands and projecting lands. Hence it comes about that the waters, stirred up by the Moon, spread themselves out too quickly, and — dashed against and broken upon the shores and the neighboring islands — are in no way able to preserve a regular motion of flow and ebb.

This is also proved by the following experiment. If you cast a stone into the middle, A, of any round vessel filled with water, you will at once observe the water spreading itself out into circles and diffusing itself regularly and uniformly, producing there a proportionate increase and decrease.

Diagram. A small woodcut in the left column showing a round vessel (seen from above) filled with water, with concentric circular ripples spreading from a central point labeled A. Below the round basin is a band of hatched shading (the vessel's base/wall in cross-section). The figure illustrates the regular, uniform circular diffusion of ripples from a stone dropped at the center.

- A (center of the round vessel): the point where the stone is cast in.

Next take a vessel A C, drawn out lengthwise and full of water, and again cast a stone into its middle. You will see the circular ripples, on account of the unevenness of their radii, soon broken and flowing off in another direction, leaving nothing in the rim of the vessel beyond a disordered, tumultuous swell.

But if you allow a little board, V, to float on it, you will see that it stops the broken water-circles from dashing against the rim of the vessel.

Diagram. A second woodcut in the left column showing an elongated, rectangular vessel (vas A C) seen from above, full of water. Point A is at the top, point C at the bottom; concentric ripples spread from a center point. A small floating board labeled V sits at the middle. The water-lines are drawn irregularly broken near the sides, illustrating how ripples in an elongated basin are fractured by the unequal radii, and how the floating board V damps their impact on the rim.

- A (top of the elongated vessel): one end / the point where the stone is cast in.
- V (middle): the floating board that breaks the impact of the ripples on the rim.
- C (bottom of the elongated vessel): the other end.

I should like you to understand that the same thing happens proportionally in the Mediterranean Sea. For the waves born from the tide are at once dashed against and stifled at the neighboring shores and islands — except in the straits, where the tide, hemmed in as if among narrow passages, exerts its full strength. Historians relate that for this reason no small flow and ebb occur between the island of Cherchel [Cherehenes — island/town off the African coast, Caesarea/Cherchell [?]] and the African mainland.

Now let us explain how the flow and ebb come about in the innermost corner of the Adriatic Gulf. Since the sea, as I have said, [is driven] from east to west — that is, since the sea stretches from east to west into an immense length between the shores of Asia, Europe, and Africa, namely 60 degrees, which make 3,500 Italian miles — therefore, just as the power and influx of the rising Moon (whose slight breadth the sea cannot accommodate) is exerted along the length of the sea, so that even thus, when it cannot do otherwise, it may be carried along: and so, when the Moon rises, the sea, thrust toward the west, begins to swell, until the Moon has stood in the line of the Euronotus [the east-south-east point, ESE], which they commonly call the Scirocco. Then the whole force of the sea is gathered together, partly toward the west, partly toward the mouth of the Adriatic Gulf (since the breadth M X — which runs from that mouth M as far as the shores X of the African Gulf — is the greatest of the whole Mediterranean Sea, as the Map shows). Thus, insinuating itself with violent motion through the jaws of that mouth into the Adriatic, in the far end of that gulf it will soon, by the successive thrusting of the waves, cause an increase and a decrease.

But the reason it leaves no trace of a tide on the side-shores of the gulf is that the sea's flow imprints no impulse upon them (being too oblique). And this flow and ebb will last until the Moon reaches the opposite quadrant, as was explained at length above.

Now let us show how so great a force of the lunar tide arises in the Sicilian Strait. Since the Mediterranean Sea, as we said above, lies 60 degrees — that is, an interval of four hours — from the shores of Syria to Cadiz, it comes about that the Moon, when it has risen four hours above the Mediterranean Sea, then first causes the Atlantic Ocean, struck and compressed by the lunar rays, to begin its increase. Therefore, the sea being swollen to the utmost, and the waves of the Ocean successively gathering strength, having entered with the greatest violence through the jaws of Cadiz, drive the swollen waters of the Mediterranean — the Moon now descending — toward the east with the utmost violence, and most of all toward the mouth of the Sicilian Strait that lies directly opposite them. There it produces the aforementioned tide, most worthy of wonder: in the perpetual inconstancy of flow and ebb, perpetually constant.

[Margin: The equality of the flow and ebb in the Sicilian sea is constant.]

And although the tide takes on various forms of motion — now surging up, now sinking down, now bending to the sides, now breaking into whirls and eddies, now into ebullitions, as we showed above in Book V on Scylla and Charybdis — nevertheless the common tide, amid such great disturbance and confusion of motions, keeps so constantly to its period of six hours of flow and as many hours of ebb that the pilots of the ships, given the time at which the Moon will [occupy] the horizon or the meridian, or some other part of the sky, define by infallible reasoning the increase and decrease of the sea and its tide. And conversely, given the increase and decrease of the sea — even with the sky overcast by clouds — they declare the position of the Moon with certainty and without any error. This I should never have believed, had I not, after making an examination, learned the truth of the matter from the sailors themselves.

The remaining [matters concerning] this strait —

[Margin: The board floating in the elongated vessel keeps it from being broken[?] — the smaller marginal note beside the second figure, partly trimmed: "the floating board V... so that... it does not break..." [?]]

[Margin (top, partly cut): *freti accidentia vide si placet, lib. 2. Ubi ea ex...men alii exotici motus alicubi occurrerint, hîc* — "see, if you please, the circumstances of

the strait in Book 2, where they are [treated]... where any other unusual motions occur here."]

constantly, so that ship-pilots, given the time at which the Moon stands on the horizon or the meridian or some other part of the sky, can determine the increase and decrease of the sea and its tide by an infallible reckoning. Conversely, given the increase and decrease of the sea — even when the sky is covered with clouds — they can announce the position of the Moon with certainty and without any error. I would never have believed this had I not learned the truth of the matter by direct examination from the sailors themselves. The remaining matters concerning this strait—

[Margin: *refluxus in mari Siculo constantia*. — "The constancy of the ebb in the Sicilian Sea."]

[The following passage belongs to the close of the preceding Mediterranean discussion, printed in the inner column beside the table:]

except in straits, where the tide — confined as it were within narrow passages [angiportus] — exerts its full force. Hence, between the island of Cherchel [Cherchenes / Cherchel, Algeria] and the African mainland a considerable flow and ebb occurs, as historians report. Let me now explain how the flow and ebb come about in the innermost corner of the Adriatic Gulf. Since the sea, as I have said, [runs] from East to West—

[The sentence breaks off at the fold; the discussion of the Adriatic continues beyond this opening.]

The Tide-Table

TABULA — "A Table indicating the time of the tides in the various harbours of the German Sea [Maris Germanici — the North Sea], extracted from the hydrography of Fr. Fournier [P. Furnerii]."

The table is a single grid printed across the central fold. The left-hand stub-column **Dies** ("Days") carries the age of the Moon in two paired sub-columns: *A Novilunio ad Plenilunium* ("from New Moon to Full Moon," days 0–15) and *A Plenilunio ad Novilunium* ("from Full Moon to New Moon," days 15–30). Each of the sixteen data rows therefore serves two lunar days (e.g. day 0 / day 15). The sixteen data columns are each headed at the top by a compass rhumb (the wind/quarter that a given harbour faces) and labelled again at the foot by the reciprocal rhumb together with the list of harbours to which that establishment-

Top compass headings (left→right): N./S. · N¼NE · NNE · NE¼N · NE · NE¼E · ENE · E¼NE · E · E¼SE · ESE · SE¼E · SE · SE¼S · SSE · S¼SE.

[Text below the table — use of the table and the volvelle]

[The two text columns at the foot of printed p. 153 explain how to construct the table and operate an accompanying four-circle volvelle.]

the days from 15 up to 30, which are the days of the Moon's age. In the third column let the hours be written, from 12 up to 12, together with their corresponding minutes — as you see — which arise from the continuous addition of 48 minutes to one another. Thus you see the New and Full Moon at hour 12 in the table answering to 12, min. 0. If to these minutes you add 48, you will have 1:48 for the hour after the New or Full Moon on the first day. If to 48 you add 48, you will have 96; from which, with 60 cast off, there remain 36 — for the second day from the New Moon... ..up to 30, which are the days of the Moon's age.

[The volvelle.] Let the third circle, which represents the Moon's age, be divided into 30 parts, and at the thirtieth let an index be set which points to the rhumbs. Let the fourth circle, displaying the Sun's circle, likewise have an index extended to the rhumbs. Their use is this: when these four circles are joined at the centre — in such a way that each one, except the first two, which are fixed, can be moved separately — set the index of the Moon over the rhumb of the wind which a given harbour faces, and you will have in front....

[the tidal phenomena of the strait, look — if you wish — at Book 3, where we have demonstrated these matters exactly. Let this much suffice concerning the motions of the Mediterranean Sea. If, however, any unusual foreign motions should turn up somewhere that we have not set out here, their explanation can nonetheless be easily deduced from these principles of ours already laid down.

SECTIO III. ARS PLEMMYRICA [The Art of the Tides]

CAPUT I. On the use and practice of the marine tide [aestus marinus] in the art of navigation.

Now that in the preceding chapter we have reasoned at length about the nature of the sea's ebb and flow, it remains — for the benefit of those who plow the sea on unending voyages — to teach as well some of the usefulness that the flux and reflux of the sea tends to afford us. This too we shall carry out carefully, as precisely and exactly as can be done.

Now the Moon holds a particular dominion over moist things, so that there is no sea that does not swell at the time of the new or full Moon; nor is there any compound body — whether of the vegetable or of the sentient economy — that does not abound in moisture more at the times of conjunction and opposition, and less at the quadratures. The cause of this is none other than that this swelling of the sea follows the Moon's motion most exactly, and the said bodies keep step with it so precisely, to the very point, that sailors use no other rule for recognizing the hours of ebb and flow than the one the astronomers use for knowing the hours of the day and the Moon's place in the Zodiac. From which we conclude that the sea's motion is driven in exact step with the Moon's motion. But so that we may proceed methodically, we shall comprise the whole art in a few propositions.

PROPOSITION I.

To recognize, by the following table, the highest swelling of the sea in any port at a given hour.

Construction of the Table.

In the first column write the numbers from 1 up to 15; and in the second column from 15 up to 30 — these are the days of the Moon's age. In the third column write the hours from 12 to 12, together with their corresponding minutes, as you see, which arise from the continual addition of 48 minutes to one another. Thus you see that the new and full Moon at hour 12 in the Table answers to 12, min. 0. If to these minutes you add 48, you will have 1·48 for the hour of the first day after the new or full Moon. If to 48 you add 48, you will have 96, from which, casting off 60, there remain 36, for the second day from the new or full Moon. If

to 36 you add another 48, you will have 84, from which, casting off 60, they give 24 min. for the third day from the new Moon; and so for the rest.

In the remaining columns, moreover, the hours with minutes calculated in the said way are displayed, insofar as they correspond to the rhumbs of the winds [rhombi ventorum], in those parts that correspond to the Moon's position in the sky.

Use of the Table.

Take the Moon's age in the first column, and in the second column the hour with minutes; and in the following columns you will have the hour of the sea's highest rise in those places that are indicated by the regions of the world on the mariner's compass [pyxis nautica] by the rhumbs of the winds. For example: if you wish to know at what hour the sea's maximum rise occurs at Amsterdam on the tenth day of the Moon, look up the Moon's age 10 in the first table, and proceed sideways across to the column marked lower down "Amstelodamo" [for Amsterdam], and you will find 11·0 — that is, 11 hours after midnight, when the highest rise occurs there. The letters NE, SO, indicate the Moon set either in the NW or the SW, and so for the rest.

Sailors, however, find all this more readily and easily by means of the mariner's compass. But since few are skilled in handling the mariner's compass, we shall prescribe a still easier method, by which anyone may detect the hours of the sea's swelling at any time.

Let four circles be made, set one within another. Let the outermost and widest be divided into 32 rhumbs of the winds, to each of which sailors assign three hours, so that half a rhumb contains $1\frac{1}{2}$ hours and one quarter-part of a rhumb contains $\frac{3}{4}$ of an hour. Let the second circle be divided into 24 hours, from 12 to 12, as you see. Let the third circle, representing the Moon's age, be divided into 30 parts, and at the thirtieth let an index be set, to point out the rhumbs. Let the fourth circle, exhibiting the Sun's circle, likewise have an index extended to the rhumbs. Their use is this: with these four circles joined at the center — so that each one (except the first two, which are fixed) can be moved separately — set the Moon's index over the rhumb of the wind that some port faces, which you will have before you [in the]

Diagram. The printed (woodcut) tidal instrument [organum maritimum] occupying the upper half of the page, captioned (in italic): "The Marine Instrument by which, given the rhumb and the Moon's age, the fullness of the tide is found for any place whatsoever." It is the schematic of the four-circle

volvelle described in the facing text. The figure shows two concentric scale-rings drawn within a sun-rayed border (a sunburst of triangular rays surrounds the whole). The figure caption beneath the construction reads "Usus Instrumenti" [Use of the Instrument]. A horizontal and a vertical diameter cross at the center.

- Outer ring (the rhumb / hour ring): bears Roman-numeral hour divisions running around the rim. Reading clockwise from the top, the upright legible numerals are I, II, III, IV, V, VI, VII, VIII (the apex group), continuing down the right side IX, X, XI, XII. On the lower arc the numerals are printed inverted (engraved to be read by the rotating slip) and are only partly resolvable: forms reading as VII, VI, V, and a four-stroke group, with XII at the bottom, then up the left side XI, X, and toward IX/the top. [Several lower-arc inverted numerals are indistinct — flagged [?].]
- Inner ring: a finer graduated scale with tick-marks (no numerals legible at this resolution), corresponding to the hour/minute subdivisions.

[The printed page 154 carries this construction-diagram in its upper half; the rotating engraved instrument — the volvelle slip itself — is the separately mounted plate that follows, engraved to be cut out and pivoted at the center.]

Diagram. The engraved, mounted **volvelle slip** (an inserted intaglio plate, with no printed caption) — the working rotating instrument corresponding to the schematic on the facing printed page. It consists of two engraved circular discs joined within a rectangular plate-border:

- **Upper disc — the Moon's-age ring [tertius circulus, ætas Lunæ]:** a graduated annulus numbered in Arabic figures **1 through 30** running around the rim (the sequence 1, 2, 3 ... 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23 ... up to 30 is legible, each at its own tick). At the foot of this disc a small pointer-tongue projects, engraved "**Index** ☾ " [the Moon's index — engraved "Index C," the lunar-crescent form], which points to the rhumb/age divisions.
- **Lower disc — the Geocosm (terrestrial globe) face:** an engraved map of a hemisphere showing landmasses and seas (continents drawn with shoreline and islands, the ocean hatched), representing the Sun's circle / the globe over which the tide is read. Across it lie two radial pointer-arms pivoting from a small circle at the disc's center, each engraved "**Index Solis**" [the Sun's index], one bearing the solar symbol ☉.
- Between the two discs, near the rim, is engraved a small decorative **rosette / compass-star ornament** (a circular foliate-and-petal device).

- **[Margin (manuscript, foot of plate, in a contemporary hand):** "fol. 154 tom[us] primus, deese a in dis[?]" — a binder's/owner's placement note, "folio 154, first volume, [it is] lacking..." — the closing words are an abbreviated cursive and not fully legible [?].]

Use of the Instrument.

[Proposition I continues, the text resuming beneath the diagram on printed p. 154:]

[which you will have before you in the] table set out; then set the Sun's index at the day of the Moon's age, and the hour that this solar index cuts on the hour-circle will be the hour sought, at which the sea's highest rise occurs in that place or port which faces the rhumb already marked.

For example: since Amsterdam faces the NE or SW wind, apply the lunar index to this rhumb on the instrument, and the solar index to the given day of the Moon's age — say, to 17 — and the index will cut for you the hour 4:36 min., the sought hour of the sea's highest rise. But if instead you set the Moon's index over SW and the Sun's index over the 17th day of the Moon's age, the index will likewise mark off for you the same hour on the hour-circle — namely the hour 4 and 36 min., the sought hour of the highest tide.

The same, briefly, by calculation.

Multiply the proposed day of the Moon — say, 17 — by 4, and the result is 68. Then [divide] this by 5, and the quotient will be $13\frac{3}{5}$ [the printed fraction is indistinct [?]]. Join the whole hours to the hours that the rhumb of the given place shows — say, 3 — and you will have 16. Subtracted from 12, this leaves 4 hours with 36 min., which remained over from the residue of the division. And this is the sought hour of the sea's rise.

PROPOSITION II.

To find, by another method, the sea's highest rise everywhere, for each single day of the Moon's age.

In the preceding proposition we set out the method by the mariner's compass; now we shall propose an easier one by means of a table, from which I say you may recognize the sea's highest rise more quickly than even by the observations of ship-masters, which we have also drawn out. For they construct this table quite differently from the way we did in the preceding one. In that one, indeed, they fitted the new moon to hour 12 of the night; in this one, to hour 3 before

midnight, with the Sun and Moon situated in the north-east, or Noto-Zephyrean, quarter — that is, with the Sun and Moon placed midway between East and North, or between West and South. Whence for the new-moon day itself they construct such a table:

[Note: is a second scan of the same printed page 154 (the "Organum Maritimum" opening), with the mounted engraved slip lifted away so that the underlying printed text and the upper diagram's rays show through; it carries the same caption, the same two text columns, and the same catchword "T A-". No new content beyond the already-transcribed p. 226 opening.]

LIBER TERTIUS — HYDROGRAPHICUS

SECTIO III — ARS PLEMMYRICA (The Art of the Tides)

CAPUT I — On the use and practice of the sea-tide in the nautical art

PROPOSITIO II (continued)

[This opening (printed folio 155) is occupied entirely by the full-page **Tabula Universalis Incrementorum Maris** — the "Universal Table of the Sea's Risings, arranged according to the monthly motion of the Moon" — which the preceding text introduced for finding the sea's highest rise on each day of the Moon's age. The table spans the two-page opening; its left half (Moon's age 0–13, New Moon to Full Moon) is transcribed first, followed by its right half (Moon's age 14–30, Full Moon to New Moon). The body text of Prop. II resumes after the table on the following pages; none of it appears on this opening.]

Table header (verbatim): **TABULA Universalis Incrementorum Maris, juxta menstruum Lunæ motum disposita.** ("Universal Table of the Increments [Risings] of the Sea, arranged according to the monthly motion of the Moon.")

NOTA (key, top-right of the verso): The marginal fractions answer to minutes as follows — | Fraction | Minutes | |---|---| | $\frac{4}{5}$ | 48 min. | | $\frac{3}{5}$ | 36 min. | | $\frac{2}{5}$ | 24 min. | | $\frac{1}{5}$ | 12 min. | | 0 | 0 |

[Margin (key): " $\frac{4}{5}$, $\frac{3}{5}$, $\frac{2}{5}$, $\frac{1}{5}$, 0 respondent [answer / correspond to] 48, 36, 24, 12, 0 minutes." The cell entries are given in hours and minutes (H.M.); the small fraction printed beside each whole hour is the minute-part, read off this key (e.g. $3\frac{4}{5}$ = 3 h 48 m).]

Row labels (left margin, two blocks):

- Upper block — **Horæ ante Meridiem, sive à Media nocte, in quibus fit Novilunium aut Plenilunium** ("Hours before noon, or from midnight, at which the New Moon or Full Moon falls"): rows 12, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12.
- Lower block — **Horæ post Meridiem, sive à Meridie, in quibus fit Novilunium aut Plenilunium** ("Hours after noon, or from midday, at which the New Moon or Full Moon falls"): rows I, II, III, IV, V, VI, VII, VIII, IX, X, XI, XII.

[Convention: Arabic row/cell figures (1–12) denote forenoon hours; Roman cell figures (I–XII) denote afternoon/evening hours. Each cell advances by $\frac{4}{5}$ hour (48 min) both down each column and across each row, wrapping 12 → I and XII → 1.]

Left half — *Ætas Lunæ à Novilunio ad Plenilunium* (Moon's age, New Moon to Full Moon): columns 0–13

[Margin (folio number, recto top): "Fol. 155"]

TABULA

For ascertaining the maximum increases of the sea, with the Sun and Moon set in the east-northeast quarter [Euro-borea plaga].

Moon's age [Ætas Lunæ]	♂☉	1	2	3	4	6	7	8	9	11	12	13	14	1
Hours of the sea's increase [Horæ incrementi maris]	3.0	3 $\frac{4}{5}$	4 $\frac{3}{5}$	5 $\frac{2}{5}$	6 $\frac{1}{5}$	7 $\frac{4}{5}$	8 $\frac{3}{5}$	9 $\frac{2}{5}$	10 $\frac{1}{5}$	11 $\frac{4}{5}$	12 $\frac{3}{5}$	13 $\frac{2}{5}$	14 $\frac{1}{5}$	1 5. 0

Moon's age [Ætas Lunæ]	16	17	18	19	21	22	23	24	26	27	28	29
Hours of the sea's increase [Horæ incrementi maris]	15 $\frac{4}{5}$	16 $\frac{3}{5}$	17 $\frac{2}{5}$	18 $\frac{1}{5}$	19 $\frac{4}{5}$	20 $\frac{3}{5}$	21 $\frac{2}{5}$	22 $\frac{1}{5}$	23 $\frac{4}{5}$	24 $\frac{3}{5}$	1 $\frac{2}{5}$	2 $\frac{1}{5}$

This table is composed by continuous addition of hours and of fifths of one hour. These fifths are, however, easily converted to clock-minutes in this way: since the Moon returns to the point it set out from 48 minutes later, if you multiply the numerators of the fifths in the fractions by 12, you obtain the clock-minutes wanted — for 12 minutes is a fifth of an hour, as is clear from dividing 60 by 5. For example, in the fraction $\frac{4}{5}$, multiply 4 by 12 and you get 48; likewise $\frac{3}{5}$ multiplied by 12 gives 36; $\frac{2}{5}$ by 12 gives 24; $\frac{1}{5}$ by 12 gives 12; and 0 by 0 gives 0.

You will also see that this table agrees exactly with the preceding one. For if in the preceding table you take the column NO or SW and proceed along the days of the Moon, you will find the sea's increase advancing in precisely the same way, according to the hours set out there: 3.0 on the first day of the Moon, 3 hours 48 minutes on the second day, 4 hours 36 minutes, and so on for the rest — which correspond beautifully to the table presented here:

♂☉	1	2
3.0	3 $\frac{4}{5}$	4 $\frac{3}{5}$

This is indeed a fine discovery. But since this table shows the sea's increase only for 3 hours before midnight, with the Sun and Moon set in the east-northeast [Euro-borea] or south-southwest [Notozephyrea] quarter, I have therefore — to make the table as universal as possible — arranged it by the method that follows. For from this, given any hour of the natural day at which the conjunction or opposition of the Sun and Moon falls, and given also any day of the Moon's age, I teach how to find the hour of the sea's increase.

Use of the Table. [Usus Tabulæ.]

Suppose you wish to know, on the first day of the Moon, at what hour the highest tide occurs, with the Moon set in the east-northeast or south-southwest position. Look up the hour 1 in the top row and the hour 8 before noon along the side — the position where the Moon stands, say, in the east-northeast — and the cell where they meet gives the answer: namely, the 10th hour. Likewise, if it is the 12th day of the Moon and you want to know — with the Moon then set in the east-northeast quarter — the tide at hour IV after noon: look up the 12th day of the

Moon in the top row, and along the side of the hours IV after noon, and the cell where they meet gives the answer: namely, 1 after midnight. Proceed no differently in the other cases. Note here that these numbers 1, 2, 3, 4, etc. indicate hours after midnight, whereas I, II, III, IV, etc. up to 12 indicate hours after noon.

Further, if a new moon [novilunium] or full moon [plenilunium] falls at any given hour — these being listed in the first column — for example: if you wish to know, supposing a new moon falls at hour 5 after midnight, when the sea's greatest increase occurs on the first day of the Moon, then look up 5 after midnight in the first column and 1 in the top row of the table, and the cell where they meet gives the hour as 7 and a half hours [7 cum $\frac{1}{2}$ hor.], the time sought. Proceed no differently in the other cases. But since these matters are far too easy to need any further explanation, I shall move on to other things.

PROPOSITION III. [Propositio III.]

To construct a universal instrument of flux and reflux for the whole globe of the earth, [drawn] for elevation 42 degrees. [ad 42. gr. elevat.]

First, let there be a movable circle marked with the letters A B C D, divided into 24 parts, which mark out the meridians around the globe of the earth, each one hour's space apart from the next; to these are inscribed the regions and seas in the order you see. Around this outermost rim draw an oval figure E F, G H, about which the first circle can conveniently revolve, furnished with the numbers and lines you see. Finally, let another, immovable circle, divided into 24 hours from 12 to 12, surround the oval figure — and you will have the instrument ready.

Its use is as follows. If you wish to know the increases and decreases of the tide at Rome throughout the whole compass of the ocean, then set the index A over the given hour of the Moon's ascent on the oval figure, and you will have the increases and decreases of the tides represented there for the whole globe of the earth, in every place at once. But note that the number of hours described on the oval figure marks the tides of the sea, which it makes by rising for six hours and falling for as many hours. You see, then, that as the Moon ascends above the horizon, for six hours continuously [the tide]

[the tide] rises, until it reaches the meridian, where the increase is at its maximum — as the watery swelling shows in the figure. The differences of the increases are aptly marked by the lines inscribed on the oval figure; and just as these increase or decrease proportionally, so they fittingly display the proportional increase or decrease of the tide in the division of the lines by points, on the assumption that the maximum increase is always 6 points.

Diagram. A large circular volvelle (the tide-instrument of Proposition III), occupying nearly the whole page. The figure shows three concentric rings:

- The **outermost ring** carries an hour-scale running 1–12 twice (the 24 hours of the natural day), read clockwise around the circle: at the top, beginning near "12," then 1, 2, 3, 4, 5, 6 (right side), then continuing 7, 8, 9, 10, 11, 12 (bottom and left side), back up through 6, 7, 8, 9, 10, 11 to the top. This is the immovable outer circle "divided into 24 hours from 12 to 12."
- The **middle (cross-hatched/stippled) band** is the oval figure E F G H, bearing the point-graduations of the tide. Around it are scattered single-digit numbers (1, 2, 3, 4, 5, 6 ...) marking the proportional tide-points, and the inscriptions "**Crescit**" (it rises) along one half and "**Decrescit**" (it falls) along the other.
- Reading labels around the band: E at the top (the cardinal point E of the oval figure); A on the left side (the index); the words **Crescit** (upper-left to lower-left, rising quadrant) and **Decrescit** (lower-right and again at bottom-left, the falling quadrants); small numerals 1–6 repeated through each quadrant marking the six points of tide-rise and tide-fall.
- Letters of the oval (E, F, G, H) lie at the four cardinal positions; E is legible at top, and an F-like mark appears at upper right near the decrescit inscription. [The letters G and H, and the inner index lettering, are partly lost in the hatching — read with care; 2 such peripheral labels flagged [?].]

The instrument as a whole models the ocean tide rising for six hours up to the meridian and falling for six, in opposite quadrants simultaneously.

[Sub-heading / rubric within Prop. III, set in italic:] *The wheel by which, for a given hour and a given meridian, the increases and decreases of the sea throughout the whole globe are found.* [Rota qua data hora & dato Meridiano, incrementa & decrementa maris in toto Orbe reperiuntur.]

Again, if you wish to know in what places the increase or decrease occurs, proceed thus: set the index A under point E of the oval figure, and you will see, among the seas lying beneath the meridian of Rome, the sea at the height of its increase in the Indian Ocean and in the Solomon Islands [Insulis Salomonis], which lie opposite the meridian of Rome. At the same time you will see, in the ocean lying beneath Persia and Mexico, the tide at the lowest point of its increase; and the remaining places, on the graduated lines, show the degrees of increase and decrease expressed in their own numbers, in each of the regions to which they correspond.

Again: if the index A is moved under the 1st hour of the Moon's ascent and increase, as described on the oval figure, you will once more see the increases and decreases throughout the whole globe of the earth; and so one must proceed through the remaining hours in order. For example: if you wish to know what the increase on land is at the time when the Moon has been five hours above the horizon, set the index A above the hour 5 — not on the outer circle, but on the inner circumference of the oval figure — and then compare the increases and decreases of any places whatever with the regions to which they are assigned, and you will have the answer. You will also see that whenever the sea's tide rises for six hours, it falls during the next six hours in the following quadrant, and the reverse; so that in opposite quadrants the sea is always rising and falling at once — all of which is shown most clearly on the instrument.

The outermost circle, divided into 24 hours, shows at what hour it is anywhere throughout the whole globe of the earth, by this procedure: if you wish to know, when it is 8 hours before noon at Rome, what hour it is in those places and regions inscribed on the circle A B C D, set the index of the Roman meridian above the given hour at Rome — namely 8 — and you will have the answer; for the hours

that correspond to the remaining regions will give what you sought. Thus in Syria it will be 12, in China 6 after noon, and so on for the rest.

PROPOSITION IV. [Propositio IV.]

To observe by an instrument, in the open sea, from where the flux and reflux arises — that is, from which quarter of the world it comes. [Undenam fluxus & refluxus, sive ex qua parte Mundi proveniat, in Albo mari per instrumentum observare.]

Let a mariner's compass [pyxis nautica] be set upon an axle CD. Let this axle extend below the water in proportion to the size of the ship — say, six paces — and let the axle have arms B B B, so that, with these driven firmly against the outside of the ship, the axle can turn freely within them like a body rotating on its poles in every direction, and as it turns can carry round with it the compass resting on top of it. Below the water, at its end, let it have attached to it a net E G [naffam E G], made of leather or even of thin sheets of brass, stretched out in the manner of a sleeve, pierced at its far end G, and fitted to the axle in such a way that it can revolve freely with the axle — and the instrument will be ready.

Diagram. A woodcut schematic of the current-finding instrument of Proposition IV. A vertical axle descends through the ship's side into the water (the water shown as horizontal wavy hatching). Labels:

- **A** (top): the mariner's compass [pyxis nautica] mounted on the head of the axle.
- **B, B, B** (three positions down the upper axle): the bracing arms driven against the ship's side, drawn as paired rounded clamps.
- **D** (on the axle, just at the waterline / lower axle): the lower part D E of the axle.
- **6** (in the water beside the axle): the depth-marker (paces below the surface).
- **E ... G/a** (lower right, the conical net): the leather or brass net stretched like a sleeve, tapering to its pierced far end G (a small letter resembling "a"/"G" at the net's point).

So, if you wish to know which way the sea-currents run, fix an instrument of this kind to the ship's side, wherever the sailors find most convenient, with the part D E of the axle thrust below the water, its brass net sunk to 6, 7, 8, or more paces by its arms. And in this way it comes about that the flowing water carries the net along according to the current's flow and direction; and the net, so carried, consequently turns round with it the axle attached to it, together with the compass; and the compass needle within its rim will show in which direction the current presses. By means of this instrument the courses and directions of the individual currents can be accurately recorded.

This is a thing not only useful to sailors but absolutely necessary; for they often suppose that with sails spread they are making for some place under a favorable wind, when in fact, owing to the sea's hidden motion, they are so far from drawing nearer that in time they find they have rather fallen far back — as happens to those who make for the island of St. Helena [Insulam S. Helenæ].

PROPOSITION V. [Propositio V.]

To construct a clock of the marine tide that may perpetually demonstrate all the increases and decreases of the tide and the degrees of them. [Horologium æstus marini construere, quod omnia æstus incrementa & decrementa, gradusque eorum perpetuo demonstret.]

Long and much did I ponder by what means a kind of clock-mechanism might be devised that would perfectly show, by its index, the increases and decreases of the tide in their degrees. At last a certain method occurred to me, which I do not so much describe as merely point out in a few words to ingenious mechanics.

In some public harbor that is governed by the marine tide, let a small round tower A B be built, in the form of a well-shaft; it must be founded within the ground B C, at a depth equal, as far as can be done, to the sea-bottom. At the bottom let it have openings D, so that the seawater may readily work its way into the hollow of the column; while above ground it may rise to whatever height B A you please. This done, let a round float [orbis] E be made of the finest latten [aurichalco] or brass, hollow within and sealed, to the end that no water may penetrate, and so that, full of air, it may float on the surface, as is usually done with a cork float. At its center E let a cord F be fastened, which is wound twice or three times around the axle G H, and at whose end a leaden weight is hung, so that the cord may not unwind. On the face of the column let another wheel K L M N be made, which marks on its circumference the increases and decreases of the sea over six hours. Then let an index be fixed to the end of the axle, which can turn this way and that on the immovable surface of the wheel K L M N — and you will have the machine ready. You will record the increases and decreases of the sea on the outermost surface of the clock's wheel by observation, with this ingenuity.

At the hour when the sea is at the lowest point of its increase, let the index be set on the meridian line, or on the horizontal — it makes no difference. And since the brass float, fixed to the cord, floats freely on the water, it comes about that as the water rising within the column gradually rises, together with the float swimming upon it, in step with the sea's successive increase — and since the cord, from which the float hangs, is wound around the axle, and the index is fixed to the end of the axle —

Diagram. A woodcut of the tide-clock of Proposition V: a tall round tower (well-shaft) standing in the sea, shown in section. Labels:

- A (top of the shaft): the top of the tower A B.
- H ... G (top crossbar): the axle G H spanning the top of the shaft.
- F (upper interior): the cord F running down from the axle.
- I (mid-interior, on the cord): a mark on the cord / the suspended weight.
- E (lower interior, the spherical float): the hollow brass float E swimming on the rising water.
- B (just below the float, at a rule across the shaft): the level B (within-ground portion B C below).
- D (near the foot): the openings D admitting seawater.
- C (at the very foot, with hatching for the foundation): the foundation B C in the ground.

- A vertical **scale 1–10** runs up the left interior of the shaft (the feet of increase).
- At the upper right, set apart as an inset, is the **dial K L M N**: a round graduated face (drawn like a compass-rose) with letters **K** (top), **L** (right), **M** (bottom), **N** (left), bearing the index that registers the tide in feet.

[Margin: Omnia in Mundo contrariis constant.] *All things in the World are composed of contraries.*

[Margin: Nihil sine motu consistere in Mundo potest.] *Nothing can subsist in the World without motion.*

[Margin: Humor quiescens putredini obnoxius est.] *Standing moisture is liable to putrefaction.*

[Margin: Mare in perpetuo motu & circulatione versatur.] *The sea is engaged in perpetual motion and circulation.*

— the index, [being so fixed,] the axle will necessarily turn together with the index. The moving index, on the outermost surface of the outer wheel, will likewise show in order the degrees of the increases or decreases.

For example: if the increase of water in the column has risen to one foot, the moving index will mark on the dial [Tabula] a space proportionate to the increase, and there on the dial you will accordingly mark I, that is, an increase of one foot. If the water, together with the brass float, has risen 2 feet within the column, then see how far the index has advanced on the outer circle, on the rim of the wheel assigned to the measure of feet; and in this way you will observe all the degrees of increase as far as feet, up to the maximum increase. When the water, together with its brass or cork float, has reached this maximum, you will then mark the limit of the index too with a special sign. As the sea falls, the water within the column will likewise descend together with its steel float; so that if it has descended one foot, you will mark the limit of the index in the same way, on the smaller circle within the dial; and so on in turn, until you have completed all the feet of increase and decrease on the dial — and you will have the device finished, contributing not so much to the great adornment of the harbor as to the profit of sailors.

These are the things I thought worth communicating, in a few words, about the clock of the sea-tide, to ingenious craftsmen, who, should they weigh this matter duly, will, I do not doubt, find it a rich harvest of new inventions.

CHAPTER II. [Caput II.]

On the Pericyclosis or Circulation of the Ocean. [De Oceani Pericyclosi seu Circulatione.]

I think no one is of so dull a mind that, considering more deeply the providence of the divine Godhead in the governance of Nature, he is not carried away into the highest admiration. The Architect and Maker of the World had founded the World most constant under certain perpetual laws of change; and just as He resolved to preserve the astral bodies of the World by a certain perpetual and unwearied revolution, so too He was pleased to preserve the elemental World by a perpetual circulation [pericyclosis] of the elements, with a certain ceaseless conflict and a counter-craft [Antitechnia] of contrary qualities. Hence there is in the nature of things no substance that is not furnished with a motion of its own or another's, deprived of which, the whole nature of things must necessarily pass away into nothing.

This principle of motion is observed above all in the watery element, which, by the condition of its fluid nature, cannot rest — being, indeed, above all in need of motion (without which, with no surviving remedy, the whole elemental nature would collapse). And it is plain from experiment: water that is not moved at once putrefies, breeds worms, shuns the air, takes in malignant impressions — the mother of innumerable diseases. Rainwaters caught within the bounds of ditches, left unmoved, first grow green, then turn black, and at last degenerate into frogs, toads, serpents, and insects of every kind, with great danger of airy infection. And how great a harm to nature would have been brought about, had that vast body of the Ocean been left without motion? Without doubt the whole elemental nature, languishing and at last overthrown, would have collapsed through a certain infinite abundance of putrefaction that would thence have overflowed into the earthly body; the springs and rivers, the lakes and pools, would have ceased; all vegetables would have vanished, with the consequent destruction of every living thing.

To avoid these harms to nature, the Author and Founder of Nature, GOD Best and Greatest, willed the Sea to be in a certain perpetual motion, stirred by the hidden influences of the Moon, the Sun, and the other stars. Hence, besides the motion of the tide — which surges in the fourfold flux and reflux within the space of a natural day — and the others pointed out above, He turns it also by another circular motion, unknown to this very day. And just as He set the Ocean [moving] from East to West according to the daily motion of the luminaries, so He

established another [motion] from the North Pole to the South; [Margin: The Ocean is absorbed beneath the Arctic Pole and regurgitated beneath the Antarctic. (Oceanus sub Polo Arctico absorbetur, & sub Antartico regurgitatur.)] by which the Sea, sucked into a vast whirlpool beneath the Arctic Pole and swallowed up, through unknown recesses and unexplored windings of its channels, with tortuous and incomprehensible meanderings at last emerges again at the Southern Pole. Just so, in the human body, in the course of a single natural day, the blood has been discovered — in these latest times — to circulate through all the channels of the veins; and the cause of this is none other than that the whole of nature — the heavens, the elements, the humors of the human body — connected and corresponding to one another by a certain perfect analogy and wondrous proportion, might in this way be preserved in their being.

But perhaps you will say: who showed you those whirlpools of the polar regions of which you speak? Who ever saw them? I ask you in turn: the origin of the sea's motion, as it discharges itself through subterranean passages into springs and rivers — neither you nor any other mortal has ever seen it; therefore it does not exist? A very poor inference indeed, which could be applied to countless other things. I say, then, that no one has indeed seen those whirlpools; yet that they exist can be shown both by reason and by experience and by authorities — and first by this reasoning:

[Margin: It is proved that the Sea is absorbed beneath the Pole. (Probatur Mare sub Polo absorberi.)] Since these regions are unsuited for the convenient sustaining of human life — both on account of their half-year of light and half-year of darkness — it was fitting, lest the nature of things should seem to be idle in those regions, that the beginnings of the hydro-circulation [hydro-pericyclosis] should be established beneath these fixed points; for from this circulation the marine water, through

[...the marine water] is drawn off through the unknown windings of the earth, channeled as it were into a kind of subterranean belly. There it meets the subterranean fires that are present everywhere, and is digested and concocted, as it were, into a seed and nourishment of nature and of all things. Its earthy body, which was congenital to it from the beginning, draws to itself the saline spirits, while the mineral clods draw into themselves that unctuous moisture necessary for completing the maturation of metals. And the species of plants draw — by a kind of magnetic power — whatever was most suited to their nature. Whatever portion of the waters remains undigested and unconcocted is expelled through the Antarctic Pole, to be more perfectly digested and concocted by a repeated

circulation. For in this way that vast body of the sea, teeming with innumerable dregs and the rubbish of terrestrial mixtures, is prepared — through such a circulation, digested and purified by the continual concoction of the subterranean fires — into an ever new seed and nourishment of nature.

[Margin: The second reason.] **Second reason.** If that circulation through both Poles did not exist, the sea beneath the Pole would without doubt remain forever condemned to frost and irresoluble ice, motionless. But an unmoving sea induces the worst putrefactions; the worst putrefactions produce exhalations and vapors; and the regions lying round about, affected by these, could not be preserved without great slaughter of men and animals.

[Margin: 3rd reason.] **The third reason** is this. For the past two centuries the entire terraqueous globe has become so well known to us through frequent and most difficult voyages that scarcely a corner of land or sea remains that has not been detected and explored — except the regions lying beneath each Pole. Indeed, after so many attempts by the Dutch and the English, after the loss of so many men extinguished by hardships, hunger, thirst, and cold, frustrated in their hope, so far were they from attaining the sub-polar tract that not even [Margin: Many have attempted access to the sub-polar tract, but no one has reached it.] the foremost of them were able to advance beyond the eightieth parallel of latitude — the clearest signs of an inaccessible sub-polar district. What did Davis [John Davis] not attempt? What did Hudson [Henry Hudson] not attempt? What did the Dutch not attempt in their threefold voyage toward the North, with Barentsz [Willem Barentsz], a man most skilled in astronomy, as director of the whole navigation? While he pressed too eagerly toward the goal he had set himself, he was extinguished by the force of the cold in the midst of his enterprise. And Hudson, cast out into a small boat by his rebellious crew, was never seen again.

[Margin: The sea around the Pole is most rapid.] **The fourth reason** is that of those who, partly by their own eyes, partly by what they have committed to writing, perceived that the sea beneath the Pole cannot be overcome on account of its rapidity. Geographers report marvels about a certain English Minorite monk of Oxford, whom — translated to the Pole by Magical Art, they say — found there a certain black rock thirty-five leagues in circuit, beneath which the Ocean, drawn in with incredible speed through four channels [Euripi] into the sub-polar region, is absorbed beneath that said region through an immense whirlpool. Whatever may be the case regarding the truth of this narration — for even if it seems fabulous to many, I would not on that account judge it altogether to be

rejected, since this sub-polar whirlpool has many Geographers as its supporters and is established by not incongruous attestations.

The English, carried to those shores — as Purchas [Samuel Purchas] reports in his Geographical relations — were warned by the natives of Greenland not to proceed further if they wished themselves and their ships to be safe; for the sea toward the Pole is so surging and so rapid that a ship once entered can by no human industry be drawn back. The *Atlas Novus* relates that sailors at Spitsbergen engaged in whale-fishing told how no ship advancing beyond the 82nd parallel of Northern latitude returned, and that the boats of their men that strayed too incautiously through those districts never appeared again; and that the sea there, rushing forth as if from some mountain, sweeps everything along with it — clear testimony indeed that beneath the Pole, or in the parts near it, there is an immense whirlpool, by which water drawing water, together with the ships floating upon it, is absorbed with irremediable violence.

[Margin: Pet. Joannes Faber in his *Panchymicum*.] All this is confirmed both by Petrus Ioannes Faber [Pierre Jean Fabre], physician, in his *Hydrographia*, and in his *Panchymicum* (book 4, ch. 7), in these words: "*There are in the North four channels [Euripi], whose interiors, on account of the rapidity of their motion, are never bound by ice, and which rush toward the Arctic Pole with such headlong violence that no one could express it in words; for there the Ocean is swallowed and devoured by the land, and there are many who have seen these channels, and have witnessed the peril of several ships which, snatched away by these very channels, were never seen again.*" And in chapter 8: "*A marvelous secret of nature, whose reasons and causes no one has yet investigated, because this motion was unknown until it became fairly well known through voyages.*"

But whoever desires to know more about the marvelous constitution of this sub-polar region — about that immense whirlpool, and the rapidity of the sea drawn in through the four channels — let him read the *Nautical Observations* of the following authors: Hugh Willoughby [Hugh Willoughby], knight; Richard Chancellor; Stephen Burrough; Charles Jackman; James Hall; Martin Frobisher; John Davis; Jacob Cnoxen of 's-Hertogenbosch; [Margin: Giraldus Cambrensis.] and Giraldus Cambrensis [Gerald of Wales] — the last of whom describes it in the following words: "*In the Northern part is found a certain immense whirlpool of the sea, toward which all the waves from remote parts seem to be moved; as if by a conduit they flow together and are devoured, and pouring themselves there into the secret recesses of nature, are as it were swallowed into an Abyss. And so if a ship by*

ill fortune should fall into it, it is snatched and drawn with such force that the irrevocable power of voracity immediately absorbs it."

These reasons will suffice to establish that sub-polar whirlpool, by which the absorbed sea — circulated through the inmost vitals of the earth by ducts incomprehensible to the human mind — is at length [Margin: The sea is vomited forth again beneath the Southern Pole.] regurgitated at the other, opposite Southern Pole, as I shall demonstrate a little further on.

Diagram. A circular plan-view schematic showing the constitution of the Arctic Pole [*Poli Arctici Constitutio*]. The figure depicts a great circular ocean spiraling inward to a central whirlpool (a tight vortex at the center), surrounded by a ring of mountainous coastlines drawn around the rim. Gaps in the encircling land mark the four channels (the four *Euripi*) through which the Ocean flows inward. Readable peripheral labels, by position around the rim:

- Upper-left (along the coast): *Americæ Borealis* — "of North America."
- Left side: *Groenlandia* — "Greenland."
- Lower-center (an island in the rim): *Spitzberga* — "Spitsbergen."
- Right side: *Tartaria* — "Tartary."
- Two box-cartouche channel labels on rim gaps: *Euripus* — "channel / strait" (marking the inflow straits; one upper-right cartouche, one lower-center cartouche beside *Spitzberga*).

Full rim set (clockwise): *Americæ Borealis*, *Euripus* (upper-right cartouche), *Tartaria*, *Euripus* (lower-center cartouche), *Spitzberga*, *Groenlandia*.

Diagram. A circular plan-view schematic showing the constitution of the Antarctic Pole [*Poli Antarctici Constitutio*]. The figure is a plain disk of radiating lines converging on a central point, depicting the place where the sub-polar sea is regurgitated and flows outward from the Southern Pole. No peripheral place-labels are present (in contrast to the Arctic figure above); the disk shows radial striations emanating from the center.

is regurgitated [*gurgitatur*], concerning which Petrus Ioannes Faber, cited a little before, speaks thus in the place quoted: "*Those who have sailed to the Southern Pole have seen that influx of waters at the Antarctic Pole rushing against them with such violence that in no way is it permitted to go against it, either by oars or by sails; just as around the Arctic Pole they are borne with such rapacity toward the Pole that no ship can by any means extricate itself from the rapidity of the waters, if it should by chance come into the very channels [Euripi] of the Ocean.*"

[Margin: Observation of the chief navigators.] The same is attested by the *Account of the discovery of the new Strait in the Magellanic Sea*, commonly called *de Maire* [the Strait of Le Maire]; in which those Dutch chief-navigators, after they had reached nearly the 60th degree of Southern latitude, on account of the contrariety of the waves and the dreadful headlong rushes of the waters, were not permitted to proceed further.

[Margin: Herrera in his *History of America*.] The same is testified by Herrera [Antonio de Herrera] in his *History of Southern America*. "*From the Kingdom of Chile*," he says, "*a maritime fleet was dispatched by royal counsel to discover the regions of the Southland; but it was impossible for it to proceed beyond the 70th degree of latitude, on account of the rapidity of the waters perpetually rushing against them — even in calm air and without winds.*"

[Margin: The Pole could not be approached on account of the violence of the onrushing waves.] The Dutch Hollanders too attempted this route toward the Southern Pole; as the inhabitants of New Holland [New Zealand / New Holland] report — their *Itineraries* mention it here and there — who, having pushed deep within the immense expanses of seas along the shores of the Southland, when they found the sea always as if headlong, driven back by the violence of the waves, judged that route by no means to be pursued further, since nature had denied access to it.

These are surely clear signs that the sea somewhere in the sub-polar region suffers a violent eruption and regurgitation. This too was the reason why, from the sixtieth degree all the way to the Southern Pole, no knowledge of the situation and constitution of the sea, or of the lands and islands, has reached us to this very day — so that it does not seem to lack a most hidden mystery of nature, that it has thus far remained unapproached and unexplored. For toward the sub-polar tract, sailors carried whether by chance or by deliberate intent, and absorbed by the force of the sea, have been unable to send back any messenger of so great and so unhappy a fate; while those carried toward the Southern Pole, surrounded on every side by the regurgitating sea, have not been able to overcome its onset.

[Margin: Georgius Bruyn in his *Theatrum Urbium* supposes there is a Paradise somewhere beneath the Pole.] When these matters were more closely considered, Georgius Bruyn [Georg Braun, of the *Civitates Orbis Terrarum* / "*Theatrum Urbium*"] supposed the Pole to be inaccessible — and therefore that God had established the terrestrial Paradise, translated there beneath it, impervious to human footsteps. But since these things do not agree with reason, he would perhaps have thought better, in agreement with us, if he had conjectured the

cause of the inaccessibility of such places to lie in nature's pericyclosis from Pole to Pole.

A distinguished philosopher, not long ago, when he had read with the greatest admiration this pericyclosis of nature in my *Itinerarium Extaticum terrestre* [*Iter Exstaticum*], proposed to me in a letter he sent the following doubt: Why has nature so girded the sub-polar region with a perpetual concatenation of Islands that the Ocean scarcely has access to it — on one side by Greenland, Spitsbergen, and Greenland; on the other by the as-yet-unexplored shores of America and of Asiatic Tartary — which, separated from one another by a fourfold narrow of straits, admit only a small quantity of Ocean? I replied that this was done by the admirable ingenuity of nature: first, so that they might, as it were by a wall, blunt and restrain the violence of the Ocean driven thither. Second, so that the said Regions might be as it were certain boundaries, which would show that one should proceed no further there, where with savage chances and deadly perils the sea would carry everything topsy-turvy, with the irremediable ruin and destruction of ships and men. Hence too nature seems to have set in opposition the glacial sea, which — rising up with its masses like mountains — so obstructs access to the surging sub-polar sea-region that it removes all hope of penetrating beyond the eightieth or eighty-second degree of latitude, as is clearly evident in the Dutch expedition toward the North. But at the opposite Pole, the very onset and violence of the regurgitating sea turns aside of its own accord those attempting to approach it, while they cannot overcome the trouble of the onrushing waves.

Here you have our opinion concerning the circulation of the sea from Pole to Pole — described, perhaps, more fully than was fitting. But to what end, or what utility it confers upon the Earth, will be shown fully in its proper place in what follows. Read, if you please, what we discuss more fully concerning this secret of nature in our *Itinerarium Extaticum II* — which is also called the forerunner of this work — Dialogue 1.

CAPUT III.

De Salsedine Maris, ejusque origine, necessitate, aliisque Oceani
Mariumque accidentibus.

On the Saltness of the Sea, its origin and necessity, and the other accidents of the Ocean and Seas.

[Margin: The great variety of opinions on the saltiness of the sea.] We have consulted thirty-three authors of great name who treat most fully of the saltiness of the sea, in order to examine what causes of so celebrated an operation of nature they might bring forward. But it can scarcely be told how great is the diversity of all their views, how great the confusion of opinions. Certainly one cannot suppose that the Ocean itself rolls up as many tides as those who, befogged with this kind of mental fog, roll them up in their minds. A certain person, since he had at that time no knowledge either of the Ocean's nature or of Geography — the latter being then unknown — went astray in many things, as may be seen in *Meteorologica* book 4, concerning which below. [Margin: No element is given pure and simple.] His followers and adherents, while they strive to defend their Master and vindicate him from errors, fall into graver ones; and in this way errors are propagated chain-fashion in the lecture-halls, while truth itself is not attended to, but in place of truth that most rotten *αὐτὸς ἔφα* [Greek: *autos epha*, "he himself said it" — the Pythagorean appeal to the master's bare authority] is ignorantly babbled — when it is not even ascertained, by the rules of knowing, whether the thing in question truly exists, what it is, and in what it consists. Instead, they contend with singular mental exertion over the difficulty of the proposed question. Add to this experience, the Mistress of all things, without whose assistance nothing in physics can be rightly unraveled. Hence many, leaving aside the proximate causes, take refuge in remote ones and in I-know-not-what metaphysical speculations. Some establish their opinion by absurd and ridiculous fictions. There are those who come close to the truth; and some recede from it as far as scarcely anyone could imagine.

We wish to contend with no one, but, following the thread of our own principles, we shall here set down our own opinion among the rest — which, even if we do not demonstrate it *ἀποδεικτικῶς* [Greek: *apodeiktikōs*, "demonstratively," by strict proof], we shall nevertheless so establish by various experiments that all who are accustomed to weigh matters in the balance of fair reasoning will concede it to be, if not true, at least not far removed from the truth — that is, most probable.

[Margin: No element is given pure and simple.] I suppose, then, first: that no element, pure and simple, considered in physical terms, can naturally exist in the nature of things; but that all bodies are mixed and elementated, packed with a manifold mixture of things, and that the individual elements exist wrapped up within one another. Hence no element can be so purified that a true resolution into the simplicity and purity of a simple element be possible — which we shall prove in innumerable ways in their proper place below.

I suppose, second: that prime matter, compounded in physical compositions, is the salt of nature inhering in all bodies, implanted in it from the first beginnings of the Chaotic mass; without which they could neither have consistency and subsistence, nor be preserved in their being — inasmuch as it (to speak chemically) fixes all bodies.

[Margin: Nothing in the nature of things is destroyed.] I suppose, third: that nothing in the nature of things is regularly destroyed, whether from the elements, or from the vapors and exhalations drawn from them, but that the individual things are restored to their elements. In this way vapors are drawn from the sea, which, a little later condensed by cold and resolved into rains, snows, hails, hoarfrost, dew, and mist, are restored to those elements from which they were extracted. The same is to be said of earthy exhalations.

These things being laid down, I say first: that saltiness was implanted by nature, in the primordial founding of things (as soon as the water, digested into its channels by the voice of God, uncovered the Earth), in the Ocean and in all the other waters — yet in such a way that, according to the proportion of the waters and of the other natural bodies, the quantity of salt inserted into them is found to vary. [Margin: Salt gives consistency to all bodily things.] For since salt, the earthy element, gives to corporeal things their consistency and (as the chemists say) their fixation, or a certain palpable density, which they would never have furnished without the fixative element salt — it follows that brackishness was necessary both to the sea and to all things. Moreover, since the Earth together with the Ocean and the Seas forms one globe, just as the whole mass of the Earth is imbued with salt, so too the sea — which, sucking the salty humor from the Earth on every side as it were from breasts, draws it as its nourishment — afterward, through subterranean passages, restores by right of nature to the Earth, as a kind of debt owed, the salty humor (which it had drawn off and sucked out), according to Supposition 3; or rather the Earth, by a kind of reciprocal attraction, takes back from the sea what it had granted to the sea, now constricted within the subterranean prisons. But how this happens will be explained hereafter.

[Margin: Salt the earthy element.] Salt, therefore, according to our opinion, is the terrestrial element, or a certain seed of nature, furnishing to all bodily things both consistency and nourishment. The clearest sign of this is that there is no body — whether from the sensitive, the vegetable, or the inanimate kingdom — which does not subsist and is not nourished by this, or which, when destroyed, is not resolved into it.

You will say: The salt waters of the sea are actually converted into fresh waters through the resolution of the extracted vapors, which cannot happen without the reparation of the salt. Therefore the conclusion is false. That this objection may be set forth more clearly:

[Margin: Salt is twofold, fixed and volatile.] It is to be noted that salt can here be considered in two ways: fixed and volatile. We call that salt *fixed* which is naturally inserted into all and singular things, and cannot be separated from them at all. But that we call *volatile* which, by reason of its spirituous substance, is separated from the fixed salt and flies off. This laid down: Granting the antecedent, I deny the consequent. The reason is that although the Sun draws vapors from the sea, which afterward, resolved, return into sweet rains, it does not therefore follow that such waters are so separated from all radical salt that not even tiny little portions of salt remain — even if these are scarcely discernible to the sense by taste. And experience teaches this to be true even in any spring water whatsoever; for water of this kind, distilled through an alembic, always leaves a little salt at the bottom, as is well known to the chemists.

COROLLARIUM I.

Corollary I.

[Margin: Salt virtually included in the Chaotic mass.] Hence it is clear that the terraqueous globe, still lying hidden in the Chaotic mass, contained salt within itself virtually from the first beginnings of things, but first burst into act on the third day, when the separation of the waters into their own channels, distributed by God, laid bare the Earth — free from the mass of waters by which it lay enveloped. And in this way many controversies about the origin of salt, with which the commenta[tors...]

Diagram. A large fold-out engraved plate depicting a full disk of the Moon, printed across two facing leaves (the left half the right half and bound to face printed p. 162. The engraving shows the lunar disk in selenographic detail: dark maria rendered in fine horizontal hatching, bright highland regions stippled, and numerous craters drawn as small rings with central points. A prominent rayed crater near the disk's center (lower middle) is drawn with radiating spokes. The plate is enclosed within a double ruled border.

No engraved or printed labels (place-names, point-letters, scale, or caption) are legible on the plate at this resolution. The only lettering present is a later manuscript annotation in the right margin in a cursive hand:

- Top right (manuscript, ink): "Tomus I 6.2" [recte: "Tomus I" with the page reference] — i.e., Volume I
- Below it (manuscript, ink): "pag. 162" — the facing printed page
- Below that (manuscript, ink): "Kircher mundus Subterraneus" — identifying the work

[The plate carries no Latin body text]

with which the records of the commentators are filled, can be resolved.

Daily experience teaches that salt is necessary for man and for the other animals — the one seasoning of all foods. For whatever salt does not correct is not corrected; and whatever is not corrected becomes wholly unhealthy, indigestible, and rotten to the man who consumes it. Salt is truly the natural medicine against diseases. Not without reason, then, does Homer [Homerus] call it divine, as that which preserves from corruption everything that we see. I would add that the principles of all generative things derive their origin from salt. This is why the poets imagine even Venus Aphrodite [Venerem Aphroditim] as born from the foam of the sea, as though by this very emblem [Greek: ἐν τῷ τύπῳ (en tō typō, "in the figure/emblem")] they meant to set forth the generative power of salt dispersed throughout the sea; and for the same reason they made the sea-gods fertile and the parents of many children. It is known to everyone that nothing is more fruitful, nothing more fertile, than the sea — as the infinite multitude of sea-monsters, the immense progeny of fish, and the abundance of innumerable spawned eggs amply attest. Let this much suffice concerning the necessity of salt.

It remains to explain how the water was steeped in that brininess from the beginning, and how that same brininess, once laid aside, is turned into freshness.

In the primordial drawing of the waters down into the channels of the Earth — which Sacred Genesis [*Genesis*] teaches was accomplished on the third day of the world — the chaotic water at once drew to itself, as a nutriment necessary to it, brininess both from itself, being already pregnant with brine, and from the very substance of the briny Earth. [Margin: How salt was instilled from the beginning by the voice of God.]

The Earth, therefore, being filled with salt — inasmuch as it consists of its natural terrestrial element — when suddenly struck by the voice of God, according to the condition of its parts first fixed the framework of the Earth, then stones of every kind, both common and precious, fixing the still-soft mud or sediment of the waters; then, with the subterranean fire, coeval with it, cooperating, it produced the various species of metals and minerals — that is, Sulphur, Mercury, and the

other minerals — as the genuine sons of salt. [Margin: That all solid things subsist by the power of salt.] And salt itself, as the base and necessary support of all things, it diffused throughout absolutely all the fibers of the Earth. From these the Ocean, sucking continuously as from breasts — besides being already itself steeped in salt — greedily drew it derived into itself.

And since in the first Book we showed the floor of the sea to be sieved through with innumerable passages and chasms, it came about that the subterranean fire, exciting the spirits of the briny Earth by its heat, communicated them everywhere to the Ocean in all places. [Margin: The subterranean fire steeps the floor of the sea everywhere with the exhaled brine of salt.] The Sun and the Moon, meanwhile, by their continual influences through the abundance of winds and vapors, agitate the sea unceasingly. Hence the briny spirits, mixed with the sea, imbued the whole Ocean with that saltiness which it retains to this day, and will retain until the consummation of the world.

That the Earth perpetually steeps the sea with its brininess, and the subterranean fires through the hidden passages and pores of the sea-floor, by sublimated spirits of salt — this I show by the following experiments.

COROLLARIUM II

There is no elementary water — whether spring, lake, or otherwise — that, once distillation is carried out, does not exhibit some residue of salt; as will be amply proved through experiments in the following Book, in the *Treatise on Salt* [*Tractatu de Sale*]. For since salt gives consistency to all things, according to Supposition 2, certainly water deprived of all salt could not obtain the consistency owed to it by nature, being deprived of its terrestrial fixative element, and so would be resolved into the purest element — which is impossible. [Margin: One element cannot subsist without another.] For since all the bodies of natural things are composed of the four elements, certainly, if one of them is lacking, the whole composite must necessarily be destroyed. Therefore no water can be deprived of its fixed salt.

For just as in any natural composite one or two elements are predominant, so too in the watery element one water has more or less saltiness than another, down to an imperceptible brininess; exactly as in the remaining elements a greater or lesser portion of this or that element always predominates, the radical element always persisting. Hence, by the truly wise design of nature, it has come about that, even though fresh water fit for drinking can be separated from any salt water by evaporating the volatile salt, nevertheless a fixed portion always

remains in the underlying body, even under the smallest quantity. [Margin: In spring water something salt always remains after distillation.] I speak here not only of salt in particular, but generically of everything that, distillation being completed, remains at the bottom of the alembic — what the chemists call the *caput mortuum* ("dead head"). For this, drained of all moisture and reduced to ashes, will at once furnish a new brood of salt, as will be taught in its place.

COROLLARIUM III

From this it is clear that salt was instilled by nature into the Terraqueous globe from the beginning of things — both to preserve the whole economy of the Terraqueous globe and to sustain and nourish it — as the balsam of nature. [Margin: The utilities of salt.] For where there is no salt, there the beginning of putrefaction must be; salt alone preserves both animate and inanimate things from rot. Nothing in nature is without salt: nothing of natural things — whether you regard metals and minerals, plants and animals, or the elements themselves, of which the Terraqueous globe is composed — can subsist without the endowment of salt. Where salt is lacking, nothing is durable, but all things are soon overrun by venomous putrefaction, necessarily deprived of the support both of the Universe and of men and animals. Hence there is no place in the world to which a supply of salt is not at hand; and so divine providence willed, not without cause, that this thing, which would be so greatly necessary, should be everywhere ready. For however much...

EXPERIMENTUM I.

[Margin: How water is steeped with its own saltiness.]

Make from plates of fossil (rock) salt a square vessel A B C, whose joints are most exactly sealed with pitch or some other material. Once this is done, pour in fresh water and leave it to settle for a while; within a short time you will find the fresh water wholly turned to saltiness, the fresh water drawing to itself the saltiness residing in the vessel — and the water becoming so much the saltier the more violently you have agitated what was poured in within the vessel.

Diagram. A small woodcut of a square box-shaped vessel built of rock-salt plates, shown in three-quarter perspective, with its lid and side faces visible.

- A (top): label "A" on the upper face of the vessel
- B (left side): label "B" on the left face
- C (implied): the third corner-label completing the designation "A B C" given in the text; not separately legible on the face [?]

From this experiment it becomes clear how fresh water, with the brinness drawn to it, becomes salt. We also made the experiment both in Sicily and in Malta [Melita]: in any soil — provided it is rich, not sandy and close to the sea — within a pit artificially excavated, fresh water poured in was at once turned to saltness. Conversely, if you pour sea water onto certain fresh chalky and sandy clods, and leave it poured out for several days, you will find the water stripped of its saltness, the earth by its own nature drawing off the salt due to it. The cause of this is nothing other than the diversity of the earthy clods: some are rich in copious salt, others have scarcely a perceptible amount.

Hence it happens that a clod heavy with salt communicates its saltness to fresh water by a certain natural and reciprocal attraction; whereas a clod possessing less salt derives into itself the salt drawn from the sea-water as a nourishment agreeable to it, so that the water, left deprived of its volatile salt, must necessarily become fresh. [Margin: The subterranean fire mixes briny spirits into the sea.]

The same is to be reckoned to happen with the sea. The Earth communicates its saltness to the Ocean, diffused through all the fibers of the terrestrial body; and lest the shores alone should seem to communicate saltness, the subterranean fire, by the perpetual sublimation of briny spirits through the sieve-like floor of the sea, so steeps all the pathways of the seas that, with the perpetual agitation of the sea supervening, a complete commingling of the waters with the briny spirits is at last achieved. For the briny spirits are, as we have learned by experience, so potent that even a small quantity of this spirit — as much, that is, as a spoon can hold — easily turns a huge cask full of fresh water into brine.

[Margin: How salt water freshens in the channels of the hydragogues (water-conduits) and becomes fit for drinking.]

I come now to the solution of the other doubt: namely, how water freshens in subterranean conduits, or how, the brinness being there laid aside, the water is turned into fresh — as springs and rivers openly demonstrate.

I say that this happens, first, by the decoction (boiling) of the waters. For since the bowels of the Earth are filled with subterranean fires, it happens that, where the conduits or passages of the waters are propagated in the manner of siphons, while they pass through the fire-chambers [pyrophylacia], the volatile spirits of the salt water, now cooked and digested, are soon sublimated; and being sublimated and attenuated to the greatest subtlety, they insinuate themselves through the inmost fibers of the Earth, and when they have been condensed by cold, turn back again into salt — and so they restore to the Earth that which they

had drawn off from it, the Earth by a natural attraction reclaiming what was its own.

It happens too that the water, licking the sides of the passages packed with fresh clods, there strains out the salty humor, and in the same way the Earth, by a certain natural attraction, derives into itself that which it had first given to the sea — according to the experiments adduced a little earlier. Hence springs and rivers, which had at first passed up from the sea as salt water through the passages of the sea-floor, for the reasons adduced lay aside their brininess, and through their outermost orifices issue and flow filled with fresh water — until, restored to the sea, they once more become salt; this cycle of things [pericyclosis] enduring perpetually.

[Margin: How salt water, drawn up into rains, freshens.]

Moreover, since the Sun perpetually draws up a great quantity of vapors from the sea, it happens that these, condensed by the cold of the middle region of the air, lay aside their volatile salt and are resolved into rains, hailstones, and snows; which, received among the peaks of the highest mountains, partly by external melting, partly insinuated into the inner water-chambers [hydrophylacia], augment the water and render it fresher with their own freshness.

But of these matters more fully in the following *Treatise on the Origin of Springs* [*Tractatu de Origine Fontium*].

[Margin: An experiment on the shores of the Sicilian Strait.]

It is a wonder that I once observed on the shores of the Mamertine or Sicilian Strait [Fretum Mamertinum sive Siculum — the Strait of Messina]. The shores are sandy and full of sand; and if anyone digs a pit there, he will at once find the freshest water, even though it be no more than two or three feet from the seashore. Indeed — what is more worthy of wonder — on the very curved arm of the harbor of Messina [portus Messanensis], which is thrust into the middle between the waters of the harbor and of the Strait, if anyone digs a pit in the manner described, he will likewise find fresh water. The same happens on the shore of Calabria [Calabria] near Reggio [Rhegium], where I recall having found fresh water in a sandy pit, distant no more than two palms from the sea water; and a spring there, built at the seashore for public use, sufficiently demonstrates it.

The cause of so exotic an effect is sought, and I shall here attempt to adduce a threefold one. The first may be that sand, by its own nature drier, derives the

brininess into itself by a certain natural attraction, as it was able to do in the preceding experiment. The second cause may be that little streams flowing out from the promontory of Pelorus [Pelorum — Cape Peloro], which overhangs the Strait, running through the sandy shore by a hidden flux, before they insinuate themselves into the Strait, supply fresh waters everywhere. The same is to be said of the shores of Reggio, into which both open and hidden streams from the mountains of Calabria that gird the Strait, gliding beneath the sand, everywhere present that same fresh water before they discharge themselves into the sea.

But from where the fresh water in the arm of the harbor of Messina — curved by nature between both seas — comes forth, doubtless has another cause, since it cannot share in the streams from the mountains. Therefore it must be said either that the Earth of this sort, by its own native property, converts the strained seawater into freshness in the way described above; or else that, from some lake or river of Sicily or Calabria, through a subterranean siphon extended below the floor of the sea — which finds its outlet in this arm of the harbor — it renders fresh the water diffused through the said tract. For the *Nautical Histories* [*Historiae Nauticae*] report that in many places, both on the floor and in some rocks of the sea, fresh water is found leaping up in the manner of a spring, as will be told concerning submarine springs in its place.

Here, reader, you have the threefold cause of the fresh water gushing on the shores; choose at your pleasure that which, with those first, will give greater satisfaction to your ingenuity — for besides those stated you will not easily find another.

CAPUT IV

Whether the saltness of the Sea is equally dispersed throughout all the pathways of the Ocean.

[Margin: Whether the sea is saltier at the bottom or at the surface.]

Since this doubt is of great moment, we have thought it should be examined just as exactly. It is to be noted, then, first, that this difficulty can be understood in several ways. First: whether the sea is saltier at the bottom than at the surface. Second: whether at the shore or in the middle. Third: whether it is saltier in places lying under the Torrid Zone, or in the Northern regions.

It is to be noted, second, that intensely cold sea water is less salt than warm salt water. It is to be noted, third, that the Earth, the bottom, and the shores of the sea,

just as they possess various properties and qualities, so too are wonderfully varied.

These things being premised, the question is asked first: Is the Sea saltier at the bottom or at the surface? I say that, since the floor of the sea behaves in one way and another in different districts of the Ocean and seas, and possesses diverse properties and powers in different places both of the bottom and of the shore, according to the proportion and disposition of the terrestrial portions — not only reason, but also sense experience has taught, that the sea sometimes abounds with greater saltiness at the bottom than at the surface, and sometimes at the shores rather than at the bottom or in the middle of the Ocean. If the sea has passed through a mine filled with salt, or has found a fissure permeable to volatile spirits of salt sublimated by the subterranean fires, then it is certain that the sea is saltier at the bottom than at the surface, since copious brininess is perpetually communicated to it directly from the underlying veins of salt.

The same is to be said of the shores of the sea; for where the sea has licked a neighboring salt-mine with its continual waves, it must necessarily be more intensely steeped with brininess at the shore than in the middle. And the salt-pans [salinae], which are set up at the seashore to the great profit of mortals, sufficiently attest it.

I say, second: Since fixed salt is heavier than the water itself, it is certain that it cannot remain at the surface, but tends downward toward the bottom; the volatile salt, however — since nothing can impede its spirituous lightness — pervades the whole body of the sea up to the surface, and, by a perfect mixture with the sea, tempers it through the continual agitation of the waves. Nevertheless the saltiness of the sea, both at the sea-floor and at the shores, can be impeded in many ways, so that it is not sharper than at the surface. [Margin: Springs gushing up in the sea-bottom diminish the saltiness.]

Of these the first is the rivers, brooks, springs, and fountains discharging themselves through subterranean passages into the floor of the sea; by these the sea water is in a wonderful way tempered, and, the saltiness being removed, it so freshens that a spring, penetrating through the middle of the sea, sometimes presents fresh water to sailors over a great expanse at the very surface — just as they report concerning certain places in the Pacific Sea by the shore of South America [America Austral], and concerning the Persian Gulf [Sinus Persicus] near Hormuz [Ormutium]. The latter, although it is the saltiest of all seas because of the surrounding salt-mountains, nevertheless at the very surface of the sea is said

to bubble up a spring of fresh water — to the great solace and profit of sailors and of the other inhabitants and neighbors of that most torrid island.

[Margin: That the natures of the sea are most diverse according to the disposition of the shores.]

Likewise it can happen, at the sea-floor or at shores not so filled with brininess, or in those places where, by the inflow of vast rivers, the sea is found to freshen for many miles. But since these things are better known than to deserve mention, I willingly omit them; for just as not every land bears all things, so most diverse are the constitutions of the terrestrial parts, by reason of which the nature of the sea is varied in a wonderful way — since it produces always one thing and another, not the same in all places, but according to the diversity of the properties of the lands it licks; of which in their place. In the same way, the sea in one place, for the causes stated, is saltier than in another; yet it happens, by the perpetual agitation of the sea, that the saltness, diffused by a perfect dilution, acquires an almost everywhere equable temper of flavor, wherever it does not reach the gushing springs of freshness.

[Margin: Whether the sea is saltier under the Torrid Zone or under the temperate or frigid.]

The other doubt is whether the sea is saltier under the Torrid Zone than under the temperate or frigid Zone. I answer that under the Torrid Zone it is, other things being equal, saltier; for since the Sun strikes it perpetually with its perpendicular rays, it happens that the volatile spirits of salt, drawn up together with the vapors by the Sun's heat, first into clouds — which, dispelled by the agitation of the winds into the various parts of the world, are partly condensed in the colder parts of the mountainous regions, and the volatile salt, dissolved by frequent agitation, is resolved into rains and most copious showers of fresh waters, partly condensed into snows. Hence the sea, with its fixed salt and...

with the heat and seething of the incumbent Sun excited, grows salt in a wonderful way. For experience establishes that salted foods, as soon as they have grown warm in boiling water, are much saltier than cold ones; the reason of which is this: that by the heat the salty corpuscles, not wholly bound by the spirits, being rarefied and separated from one another, by such a resolution of the corpuscles confer the highest acridity upon the sea. [Margin: Salt is cooked by the heat of the Sun on the shores of the seas.]

And it is established by daily experience that, on the shores of Sicily, Calabria, and the other shores of the Mediterranean Sea, sea water led off into certain little

beds is, in the space of a few days, cooked into the whitest salt by the heat of the Sun. In Malta too, in the rocky pits of the shores, into which the sea is diffused by the force of the winds, it grows of its own accord, by no industry of art, into copious salt, to the great profit of the inhabitants. The same is reported to occur on all the shores lying under the Torrid Zone, by all who have visited those places — which, however, does not happen in the Northern parts. It is a most luminous sign that the more violently sea water is beaten by the rays, the more copious salt it produces, and so the saltier it becomes.

[Margin: Why in Iceland the sea is so salt, but not in the icy sea.]

In the Northern parts, however, it is known by experience that the sea is more insipid — not because it is not imbued with an equal portion of salt, but because the fixed salt is, by the violence of the cold, irresolvable. In Iceland [Islandia], nevertheless, the *Nautical Histories* attest that it is most salt; the reason of which is none other than the subterranean fire dominating that island, which, just as through the roots of the mountain they call Hekla [Hecla] it fills everything round about with salt, sulphur, and bitumen or naphtha, so the briny spirits, bursting through the floor of the sea, tinge the Ocean with such native brininess that it can vie with the saltness of the Torrid Zone — which, however, mixed with the neighboring glacial sea, in time loses the sharpness of its saltness.

I say, therefore, that in the farthest North the sea, even though it abounds in copious salt, cannot, because of the efficacy of the most intense cold, be dissolved. It happens also, because of the continual rains, perennial snows, and hailstones, which at no time are lacking in those places, that the sea is to some degree augmented both in bulk and in freshness; for since salt water, being heavier through the fixed salt, clings the closer to the bottom, while the fresh water, being lighter, floats upon it — which, being thin and subtle, is easily frozen by the surrounding cold once the brininess is laid aside, and congeals into ice.

[Margin: Why the ice of the sea is fresh.]

But as to why the ice of the sea is fresh, the reason is that the saltier water, condensed by cold, by its own weight settles down, while the fresh water, stripped of saltness and continually augmented by rains and snows, as it floats by its lightness upon the heavier, so by the surrounding frost is easily bound fast. For, as experience teaches, salt water, because of its grossness and fattiness, is converted into ice so much the more difficultly as fresh water, because of its lightness, more easily.

COROLLARIUM I

From this it is clear why, on the shores of those seas which are girt by the highest mountains, the water is fresher than in the middle. [Margin: Why on the shores of the seas which are girt by the highest mountains the sea water is fresher than in the middle.] This is because the most copious showers, with which the mountainous tracts are drenched at stated times, while they run down through the valleys of the mountains in the manner of rivers, and, mingled together with the sea water, convert it to some extent into freshness — as is wont to happen on the shores of the Malabar Ocean [Oceanus Malabaricus], at Cape Comorin [Mons Gatis — the Western Ghats] and Ceylon [Zeilanum], and on the Western shores of America that are stretched beneath the Andes [Andes], in the time of rains. This effect is common to all rivers discharging themselves into the sea.

COROLLARIUM II

It is also clear why, in the Northern parts, no salt congeals on the shores in the summer time, while under the Torrid Zone, or in regions neighboring it, most copious salt is found. [Margin: Why the Northern maritime regions are less productive of salt.] This is because, in those regions, on account of the most oblique rays of the Sun, the salty bodies, frozen by cold, can neither be dissolved nor, for lack of solar heat, be cooked. It is otherwise in these places hottest by the seething of the Sun, in which, by the heat, the salty corpuscles, dissolved and mixed with the surface waters, while they are poured out onto the shores, produce copious salt, the Sun being the cook.

[Margin: Why sea water, drawn out into rains, freshens.]

The third Doubt is: why sea water, raised up by the power of the Sun through vapors and stripped of saltiness, is converted into fresh water; whereas, by contrast, sea water distilled through an alembic is always found in the receiver unfit for drinking, nor can it come about that they be entirely separated from one another?

I answer that sea waters raised up by the Sun's heat degenerate into fresh: First, either because the briny spirits, which it carries up with itself, separated from the vapor, transcend the middle region of the air, or, condensed by cold, sink down, or, mixed with dewy air, are absorbed, the water element predominating. Secondly, either on account of the most free motion of the clouds in the air, by which, drawn apart into various tracts, they are at last so weakened and

disunited that they leave no further vestige of salt in the air drawn up; whence these spirits, separated in the said ways, must necessarily leave the water fresh.

In the alembic, however, on account of the receptacle being closed on every side, the spirits separated and sublimated by the fire, just as they find no exit, so, commingled with the water, cannot be entirely separated; whence the water, somewhat freed from the fixed salt, but still mixed with the volatile spirits, even though it does not contain so great a saltiness, nevertheless has — I know not what — of a slightly bitter and unpleasant flavor mixed in, by which it is rendered unfit for drinking.

[Margin: Whether sea water can be freed from all saltiness by distillation.]

But whether sea water, distilled repeatedly — as is wont to be done in the quintessence of wine — can at last be freed from all its saltiness, since we have not not made an experiment of it...

I also cannot affirm it with certainty; yet it seems plausible that, even if only in the smallest portion, [the salt] can be separated out. Here is how I would propose to attempt the matter.

Diagram. A distillation apparatus shaped as a coiled tube (a spiral siphon). A round-bottomed vessel sits over an open flame at the base; from it a long helical (corkscrew) tube rises, and near the top a side-tube leads off to a small flask resting on a footed stand, while the very top of the helix terminates in a round receiver. The printed caption reads: "Let a siphon be made, coiled into a helix, whose vessel filled with sea water is A, the helix is B C D, and the receiver E."

- A (vessel at base, over the flame): the vessel filled with sea water
- B (lowest coil of the helix): lower part of the helix
- C (middle coil of the helix): middle part of the helix
- D (upper coil of the helix): upper part of the helix
- E (small footed flask at right): the receiving flask [cyathum, cup] — but see note: in the body text the receiving cup is also called E and the top receiver F
- F (round receiver at the very top of the helix): the upper receiver / lid where the vapor is resolved

The text continues: Let a siphon be made, coiled into a helix, whose vessel filled with sea water is A, and the helix B C D, with E as the receiver. Then, once a fire is set beneath vessel A, the salty spirits, loosened by the heat, begin to ascend through the coils. But because, condensed amid so many turns, they meet a great

obstacle in the very act of rising higher, they are necessarily forced to stop their further ascent — especially if the winding siphon is repeatedly sprinkled with cold water. The fresh water, however, raised up by its own fineness through the fumes into the lid F, and from there resolved back into water, will pour itself out into the cup E. I am convinced by many considerations that this water must be fresh, because it is well known that the salty spirits either subside at the first chill, or are condensed; whereas the vapor, like that of clouds, makes its way through the winding paths, is at last resolved in the lid F, and pours itself out drop by drop into the vessel E, free of all saltiness — the volatile salt being left behind, condensed within the passages of the siphon, caked in leafy growth along the sides of the helix.

I should like to have chemists make trial of this matter, and perhaps they will find what I have said to be true. For since I myself have used a siphon of this kind in other operations, it can scarcely be told how thoroughly, by this device, you may find the water purified of all dregs and phlegm. But other ways of separating fresh water from salt water will be treated at length in the Eighth Book of this work [in Octavo hujus Libro].

Here, therefore, we shall put an end to this section. From the first principle of all nature — which we call water — we now proceed to the second, which is fire.

MUNDI SUBTERRANEI LIBER QUARTUS

ΠΥΡΟΓΡΑΦΙΚΟΣ [Greek: Πυρογραφικός (Pyrographikos, "On the Description of Fire" / "Pyrographic")]

DE IGNIS SUBTERRANEI, Ventorum, Fluminum, Fontiumque origine.

On the origin of Subterranean Fire, of the Winds, the Rivers, and the Springs.

SECTIO I.

De Natura Ignis Subterranei, ejus situ et operationibus.

On the Nature of Subterranean Fire, its location and operations.

PRÆFATIO. (Preface)

Just as the height of the Divine power set up two Luminaries in the Heavenly World, the Sun and the Moon — willing that the former be of fiery substance and the latter of watery — to this end: that the burning heats of the Sun might be

tempered by the moist effluvium of the Moon, and that the excessive moisture of the Moon might in turn be checked by the fiery dryness of the Sun; so that in this way there might exist the genuine principles of all the things that can be generated on the surface of the Earth. These supports of nature were so necessary that, if either of the two were lacking, the World could not have been preserved.

[Margin: *Uti se habent Sol et Luna in cœlo, ita se habent ad invicem Ignis et aqua subterranea. — As the Sun and Moon stand in the heavens, so do subterranean Fire and water stand to one another.*]

But although both the watery element of the Sea and the superficial mass of the Earthen body powerfully promote the generation of things, it could not happen that they should reach by their influxive power into the innermost core of the terrestrial entrails, since they possess a sphere of activity that is determined and bounded by its own limits. Hence, lest the inner storehouse of the Earthen globe should grow stiff with the harshness of cold, and become useless for the inner actions of nature in the generation of minerals and metals, it was brought about by the supreme counsel of Divine wisdom that fire, together with water, should be established within it — these being, as it were, a kind of subterranean Sun and a subterranean Moon. By their mutual aid, and by a certain concord of discordant reciprocal action, all the seeds of nature inborn in the Earth-and-water globe might be quickened into that multitude and variety of things which we behold with wonder, both within the inmost entrails of the Earth and on its outer surface.

It remains, therefore, for us to show: what that subterranean fire is; what it does; in what place of the subterranean regions it is located; and how, or by what nourishment, fires of this kind sustain their perennial conflagrations.

CAPUT I.

De necessitate et essentia Ignis Subterranei, et utrum verum elementum sit.

On the necessity and essence of Subterranean Fire, and whether it is a true element.

That Subterranean Fire exists is so certain that no one but a philosopher of unsound mind could deny it. For whoever has considered the fire-vomiting mountains, the sulphurous fires bursting forth not only from the earth but even from the sea itself, the multitude of hot springs [thermarum] and their certainty

and variety everywhere in every place — such a person will, beyond doubt, be compelled, however unwilling, to affirm that these fires, these heats, the seething craters of the great Volcanoes [Vulcaniorum craterum æstuarial], have their birthplace not in the air, not in the water, but in the very inmost recesses of the Earth.

[Margin: Ignis Subterraneus ex quibus signis colligatur. — From what signs Subterranean Fire is inferred.]

For how could it be that, where everywhere there is so great an abundance of minerals, of so much sulphur, bitumen, and naphtha occurring everywhere, this should arise without fire, without any natural seething heat — in those most cold prisons of darkness, the farthest removed from the Sun's influx, conceived from the conflict of cold air and moisture? Subterranean fire was therefore necessary for the economy of the inner Earth.

Certainly Plato, contemplating all these things more deeply, recognized in the *Phaedrus* perennial flames, an incredible quantity of waters both hot and cold, and great rivers, of both water and fire. Indeed, Aristotle too, from the observed effects of fire — which he had once recounted among his "wondrous things heard" [auditiones] — taught (*On the World*, ch. 4) that the Earth, like water, contains very ample fountains of breath [spiritus] and fire; a point he then repeated in *Meteorology* IV, when he investigates the causes of the motion of the winds in the Earth.

[Margin: Ignis nullibi deest. — Fire is nowhere absent.]

Pliny too, Vitruvius, and Cicero noted this secret of nature; for when craftsmen probe the entrails of the Earth, they observe heat lurking there. Indeed, the greatest parts of the world are upheld and sustained by heat; we see fire struck out by the conflict and friction of stones, and when the Earth has just been dug we see it steaming warm; and even from wells, perpetual hot water is drawn — and this happens most of all in the winter seasons, because a great force of heat is contained in the caverns of the Earth.

[Margin: Fabulæ poëtarum alludunt ad ignem subterraneum. — The fables of the poets allude to subterranean fire.]

To the poets, too, this subterranean fire was so well established that all the fables concerning Vulcan, Vesta, and the Cyclopes seem to allude to it. Let us hear Lucretius singing in these words:

[Margin: Lucretius.]

In the first place, the Earth has within itself the primal bodies By which the boundless sea, the rolling rivers and springs, Ceaselessly renew themselves; it has fires, from which they arise. For in many places the ground burns, set alight beneath; But from the depths it is the force of fire that makes Aetna rage.

Manilius, in his *Astronomica*:

[Margin: Manilius.]

But there are fires admitted into all the parts, Which inhabit the pregnant clouds that forge the thunderbolts, And they pierce the Lands, and Aetna threatens Olympus, And they make the waters warm in their very springs.

Who is, and what properly is, that Subterranean Fire — receive it here in brief.

[Margin: Quid sit ignis Subterraneus. — What Subterranean Fire is.]

Subterranean Fire is a portion of elemental fire, not pure, but contaminated by a mixture of various combustible things, enclosed within the caverns of the Earth — that is, the Fire-vaults [Pyrophylacia] — by God Most Good and Greatest, from the very beginning of the World, for the protection of sublunary nature, its preservation, and the production of all things.

It is said, first, to be a *portion of elemental fire, not pure but mixed* — in order to exclude the view and opinion of those who said that this fire was a thing of its own kind, distinct from elemental fire, incorporeal and invisible. That view — quite apart from the fact that it conflicts with the sanctions of the Church and of the holy Fathers (who hold that even infernal fire itself is not incorporeal and spiritual, but material, corporeal, and of the same kind as artificial fire, that is, mixed elemental fire — as they everywhere assert it to be of that species) — also conflicts with the laws of nature and with the decrees of almost all Philosophers; since it is too well known to need stating or to be properly stated, that an incorporeal fire has no power, no proportion for acting upon a corporeal substance.

It is said, secondly, that *Subterranean Fire is a portion of mixed elemental fire* — to refute the opinion of those who held that this Subterranean fire was not corporeal, not actual, but virtual or eminential (of the kind that is in the stomach), endowed with a power of concoction [vi decoctiva]. This was refuted at length in our *Itinerarium Extaticum* [*Ecstatic Journey*], and we shall presently demonstrate its falsity openly.

[Margin: Democriti sententia. — The view of Democritus.]

Democritus, to avoid seeming to grant an actual fire, said that subterranean heat arises from quicklime and ash, by *antiperistasis* [περίστασις, the surrounding of a thing by its contrary] — than which nothing more inept could be said. For if quicklime and ash are hidden within the Earth, one might justly ask: who reduced the lime and ash to a consistency of this kind? Since it is impossible for lime and ash to be made without fire. Add to this that the whole globe of the terrestrial World would have to be composed of lime and ash, since there is scarcely any place in the whole Earth, as will later be shown, that does not display the effects of this heat.

[Margin: Non fit ex calce et cinere. — It does not arise from quicklime and ash.]

This is likewise repugnant to sensible experience, and so we more truly leave that opinion to be explained not by reasonings but by the old wives' tales of little women. Nor does reason dictate that this heat arises in subterranean places by the agency of *antiperistasis*. For since antiperistasis, on Philo's testimony, is nothing other than a struggle of contraries, of hot and cold — and that struggle, because no violent thing is perpetual, cannot endure in a continual conflict — if it could not endure, then surely all the hot springs would long since have ceased, the Volcanic pits and the flame-vomiting Mountains would long ago have been extinguished; which, again, experience cries out against, since just as they have burned from the beginning of things, so down to this very day they do not cease to continue their heat.

[Margin: Non antiperistasi. — Not by antiperistasis.]

Add this: that if that heat were kindled by antiperistasis, then beyond doubt that heat would have existed first, since antiperistasis requires an actual and simultaneous positioning of contraries. And if that is so, then I ask: from where was this prior heat produced? Certainly not from cold, since it is impossible for antiperistasis to occur through two cold things in the highest degree — for then like would act upon like, which is against the common axiom of the Philosophers. Nor from heat eminently contained in the entrails of the Earth; since this is, by no sensible Philosopher, granted to be opposed to the elemental cold, nor can it be merely virtual or potential — seeing that it contains in itself the properties of actual fire only, even according to the opinion of the adversaries themselves.

[Margin: Non est ignis virtualis aut eminentialis. — It is not a virtual or eminential fire.]

Whatever, therefore, they may say, wherever they may turn, they will find no other way to extricate themselves from this mire except to assert a formal heat excited by an actual fire lurking in the entrails of the Earth.

I have said that Subterranean Fire is a portion of elemental fire, not pure but tinged with a mixture of various combustible things — in order to exclude the opinion of those who think that every ordinary or culinary fire is the element of fire. But in order that it may be made more clearly known in what sense we here take "the element of fire," it has seemed good to begin upon that matter a little differently.

CAPUT II.

Quodnam sit verum Ignis elementum, et ubinam proprius ipsius locus sit.

What the true element of Fire is, and where its proper place is.

[Margin: Variæ sententiæ Veterum. — The various views of the Ancients.]

The ancient Philosophers — Trismegistus [Hermes Trismegistus], Zoroaster, Orpheus — held that the whole World was composed of four elements: fire, air, water, earth; where by "fire" they understood not a fixed place but the substance of the universal aether, which they also call the life-giving fire. Orpheus, however, teaches in these words that all things were established by the Maker out of fire, water, Earth, and the all-nourishing aether:

[Greek: τὸν ὅλον κόσμον ἐκ πυρὸς καὶ ὕδατος καὶ γῆς καὶ πνεύματος — "the whole cosmos out of fire and water and earth and breath [pneuma]"] [?: the final word of the printed Greek is abraded; read as πνεύματος / aether per the Latin gloss]

Ocellus [Ocellus Lucanus], the pupil of Pythagoras, was the first of all to place fire below the Moon and above the air; and in this way, by his doctrine, the Universe is constituted of five elements — earth, water, air, fire, and aether — of which the first four are perpetually subject to the motion of corruption and generation, while he taught that the Moon is, as it were, a fence and a barrier between the incorruptible and the corruptible things:

[Greek: ὅρος γὰρ ἀθανασίας καὶ γενέσεώς ἐστιν ἡ σελήνη ὁδός — "for the boundary of immortality and of generation is the path of the Moon"] — that is, the orbit of the changeable Moon.

And a little after he says:

[Greek: τὸ μὲν οὖν πῦρ καὶ ἡ γῆ ἄκρα, τὸ δ' ὕδωρ καὶ ἀήρ μεσότητες — "Fire indeed and Earth are the extremes, but water and air the means"].

Empedocles followed this view, and after him Hippocrates; but the Peripatetic school, misunderstanding their own Master, propagated it. We wish to contend with no one, but, eager for the truth, in this place — where the genuine location of fire is to be defined by us — we shall try to demonstrate, even from Aristotle himself, that the Sphere of fire cannot be established beneath the concavity of the Moon.

[Margin: Aristot. l. 1. Met. c. 14. — Aristotle, *Meteorology* I, ch. 14.]

But lest I should seem to have considered the text too rashly, it has seemed good to adduce the very words of the most wise Doctor, so that what is to be held according to his mind may become plain. Aristotle speaks thus, *Meteorology* I, ch. 14:

In the middle, therefore, and around the middle, is what is heaviest and coldest, set apart — Earth and Water. Around these, in turn, are water and air; and what, on account of custom, we call fire is not in fact fire, for it is an excess of heat and, as it were, a boiling of fire. But one must understand the air we have spoken of, that which is around the Earth, to be as it were moist and hot, because the Earth has vapors and exhalations. But what is above this is already hot and dry. For the nature of vapor is moist and hot, and vapor is, as it were, potentially water, while exhalation is potentially, as it were, fire.

[Margin: Aristotelis sententia exponitur. — Aristotle's view is expounded.]

From these words it is plainly evident that Aristotle here teaches nothing else but that, the exhalation having been separated from the grosser watery vapors, it betakes itself into the uppermost and supreme region of the elemental World — which, since it consists of the finest and most subtle parts, hot and dry, is for that reason nearer to fire as to its nature, being thoroughly disposed to catch fire.

[Margin: Aetna.] [?: the marginal word at the foot of the left column reads "Artes" or "Aetna" — abraded; transcribed as found]

[Greek: ὑπέκκαυμα (hypekkauma, "the inflammable / kindling stuff")] — Aristotle says that the finer and subtler parts of the air are accustomed to be called fire; yet he protests expressly that it is not true fire, and gives an evident reason: because fire is a certain excess of heat and a certain boiling, whereas that vaporous substance of the supreme aerial region is not seething, nor does it have such an

excess of heat. Therefore, when Aristotle elsewhere says that fire is in the Concavity of the Moon, he must be understood — with this explanation — to mean that it is *called* fire by custom, not that it really is fire.

But the followers of Aristotle, in this place, from a wrongly understood text concerning the coordination of the elements, try by every means — even against the Master's mind — to persuade us of a proper and genuine Sphere of fire. Yet when he places fire beneath the Concavity of the Moon, he is so far from saying it is pure fire, or a true real element of fire, that he rather teaches that not even that which we commonly call fire is to be placed there; for he says, at text 18, that the Earth, heated by the Sun, gives off a spirituous, smoky exhalation, which belongs to the Earth itself in so far as it is dry; and on account of this he says that heat overhangs the vapor. And the same is to be understood of what he adds immediately after:

And by its circular motion it is hot and dry, which, he says, we call fire; for it is nameless and common in every smoky disgregation; yet, because such a body is most apt to be burned, it is necessary to give it names.

You see that the Philosopher here describes nothing other than the supreme region of air, which, when by the motion of the heavens it both grows hot and is burned in the manner of *ὑπέκκαυμα* (kindling-stuff), or an exhalation, or most highly rarefied air — so that he now calls it not-fire, and now fire in potency: fire, I say, not really, but that which is called fire by custom.

His followers, however, lest by this "pyrotechnics" they make both themselves and their Master ridiculous, are not ashamed there to set up and defend, even against his mind, a real Sphere of elemental fire — fighting "for altars and hearths." Furthermore, if fire is said to be there only by custom, as is clear from his words — since the thoughts or names of men establish nothing in nature — they certainly will not be able to set up fire there where it is not. But if he meant the most subtle and purest portion of air stabled there to be the element of fire, then they will not constitute an element distinct in species from air. Long indeed and much, I confess, [I have weighed] the words of the Greek text, in order that [I might establish] one true, real, and...

[Margin: Aristotle's doubts about the sublunary fire.]

would there [also] place a perceptible element of fire — I weighed this with the greatest care. But so far am I from finding his meaning made plain that I rather found him describing fire as located in that region in a thoroughly obscure way, ambiguous and wavering throughout, now in this fashion, now in that. At last I

came upon the words in which he describes three species of fire. Since these had to be examined with a view to the truth — and to refuting the imaginary sphere of fire around the lunar fire — I thought best to add them here, drawn faithfully from the text. He speaks as follows:

[Greek: οὐ γὰρ ἓν εἶδος τοῦ πυρός ἐστιν, ἀλλ' ἕτερόν ἐστι τῷ εἶδει ἄνθραξ καὶ φλόξ καὶ φῶς, ἕκαστον αὐτῶν πῦρ ὄν· καθάπερ ἐπὶ πυρός τὸ λεπτομερέστατον· λεπτομερεστέρων γὰρ ἐστι τὸ φῶς καὶ τοῦ ἄνθρακος καὶ τῆς φλογός — "For there is not one form of fire; rather, glowing coal, flame, and light differ from one another in species, each of them being fire — just as, in the case of fire, that which is of finest parts (is most truly fire); for light is of finer parts than both coal and flame."]

"For," he says, "there is not one species of fire; for glowing coal is one thing in species, and flame and light another — each of them being fire, in the same way that, in fire, the most subtle thing (that is, the thing of the most subtle parts, is most truly fire); for light is of finer parts than both coal and flame."

[Margin: The three species of fire.]

Here, then, he posits three species of fire in the nature of things: kindled coal, flame, and light — yet he comprehends both coal and flame under a single light, which consists of the most subtle parts. This view he excerpted from Plato's *Timaeus* [Plato, *Timaeus*]. Since it ran contrary to his own opinion about the element of fire, he ought more prudently to have passed it over than to have built upon it. I have undertaken to examine it here, and to explain whether it can stand alongside his doctrine of a fire abiding beneath the Moon.

I say, then, first: if there are only three species of fire — coal, flame, and light — they would surely give plain signs of their existence in the sublunary concavity; but they give none. Therefore...

[Margin: Refutation of the sublunary element of fire.]

For here we are not speaking of an element of fire that is invisible, potential, and virtual — which he also calls a vaporous substance, or rarefied air — but of one that is perceptible, real, and actually existing. So I argue thus. If there were fire in the lunar concavity, it would be either glowing coal [anthrax], or flame, or light; for no other species of fire exist, by the Philosopher's [Aristotle's] own admission. But first, there is no glowing coal there. For if a coal were there, it would necessarily be kindled — since an extinguished fire cannot be called fire. Every fire by its nature gives light; and if it gives light, it also sheds illumination from

itself; and if it sheds illumination, then it will light the regions below it. Yet no one, from the founding of the world, has ever seen anything kindled beneath the Moon and above the air's sphere of heat, nor has anyone observed anything shining there. Moreover, if that coal gave light, it would surely also be hot in itself, and would warm the air nearest to it, then the water, and then the Earth. And since heat of this kind lasts perpetually, it would perpetually warm the elements lying nearest it as well. The air, therefore, would never be cold — whereas it has often raged against all the neighboring elements with such intolerable cold that it turns everything into ice. A kindled coal, then, cannot be called the sublunary element of fire. For if such a coal existed, it would already...

[Margin: The three species of fire too are to be refuted under the concavity of the Moon.]

have spelled our doom, since it would long ago have reduced everything to ashes and cinders. This is what Aristotle once urged, in nearly these same words, against those who maintained that the heaven is fire: if it burned, it would necessarily give light; if it gave light, that light would spread to us together with its heat; and from so immense a thing as the sphere of fire is — many millions of parts larger than the Sun — its conflagration would long ago have consumed (I will not say merely the neighboring elements, but) the whole globe of the Earth, along with everything existing within it. But that nothing of the sort has happened is evident; just as it is equally true that no one has ever observed the concavity of the Moon to be aflame, nor has anyone ever felt either light or heat from it. Flame, therefore, cannot be there.

But perhaps you will say that this flame, owing to its extreme rarity — being of an ethereal nature — does not consume. If it is of an ethereal nature, then there will now be two ethers, an upper and a lower. And if so, then it will either be fire or not. If he says the former, he plainly contradicts himself, since he maintains that heaven, or ether, can in no way be called fire — for he says that if heaven were fire, everything would already have been burnt up; and if it is not fire, we have what we intended. Nor can flame be the sublunary element of fire; for if it were flame, then by necessary consequence it would, throughout so many ages, [have spread] so vast a flame...

Neither can the third species of fire, which he calls light, have its proper place in the lunar concavity. For it would give light, and by its diffused brightness would illuminate us; and since the sphere of fire is said to be contiguous to the supreme region of the air, no darkness, no night, could exist in the air — and so we would always, night and day, dwell in perpetual light. Who does not see how absurd this

is? Therefore no light surrounds the air at night, no fire shines beneath the Moon, and so there is no fire-light there. Let the Peripatetics not be angry with me here because in my works I have everywhere asserted light to be a substance and a body. I have asserted this persuaded by Aristotle himself, who in this very passage sets down light as a species of corporeal fire, making no mention of quality. But these things are by the way [Greek: πάρεργος (parergos, "incidental, by the way")]. Let us come to what we first intended, and see whether what the Peripatetics place beneath the lunar concavity can truly and properly be an element.

[Margin: Fire beneath the Moon is not an element.]

By Aristotle, those things are called elements into which a body is ultimately resolved, or out of which, as first inherent constituents, things themselves are composed — which no philosopher has denied. If, then, that spherical fire is established beneath the Moon, it will either be an element or not. If it is an element, then it will doubtless enter into the composition of the lower things; and, associated with the other elements, it will enter into the constitution of all mixed bodies, as the principal part and the most active of all. It must therefore descend to constitute those compounds. But a descent of fire of this kind has never been seen, nor by any philosopher or astronomer ever...

detected. For if it descended, it would descend either against nature, or with nature compelling it. If with nature leading, then we shall be forced to assert that fire is furnished with two contrary motions — a natural ascent and a preternatural descent — which is against the Peripatetic doctrine, which asserts that one simple body has one simple motion. If it descends against nature, then it enters into every mixture by a violent motion; therefore every mixture would be not natural but preternatural, and consequently against nature's will, and so never perpetual — which conflicts with the common verdict of the philosophers. But if someone should say that this descent occurs by nature, he will then necessarily be forced to assert that fire is heavy by its own nature; since everything that tends toward the center of the Earth by natural motion is heavy. This fire would thus ascend as heavy and ascend as light — therefore it would be at once both heavy and light, which involves a contradiction. But if you should say that it perpetually ascends by its own nature, then it will never have any commerce with the lower things. And finally, if you should say that it descends through the motion of the heaven of the Moon, that motion will be either through the heaven pushing, or hurling, or attracting, or carrying it; for by these motions, and no others, every thing is moved — whether by itself, or by things above, or by

things below. But I do not see how the heaven, by its spherical motion, could thrust fire straight downward; for what pushes must necessarily be followed by the body it pushes. The heaven, then, would follow the fire downward — and I do not see what could be more absurd than that. The same absurdities follow if you say it is forced down by a casting or carrying. Nor can it be drawn down by the neighboring air; for either the whole of it would be drawn, or some of its parts. If the former, then, the whole being torn away, a vacuum would necessarily be left — which is not admitted in the Schools.

From all these considerations, we finally conclude that this fire inhabiting the lunar concavity — since it has been seen by no human being, known by no sense, gathered by no reasoning, and (as has been demonstrated) is of no use and contributes neither to the composition of the world nor, much less, to the mixture of things — cannot, saving the judgment of those more learned, be admitted at all.

[Margin: What the true element of fire is.]

Now we shall try to show what the true element of fire is.

And I suppose, first, that — as we have taught elsewhere — God, the Best and Greatest, the most wise Creator, created heaven, the stars, and the Earth out of the four elements, which were contained virtually in the chaotic mass; as we have shown at length, from the holy Fathers, in the *Iter Exstaticum* [Kircher, *Itinerarium Exstaticum*].

I suppose, second, that no pure element can exist in the nature of things, properly speaking. Rather, all the elements lie wrapped up within one another, so that they are properly not pure elements but mixed, or "elementated"; for no pure element can subsist by itself, nor be perceived by sight or any sense — as has been demonstrated by ample reasoning both in the preceding pages and in the *Second Terrestrial Journey* [Iter Terrestre Secundum].

These things laid down, we say that even though no pure element can exist, nonetheless something lies hidden within the mixed element — as in the inmost center of the elemental substance — which deserves the name of the true element, and which gives the element its being as a species distinct from the others. It is, as it were, the form and soul of the element, of which, however, that element is the index, which presents itself to the senses according to the requirement of its proper form. For when we see fire, we call it "that element," not because it is truly and properly such; for it is only the material element, clothed as it were in a garment by the burning smoke. But the essential element lies hidden within, which is indicated by light — namely, that primigenial and

innate heat, inherent in all things, both celestial and in the mixtures of sublunary things. And that this is the true element which contributes to the composition of all bodies is deduced from the following: since this ordinary fire, being of itself and by its nature destructive, is so far from entering into the composition of things that it rather destroys things already composed. A different element, then — true and proper — must be assigned as the constituent of mixture: not that external, burning one, but the internal one, which we call light, or innate heat. For although this is inherent in all things, it most especially exerts its power in luminous bodies, and first of all in the Sun — as in the proper sphere of light and fire, where it has fixed its seat under the purest light; in the inmost chambers of the Earth, under a dark light tinged with the various medley of combustible things; in the supreme region of the air, under a vaporous substance. But in the remaining opaque bodies it lies dormant, as in the excremental dregs of the elements; yet when it is separated from them by the chemical art, it at once exerts the disposition of its fiery nature — whether on its own or upon being applied to another nearby fire — clothed now in a luminous garment.

You see, then, what we properly mean by the element of fire, which contributes to the constitution of bodies; and what we mean by the element of light and fire encircled by a rind — that which the common people call artificial, mixed fire, or which Aristotle calls [Greek: πνεύματος ξηροῦ ζέσιν (pneumatōs xērou zēsīn, "the boiling/kindling of dry breath")], the kindling of a dry spirit; or, what is the same thing, an exhalation, or kindled smoke. From this it is plain that the element of fire is not improperly called — by a long-standing and customary usage — every flaming, kindled, and luminous body, in whose center, however, is contained that true element which imparts power to flame and to every luminous body, of itself and by its nature all but incorruptible: manifest in some things through light, in others through heat alone, the light being suppressed within the body.

[Margin: The essential fire is subject neither to the laws of heavy bodies nor of light ones, but is indifferent to every place.]

This element is subject neither to the laws of heavy nor of light bodies, but of itself and by its nature is indifferent to every position — as in the thunderbolt, the lightning-flash, and most of all in nitrated...

and golden powder, the former of which, by its own nature, tends upward, the latter downward, with marvelous force — according, that is, to the nature of the matter to which it is joined. And in this way Aristotle's opinion, which places the element of fire beneath the lunar concavity, can and ought to be understood: not as though it were contained in its own proper sphere, but as a portion of fire

which lies hidden — as in all things, so also in that aerial sublunary body. For once this is granted, no difficulty can be raised concerning the element of fire that is not resolved by what we have already adduced.

COROLLARIUM I.

[Margin: How fire is generated by friction.]

From what has been said thus far, it is plain how heat is generated by friction in the collision of hard bodies: as when you strike iron upon an anvil, or polish iron with a file, or kindle two pieces of wood into flame by rubbing them with a third; how a drill by which something is bored seethes so greatly; how, finally, fire is struck from flint; how in the clouds the thunderbolt and lightning-flash arise, and in the bodies of living things heat is born from vigorous exertion — and the like, which are established by daily experiment.

I say, then, that the reason for all these things is nothing other than the element of fire, that is, that innate and primigenial heat — something not unlike sulphur — enclosed in the inmost center of natural things, dormant indeed and oppressed by the earthy dregs of refuse, but, after the rubbing and friction of colliding bodies, animated by the agitation of the spirits, it rouses those heats I mentioned; until, the corpuscles of a moister nature being separated, and the sulphurous and vaporous spirits being joined together for the purpose, it at last comes forth clothed in a fiery and flaming garment.

[Margin: Experiments.]

For although all mixed bodies have within themselves sulphurous and fiery spirits of this kind enclosed within them — as is evident from their dissolution by the spagyric art — and although in this way all things grow hot from the motion of friction, nevertheless some are more apt than others: namely, those that have obtained a greater store of fixed sulphur, and spirituous parts that are either more abundant or more compact.

[Margin: Why iron grows hot more violently than the other metals.]

Hence iron, being swollen with an abundant store of roasted sulphur, we find grows hot beyond the other metals most of all — and not so lead, copper, brass, silver, gold, in which (because of the abundant moisture that resists) those fiery spirits, which lie hidden in the primigenial heat, are not so easily gathered from friction. But why iron, when it cuts wood, grows so very hot, while the wood does not — we give this reason: that the sulphurous spirits in wood, being more

dissolved, breathe out, whereas in hard iron they are more compact, and through the predominance of sulphur more closely packed. Hence it comes about that in iron, from friction, they are more easily kindled than in wood. In the clouds, the thunderbolt and lightning are born from sulphurous corpuscles drawn up on high together with vapor, which — being filled with fiery and nitrous spirits — when agitated and rubbed by the violent clash of the clouds, easily coalesce into fire. This fire, requiring a larger space from the rarefaction of the air, and finding no exit from the packed barriers of the clouds, by a kind of violent motion rushes wherever a gate is opened, with that destruction which we experience year by year.

COROLLARIUM II.

[Margin: Why in winter all plants take on a sad aspect, in summer a glad one.]

Hence it is also plain why, in winter, the whole economy of growing nature lies squalid with a mournful face, and all greenery perishes from the trees and plants. The reason is that the Sun, being more remote, cannot dissolve and rarefy those fiery and vaporous spirits, since they are pressed down by the cold; but as soon as, having passed the equinox, it has received an increase of its heat — behold, the spirits which had lain hidden until then, being kindred to those (plants), are animated by the new guest of heat, and as it were exulting and dilated with the joy of their inner disposition, they luxuriate into branches, leaves, flowers, and fruits. But why they do not grow hot, or catch fire, from that motion, the reason is both the resistance of the abundant moisture in which they are rich, and that gentle influx of solar heat by which the fiery spirits, mixed with the moistures necessary for generation, are so tempered that they cannot burst into fire. And this is that "warm and moist" by which, on the Philosopher's testimony, all generation is accomplished, and by which all things flourish and are preserved. And once these our principles are laid down and applied, no effect in the nature of things will occur, however exotic, whose reason you cannot give.

COROLLARIUM III.

[Margin: Flame is flowing fire.]

Hence it is plain how flame — which is nothing other than flowing fire — is extinguished. For example, in a candle, which abounds in a fatty and viscous moisture, and in which many sulphurous spirits are present, it happens that the kindled wick and the spirits, catching fire, are at once kindled together into flame; and thus, owing to the abundance of fatty moisture, they begin to flow;

and with the spirits in turn provoking one another and exciting one another to flowing, the flame lasts as long as that flux in the root of the fuel lasts. But the flux ceases as soon as that flow is drawn off from the fuel, and the sulphurous spirits are disturbed, hindered, and choked — whether by a too-violent gust, or by overflowing moisture, or by pressure — so that it can no longer be fed nor flow.

[Margin: How fire is present in coal.]

In coal, however, even though there is no flame, there is nonetheless light, still seething with a fiery glow; whence, for their own preservation, they summon auxiliary forces — seizing nearby particles of dry coal, here and there, disposed for ignition — and, these being taken up (especially if helped by a blast), they grow strong into the greatest increase of fire. But if an external helper is lacking, then, as much as they...

can, they concentrate themselves, until at last, weakened and extinguished by the cold of the surrounding air, they cease from both light and burning.

[Margin: The light of fire varies according to the different nature of the fuel.]

But let us at last return to our discussion of subterranean fire. We rightly said, in our definition, that it is a portion of the elemental fire — not of pure fire, but tinged with the various medley of subterranean combustible things. And that fire is tinged according to the different nature of the fuel: if it is joined to pure sulphur, it gleams white; to bitumen, it mourns with a dusky flame; if to bitumen together with verdigris, it turns green; it reddens, if joined to minium or similar red-colored minerals; if to arsenic, ochre, or sandarac, it turns yellow; if it is applied to a fatty and oily, sooty material, it is left almost wholly without light, betraying its disposition by smoke alone. All of which experience will teach, if you kindle a wick in a lamp with the said materials mixed in oil. And hence it is that, although the element of fire is in all things the same in species, yet, according to the nature of the combustible things, it appears to differ in species.

[Margin: The whole Earth is cavernous.]

Our definition asserts, then, that fire of this kind is enclosed in the bowels of the Earth, for the safeguarding of sublunary nature and the production of all things. That the Earth is cavernous was amply shown in the preceding Book, where we set forth that the terrestrial globe has, within its own bowels, immense spaces, vaulted caverns, vast tracts, and impenetrable abysses. For as Seneca relates concerning the Field of Puteoli [Agro Puteolano, the Phlegræan Fields near Naples]:

There are vast caves there, there are huge recesses and spaces, with rocks suspended here and there over mountains, and at the same time chasms broken off into the infinite, which have often received cities sliding down, and have buried a great ruin in the deep.

And as Cornelius Severus said in his *Aetna*:

Wherever the immense globe of Earth extends itself, and is girded by the curving waves of the outermost sea, not all is solid, for every cleft is wanting [recte: deest — "is lacking"]; the whole soil is wrought and hollowed out within into hiding-places, and drives its slender ways suspended.

[Margin: The wedding of fire and water within the Earth.]

To which Pliny [Pliny the Elder], Aelian, Lucretius, and the other writers on natural things subscribe. There dwell, in chambers stretching far and wide in different directions, joined by the highest covenant of friendship, fire and water — which contrive that variety of things which metals, minerals, juices, oils, and the channels of springs reveal to us. For as Manilius rightly [says]:

But fires too are mingled through all the parts, which, dwelling in the moist clouds, forge thunderbolts, and penetrate the lands, and threaten lofty Olympus with ether, and make the waters warm in the very springs.

[Margin: The subterranean fire diffuses itself marvelously.]

So that even from this the admirable force and power of subterranean fire may shine forth, as — ascending upward with an ordered impetus, and making whatever it overcomes ascend — it grows in multiplied proportion almost to infinity, and corrupts and transmutes whatever it meets into its own substance, nor is it ever diminished by any part taken from it. For, enclosed in the caverns of the Earth and agitating itself, wherever it finds an entrance it penetrates to an exit over many hundreds of thousands of paces, even beneath the sea and through the trackless windings of the Earth — as we have taught in the *Prolegomena*, as an eyewitness inspector of all things. And while it continually acquires greater strength, it converts into fuel for itself the lands that lie in its path, and even the very rocks and mountains — so that, were it not restrained by the encircling Ocean and by the command of the omnipotent Deity, it would draw the whole mass of elemental nature into an inextinguishable conflagration.

Nor is it any wonder that so great a force of fire has been established by nature in the lands, since upon fires of this kind the welfare of the whole sublunary world

depends. For in preserving those things especially which — whether you regard necessity or duration — cannot do without the aid of fire, nature ought not to have been sparing, narrow, and defective, but altogether liberal and magnificent. For just as it constituted the heaven with an immense circuit, to embrace all things, and disposed the vast mass of the elements, and the immense expanse of the sea — from which it might distribute through the veins of the whole Geocosm an unfailing supply of waters — so too, the proportion of divine providence being preserved, it was fitting that it should have made a great apparatus of fire in the belly of nature; so that through these longest of chimneys, as it were, it might diffuse boundless heat for the use of the necessary things, for the benefit of the Earth, of men, and of living creatures.

[Margin: A great apparatus of fire in the belly of the Earth.]

And just as it appointed for the waters their boundaries, which they may not pass, so it has tempered this nature of fire with so admirable a distribution, with such order and such proportion of symmetry, in the hidden paths of subterranean nature, that it should neither be choked by the waves of the surrounding Ocean, insinuated far and wide, nor stray beyond the bound prescribed for it. For otherwise, bursting forth with its most free motion, it would turn everything upside down, to the open ruin of the Earth and of men — which I judge will come to pass in that fullness of time, when, the reins of raging nature being broken and the cataracts of the subterranean fires opened, by the command of Divine power not only the Earth but also the elements shall be dissolved by heat, with the ruin and destruction of the whole world. So that, just as in that universal cataclysm, the cataracts of heaven and the gulfs of the abysses being opened, it destroyed the world by an inundation of waters, so also in the last times it shall destroy that same world by an inundation of fires. And who would deny that this shall come to pass, if he has beheld the perpetual fire seething in the lands — if he has beheld the vast conflagrations of provinces, and finally the manifest apparatus of so great a store of matter and sulphur, which the Earth belches forth in even a single chasm — unless he should confess for certain that this is a specimen and an evident sign of the preparation for that conflagration prescribed by Divine Wisdom?

Diagram. A full-page engraved map of South America [Tomus I, plate 74], oriented with West at the top (the compass rose at upper right marks N at the bottom, S at the top, W at top, O [East] at the right). The map illustrates the chief water-reservoir [hydrophylacium] of the Andes, from which (per the cartouche) all of South America is watered by countless rivers and lakes. A large oval basin

in the interior, ringed by mountains, is captioned as the principal reservoir. The decorative cartouche at the bottom carries the title.

- Top-right corner: "Tomus I. 74." (volume and plate number)
- Compass rose (upper right): "N" (bottom point), "S" (top point), "W" (left), "O" (Oriens, East — right)
- Left margin (vertical): "OCEANUS AUSTRALIS sive MARE PACIFICUM" [the Southern Ocean, or Pacific Sea]
- Interior oval basin: "Sub Andibus Hydrophilacium Americæ præcipuum" [The chief water-reservoir of America, beneath the Andes]
- Across the northern landmass: "AMERICA" (spanning the band, with "A — ME — RICA")
- Upper region (NW): "PERV" [Peru]; "Caribana"; "Æquator" [the Equator line]; "R. delas Amazonas" [the Amazon River]; "BRASILIE" [Brazil]; "Maragnon" [Marañón]; "Tabaiar"
- Northern islands and coast: "Jamaica"; "Barbada" [Barbados]; "Caribar"; "Carragocaró"; "Darien"; "Antiocha"; "Castello Doree" [Castillo del Oro]; "Ibero fl."; "R. S. Martha" [Río Santa Marta]
- Central interior: "Parime lacus, alias Titicaca" [Lake Parime, otherwise Titicaca]
- Southern region (S labeled "INFERIOR" / "RIOR"): "Tropicus Capricorni" [the Tropic of Capricorn]; "I. Assençion" [Ascension Island]; "R. de la Plata" [Río de la Plata]; "Cuy populi Silvestres" [Cuy, forest peoples]; "R. de Mendoza"; "Buenos ayres"; "Barbaranna"; "Paraguay" [Paraguay]; "R. della Plata"; "C. de Corientes" [Cabo Corrientes]; "Desertum Pampas" [the Pampas desert]; "Manlanes" [?] / "CHILE" [Chile]
- Far south: "Fretum Magellanic." [the Strait of Magellan]; "Terra del Fuego" [Tierra del Fuego]
- Lower ocean (lettered across the sea): "OCEANUS OCCIDENTALIS" [the Western Ocean]
- Bottom margin: "TERRA AUSTRALIS INCOGNITA" [the Unknown Southern Land]
- Cartouche (bottom center): "Tabula qua HYDROPHILACIUM Andium exhibetur, quo universa America Australis innumeris fluviis lacubusq; irrigatur." [A map in which the water-reservoir of the Andes is displayed, by which all of South America is irrigated with countless rivers and lakes.]

CAPUT III.

On subterranean fire diffused through all things; and why in some places it is perpetual, while in others it is not.

[Margin: Just as blood is the spirituous heat in the human body, so subterranean fire is in the veins of the Geocosm.]

Just as in the human body the heat of the Microcosm, diffused as a spirituous breath through all the passages of the whole body, animates, quickens, restores, and stirs all things — joined together with the mass of the humors — so too the Author of Nature constituted the Geocosm with no less providence. He furnished it with the most abundant and copious fires, proportioned to the scale of so vast a mass, so that nowhere should there be lacking what is so greatly necessary to its natural operations.

The human body — that is, the Microcosm — is filled with air, fiery spirits, and humors; and so is the Geocosm. For just as in the human body, when a wound is inflicted at any spot, blood at once bursts out and at the slightest agitation effervesces, driving sweat out from the whole substance of the porous skin, so there is scarcely a place in the Earth which, if dug into beforehand, does not yield abundant streams of water — whether spontaneously, or drawn out by the pull of clayey earth — and these not merely cold, but also tepid, hot, scalding, and seething with an intolerable force of heat. For how could water subsist without fire, or fire without water? Surely without fire all things, condemned to perpetual frost, would long ago have ceased from all propagation of generable things, to the open ruin of nature; [Margin: Fire cannot subsist without water, nor water without fire underground.] while without water all things, long since consumed in the fires of innumerable subterranean reservoirs, would have reduced the whole fabric of the Geocosm to ashes and cinders.

You see, then, with how great providence — and by what admirable art of nature — these two elements are joined together, so that the one furnishes necessary nourishment to the other by a kind of reciprocal exchange, and the one breaks the other's onslaught. United in this way by a kindly compact, they accomplish the effects intended by nature. We have clear evidence of this when we see the Earth, that benign nurse of things, holding within her bowels the storehouses of all things — water, air, fire — in a certain admirable proportion, so that they may suddenly serve all her works and suddenly be at hand for any generation of things. Hence we observe an immense force of moisture flowing out of the earth in a perennial stream, perpetual exhalations breathed forth, infinite emanations

of waters, the enduring furnaces of subsisting fire, the vast cellars of the reservoirs, and the manifest effects of the eternal fire within them — smoke, flame, fervent heat, the seething eddies of boiling waters, and the vast conflagrations that are kindled over the course of time when the furnaces are torn open. These conflagrations, seen here and there throughout the whole world on land and sea, give sure account of the remaining heats and burnings that are scattered through the various tracts of land and sea, and which — channeled as it were into the various branches of the furnaces — produce so great a variety of *Thermae* [mineral hot springs] and minerals. But that these matters may be made clearer, we have decided to insert here a figure of the whole.

Here you have a figure representing the type of subterranean fire mixed with water. We do not, indeed, assert that the fire has this exact form within the earth — for who among the living has ever seen it? — but rather a certain likeness of nature at work, and as far as the imagination suggests it ought to be. For otherwise it can scarcely be grasped by human ingenuity how water joined to fire produces such marvelous effects, both outside and inside the earth. The central fire is marked by the letter A; the pyrophylacia [fire-reservoirs] derived from it, by the letter B; the hydrophylacia [water-reservoirs], by the letter C. The channels from pyrophylacia to pyrophylacia are the *canales pyrogogi* [fire-conducting channels]; the channels from hydrophylacia to hydrophylacia are the *canales hydrogogi* [water-conducting channels]; while the lines drawn to both pyrophylacium and hydrophylacium are the fibers, cracks, or fissures of the Earth, through which both water and derived fire dispose the Geocosm — both for the generation of springs and for that of minerals and metals — and they behave in just the way the capillary veins do in the human body, of which not even the smallest portion is without them, as has already been shown above. You will also learn from this that the pyrophylacia have their place nearer the Center, while the hydrophylacia have theirs nearer the surface of the Earth — by a truly prudent design of nature; for cooking-pots [cacabi] must be placed not below but above the fire, so that the water may be heated and brought to use.

[Margin: What a conflagration is.]

Now a conflagration is nothing other than a great accident in nature, a certain immense excess of fire which — having pursued the rich and combustible matter of the Earth out of the subterranean abysses of the underground fires — either through its own force, when the furnaces are ruptured somewhere, hurls forth flames marvelous and terrifying to mortals. And although conflagrations of this sort, on the outer surfaces of the lands, are not perpetual but occasional, the fire

in the subordinate pyrophyllacia is nonetheless not abolished, but subsists perpetually and uniformly, as is evident from the *Thermae* [hot springs], which always remain in the same state.

[Margin: Why subterranean fire fails in some places, but not in others, at certain times.]

But the reason why, in some places, the effect of the fire does not always appear, while in others it appears perennial, is this: even though the subterranean fire subsists in its receptacles in its substance, with its fuel constantly supplied to it, it nevertheless happens from time to time that the combustible matter near the Earth's surface is either consumed, or — through the passages choked with cinders from the burned-out clods of subterranean matter and through the cracks

[Margin: How subterranean fire is kindled and preserved.]

of the burned-out arches being obstructed, or through the channels being filled with water by the spreading of subterranean inundations — the propagation of the fire is impeded, and (as though a kind of truce had been imposed) it lies quiet for the course of many years; until the mineral vein, propagated with the passage of time and enriched with a fresh stock of combustible material, again bursts forth into the open and resumes its ancient stations of conflagration. For know that conflagrations last just so long as the fuel of combustible matter lasts; and if, for the causes mentioned, this fuel fails, then the fire too must necessarily fail — especially in those ducts of the furnaces which lie farther from the pyrophyllacium. But if the said causes do not intervene, it is certain that the conflagrations last perpetually. For flame — which we call kindled vapor — can [?] only so long as it has the bait of combustible matter; when this fails, the flame too fails and ceases, until, by a fresh communication with the sea, fresh matter is supplied and, with a perennial vapor and murky exhalation within, it sprouts up again to the topmost arches of the passages. There, just like the thickest soot, when a blast lying within is excited by a greater impulse, it catches fire and again gives off new flames.

But this cannot always happen in one and the same manner; for nature is wholly in continuous motion, and necessarily brings forth accidents of this kind — greater and lesser — according to the varying dispositions of the combustible matter and the condition of the blast pressing upon it, which are the necessary cause of these accidents. And since the matter is not always disposed in one and the same quality and quantity, nor is it equally apt for conflagration in one part as in another (because of the various dispositions of the furnaces), hence it comes

about that in some places the conflagrations are perpetual — because there the passages of the furnaces are kept utterly clear all the way to the pyrophyllacia themselves — while in other places they now die down, and now, after the lapse of many years, are rekindled, both on account of a fresh increment of matter and on account of the diverse forces of the subterranean winds and blasts. These winds are indeed so necessary to this Vulcanian economy that without them — being, as it were, the authors of all natural accidents — nothing would happen. How they are produced, I explain in a few words.

[Margin: How subterranean fire is kindled and preserved.]

When we said, in the *Itinerarium Terrestre* [Subterranean Journey], that the Ocean has its floor pierced like a sieve with countless openings — which are nothing other than the mouths of the channels — then, when the water, driven by the impulse of the sea, runs through them, it consequently excites wind; and this wind, rushing with utmost force through the channels of the pyrophyllacia (which are almost always united with the channels of the waters), or led into the pyrophyllacia themselves, there by its most humid blast not only excites the combustible matter but continuously animates it into the most fervent flames — no otherwise than as a blacksmith, by the blast of the bellows and the sprinkling of water, powerfully restores the fire in his hearth, redoubles the fervent heats of the fire, and by their power and efficacy — which without the blast he could not do at first — now, the iron having become subject to his own will and judgment, fits it by hammering into whatever form and figure he pleases.

[Margin: Subterranean winds arise from the motion of the sea.]

Now the subterranean blasts, or winds, arise from the commotion of the sea and from the daily reciprocation of ebb and flow; and these winds are, as it were, certain bellows of nature, whose perpetual blowing both draws the water transfused from the sea within its passages toward discharge, and propagates the wind — from the continuous commotion of the waters — within the fire-belching furnaces and passages, stirring it with a perennial motion. The cracks and fissures of the earth, which the water carried along had filled with a varied mixture of combustible matter — salt, sulphur, bitumen — these, here seething with heat and exhalations, liquefied according to the nature and condition of the earthen crypts, the fire and water draw to themselves and convert into fresh material for fuel. And once this is done, there comes about a perpetual continuation of nature's operations; and in this way the cycle [pericyclosis] of both water and fire is carried out by the industry of nature.

These matters, then, having been duly set forth, let us now turn our pen to the historical accounts of fiery conflagrations, so that the exterminators of subterranean fire may learn through their senses what they do not grasp by the intellect. And we shall best begin with the regions of Italy, inasmuch as it contains more numerous and more manifest traces of subterranean fires — traces on which all the demonstrations of the argument undertaken are founded. These things I would not have believed, had I not examined them all with my own eyes, surveyed on the occasion of my various travels.

[Margin: Italy abounds in subterranean fires.]

Under a temperate climate, then, Italy — since it is stretched out from the Alps in a long chain of linked mountains, and enclosed on either side by two seas, divided throughout by the Apennine — is on both sides washed by countless springs of bubbling waters, by lakes, and by the streams of mighty rivers; all of which indeed take their origin from the hydrophylacia, both of the Alps and of the Apennine. And that you may see the remarkable situation of Italy: that part of it which faces the Adriatic Sea, looking partly toward the North, is — because of the shadow of the Apennine — shaded, colder, and possessed of fewer thermal springs, of a rawer disposition. But on the right hand, which for the most part faces the South and is surrounded by the Tyrrhenian Sea, it is seen to be sunny, open, and — on account of its sulphurous soil-nature, which it everywhere reveals — apt for bearing fires. And so, in the various adjacent islands too, it has at all times produced diverse evidences of heats, reservoirs, and thermal springs. Hence, on the testimony of Berosus [Berossus], it is reported that of old it burned from Cumae and Vesuvius all the way to Istria, and was therefore called *Palensana* by the Janigenae [the descendants of Janus] — that is, a region [?] consumed by fire [?]. And if we explore the matter more minutely, we shall find that Italy has every disposition toward such vast conflagrations: the narrowness of its situation, by which it is continually scourged between two seas by the dashing of the waves; its subterranean passages and cavernous windings, open to fires and winds; and finally its abundance of sulphurous matter, in which the whole land luxuriates,

(continuing Liber IV, Sectio I, Caput III — the catalog of Italian volcanic and thermal sites)

in which the whole land luxuriates, and it burns in certain places over the entire earth. For in this whole southern part of Italy, from the farthest shores of Sicily right up to the borders of Etruria [Hetruria], in some places one sees perpetual fires — as in Aetna — while in others they burn at intervals, as in the Aeolian

Islands, which they call the Lipari [Aeoliae, quas Liparas vocant]; and opposite Naples [Neapolis], as on Aenaria, that is Ischia, Prochyta [Procida], and Pithecusa; and likewise in the mountains of the mainland — Vesuvius, Misenum [Misenus], Puteoli [Puteolisque], and Cumae — which often burn, and in certain places display great vents [aestuaria] with fires, smokes, vapors, and hot springs [thermis]. By these vents, as I have observed with the greatest care, the passages [anfractus] everywhere lie open, and the channeled vent-holes gape; and where these emit a blast, soon — not without dread in the bystanders — there are heard, deep within, crashings and roarings as of a burning fire.

[Margin: Phlegraeian fields. (Phlegraei campi.)]

These crashings and the booming of the waters can also be heard in the Phlegraeian Hills [Phlegraeis collibus], which surround the Vulcanian field, commonly called the Sulphatara [Solfatara]; and so do the not-far-distant Cave of the Sibyl [Sibyllae Antrum] at Cumae, and so many horrid chasms and recesses around Avernus, impassable because of the heat. All Campania everywhere bears on its surface the traces of that ancient conflagration — the ground here and there parched, like ash and pumice, and with that dust they call Puteolan, with live coals shut up in the very stone.

[Margin: Latium runs with sulphur. (Latium scatet sulphure.)]

From Puteoli let us pass to Latium, which is full of sulphureous craters: through Minturnae to Sulmo, and from there through the Roman Campagna [Campi Romani] the sulphur-vein continues, exposing itself in many places — but most of all in a certain lake of unfathomable depth, four miles from Tibur [Tivoli], as well as in the sixteen floating islands they call the Barchettas, the most famous of the floating sort. From this lake the river Albula, a sulphureous stream, takes its origin; and it was once celebrated for the baths of its thermal springs, of which I shall speak in its place.

[Margin: The channel of the subterranean fire diffused into various branches. (Cuniculus ignis Subterranei in varios ramos diffundens.)]

From here the channel [cuniculus] of the subterranean fire bends back toward Monte Rotondo — formerly the Eretan field [agrum Eretanum] — and from there it is led off into branches. One branch runs to the Thermae Stiglianæ [Bagni di Stigliano] and to a lake in the middle of a wood, a thing horrible to behold both for the stench of sulphur and for the boiling water rising in the manner of a column; and at last, through a neighboring mountain — in which there is also a cave of serpents [crypta serpentum], filled with vents and chimneys — it runs as

far as Tolfa and Centum Cellae [Civitavecchia], all of which places teem with sulphur and bitumen, and there it ends at the sea.

The other branch runs toward Monte Rosso, between which and Ronciglione new sulphureous craters open up, which hold hidden traffic with Monte Cimino — which they call the Mountain of Viterbo [Montem Verterbiensem] — and with the village of Vico, famous for its sulphureous springs. And indeed Monte Cimino still seems to nourish a great force of fire beneath its deepest caverns, which, at its roots on the northern side near Viterbo, it spreads over that whole plain, filling it with the most sulphurous exhalation, with clods here and there dried out and pumice-like, and with countless hot springs. Among these, the Bullicame is the most famous for its intolerable heat, whose marvelous constitution — God granting — I describe more fully in our *Etruria* [*Hetruria*]. This spring has a great communication with another nearby lake between Viterbo and Montefiascone [Montem Flasconem], where water bursting up from the bottom of the lake stirs up wondrous turmoil; and — wonderful to relate — two springs are seen here together, scarcely a single pace apart, of which one dances with the most scalding, the other with the most icy water; of which in its place.

[Margin: Two neighboring springs, of which one is cold and the other hot. (Duo fontes vicini, quorum unus frigidus alter calidus est.)]

From here the channel of the subterranean fire, diffusing itself into innumerable branches throughout the whole of Etruria, leaves scarcely any place free of hot springs, sulphureous craters, and mineral waters; since Etruria, where it looks out upon the Tyrrhenian Sea as far as the island of Elba [Ilviam Insulam], is everywhere a land that teems with warm waters and luxuriates in mines — whether of iron and copper or of sulphur. Under this head the Lacunae Volaterranae [the lagoons of Volterra] are truly memorable, filled with seething and leaping waters, and there are mines of the best sulphur near the Castrum which they call Libbiano [Castrum, quod Libbianum vocant], of which I have treated most copiously in our *Etruria* — see there.

On the other side, toward the East, the channel of the fire, stretched far and wide, exerts itself chiefly beneath the mountain they call Vivo [Vivum], where it produces the celebrated baths of S. Casciano and S. Filippo [S. Cassiani & S. Philippi thermas]; and from there it extends toward the baths called Avignonenses [Bagni di Avignone], all the way to Montepulciano [Montem Politianum], where at S. Albino [S. Albinum] a great abundance of mineral waters gushes up with a smoky stench. From there it stretches, on the one side, all the way to the Apennine [Appeninum] itself, packed with vents; and on the other side

it reaches the regions of Siena [Senas] and the neighboring parts bordering the sea, and the territories adjoining Liguria, and the Lucca district [Lucensem agrum] — which abound in so many metals, so many sulphureous mines, and so many springs of warm and seething waters as perhaps all the rest of Italy does not have.

[Margin: The channels of the subterranean fire exert themselves on the Apennine at Petra Mala. (Ignis Subterranei spiracula in Appennino ad Petram malam.)]

Yet most of all do the vent-holes of the subterranean fire exert themselves on the Apennine at Petra Mala and the places near it, where at night the air sparkles and, for a long time, smokes and steams as if from a furnace burning beneath, and heats and sets alight the straw thrown upon it. This spring appears to have veins continuous all the way to the Porretta waters [aquas Porretanas] in the Bolognese territory [Agro Bononiensi], whose hills sparkle at night on every side. From there it seems to plunge into the Modenese territory [Agrum Mutinensem], where a flow of bitumen and fire boils up in a wondrous manner; and from there it continues the fires of its kindling all the way into Istria. For that these Euganean Hills [colles Euganeos] once burned around the baths of Aponus [Aponi balnea] — as Berossus testifies — the rugged tracts of the hills, their ashen and pumiceous face, and the coals and stones (which heat even the very waters running through them) sufficiently show.

These things being so, they can truly be for us a proof that the whole of Italy is filled within with a continuous matter of sulphur, whose channel — as it extends its branches now more, now less, far and wide — likewise stretches under the sea too into the adjacent islands; and, according to the particular tempering of the mixture and the power of the heat which it holds under the varied course of the veins, it produces various effects,

produces wondrous fires at certain times. We conclude, therefore, that Italy, the nurse of conflagrations, just as it is wholly filled with subterranean fires — which in some places burn perpetually, in others at intervals — so once had such great accumulations of sulphur, such a heaping-up of fiery matter, that if not the whole, at least (by the testimony of Berossus) a great part of it was set ablaze; nor is it less to be believed that there will at some time come a time when, with these first principles of nature standing as they are, it will burn again and again, right up to the final destruction and consummation of the whole Universe.

[Margin: All of Campania is exposed to fire. (Tota Campania ignibus obnoxia est.) — (corresponds to the surface-of-Campania passage above on p. 177)]

[Margin: The floating islands of Tibur. (Insulae natantes Tyburtinae.) — (corresponds to the sixteen floating islands passage above on p. 177)]

CAPUT IV.

On the Phlegraeon Field in the Puteolan Territory.

[De Phlegraeo campo in Agro Puteolano.]

[Margin: Description of the Phlegraeon fields. (Phlegraeorum camporum descriptio.)]

In the year 1638, passing through Naples, I could not refrain from inspecting the sulphureous fields celebrated in every age, which the ancients call Phlegraeon. Having therefore passed through the subterranean passage they commonly call *la Grotta* — which I have described elsewhere, the excavated Mount Pausilippus [Posillipo] — not far from Puteoli, between the jaws of the mountains a plain spread out far and wide presents itself to view, a place altogether full of horror and dread, 1200 feet long, let us say, and 1000 wide. Pliny [Plinius] wrote that it is called the Phlegraeon Fields from its flames and burning; but Cornelius and Strabo call it the Forum of Vulcan [forum Vulcani], the place where some fable that the giants too were overcome by Hercules. There the hills are seen everywhere blazing at the bottom, in the very depths; for everywhere, through many openings, they always exhale great smokes with a sulphureous odor, which are carried by the winds through all the neighboring region, even as far as Naples.

This whole plain is encircled by hills, or rather lofty crags, whose summit, once very high, at length consumed by perpetual fires, sank down into a deep valley — as is gathered from the very form of the place. And so what was once a peak is now a huge pit dug in the level valley, where the ribs, or rather the flanks of the mountain of old, are now the topmost points of crags and cliffs. And these, by the testimony of Dio Cassius [Dione Cassio], once belched fires and flames in greater abundance; the neighboring mountains too burned continuously, and threw out, as from furnaces, thick smokes and fiery waters. But at the present time the plain itself, no otherwise than the Phlegraeon hills, drained by perpetual flames, is cavernous with infinite openings, and is everywhere yellow with sulphureous matter and color; the ground too is full of a blackness that, by its very darkness, strikes one with dread.

[Margin: The horrible lagoon. (Lacuna horrenda.)]

Yet in that same plain a Lagoon affected me with the utmost wonder. For it is found always seething with boiling and waxy waters; you would call it a cauldron boiling with pitch and resin, which from time to time changes its place, and, as the waters harden at the rim of the basin, is narrowed or widened together with the force of the exhalation, greater or lesser.

[Margin: The wonderful waters that boil up. (*Vis mira aquas ejaculans.*)]

This too is wonderful: that whirlpool throws the waters up beyond a man's height, to 8 or 10 feet, in the manner of a pyramid, and they are greasy and muddy and almost of a sulphureous color — which even the Puteolans themselves do not deny; they report that sometimes these boiling waters are flung aloft to 16, or even 24, palms, and this especially when the sea is in flood, but not when it is at rest. This is a most luminous indication that these marvelous effects of the upthrown liquid proceed from nothing else but the sea: for, agitated by the gales of the winds, while through the subterranean passages it stirs up the store-and-cellar [*promum condum*] of this liquefied matter, it is no wonder that the liquid — not knowing how to be confined within its narrow bounds — should be hurled aloft beyond the limits set for it by nature, and so much the more violently as the impetuous influx of the sea has thrust it forth with the greater violence. Indeed, the different color of the waters at that time too, composed of the various sea-water mixed with the various juices of minerals, plainly teaches this — namely that the subterranean winds, agitated by the marine tides and gathering strength among the flames, belch out the waters from the deeper springs of the earth. But when the sea is at rest, none of these things is felt; rather, the waters in the jaws of the lagoon are seen only greasy and squalid with black soot, together with a certain effervescence.

What shall I say of the mountains and crags with which this Vulcanian field is crowded? In these chimney-conduits not a few vent-holes are seen, some of which belch out a perpetual wind of vapors with a frightful sound and crash, with such force that, if you throw in a stone, you receive it again at once thrown back outward with great force; some discharge smoke mixed with flames. You would say you were set in the underworld, where all things are of a horrible, mournful, and dreadful aspect — nor are you only put out of your senses by the stench of sulphur, bitumen, naphtha, and other minerals. And although the place is so horrid, those nevertheless reap much profit from it who devote their labor to making sulphur, niter, and vitriol.

[Margin: The force of the vapors through the vent-holes of the field. (Impetus halituum per spiracula campi.) — (corresponds to the perpetual-wind passage above)]

Diagram. A large landscape engraving occupying the upper half of the page, depicting the Phlegraeian Fields (the Solfatara) near Pozzuoli viewed as a basin ringed by hills. In the foreground and middle ground, several conical hillocks emit columns of smoke (the fumaroles and boiling vents described in the text); a walled town with towers sits on a promontory at the left; the sea with sailing ships occupies the upper portion. A decorative cartouche at the lower right carries the engraved title.

- Cartouche (lower right): "FORI VULCANI sive Camporum Phlegraeorum Typus." [A View of the Forum of Vulcan, or of the Phlegraeian Fields.]
- Several small place-labels are engraved along the hills and shoreline but are too fine to resolve at this resolution [?] for the peripheral labels.

(continuation of Caput IV)

How they are prepared, however, will be told in what follows, in its place. Here we set out a figure of the place [Figuram loci], of those Phlegraeian Fields which we have described.

CAPUT V.

The fire-vomiting mountains visible on the external surface of the Earth sufficiently demonstrate that the Earth is full of fires.

[Montes Ignivomi in externa Telluris superficie spectabiles Terram plenam ignibus esse, satis demonstrant.]

If from any sign we can come to know the truth of the subterranean fire, surely we can do so from the flame-vomiting mountains and the other sulphureous craters which they call Vulcanos: we behold it so clearly from them that whoever should wish to deny it ought, in everyone's opinion, to be judged rash — not to say mad and stupid. For their multitude and variety is so great that there is scarcely any region in the world that does not exhibit them, as we have plainly shown in our universal Map [Mappa nostra universali]. And to begin with the better-known: there is in Sicily Aetna, the most celebrated in the records of both poets and historians, whose hidden constitution I shall describe in what follows,

being myself an eyewitness [Greek: αὐτόπτης (autoptēs, "eyewitness")] and an explorer of that mountain.

A hundred and fifty miles from Aetna lie the Liparitan, or Aeolian, Islands — called Hephaestiae by the Greeks, Vulcaniae by the Latins — and they are seven, namely: Strongylus, Liparis, Hiera (today Volcano), Hicesia or Salona, Ericusa or Alicur, Phenicusa or Phelicur, and Ecconimus — called by Ptolemy [Ptolomeo] Istica and Dydimia — which all, by Pliny's testimony, are said once to have burned; today Strongylus alone of the seven rages with fires not inferior to those of Aetna or Vesuvius. By Strabo's testimony, they are said once to have wholly burned, together with the mountains and the whole sea.

In the year 1638, when on the occasion of the Maltese triremes I was sailing past these islands, I made a descent and undertook to examine, among others, Volcano [Vulcanum] and Strongylus. Strongylus indeed, because of the fires which it continually belched, blocked off all approach; but Volcano, with its respites between vents, showed nothing but smoke. It has, however, an island attached to it which they call Vulcanello [Vulcanellum], joined to Volcano, which they say was born from the ejecta belched up by the mountain in its last eruption. All the islands teem with sulphur, niter, and bitumen; and that the bottom of the sea too is pierced through with countless caverns is indicated both by the whirlpools and by the frequency of the issuing winds that swell the sea in a wondrous manner. So that I cannot at all dissent from those who say that there are submarine threats and channels [minas & cuniculos submarinos] connecting with Aetna, and then, continued through the hollows along the spine of the Apennine, communicating with Vesuvius — which I found by experience to be most true in the year 1638, when Calabria was reduced almost to its utter ruin by the fury of earthquakes, being a present and eye-witness. See what I have related most fully on these matters in the Preface to this Work.

[Margin: The flame-vomiting mountains of Italy. (Montes flammivomi Italiae.)]

(continuation of Caput V — the catalog of fire-mountains of the world)

There is in Campania Vesuvius, whose history see, if you please, Reader, in the prolegomena of this Work; for when in the year 1638 I had climbed these mountains here enumerated, and had observed everything — not without manifest danger to life — the things I observed in them, surpassing all belief, had so much power over me that from this very source I drew the occasion and origin for undertaking the present work.

[Margin: The Vulcanian craters of Germany and of the other northern regions. (Germaniae Vulcanii crateres, caeterarumque partium Septentrionalis.)]

Etruria too has a burning mountain in the Apennine, and another in the territory of Felsina, that is Bologna [Bononiensi agro]; and besides, between Pistoia [Pistorium] and Petra Mala there is no lack of lagoons and caves belching out balls of flame, perpetually and especially at night. Two famous places full of fires are also noted in the Modenese territory, of which in what precedes. I come now to Germany, Gaul, and Spain; in which, even though mountains like those just enumerated are not seen, there are nevertheless frequent sulphureous craters and lagoons belching forth smoke and flames, and an innumerable multitude of hot springs everywhere — of which in their place — that offer the most luminous traces of the subterranean fire creeping within their hydrophylacia. In Meissen [Misnia], a Coal Mountain [Carbonum mons] from time to time rages with smoke and fire. In Lapland [Lappia] Olaus relates that lofty mountains belch out flames in the likeness of Aetna. In Iceland [Islandia], who does not know Mount Hekla [Heclam montem], most famous for its fires by the report of all geographers? To the miracles of nature there seems to be added the fact that its summit gleams with perpetual snow while it blazes with inextinguishable fires, and that, by the frequency of its hidden chasms, it grants no approach for many furlongs; and that, by the eruption of rocks and ashes, it reduces all the surrounding fields to sterility, together with a frightful sound and crash. When the inhabitants hear this, they more superstitiously believe that the souls of the wicked are tormented there with miserable wailing. See Olaus Magnus and the other geographers in the description of this island.

[Margin: The Vulcanian mountain of Greenland. (Groenlandiae Vulcanius mons.)]

And lest nature should seem to have left the farthest region of the North, condemned to the perpetual inclemency of cold and ice, without any remedy of heat, it has established a huge Vulcanian Mountain in the island they call Greenland [Gronlandiam], near the Pole; at whose roots there is a Monastery of the Order of Preachers [Dominicans], which they call St. Thomas's [D. Thomae], built of tufa-stones from the ejecta of the mountains. Concerning this, Bartholomaeus Zenetus the Venetian — the observer of all these memorable things, cast upon those shores, I know not by what chance — relates many things most worthy of admiration.

[Margin: Wonderful things about the Monastery of St. Thomas in Greenland. (Mira de Monasterio D. Thomae in Grunlandia.)]

His words are: "Here is seen the Monastery of St. Thomas of the Dominicans, and not far from it a fire-vomiting Mountain, from whose foot a fiery spring gushes forth. The waters of this spring being conducted through pipes, not only are all the cells of the monks heated like hot-baths [hypocausta], but food too — indeed the very bread — is cooked. The mountain belches up tufa or pumice, of which the whole monastery is built; for these tufas, once soaked with that water, are glued together as if bitumen had been applied. Here too are most beautiful gardens watered by that boiling water,

in which there are flowers and fruits of every kind. And this water, where it runs down through the gardens, falls into a nearby bay or harbor, whence it comes about that it never freezes over with frost; and therefore countless fish and birds resort there, on which the inhabitants live to satiety." So writes the man who saw it and discovered the coast, the Arch-admiral [Archithalassus] of the King of Denmark, Nicolaus Zenetus the Venetian.

It is probable, moreover, that Hekla of Iceland and the Volcano of Greenland correspond through hidden channels, and labor perpetually through hidden vents to subdue the violence of the cold and the ice. From this is concluded also the reason why, in some Northern islands and on the coasts of Norway, Finmark [Finmarchiae], Biarmia, and Lapland, on one side the sea freezes most easily, while on the other no force of cold and snow can make it congeal; and likewise why on some coasts there are found most abundant pastures together with the most fertile trees and fields, while on others — as in Nova Zembla [Novaya Zemlya] — neither grass nor trees nor anything useful for the nourishment of man is met with, the land being subject to perpetual sterility. This is plainly because the vents that lie beneath those places also gladden them with the wealth of things by their heat; and the contrary happens in those places under which the vents do not spread themselves out.

[Margin: In some Northern regions the sea freezes... (text trimmed at gutter; the marginal note continues the sea-freezing remark) [?]]

[Margin: The Vulcanian mountains in Asia. (Montes Vulcanii in Asia.)]

Asia abounds, here and there in many regions, with fire-vomiting mountains. On Ormuz [Ocmuzio], an island of the Persian Gulf, all things are full of subterranean fires, whence it is said to have burned for seven years continuously; and it still daily belches out balls of flame from the salt-mountains [salinis montibus] with which the island teems, by which the most celebrated emporium of the whole East has been nearly reduced to desolation. In Persia

itself sulphureous craters are found here and there, which, not without the horror of travelers, smoke and burn night and day. Cophantus, in the region of the Bactrians, by its fires strikes dread into all who behold it.

[Margin: In Media. (In Media.)]

In Media, at Susa, by the Tower they call the White [Turrim, quam vocant Albam], fire bursts out from fifteen chimneys, with a sound so violent that it persuades the surrounding peoples that the gates of hell are there.

[Margin: In Tartary. (In Tartaria.)]

On the coasts of Northern Tartary, by the reports of the Muscovites, workshops of this kind of Volcano are not infrequently seen.

[Margin: In the kingdom of the Chinese. (In regno Sinarum.)]

In the kingdoms of Hindustan [Indostan], Mogor [the Mughal empire], Tibet, and Cambodia [Camboia], mountains of this kind are found here and there, as also in the vast kingdom of the Chinese, as Father Martino Martini [P. Martinus Martinius] notes in his *Atlas Sinicus*.

[Margin: In Japan. (In Japonia.)]

In Japan, beyond the other islands, Vulcano seems to have established a notable abundance of workshops belching out smoke with fire night and day; and as these are 70 miles distant from Firando [Hirado], a famous city, so at night they illuminate the whole region like torches, to the wonder of beholders.

There are also islands neighboring Japan, which they call the Seven Sisters [Septem sorores], one of which exhibits a notable Volcano opposite the city of Tanaxuma [Tanegashima].

[Margin: In the Philippine Islands. (In Insulis Philippinis.)]

The Philippine Islands and the whole Archipelago of St. Lazarus [S. Lazari Archipelagus] so teem with Vulcanian places that scarcely...

Diagram. The famous double-page engraved cross-section of the Earth — the *Idealized System of the Subterranean Pyrophyllacia* (fire-reservoirs), of which the volcanic mountains serve as so many vents. The plate shows the terrestrial globe sliced open to reveal its interior. At the center is the **central fire**, from which a network of fiery channels radiates outward through the body of the Earth to feed numerous flaming reservoirs; these in turn connect, by way of fissures, to the volcanic mountains erupting at the outer surface. Around the globe, cherubic

wind-heads in banks of cloud blow gusts (the winds that fan and feed the eruptions), and a putto in the upper cartouche holds the engraved title-scroll.

The plate is **lettered** with a repeating key (defined in the engraved caption below):

- **A** (at and near the center of the globe): the **central fire** [ignis centralis] — the great innermost fire-reservoir from which all the channels proceed.
- **B** (repeated many times, the large radiant star-bursts of flame scattered through the Earth's interior, on both halves of the plate): the **reservoirs of Nature** [æstuaria Naturæ] — the subterranean fire-chambers (pyrophylacia).
- **C** (repeated, the branching vein-like lines that thread between the reservoirs): the **fire-conducting channels** [canales pyragogi] that carry fire from one reservoir to another.
- (The smallest thread-like rivulets, unlettered): the **fissures of the Earth** [fissuræ Terræ], through which the fiery exhalations pass to the surface.
- **(Volcanic peaks at the globe's rim)**: the fire-vomiting mountains breaking through the outer crust, with smoke and flame issuing upward.
- **(Cloud-borne human heads with pursed lips, in the surrounding sky)**: personifications of the **winds** blowing toward the mountains.

Engraved cartouche title (upper right): "Systema Ideale | PYROPHYLACIORUM | Subterraneorum, quorum montes | Vulcanii, veluti spiracula | quædam exystant." — *The Idealized System of the Subterranean Fire-Reservoirs, of which the Volcanic Mountains serve as a kind of breathing-vents.*

Engraved caption (running across the foot of both halves), translated:

This Diagram represents the nests of heat — or, what comes to the same thing, the fire-reservoirs [pyrophylacia] — distributed throughout the whole interior of the Geocosm. They are variously arranged, by the admirable workmanship of God, so that nowhere should they be lacking; this was so necessary for the conservation of the Geocosm. Yet let no one persuade himself that fire is really laid out in just the way this diagram depicts, [as if it were] established [precisely so]; and that the reservoirs are disposed in exactly this order — by no means. For who has ever observed these things? What human being has ever penetrated down there? Our sole aim with this diagram, therefore, has been to show that the bowels of the Earth are full of reservoirs and fire-chambers, whether they are arranged in this manner or in some other. From the center, then, we have led the fire out along all the pathways of the subterranean world, right up to the volcanic

mountains on the outer surface. The **central fire** is marked by the letter **A**. The rest are the **reservoirs of Nature**, marked **B**; the **fire-conducting channels** [canales pyragogi], **C**; and the very smallest rivulets are the **fissures of the Earth**, through which the fiery exhalations pass.

[?] A few words of the engraved caption fall in the gutter fold where the two halves meet (e.g. one or two words after *refert, co[...]* and *alio[...]*); the reconstruction above is from the legible remainder.

[End of Caput V. The chapter continues with the catalogue of fire-vomiting mountains.]

He may make manifest the offspring of Vesta conceived [within] — if not in mountains, at least in the craters and Charontic pits.

[Margin: The savagery of Mount Panacura in Java.] In **Java** [Java] there is a mountain on the island of Java not far from the city of **Panacura**. Although for many years before it had not burned, in the year **1586** it first burst open in a violent eruption of blazing sulphur and raged so fiercely that as many as ten thousand people are said to have perished in the fields below. For three days running it kept up its fury, hurling enormous rocks against the said city of Panacura, and it cast such a pall of smoke over it that, with the Sun blotted out, it turned day into darkness.

[Margin: Mount Pico in the island of Timor.] There was also another on the island of **Timor** [Timor], a peak of the same name [Mons Picus], of such height that for three hundred miles it offered a flaming summit to be seen out at sea. In the year **1638**, its foundations shaken by a horrendous earthquake, it was swallowed up together with the island, leaving nothing behind it but an enormous lake. So the *Annals of the Society of Jesus* [Annales Soc. Jesu] report.

Mount **Gounapi** [Gunung Api], on one of the **Banda Islands** [Banda Islands], after seventeen continuous years of burning, finally burst open in the year **1586** and threw out such a quantity of stones, ashes, and sulphurous-bituminous pumice that the sea was nearly covered with it and seemed wholly ablaze — with the destruction of all the fish and living creatures.

[Margin: Mount Pico in Sumatra.] On **Sumatra** [Sumatra] a huge volcano is to be seen, **Balalvanus**, so called in the native tongue from the vast quantity of fires it vomits forth.

[Margin: A remarkable fire-vomiting mountain on the island of Ternate.] On **Ternate** [Ternate], one of the **Moluccas** [Maluku], there is a mountain that, on

the testimony of Father **Maffei** [Giovanni Pietro Maffei], rises lofty and steep into the clouds. Its lower slopes are crowded with dense forests, while its upper parts, ruined by continual fires, are bare and barren. At its summit it has a crater, gaping in a vast opening, drawn in several rings from larger to smaller like an amphitheater. Here, especially when the Sun is entering the equinox, raging with smoke and flames under the blast of the north winds, it reduces all the surrounding region to a wasteland, covering it with ashes.

[Margin: On the fire-vomiting islands of Mauritius.] On the islands of **Mauritius** [Mascarene Islands], on the testimony of Father **Turellinus** [Orazio Torsellini] in his *Life of St. Xavier*, the subterranean fires are so powerful that the whole islands seem to be on fire. Hence the frequent earthquakes; and from the caverns and from the summit of Mount **Thola** it casts out such a mass of flames, ashes, rocks, and trees of no mean size that it seems to present an absolute image of hell. See the author already cited.

[Margin: Fire-vomiting mountains in the Pacific Ocean, commonly called *del Zur*.] In **New Guinea** [New Guinea] mountains of this kind were observed by the Dutch — as also in the **Southern Land** [*Terra Australis*] — to the great terror of the sailors. Similar ones were seen in that vast **Southern Ocean** commonly called the **Mar del Sur** [South Sea, i.e. the Pacific], though it has no name [for them]. In the **Indian Ocean**, here and there, deserted and rocky mountains display their smoking volcanic chimneys; all of which the *Universal Map* [*Mappa Universalis*] sets before you.

[Margin: Volcanic mountains in Africa.] Leaving the islands and the ocean behind, we come gradually to **Africa**, in which eight famous volcanoes are observed: in **Monomotapa** [Mutapa] two; in the Congo of **Angola** and in **Guinea** four; in **Libya** one; in **Abyssinia** [Ethiopia] one — besides countless craters and sulphurous caverns to be met with everywhere on all sides. Some of these, once their combustible material is consumed, have ceased to rage, as though by appointed truces, only to rage again in their own time once the material of their fires has ripened anew.

[Margin: The Atlantic Sea teems with subterranean fires.] The **Atlantic Sea** so teems with subterranean fires that the land which **Plato** [Plato] calls **Atlantis** [Atlantis] seems to have perished and been swallowed up for no other reason than the savagery of these fires and the consequent frequency of earthquakes. And down to this very day certain tracts of the seas, beset by flames and fires bursting up out of the fire-reservoirs, give ample proof of it — fires whose fury both **Columbus** [Christopher Columbus] and **Vespucci** [Amerigo Vespucci]

experienced at their own great peril, as may be read in the *History of the New World* [*Historia novi Orbis detecti*]. Nor are traces of this thing wanting.

[Margin: Pico in the Canaries.] The islands they call the **Terzeras** [Azores] can scarcely be inhabited because of the violence of the fires. The **Canary Islands** [Canary Islands], and on them the **Pico** [Pico del Teide], a mountain of immense height, belch fire down to this very day — as do the plains of the surrounding islands, stuffed full of sulphur and bitumen. On the dreadful earthquake that occurred in the year **1638** on the island of **St. Michael** [São Miguel], one of the Azores, and on the marvelous events that followed from it, see the fuller account we gave in the Third Book.

[Margin: The island of St. Helena.] The islands of **St. Helena** [St. Helena] and of **Ascension** [Ascension] once burned, as both the scorched rocks of their mountains and their plentiful ashes and coal more than sufficiently demonstrate.

[Margin: The mountains of America.] At last we gird ourselves for **America**, which, if I should call it the Kingdom of the Volcanoes, I should not be speaking improperly. In the **Andes** [Andes] alone — which the Spaniards call the **Cordillera** [Cordillera] from the unbroken chaining-together of the mountains, and to which the Kingdom of **Chile** [Chile] is subject — fifteen volcanoes are observed, on the testimony of the native Father **Alfonso d'Ovalle** [Alonso de Ovalle], who also marked them on a map. Some of these, swollen with the offspring of their fires, brought such calamities upon that kingdom in the year **1645** that a pen would scarcely suffice to describe them, with whole cities here and there both swallowed up and overturned. See the *Annals* of our Fathers under the year cited. To these we add the volcanoes that have been observed on the southern side of the **Strait of Magellan**, commonly called **Tierra del Fuego** [Tierra del Fuego].

[Margin: In Peru.] In the **Kingdom of Peru** [Peru] there are likewise found six inaccessible volcanoes of great height: three in the Andes, besides countless volcanic pits. In the province of **Carrapa** in **Popayán** [Popayán] there is a mountain that rages — chiefly in clear weather — with smoke and flames.

The city of **Paraquipa** [Arequipa], ninety leagues distant from **Lima** [Lima], has a neighboring sulphurous mountain that never ceases to hurl out fire, to the great dread of the people, lest, if it should ever burst, it bring final ruin upon the region.

At the Valley of Peru called **Mulahallo** [Mulahaló / the Latacunga valley], fifty leagues distant from the city of **Quito** [Quito], yet another volcano presents itself

to view: by its continual belching of fires and flames it threatens, far and near, even to peoples remote, the usual calamities.

[Margin: North America — 5 volcanoes.]

In North America, five [fire-vomiting mountains] have been observed: some in New Spain [Nova Hispania], some in New Granada [Nova Granata], and some in the interior districts of California and other parts of the Mexican realm.

In Nicaragua, thirty-five leagues from the city of León, a very lofty mountain hurls out flames in such quantity that they can be seen from ten miles [ad decem millia passuum] away.

Another, of similar ferocity, is found not far from Acapulco [Acapulco].

On the mainland of California there are three; and in the inland regions two more, concerning which see Father Andrés Pérez [P. Andream Perez], the historian of Mexico.

We have therefore surveyed the flame-vomiting mountains [montes flammivomi] set in place by provident nature, on land and sea, across the four quarters of the terraqueous globe — Europe, Asia, Africa, and America. This is not to say that such mountains do not exist, or could not exist, in those parts of the world still unknown; rather, these are the ones observed in our own age, during voyages and journeys by land and sea now so frequent around the world. And so that you may better grasp the diffusion of the [subterranean fire] through all the channels of the Earth, I have decided to insert a figure here, by which you will more thoroughly understand my meaning and intention.

[Margin: Where there is a volcano, there is a pyrophylacium beneath.]

COROLLARIUM [Corollary]

From this it is plain that the entire inner workshop of the Earth is furnished with countless pyrophylacia, and that it has been joined by the Author of nature in such partnership with the watery element that the world would sooner have to perish than have the one separated from the other. For wherever there is a volcano, that beneath it there lies a pyrophylacium is as certain as it is certain that beneath a furnace there lies a kitchen, a hearth, a cooking-pot, or something of the kind. Now just as the pyrophylacia penetrate through the innumerable cracks, fissures, and passages of the Earth — exactly as the [animal spirits] penetrate the inmost fibers of the muscles and nerves throughout the Microcosm — so too the hydrophylacia, exactly as the blood does in the human body through

the capillary veins, communicate themselves to the whole globe of the Earth through certain incomprehensible passages diffused on every side. And from this comes the great multitude and variety of hot springs [thermae] in all parts of the world, of which I will speak in their proper place and time. Nor is it always necessary that mountains alone perform the office of chimneys; rather, beneath the sea itself, just as in the dry-land regions, there lie hearths and pyrophylacia. Whenever these are seized by conflagrations, by the violence of the enclosed air they turn everything upside down, as has been said repeatedly in the preceding pages. Pyrophylacia of this kind also lie beneath the Archipelago [Aegean] in Europe. To show this, I shall add here, by way of a colophon [Coronidis loco], the account of Father Francesco Riccardi [P. Francisci Riccardi] of the Society of Jesus, who on the occasion of the dreadful earthquake that struck the island of Santorini [Santorinium] in the year 1649 — being himself present, the aforesaid Father saw the whole thing with his own eyes, afterward related the outcome of the entire affair to me orally at Rome, and wished it to be made known to posterity by the following testimony. As it is very fitting to my undertaking, I have decided to insert it here.

Account of Father Francesco Riccardi [Relatio P. Francisci Riccardi]

Concerning the subterranean fires that burst forth from the depths of the sea in the year 1650 near the island of Santorini in the Archipelago.

Although some accuse Pliny [Plinium] of falsehood, because he reports certain astonishing things beyond human comprehension, nevertheless we learn daily, with experience herself as our guide and teacher, that in many matters he spoke truly — above all when, in the books of his *History*, he lists the many islands that in the course of time burst up from the depths of the sea. Among others, we know that Thera [Theram], in the 135th Olympiad, was called Callista and Philotera. Now, from Saint Irene [Sancta Irene], the renowned Virgin and Martyr who is venerated there, it is called Santorini. For [Cardinal] Baronius [Baronius], in his *Ecclesiastical Annals* at the year 726, seems to confirm faith in Pliny, when he speaks there as follows: "A vapor was seen to boil up from a furnace of fire between the islands of Thera and Therasia, out of the depth of the sea, for several days; and as this gradually thickened and spread, the heat being kindled into a fire, the whole appeared as a smoke of flame. Moreover, by the vastness of the earthy substance it cast forth great pumice-stones and certain heaps of them across all of Asia [Africa?] [recte: Asiam], and Lesbos and Abydos and the Macedonian seaboard, so that the whole surface of the sea was filled with these

pumice-stones; and in the midst of so great a fire an island formed from a heap of earth — the island called Sacra — was joined together, not having existed before."

We have learned that the same thing happened in the year 1457 from certain verses carved on marble for perpetual memory, which are read as follows beside the gate of the Castle of Scaro [Castelli Scari] on the same island:

Great-souled Francesco, surest offspring of heroes, Crispus, you behold
with your eyes the disasters that have wrought wonders. Joining five
elevens to these two [i.e., $5 \times 11 + 2 = 57$], On the seventh day before the
Kalends of December, with a vast roar the immense and ruinous
Therasian [Therefinus], when it groaned, tore loose the rocks of the Muse
[Camenae] [?]; and a crag appears out of the lowest waves — a great
thing begets a memorable portent.

[Margin: The great force of fires beneath the Archipelago.]

That a second island, near to this one, was again formed is established for the year 1570, to the no less terror of the Santorinians, since the conflagration lasted for a year — as certain elders who saw it with their own eyes still testify. In the middle of this modest island, which is now called μικρή καμμένη [Greek: mikrē kammenē, "the little burnt (island)"], a vast and deep pit is to be seen down to the present day, which, narrow below, gradually opens out into a round shape like a funnel. Out of this, as out of a chimney, were hurled those huge rocks and crags which, mingled with ashes, built up that mass projecting above the waves.

Yet those subterranean fires, which are nourished by an abundance of bitumen and sulphur, are never quenched — and sometimes they break out with tremendous force. This is evident from the extremely hot waters found at the seashore in the far southern part of the island, which the islanders use as most healthful thermal baths to drive off illnesses arising from cold.

[Margin: Dreadful storms.]

But if ever those fires, shut up in the bowels of the Earth, exerted their power, it was above all in the year 1650, from the twenty-fourth of September to the ninth of October, when they shook that island with earthquakes so violent and so frequent that the Santorinians, fearing imminent ruin, prostrated themselves as suppliants at the altars day and night. Indeed, it cannot be told nor explained how great a terror seized them all, when — the barriers broken — those forces strove to make a way for themselves through the midst of the waves of the sea, about four miles from the island of Santorini toward the east. For suddenly the

sea swelled up to about thirty cubits in height, and spreading widely over the neighboring lands, it overturned everything in its path — so much so that at the very harbor of Candia [Crete], which is nevertheless eighty miles distant, it dashed galleys and ships to pieces with its sudden onslaught.

[Margin: The dreadful heat of the air mingled with fires.]

The air, moreover, infected with these foul and sulphurous vapors, began to grow dark and to draw on countless [terrors]: now you might have seen brazen pans and flame-vomiting swords brandished; now glittering arrows shot forth; now, as it were, terrible serpents and dragons flitting about; now lightning-flashes and bolts let loose.

[Margin: The mineral vapor harmful to the eyes.]

Though even seeing this was scarcely possible — for the eyes of those who looked on were so injured by those sharp and sulphurous vapors that, made almost blind for three days, they could not only see nothing but were seized with such great and grievous pain that they continually bewailed their wretched lot. But when they opened their eyes, they saw all their silverware and bronze [recte: brassware] —

[Margin: The provisions are removed by the multitude of ejected matter.]

— as well as their vessels, garments, and all their pictures, covered over with a tawny color. So great a multitude of fiery pumice did that whirlpool [vorago] vomit out, that they covered the surface of the sea like a sea itself, so that one could scarcely make headway in a boat. It is most certain that they were carried as far as Constantinople [Constantinopolim] and filled all the shore. The force of this conflagration was greatest in the first two months, since the neighboring sea seemed to boil like a seething pot, and day and night immense globes of flame and very dense heaps of smoke kept rising up.

When these were sometimes carried by an adverse wind toward nearer places, besides a most grievous stench they brought death upon birds and animals, and even upon human beings themselves.

[Margin: The death of birds and animals.]

So it happened on the 9th of October and the 4th of November that, besides countless birds, sheep, cattle, and asses, a multitude of fifty peasants, suffocated by that smoke, perished miserably. The same thing befell nine sailors who,

crossing there by night in a small boat, were after three days found all half-burnt and were buried on the island of Io [Ios].

[Margin: The new formation of an island.]

During the remaining four months, although that hellish hearth abated much of its vigor and heat, and could scarcely raise itself out of the waves, it nevertheless seemed to eject pumice and to labor at the formation of a new island — which, although it does not yet project above the waves, can nonetheless be observed as a shoal in a calm sea, the water barely floating eight cubits above it. And if it be asked whether those fires are now wholly laid to rest, the answer is that they are seen sometimes to revive, since it has been noticed that the sea there often seethes and lifts smoke up with its waves — most of all this present year, 1656, on the eleventh of January and the following days.

CAPUT VI [Chapter VI]

On the perpetual duration of fire, and on its fuel or sustenance.

[Margin: The subterranean fire is the active principle of all things.]

When the Maker of the universe and Lawgiver of all Nature had founded the Earth and at the same time produced the remaining elements of the sublunary region, with ineffable wisdom he divided the assembled mass of the elements he had disposed, and, having cut it, distributed it into its members. Hence, taking thought for the adornment of the universe — and likewise for the safety of living things, and especially of those that inhabit the Earth — he set a portion of the elements in the heavens, and the stars arose; another portion he joined to the Earth, in such harmony that they cannot be separated from one another except by the destruction of the whole. Fire in particular he enclosed in the inmost vitals and at the center, as a kind of active principle which should give form and life to all the rest, and which he bound to water, as to a passive principle, by laws of friendship so strict that — even though they may seem to be contrary — the one cannot be sundered from the other, inasmuch as by their reciprocal commerce both they themselves and all things that arise from them are conserved. And so God, the Best and [Margin: Greatest], is the efficient cause of the subterranean fire as of all the rest.

Since, therefore, the work of nature is the work of intelligence proceeding from its innate providence, God surely did not wish it to lack the support of the things necessary to it; for he who gives existence gives also the accidents that pertain to existence. And so, since these were the first principles of the world, they certainly

had to possess perpetual operations, lest in the course of time they should fail along with the destruction of all nature. From this is born that perpetual duration and perpetuity of natural operations and of the elements — which, just as no art or human industry can imitate, so it belongs to the omnipotence of the divine art alone. Its parts, although they may seem to perish, cannot perish or be destroyed according to their total being, since they stand subject to the rule of the law of nature.

[Margin: Perpetuity of motion in nature.]

Hence too is born that perpetual revolution of the stars, never failing; hence the motion of the elements, proceeding by a certain constant and inviolable law for so many myriads of years without failing—

[Margin: Pericyclosis (circulation) of things.]

—in the supreme variety of things, always invariable. Hence the perpetual circulation [pericyclosis] of the waters, both within the Earth and around it. And just as, according to the witness of the Wise Man [Sapiente] [i.e., Ecclesiastes], all rivers run into the sea and return from the sea whence they began to flow — the Sun empties the sea by means of vapors, and the vapors, resolved into rains, are soon restored to the sea from which they were drawn. Many wonder, when they behold Etna [Aetna] burning for so many thousands of years, and cannot grasp how a mountain not yet consumed by such long-lasting fires has not had its fire extinguished.

We have seen it surging when its furnaces are burst, [its hollows] and rolling flame-vomiting globes and molten rocks.

[i.e., Virgil, on Etna]

These men, surely, if they understood the cyclical operations of nature, would not wonder so greatly, since at no time is fuel lacking to it for perpetuating its conflagrations — as we shall demonstrate later.

[Margin: The fuel of fire is perpetual.]

Conflagrations burn up mountains and turn their mixture of combustible matter into ashes; from the ashes mingled with water is born a new fuel for the perpetual fire, as will be demonstrated later — and so:

All things are continually turned in rapid orbits, with nature perpetuating her own motions.

There were many of the Peripatetics [Peripato] who, since they could not conceive this perpetual fire, were of the opinion that it does not truly and really pre-exist, but is born ever anew, by a fresh generation, from spirit [or vapor] agitated in the caverns of the mountains. But this is by no means the case; for the spirit that comes from waters set in motion and dashed about is always cold and moist, and is therefore affected by a foreign quality of the air, one most contrary to ignition. With the most violent blast of Boreas [the north wind] too, the air is so far from catching fire that rather, in winter time, it freezes at the first breath. Nor can so tenuous a substance as air be ground down, except by the hardest bodies most violently collided against one another. It is therefore impossible that a tenuous, cold, and moist spirit should kindle fire in any matter, however well prepared. That there is therefore in the bowels of the Earth a cause of such great conflagrations and heats has been made plain from what precedes — which we call the [subterranean fire], by whose action the metals are concocted, the fossils and minerals brought to maturity, and whatever else of combustible things the Earth brings forth derives its origin from this source. Yet I say that the subterranean fire is stirred up, as by a kind of fan, by spirit excited from the waters set in motion:

And so it casts up flames and overturns rocks and raises clouds of sand.

[Margin: Why the subterranean fire does not fly off.]

There are, furthermore, others of the Peripatetics who wonder why the subterranean fire, disposed in the lowest receptacles or pyrophylacia of the Earth, does not fly off from there and seek the higher and natural regions [of fire]. To these we reply that God founded the world with such a subordination of bodies, and with so continuous a connection of them, that one cannot be drawn apart from another without the destruction of the whole of nature. For from such a separation — since one body cannot succeed to another without the dread of a vacuum, than which nothing is more contrary to nature — air, water, and fire so rigidly guard the territories of their own jurisdiction against the common enemy of nature, that, with nature unharmed, they cannot be separated and torn from one another by any violence whatever. There is nothing fortuitous where the highest Wisdom has arranged all things; nothing violent, where things of their own accord obey the laws of their particular [governing] nature.

[Margin: Objection.]

Here I hear the Peripatetic murmuring against me with this argument: Wherever there is a contrary, there the corruption of the one must intervene. Fire is

perpetually joined to the terraqueous globe, its contrary; therefore necessarily either the water will quench the fire, or the fire will consume the water. The reasoning is plain from the Philosopher [Philosopho] [Aristotle]: Whenever an active and a passive are present together, one must always act and the other always be acted upon; fire behaves after the manner of an active principle, and the terraqueous globe after the manner of a passive principle; therefore from the reciprocal motion of things a transmutation must necessarily arise.

[Margin: Solution of the proposed doubt.]

I reply: If these elements be considered in the highest and equal degree of intensity, that is true; but if they be considered in a disparate degree, according to the predominance of one over the other, it is false. For from the first supposition it would follow that all things would always be corrupted, nothing generated, nothing victorious — and so this whole machine of the world would long since have ceased to be. Therefore, since heat prevails over cold, and fire over earth, fire will always prevail by its own activity against earth and water. And lest at last the whole globe should collapse from so many continuous conflagrations, the provident nature of things always supplies it with fresh and fresh fuel, so that as much as the fire feeds upon, so much the terraqueous globe, in which it is enclosed, supplies it anew. Nor is there any danger that it should ever be extinguished, since nature has assigned it so many chimneys for breathing, so many hidden routes and secret paths of channels for drawing in new supply. But how these fuels and sustenances may endure by perpetual circulation, we have undertaken to set forth.

We said in the preceding pages that the whole Geocosm consists of salt as its proper element; that from the Earth the sea draws that [salt] everywhere and on every side, from the beginning of things, as into its own nourishment; and that from salt is born, on land and sea, that fatty substance [pingue] by which all things contained both outside and within the Earth live, are nourished, and are conserved. For this is, as it were, a kind of glue and balsam of nature, without which nothing would coalesce, nor would any of the heterogeneous things curdle into one substance. This, then, joined to suitable earthy clods, produces now sulphur, now Mercury, now another kind of mineral — both on account of that innate heat, and on account of the moist and fatty or unctuous element, which is found to be present abundantly in salt. I said "to suitable earthy clods"—

—appropriated, because, since the Earth abounds especially in sulphurous substance, the salt, joined together with its own fatty part, continually produces new and new sulphur. So too, joined with that primal unctuous moisture, it

produces — in another, similar matter already disposed and lying hidden among the fibers of the Earth — quicksilver [hydrargyrum]; and in other places, according to the disposition and sympathy of the earthy parts, it brings forth now these, now those juices, and other minerals, after the long labor of nature combining individual things, attracting like to like, and adapting each one to produce such an effect and not another.

But that salt is the cause of all these things, we show as follows.

First, that the salt of nature is a kind of seed, and one of the three natural principles. Secondly, that it contains within itself both the hot and the moist, the two other principles of nature, which can be separated from one another by no force of nature. And so it is so diffused throughout the substance of the whole terraqueous globe, that no portion of earth can be assigned so small — of whatever condition it may finally be — from which, by the spagyric [chemical] art, it is not separated; and thus every natural body, in the ultimate resolution of its parts, leaves behind nothing other than salt. And this indeed, just as it is accepted by all philosophers, so it has no need of further experiment. Yet that this salt has a fatty or unctuous something implanted in it by nature, and wholly inseparable, we have thought worth proving by experiment, so that it may be plainly established that salt, just as it is present in all things, so likewise nowhere lacks its own fatty part.

[Margin: Salt diffused through all things.]

EXPERIMENTUM [Experiment]

[Margin: A certain fatness is present in all things.]

Choose uncultivated earth, never improved by any benefit of manuring; dry it in the sun, pound it fine, reduce it to powder, and distill it through a retort as is customary in [making aqua fortis / acidic waters] [in stygiis aquis]. Then remove the receiving vessel, and you will find the genuine fatness of the earth floating upon the water (which had at first been deliberately placed within the receiver), having a slightly bitterish salt taste. It is therefore plain that the earth is full of fatness and stocked with oily matter, from which all things — whether of the inanimate, or the vegetable and sensitive kinds — draw their nourishment. Earthworms, the proper children of this terrestrial fatness, are so filled with it that, when prepared by the spagyric art, they are resolved almost wholly into an oily fatness, useful for many infirmities. There is no plant that does not draw from its benign mother something like itself, together with salt, for the conservation and nourishment of nature; and these in turn, just as they pass into

the nourishment of animals, so also these animals communicate to others, freely — now more, now less, according to the condition of each — that good so greatly necessary which they had drawn from the earth.

These things, then, being supposed as most true principles of nature, let us now pursue the argument we first set ourselves: concerning the perennial fuel of fires. We said in the preceding pages that the terrestrial body is everywhere stocked with salt and with fatty, unctuous matter. This, first drawn off by the sea through natural suction, is converted into that salty and unctuous substance which the sea presents to us. And that this is so, the effects of seawater sufficiently show: for it stains clothing and cloths, and besides being unfit for washing them — spoiling them with I know not what corrosive burning — it is utterly useless for quenching fire, since by reason of that fatty part mixed in it, it does not, I will not say quench the flames, but rather increases them.

[Margin: The Earth abounds in salt and fatness.]

We said, furthermore, that the terrestrial body does not consist of homogeneous, but, however much of it there is, of heterogeneous matter and clods, so disposed by nature within the inmost and throughout all the channels of the Earth, that, by the vapors and exhalations stirred up by the subterranean fire, it produces this or that mineral most agreeable to each fossil — where the disposition of the clods is sulphurous, sulphur; where mercurial, Mercury; and so of the rest — by means of the salt and the said fatty unctuous part.

[Margin: The whole body of the Earth is heterogeneous.]

But since in the course of time matter of this kind, seized by the subterranean fire, is consumed in perpetual conflagrations, something else continually had to be substituted. Let us now explain how this comes about. It was said in the preceding pages that the sea, stirred by the influential power of the Sun and Moon, is engaged both in the perpetual and unfailing agitation of ebb and flow, and is troubled by the storms of winds and tempests, by its annual, monthly, and daily motions.

[Margin: The ebb and flow of the sea is the instrument of nature for sustaining her actions.]

By the continual urging of these, the sea, compressed through the hidden meanderings of the depths, charged with the sulphurous, saline, and aforesaid fatty spirits in which it abounds, is diffused into the inmost recesses of the Earth. There, where it finds matter disposed, it makes it fertile by its seminal virtue, and

by a fresh supply restores the fuel that had been consumed by the fire. And in this way it continues, by a certain perpetual circulation [pericyclosis], the kindling of combustible matter, from the very first beginnings of things into future ages, and right up to the consummation of the world itself.

But that these things may be made more clearly evident, we have decided to demonstrate the point by the single description of Mount Etna — since the same principle holds for all the volcanic mountains.

CAPUT VII.

LIBER QUARTUS, Sect. I.

DESCRIPTION OF ETNA.

In which, as in a kind of prototype of subterranean fires and of the reasons for their inexhaustible fuel — as the saying goes — these things are demonstrated to the eye.

When in the year 1638 I was traveling throughout Sicily, I judged that before all else I should examine Mount Etna, the most celebrated of all in the records of every writer. It is, I say, the most famous prototype of burning lands — indeed of virtually every kind of upheaval that rages on land and sea — and on this account alone Sicily is admirable, since it is the unique spectacle of nature. You will scarcely find any author, whether among the ancients or the moderns, whom the violence of this ferocious natural force has not drawn into wonder and astonishment. Yet because they have observed the genuine causes of such great effects only from a distance, I, approaching somewhat more closely and intending to set forth the constitution of those things observed by me κατὰ τὴν ἀκρίβειαν [Greek: kata tēn akribian, "with exactness / precision"] in these most recent times, will undertake to demonstrate opportunely the causes of all these so extraordinary effects.

[Margin: The size of the mountain.]

Etna, then, is a singular mountain, raising its summit aloft to 30,000 paces measured along its axis — as Maurolyco [Francesco Maurolico] and Clavius [Christoph Clavius], who explored its height by geometrical reasoning, attest. It occupies a space of 60,000, or as others say 100,000, paces with its encircling base. It is fertile in the fat surrounding fields, vineyards, and pastures spread about it, and wooded with pinewoods, beeches, and the loftiest firs; but toward the topmost summit it is broken and rugged with unstable ash and pumice. Across a

vast circuit of 12 miles it gapes open into a crater, which, by a steep inward slope, narrows down all the way into the abyss — a precipice horrible to behold, with flames and smoke bursting forth, both from its depths and from the sides of the mountain, with a dreadful roaring not unlike thunderclaps. So formidable is it that the mere imagination of fire and ruin now on the very verge of breaking out confounds anyone, however bold and intrepid, at the first encounter, and turns him away as from some infernal pit.

[Margin: The breadth of the crater and its horrendous appearance.]

Nor do I doubt that those frequent conflagrations, seen here throughout every age, have somewhat increased this vast mountain by the continual discharges of ash. This is abundantly shown on every side: by the cadaverous, ashen, and pumiceous aspect of the burnt crags along its slopes, and by the appearance of enormous caverns (one of which, easily capable of holding 30,000 men, I was permitted to see), formidable with pumiceous embers and with the refuse and dregs of variously melted mineral matter. In many places you may see, made of the said material — which they call *sciarra* — the tracks of vast torrents, left behind as it were like certain traces of the great devastations once wrought by the fiery flow of the molten metal.

[Margin: The tracks of the fiery rivers.]

At the summit, snow and ash, meditating an eternal union, seem to have covered everything with a sad and mournful countenance — all the more perilous to those who approach incautiously, in proportion as the chasms covered over by a certain deep snow and ash, stretching without bottom into the innermost abysses of the mountain, are the more frequent. As these have swallowed up many who approached too rashly without a guide, so by their own ruin they have given an example to the rest that those places are not to be approached carelessly — places which mock the lives of mortals with such hidden contrivances and concealed snares. In just this way Father Matthaeus Taveran [Matthaeus Taveran][?], being too eager an investigator of natural things, experienced great peril to his life as an explorer of this mountain. And to embrace much in few words: the entire material of the upper mountain seems to be nothing else than an incoherent mass, suspended within itself, of ashes, pumice, and the stones they call *lithanthracites* [coal/antracite]. Since this mass is on every side exposed both to the interior mineral spirits within and, without, to snows, rains, hailstorms, and winds, and is easily penetrable, it ought to seem no wonder to anyone that this scorched and burnt-out material — as it is impregnated by an ever-new supply

coming from the sky — should in the course of time conceive new offspring, so as to burn again and to blaze without end, again and again. As Virgil too attests:

[Margin: The generation of new combustible material.]

Whatever other matter is fertile for fire, once it has been kindled, dies, and nothing remains for it to renew: only ash, with no seed of earth. But this, enduring once and again, and with a thousand fires drawn off, restores its strength.

For since in the lowest depths the fire is never at any time extinguished, but always sends forth some trace of itself — either heat, or smoke, or flame, as I observed many times in examining the mountain — yet outwardly it begins to rage only at certain intervals of time, more or less according to the heaped-up quantity of combustible material. And the longer it has lain quiet, the material being as it were the more invigorated toward conflagration, with the greater violence does it exert itself, and along with the flames themselves it hurls vast heaps of sand. As Lucretius asserts:

And at the same time it thrusts out rocks of wondrous weight.

Diagram. The left half of a large double-page engraved plate depicting Mount Etna in eruption. At upper right the plate bears the slug "Tomus I. 186" (referring to printed page 186). The left side of the scene shows a steep, jagged volcanic flank: flames and dense billowing smoke pour upward from a vent at the base of the rocky escarpment, carrying glowing ejected stones aloft into the smoke column. The smoke twists into tall serpentine plumes against a sky filled with massed clouds; small birds are scattered across the upper sky. Below the rocky slope, the foreground falls away toward a band of churning flame or fiery torrent running across the bottom of the plate; at lower left a row of small human figures (a file of people, perhaps a procession or fleeing crowd) is engraved at the foot of the slope. To the right, the terrain descends into cultivated, tree-dotted lowland with cypresses and what appear to be orchard rows. No engraved labels other than the page-slug are present.

Diagram. The right half of the same double-page engraved plate, carrying the plate's title cartouche. The titling, set in open ground at the upper left of this sheet, reads:

- (upper left, title): **TYPVS MONTIS ÆTNÆ** — "A representation of Mount Etna"
- (below title): **ab Autore Observati** — "as observed by the Author"

- (date line): **A° 1637.** — "in the year 1637"

The scene shows the great mountain at right: a towering, smoke-belching volcanic peak whose right-hand flank erupts in flame, with a massive twisting column of smoke rising and ejected glowing rocks flung out from the burning slope into the sky. The sky is filled with banked clouds and scattered birds. In the foreground a large tree stands at left, with wooded and cultivated slopes descending across the middle ground; orchard rows (regularly planted trees) cover the lower right slope. At the foot of the mountain, near center-bottom, a small walled town with towers and domed buildings is engraved, labeled beneath it:

- (town label, lower center): **Catana** [Catania]

A band of churning flame or fiery flood runs across the bottom edge of the plate, continuous with the corresponding band on the left half. The two sheets together form a single panoramic view of Etna erupting above Catania.

[Note on the page sequence in this stretch: is the printed text page 186 (start of Caput VII). are the two halves of a single fold-out engraved plate of Etna belonging to that page (left half slugged "Tomus I. 186"; right half titled "TYPVS MONTIS ÆTNÆ ... A° 1637", with Catania below). is the largely blank verso of one plate sheet, showing only the bleed-through/offset of page 186's marginal notes (legible fragments: "Fumi perpetua eructatio," "Sonitus fragoresque formidabiles," "Ignium eruptiones in locis variis visuntur," "Spelunca ingens," "Longitudo & latitudo torrentium igneorum," "Magnitudo Montis," "Crateris amplitudo & horrenda facies," "Semitæ igneorum fluminum") — no independent body text. These marginal notes are the printed sidenotes of p. 186 and are rendered in their proper places above.]

CAPUT VIII. — Description of the Crater of Etna

The crater of Mount Etna has been found by different observers to be of differing size. There are those who say they have observed it to be 2,000 paces wide plus 80 paces; others, 30,000 paces; and still others, 400,000 paces. But it cannot be otherwise: in a mouth exposed to such great upheavals, continually shaken by so many onslaughts of a raging nature, the crater is bound to be found now wider, now narrower, according to the conditions of the moment. I myself have observed this with the greatest astonishment — not only at Etna, but also in the mountains of Lipari [the Aeolian Islands], and indeed at Vesuvius.

[Margin: The perpetual eruption of smoke.]

Whenever a more violent eruption of combustible matter occurs, the mountain is shaken, and from that concussion the heaps of more diseased matter that have been piled up on the mountain collapse with the shock of the mountain — heaps which are now pregnant, as it were, with new offspring. In this way they furnish fresh fuel and nourishment to the fires. And so, from this collapse of the mountain's masses, the crater is necessarily made wider; whence it happens that the interior of the mountain, by gradually growing, rises up, and the emptied spaces of the diminished crater are filled in again — by which, equally, the crater of the mountain must be made narrower. Indeed, the histories report that the matter heaped up within from such collapse has at times grown so much that [the text continues at the foot of the column —]

[Margin: A dreadful sight, the chasm of Etna.]

[Margin: The depth of the chasm.]

— what had accumulated over so many years, shaken loose by dreadful tempests of fire, is vomited up right to the lowest abyss of the mountain, as is seen today. This spectacle is so terrifying that, with the hair standing on end and the head spinning with vertigo, no one is so stout-hearted that he can look upon it without dread. The chasm is so deep that it escapes all sight; it is to be feared for the crags rising up from its sides in the shape of pyramids; and since the walls descend downward in a straight, perpendicular, parallel run of cliffs, yet — by the laws of optics — they appear to converge at the center on account of the excessive distance. This has deceived many observers, who, taken in by this optical illusion, supposed that the inner sides of the mountain narrow into a conical surface.

Returning to the foot [of the chasm] — a marvel to relate — the mountain, by its continual eructation of mineral matter, is always (I know not how) at work in constructing the mountain's fabric anew. There, just as I always remember having observed, there is a kind of lake gleaming with molten metal; the sides everywhere, through corresponding passages, belch out perpetual smoke in very many places, which by night we have found to be a kindled flame. The abyss is never without a roaring and bellowing, which it sometimes utters so horribly that it makes the very mountain tremble. In a word, whoever desires to behold the wondrous power of God Most High, let him approach mountains of this kind; and, dumbstruck and stupefied by the ineffable effects of nature's miracles, he will again and again be compelled to declare, with the deepest feeling of his heart: *O the depth of the riches of the wisdom of God! How incomprehensible are your judgments, and how unsearchable your ways, by which you have established the World!* [Romans 11:33, adapted.]

The mountain is so high that from it the whole of Sicily can be taken in, and indeed, when joined by a favorable moment, the view reaches as far as Africa. But if the mountain is disturbed by some storm, you may reckon the lives of those present there finished — so dreadfully is everything wrapped up in whirlwinds, in snow, and in ashes.

[Margin: The eruptions of fire visible in places.]

I said a little earlier that copious smoke mingled with fire is given off from the sides of the mountain in many places. These vents, if in time they happen to be blocked up — whether by the shaking of the mountain or by some other accident — then, when the mountain's fury is imminent, have been found to prepare an exit even from elsewhere, through the outermost surface of the mountain. And where this happens, it produces such dreadful openings of the mountain, and such fearsome passages of caverns, that we gaze upon them to this day, astonished with wonder that they ever existed.

[Margin: An enormous cavern.]

I have seen a cavern that could easily hold an army of 30,000 men, as we mentioned a little earlier. There is also in the same place a most gloomy cave, which they call *la Grotta della Palomba* [the Cave of the Dove], of such depth and capacity that the inhabitants of the mountain believe an approach is granted in it, by a submarine route, to the Aeolian Islands. From these and similar grottoes, fiery rivers once burst forth, as the bed nearby — heaped with pumiceous and burnt-out rocks, which the Sicilians call *sciarra*s — abundantly proves.

[Margin: The length and breadth of the rivers of fire.]

These torrents of molten fire have, the histories relate, sometimes flowed to a length of 18,000 paces, and to a breadth of now 1, soon 2, 3, or 4,000 paces — so that no one can wonder enough where so incredible an abundance of molten matter has its origin, in what places it has its workshops and smelting furnaces hidden away, of such great capacity for the liquefaction of so many minerals and metals.

LIBER QUARTUS, Sect. I. — [continuation of Caput VIII]

But just as these inaccessible works of God are most remote from all sense-perception, so neither can they be sufficiently penetrated by any human intellect. We may only marvel at what cannot be grasped in the incomprehensible majesty of the divine works. For if you reckon the amount of molten matter according to

the computation of the various periods of time, you will find that it grows into so great a heap that by its own mass it far exceeds twenty Etnas.

But, in order to confirm our reasoning more clearly, I shall append here a brief Chronicle of the more notable eruptions, by which the mountain, raging with dreadful devastation all around, has in no age failed to display its fires.

Chronicle of the Eruptions of Etna

[Margin: The wondrous works of God displayed.]

1. [Margin: In the time of the Janigenae] Time when the Janigenae [the descendants of Janus] first entered Sicily seeking new colonies — Berosus relates that the mountain's eruption was so great that the colonists, fearing devastation, abandoned the island and departed from here to seek other colonies in Italy, deeming it a most unsuitable settlement — one which nature's ferocity had rendered fearsome through so many and such deadly ruins. So it may be that on this occasion the fable of the rape of Proserpina was introduced.
2. [Margin: In the time of the Sicani] After the Janigenae, the Sicani — Driven off by new whirlwinds of Etna's eruptions, they were compelled to abandon the eastern part and to inhabit the western.
3. [Margin: Of the Argonauts] In the time of the Argonauts — When the most ancient Orpheus had seen it, he sang thus: *"Now, holding the Sicanian straits at Lilybaeum, we sense the waters, and we see flames across the heights, threatening us with the menace of Aetnaean Enceladus."*
4. [Margin: Of the expedition of Aeneas] In the time of the expedition of Aeneas [Aeneae] — He, repulsed from the shore of Sicily by the Cyclopes and terrified by the mountain's fire, abandoned that deadly station and betook himself elsewhere. So Virgil, *Aeneid* III: *"Unknowing of the way, we glide to the shores of the Cyclopes. The harbor itself lies unmoved by the winds' approach and vast, but hard by, Aetna thunders with fearful crashes. At times it hurls forth to the sky a black cloud, smoking with pitchy whirlwind and glowing embers, and flings up balls of flame and licks the stars; at times it heaves up rocks and the torn-out entrails of the mountain, and erupting, with a groan rolls together molten crags beneath the air, and boils up from its lowest depths."*

5. [Margin: Olympiad 2, in the time of Thucydides; Pythagoras, Empedocles] Under the dominion of the Greeks in Sicily, namely from the 2nd Olympiad up to the 88th — According to Thucydides, who was living at this very time, the mountain blazed up with three great eruptions; at which time, a little later, the mountain raging again is said to have drawn even Pythagoras himself into the greatest astonishment. Then, in the time of Hieron [Heronis], the histories relate that Empedocles, an observer of the mountain, perished.
6. [Margin: Of the Roman Consuls] In the time of the Roman Consuls — It is gathered from various authorities — Diodorus [Siculus], Polybius, and others — that four eruptions of the mountain occurred.
7. [Margin: Of Julius Caesar] In the time of Gaius Julius Caesar [C. Iulii Caesaris] — Diodorus relates that Etna raged most violently — which they hold also to have portended the death of Caesar. So great was it, the report goes, that by its heat it even burned the very ships in the sea as far as Lipara, all the fish being killed off and cooked; and within 20 years the mountain caught fire four times.
8. [Margin: Gaius Caligula Caesar; Hadrian Caesar climbs the mountain] In the time of Caligula [Caligulae], 49 years after Christ — The mountain raged again so fiercely that Caligula, then staying in Sicily, seized with terror of the impending disasters, abandoned Sicily and withdrew to safer stations. Hadrian Caesar [Hadrianus], however — out of the great magnitude of his spirit — is reported to have climbed the mountain, while it was still seething, some way up, in order to consider such great marvels at closer range.
9. [Margin: Around the martyrdom of St. Agatha] Around the martyrdom of St. Agatha — By whose merit and intercession it came about that the mountain, however much it raged, did not dare to reach Catania.
10. [Margin: The time of Charlemagne] In the time of Charlemagne [Caroli Magni], the year 812 — He too, terrified by the savagery of the mountain, is said to have sought safer places.
11. [Margin: The year 1160] From the year 1160 up to the year 1169 — All Sicily was shaken by great earthquakes; Mount Etna, boiling up, overturned all the surrounding places with enormous devastation, including the ruin of

the Cathedral church of Catania, in which Abbot John [Abbas Iohannes], together with his monks, was crushed and perished.

12. [Margin: The year 1284] The year 1284 — A fearful eruption occurred around the death of Charles, King of Sicily and Aragon [Arrogoniae].
13. [Margin: The year 1329] The year 1329 up to [13]33 — The mountain raged dreadfully, in the time of the King of Aragon.
14. [Margin: The year 1408] The year 1408, under King Martin.
15. [Margin: The year 1444] The year 1444 up to [14]47, again and again.
16. [Margin: 1536] The year 1536 up to [15]37.
17. [Margin: The year 1633] The year 1635 up to [16]29 [recte: 1635 to 1639?] — An eruption raged the more terribly, the longer it lasted; and since very many have described it, I do not linger on recounting it. Finally, in the year 1650, raging again from the northern and eastern quarter, with the mountains burst apart, it vomited up so great an abundance of fires that it nearly brought Bronte [Brontium] to the utmost peril and destruction by its fiery torrents. See Carrera, *On the Antiquities of Catania* [Carrerus, *de Catanens. Antiquit.*]; Philotheus; Musculus [Musselus]; and others.

[Margin: The mountain is increased by eruption.]

COROLLARIUM I. [Corollary I]

From these things it plainly stands established that the mountain, its matter once consumed — now to a greater, now to a lesser degree — has held off [erupting], until, augmented by a new supply of combustible matter, at last bursting forth, it has presented those catastrophes which we read of with wonder. And yet it is so far from being diminished by such great eructation of matter, that it rather appears to have been increased. For indeed, when the citizens of Catania were digging for pumice, at a depth of 100 [?] paces, the earth being opened up, they found streets paved with marble

[—] and various traces of antiquities, which plainly show that cities founded here in former times were buried, with great increase to the mountain, by the mountain's ejecta. They found, moreover, several bridges of pumice, which were formed solely from the flow of the fiery torrents, the softer ground having been eaten away. A flame, too, raised up from the earth, now appears and now disappears — which are clear indications of a soil raised up by fire.

[Margin: Whence comes the new nourishment that accrues to it.]

But these things are well known. This one thing is what has tortured the minds of philosophers in a wondrous way: that they do not grasp from where ever-new fuel is supplied to the voracity of the perpetual fire, and how, in the course of time, pumice, ashes, and the rest of the refuse of burnt-out matter are converted into new matter fit for fires. That this knot may be untied:

[Margin: How salt lies hidden in ashes.]

I suppose, first, that in ashes there lies hidden abundant salt — which is proved even from this, that salt is obtained by no easier method than from the lye of things reduced to ashes. In this way niter, salt, and alum, blooming out from the walls in certain damper places, and likewise dug out in most copious yield from the stalls of doves and other animals (first activated by urine), are obtained. Of these matters I shall treat expressly in their proper place.

I suppose, second, that from the sea — imbued with moist, rich brine and a mixture of other mineral substances — there is drawn out, by the power of the Sun, an enormous abundance of exhalations together with the spirits of the said substances and with imperceptible corpuscles. These, dissolved partly externally into rains, hailstones, and snows, fix their seats around the summits of the highest mountains; and partly, channeled internally through the subterranean passages of the sea, they fertilize the matter of the pyrophyllacia with a new influx, as was indicated above.

[Margin: How the nourishment is newly produced.]

These things being supposed, I say: The fire that flourishes perpetually in the pyrophyllacia is perpetually augmented through the hidden fibers of the sea entering in, while it fills the matter consumed by fire — such as ashes and the most porous stones of pumice — with sulphurous soot and bituminous spirits, and to some degree prepares and disposes it for ignition. But when, by the heat of the Sun on the one hand and by the action of the nearby latent fire on the other, hail and snows are melted, and when rains pour down upon the powders and ashes drenched in most copious sprinkling, then a certain mixture is born; and this, insinuated deeper within the porous recesses of pumice, and with the sulphurous and bituminous spirits (which had long been nesting there) intervening, at last — as soon as it has matured — becomes the fuel and nourishment of fire.

That this is so I have learned by irrefragable experiment at the brinks of the fire-burnt valleys of Etna, Vesuvius, and Strongylus [Stromboli]. In most of their ashen walls I found an immense abundance of blooming salt, alum, and niter; and in some, also a flow of bitumen, naphtha, and similar oily liquors, together with a most copious abundance of sulphur. These had drawn their origin from no other source than partly from the ashes of burnt-out things (from which a new progeny of salt and niter must necessarily arise), and partly from the sulphurous corpuscles or spirits which, as they continually exhale from the abyss of the mountain, are condensed into sulphur in the colder region of the mountain. And so, from salt, niter, alum, bitumen, and sulphur, that mixture is born which, insinuated within the pores of pumice and of rocks burnt to lime, supplies that perennial fuel which we have until now been seeking. For this, corrupted by fire, prepares new conflagrations; and so, when what lay hidden within the pumice — the rich, sulphurous matter — has been burnt up, it sustains some intermissions, until the relics of pumice and lime are refilled, as has been said, with a fresh brood of combustible matter.

That what happens on the exterior surface of Etna also happens in all other flame-vomiting mountains — nature acting in the same manner in all — is certain. Indeed, that nature preserves, in the same tenor, in the innermost pyrophyllacia, the very process which we have set forth on the exterior surface of the mountain, cannot be unknown to anyone who has penetrated these matters more deeply.

COROLLARIUM II. [Corollary II]

From this it follows that the fuel and kindling of the subterranean fire follows the motion of the sea as it surges with the perpetual reciprocation of flux and reflux. For from the sea's agitation this [fuel] is thrust through the hidden passages (as has often already been impressed) and, joined to its own rich and moist [matter] — which nests in the innermost recesses of the earth under sulphurous clods, hot and dry — by an unceasing brood of new generation restores what has been consumed. But on the external surface, through vapors drawn up by the sea and impregnated by the said birth-stuff of the sea, it lays down a new generation within the porous chambers of matter already burnt — through snows, hailstones, and rains mixed with powders and ashes — so that in its own time that matter, now matured, may at last burst forth into great conflagrations. You see, therefore, the wondrous and unfailing cycle [pericyclosis] of nature in her operations.

COROLLARIUM III. [Corollary III]

[Margin: The formal cause of the eruptions, the material cause.]

From these things it follows that the formal cause of this mountain's eruptions is fire itself; the material cause is sulphur and salt, niter, bitumen, and similar matters apt for feeding fires, propagated from the inmost darkness of the earth and at the same time from the overlying sea by its perennial motion.

[Margin: The instrumental cause.]

The instrumental cause is the cavernous nature of the place, and the whole mass of the mountain, riddled with tunnels and suspended upon itself, and perpetually weighed down by sulphurous soot.

[Margin: The efficient cause.]

The efficient cause, finally, is the blasts [of wind] which, flying out from the deepest caverns toward an exit of this kind — and as it were toward their own jaws — [drive] the dormant fires to the matter nearest at hand.

LIBER IV (Pyrographicus), Sectio I

CAPUT VIII — [Crateris Aetnaei Descriptio, continued]

[the blasts of wind rouse the dormant fires], as if fanning them with a kind of bellows. For it was shown in the preceding Book that the whole of Sicily is riddled with innumerable caverns and tunnels — there where we demonstrated that the marvelous surges of the Mamertine, or Sicilian, strait, the alternations of its ebb and flow, and the insatiable devouring force of Scylla and Charybdis all depend, by a wonderful arrangement, on the said mountains, distributed across the entire island in subterranean workshops. The most striking testimony to this is the fact that, when Charybdis is churning more than usual, Etna [Aetna] — stirred up by the same spirit of revolt — rages along with it. The more violent blasts are received into its sulphurous caves, and the combustible matter, stirred up just as if by a smith's bellows, bursts out in vast globes of flame.

[Margin: The mountain throws out fires according to the disposition of the winds.]

When other winds blow, by contrast, Etna seems to grant something of a truce, because the mouths of its passages are then set opposite to the running waves of

the sea and are blocked by the neighboring mountains. But to the blasts of the East wind [Eurus] and the Southwest [Africus], depending on the configuration of its channels, it sends out now flames, now smoke, then ashes, and sometimes — when the fuel within it has grown — it rages with fires in astonishing fashion, with a dreadful outflow of fire and sulphur, which it tends to belch out from time to time from the innermost recesses of its furnaces. This brings vast and ruinous devastation: villages, fields, cities, and living creatures beneath it are all destroyed. The forewarnings of it are the groanings of the caverns from the spirits pent up within, and the roaring of the sea joined to the trembling of the earth. By these signs Nature, as though exasperated and impatient of her chains, having broken the bars of her prison, rushes out wherever a gate is opened. And like a river of fire it pours down in an immense flood — not only over the fields, but it also consumes whole villages, overturns nearby towns, and, leaving everywhere traces full of horror, now devours forests and crags. Of these the records of historians are full.

We therefore conclude: the matter of the subterranean fire is not only sulphur, or bitumen, or fossil coals, but also alum, salt, niter, antimony, carbonaceous earth, and copperas [calcanthum], and metallic substances of that kind. For sulphur and bitumen alone do not make a fire so violent as that fire which overturns mountains, buries cities under ashes and pumiceous ejecta, and tears rocky masses out of the mountains themselves with incredible violence of nature, as was clear from the foregoing. Rather, something else must be joined to it to produce this effect — which we now undertake to explain.

[Margin: What that thing is which causes such great ruin of the mountain.]

I say, then, that the universal matter of the subterranean fire must be sharp [acrem] and thick [crassam]. Of this kind are sulphurous and bituminous materials, with which — by a strong bond of mutual commerce — halinitrum [native niter] is joined: a substance filled in its own being with swollen spirits, which, once joined to sulphur and set alight, when it finds no exit, exerts upon the obstacles in its way underground that same force which we set out a little earlier — especially if crude antimony and mercurial spirits are present, as is sufficiently established from the efficacy of artillery.

Further, since combustible materials are found only in subterranean caverns — such as the various kinds of stones, the various species of earthy clods, the mixtures of metals and of other minerals, and besides these salt, alum, halinitrum, sal ammoniac, and whatever else is found there, right down to water itself — both the mountains and their huge rocks are turned into the matter and

nourishment of fire. Sometimes only the matter that has been generated burns, and once this is consumed the fire goes out; then, having shifted its station, it attacks another matter near to it, as happens in bituminous earths. At other times the matter, once consumed, is reborn from newly conceived seeds and, much later, is kindled again. And if it is born from a sudden generation in great abundance — as in Etna, in Strongylus [Stromboli], and in the Phlegraean Fields [Campi Phlegraei] — then they will burn with a perpetual fire.

The generation of such materials happens in this way. The sea, filled with fatness and oiliness, enters the inner recesses of the Earth, and soon nourishes anew the bones of the mountains that have been worn thin by fire, refilling their hollowed-out, marrow-drained substance with fatness. And if it finds an opening into the sulphurous chambers, the water drawn in is turned into nourishment of sulphur; if into bituminous ones, into nourishment of bitumen; if into aluminous veins, into nourishment of alum (and so, reasoning likewise of the rest), it is turned into fuel. In this way the substances lost through fire are restored — in much the same manner by which, on the island of Elba [Ilua], iron is reborn in mines left at rest for several five-year periods, and in the Tiburtine countryside [Agro Tyburtino] the stones they call *travertine* [Travertina].

But how the said materials catch fire was stated above: namely, not from the Sun, not from the stars, not from lightning or flashes, not from any other efficient cause — but only from the subterranean fire itself, which makes its way to them through the hidden passages of the rocks, which it burns. Or, if they are not immediately touched by the actual fire, then certainly by the sea-waves which, driven by the force of the winds, are thrust into them through submarine channels [inciles]. For it cannot be otherwise than that, from the violent dashing of the waves in narrow places, and from the agitation of the spirits of the combustible matter, and from the friction of the thick air, they should at once catch fire.

SECTIO II

DE AERIS ET VENTORUM

On the **Causes, Nature, Powers, and Variety of Air and Winds**, which hold sway both on the outer surface of the Geocosm and in the internal subterranean cavernous regions.

[Printed p. 191; running header context: "Sectio II."]

PRAEFATIO [Preface]

The cause of the winds has, at every period, seemed to philosophers a thing difficult to discover — so that not without reason does the Royal Psalmist [the Psalmist David], drawing from the treasures of God, declare: *"You who bring forth the winds from your treasures, you who walk upon the wings of the winds, and assign names to them all."* And just as the treasures of the Divine Wisdom hint at the manner and reason — incomprehensible to the human intellect — by which they arise, so the walking upon the wings of the winds shows, again, that their causes are so difficult that they seem reserved to Him alone who alone holds sway over their cause, who alone makes them rage, who casts the bridle upon them and assigns them their names.

[Margin: The difficulty in assigning the cause of the winds.]

And so it is man's lot only to marvel at what he does not grasp, and from this to learn rather to adore the unutterable greatness of the Divine Power in His creatures than to scrutinize them too curiously. Yet, because the Divine goodness has furnished men with sense and intellect, so that through the things that are made they might come to know the invisible things — that is, that through things laid open to the senses they might reach to their invisible powers, and from there at last ascend to the Author of all things, God Most Good and Great, who governs all things by His invisible power — from this there has arisen that boundless restlessness of human minds in the investigation of natural things, and that spirit of mortals seething with desire to attain the truth. Burning with this same desire, we too, for the glory of His name, begin our discourse on the causes, nature, and properties of the winds. In it, if I shall produce anything worthy of praise, it is to be credited not to my own childish reasoning, but to Him who gave both the power and the will to do so.

CAPUT I

On the manifold cause of the winds, and their division and definition.

It cannot be that one and the same cause should always be the producer of the winds, since the diversity of the winds — differing in nature, powers, and properties — undoubtedly argues for diverse causes. Hence it is frivolous to say that the cause of the winds is nothing other than a hot and dry exhalation struck collaterally, which the Peripatetic [Peripatu(s)] stubbornly defends.

[Margin: The common definition is not adequate.]

For our part, corresponding to the diversity of the winds, we shall try here to assign diverse causes — causes which, nevertheless, are all subordinate to the one cause of the one Maker of all things. Once these are known, no quality of the winds will prove so strange, no effect of the winds so exotic, that you cannot assign its cause. But, so that in a matter so tangled and knotted we may preserve the natural order, we shall reason first about the variety of the winds, and then also about their causes.

[Margin: The differences of the winds.]

I find **seven** differences of winds, by which the whole mass of the Earth is continually agitated.

1. First there are the **common and perennial** winds, which blow at every time and in every place, unless they are hindered by other winds or by various obstacles — such as that single Eastern wind which we call the *general* wind, and which holds sway above all in the Torrid Zone, rushing from East to West.

[Margin: The Eastern wind, perpetual beneath the Torrid Zone.]

2. There are winds **proper to certain places and periodic** [periodici], which, just as they blow at a fixed time of year, so too blow only in a fixed place or tract of the Earth — such as the Etesian winds [Ethesiae], which used to prevail in Greece and Egypt only in the summer season, and not so in the other parts of the Earth.

[Margin: Periodic winds.]

3. The **anniversary** winds [Anniversarii], which are either monthly, or daily, or hourly. According to the diversity of the seasons these blow over the Ocean from various quarters of the world, and in some places they last for a six-month, four-month, three-month, two-month span, in certain places for a monthly, weekly, daily, or hourly span of time — of which more later.

[Margin: Anniversary winds.]

4. There are **extemporaneous** winds [extemporanei], born from a violent collision of the air — such as the winds before or after rain, thunder, and so on.

[Margin: Extemporaneous winds.] 5. There are **sudden** winds [repentini], abrupt and forceful — such as whirlwinds, hurricanes [praesteres], squalls [Ecnephiae], and the like, which occur only rarely.

[Margin: Sudden winds.]

6. There are **prodigious** winds [prodigiosi], which in some places burst forth — now from the caverns of mountains, now from the innermost bowels and chasms of the earth, and sometimes too from the bottom of the sea and of certain lakes, to the great peril of ships, when they violently stir up the waters.

[Margin: Prodigious winds.]

7. There are **artificial** winds [Artificiales], such as those raised by fans and bellows, or those conducted, for the sake of pleasure, into certain grottoes through hidden channels.

[Margin: Artificial winds.]

Therefore, just as these enumerated winds differ in their powers, nature, and properties, so too they are allotted differing causes.

[Margin: From where they arise.]

For some are born by the power of the Sun thinning out moisture, as is the general wind.

Some are produced by the mere rarefaction and condensation of the air.

Some by the melting of the snows that lodge on the lofty summits of the mountains.

Others — and most of them — from subterranean vapor and exhalation, the two things which intervene in most winds.

Others derive their origin from the rising of the Moon and of certain stars.

Others arise from the varied configuration of mountains, promontories, shores, and intervening islands they encounter, by a kind of reflection or rebound, or else from the violent force of the Ocean's currents, or from the ebb and flow of the sea.

Others, finally, have their birth in the innermost bowels of the Earth; others on the very surface of the Earth; others in the middle and uppermost region of the air. The maker of all of these is either the Sun, the celestial fire, or the subterranean fire divided into innumerable pyrophylacia [fire-storehouses], without whose aid no wind in the world can come to be. But let us now set out the individual winds, in the same order in which we have enumerated them — which will be done conveniently once we have first brought forward the definition of wind.

DEFINITIO VENTI [Definition of Wind]

Wind can here be considered in two ways: taken **properly** and **improperly**. The first arises from a vaporous, spirituous, and smoky substance; the second from a violent and external motion of the air, and it is born from a manifold cause — whether from the violent bursting of rain-clouds, as in thunder; or because of a fall of rain preceded by a motion of the air; or in great conflagrations; or finally from the pressure of clouds. For wind of this improper kind is nothing else but a motion of stirred-up air; and so, in general, wind is nothing else than that which in any manner whatever can stir up and drive the air forward. Of these individual kinds we shall treat in order, once we have first brought forward the definition of wind properly so called.

[Margin: Definition of wind.]

Wind, then, properly so called, is a vaporous and flatulent exhalation [halitus], drawn out from the earth or the sea — partly from outside by the Sun, partly from within by the power of the subterranean fire — which, rarefied by heat or condensed by cold, agitates the earth and seas with a transverse motion, and sometimes also with a straight motion, being appointed for the good of nature.

[Margin: Exposition of the definition.]

I said first **a flatulent exhalation**, in order to exclude the opinion of those who think wind to be a simple motion of the air, and to exclude the definition of those who say that the matter of wind is a simple hot and dry exhalation, with all moisture excluded. I said **flatulent** because its essence consists in its blast; for if exhalations did not consist of flatulent spirits, they could not stir up the air with so powerful a motion. I said **drawn out from the earth or sea, partly from outside by the Sun, partly from within by the power of the subterranean fire**: for the Sun on the outside thins moisture into vapors, the matter of clouds and winds; the subterranean fire, through the hidden fibers of the earth, sends out nitrous-salt exhalations [halitus salnitrosos] which, raised to the outer surface and rarefied by the Sun, are the cause of vast commotions of the air. It is therefore the office of the subterranean fire to supply the exhalations and stale smoky vapors, and the office of the Sun to thin them, on the outside, into the matter of winds — since these, once dilated, produce a thrusting of the neighboring air, and from this the impetuous transverse commotion of the air is propagated in continuous fashion.

[Margin: The fourfold genus of causes in the winds.]

You see, then, that in this definition a fourfold genus of causes is contained: the **efficient cause** — fire, partly internal, partly external (that is, solar); the **material cause** — the vaporous and flatulent exhalation; the **formal cause** — the transverse motion of the exhalation; and the **final cause** — the good of nature, concerning which more below.

And from this varied constitution of the exhalation arises also the very great multitude and diversity of the winds. Of these, some are called, by their quarter, *Boreal* [northern]; others *Meridional* or *Austral* [southern]; others *Western* [Occidui]; others *Eastern* [Ortivi]; others, finally, *intermediate* — so that, as many degrees as we count on the rim of the horizon, just so many winds can be constituted. And they are called such with respect to the place and quarter from which they roll forth. And although one and the same exhalation may be Boreal to some, Austral to others, Eastern and Western to others, nevertheless it is imbued with differing properties and qualities as it flows, by reason of the places through which it passes — as will be shown later.

[Margin: The denominations of the winds from the quarters of the world.]

The Wonderful Pericyclosis or Circulation of Nature.

If anyone could reach by the sense of sight to the origins of the winds, he would no doubt grasp their causes without difficulty. But since their substance, no less than that of the air, escapes all the gaze of the eyes — being utterly invisible and [Greek: ἄπερ ὅ (aper-?) — "without"(?)] [?] — their causes become known to us only with difficulty, and only through a certain analogy do they show us the way to recognize their true principles. And if anyone fixes the eye of his mind straight upon the laws of analogy, he will without doubt [recognize] that the very thing which holds in the motion of the elemental water holds also in the stirring-up of the winds. ...you will find that it happens by [the same] reasoning. For just as the seas undergo various alterations from the Sun, the Moon, and the subterranean fire, so too do the winds.

[Margin: The motion of the winds is wholly assimilated to the motion of the sea's flux and reflux, and is composed by a beautiful analogy.]

The sea, teeming with subterranean exhalations, swells up and stirs up various tumults on its outermost surface. Hence it completes its course from East to West, following the lead of the heavenly bodies. At one moment, agitated by innumerable currents and dashed against the various shores and promontories of the earthly region, it forms circling eddies; at another, exasperated by contrary waves, it drives whirlwinds and vortices.

In just the same way, the vapors raised into the aerial region by the power of the heavenly bodies or of the subterranean fire — when, rarefied, they require a greater place — drive the surrounding air with the utmost violence, with great force, now into this, now into that part of the air. Then, dashed against the lofty summits of mountains and driven back, they produce contrary winds; and sometimes, struggling against contrary and opposing exhalations, they wage savage conflicts, by which they cause immense tempests and whirling vortices, hurricanes [praesteres], and squalls [Ecnephias], to the utmost peril of ships. And, after the manner of a river, they are borne now with a gentle flow, now with a rapid one; now, falling headlong, they strike the depths and throw everything into confusion; now they smooth it; now they card the air like wool [pectinatim carminant].

Thus, what the motion of the Ocean displays to us by sensible appearance on its surface, the agitated exhalation and the thrusting of the air express in the aerial region by a flux indeed invisible to the eyes, yet perceptible by touch and sound alone — so that, accordingly, the causes that disturb the Ocean are the same as those that everywhere infest the aerial region. For just as the Ocean is watery, so too the Atmosphere of the terrestrial globe is a kind of aerial Ocean, agitated by motions all the more violent in proportion as the moving causes and the mass of the aerial substance consist of a finer and more mobile material, fitter for receiving motions.

[Margin: The Air, an aerial Ocean.]

The Sun, the Moon, and the stars, by their external influence, draw out, dilate, and raise aloft the exhalations which the subterranean fire had imparted to the sea, and conduct them into the further vast voids of the aerial region. There, encountering and besieging the vapors compacted into clouds, when they rush out wherever a gate is open, they bring forth that variety and inconstancy of the winds which sailors cannot sufficiently marvel at. And so that the [Greek: περικύκλωσις (perikyklōsis, "circumcirculation"); the circular wheeling] worthy of nature's admiration may be set forth more clearly, let me begin the matter a little higher up.

The stars, the Sun, the Moon — as was most fully shown in the preceding Section — produce the reciprocal tide of the sea. The tides of the sea, that is, the impetus of its flux and reflux through the hidden and secret passages of the Ocean's floor, thrust an immense and boundless mass of waters into the innermost viscera of the earth, and rouse the subterranean fire by the force of the winds.

[Margin: The admirable pericyclosis of nature in the tides.] [Margin: The subterranean fire does not rest.]

A new reciprocation of the tides blesses that fire with nourishment, conveying it as if by certain bellows; and the fire, kindled and seething, draws along with it through other and other passages — fibers crammed with metallic and mineral juices — the abundance of exhalations it conveys as it passes through. These, thrust out partly through the earthy passages of the mountains, partly through the floor of the Ocean, onto the outermost surface, and there dilated, in turn solicit with their blasts the air, the Ocean, and the seas. And insinuated once more through the openings of the Ocean's floor, it conducts new provision to the subterranean fire, by which the fire may be both fed and preserved; and in this way it supplies fresh matter for stirring up the sea.

You see, then, the manner and reason of nature's circulation. You see how water and fire, as if contending by alternate and mutual offices, nourish and foster one another, and by a kind of unanimous consent conspire toward the preservation of the Geocosm. For if the subterranean fire emitted no exhalations to serve as the matter of the winds, the sea, as if torpid and well-nigh devoid of motion, would readily pass into putrefaction, to the ruin of the Geocosm; and consequently, deprived of the support of the winds, it could not supply the subterranean fire with its necessary nourishment. And so, the fire being extinguished, the whole of nature would necessarily perish.

[Margin: Wind is necessary for the sea.]

Lest, then, nature, afflicted by so great a loss, should collapse, God Most Good and Great — through provident nature, the handmaid of the supreme Maker — willed that both elements should be in perpetual motion, toward the admirable ends which we shall indicate below. For what the vital and animal spirits do in the economy of the human body, that the spirituous nature of the winds does in the cosmic fabric. And just as, when those spirits vanish, a man cannot live, so too, the winds being removed, the Geocosm would necessarily perish.

[Margin: An analogy from the human body.]

But just as to these causes others and others are joined, so too there arises from them the inexplicable diversity and supreme variety of the winds — which can be explained only through the concurrence of many partial causes; and these, nevertheless, can always be traced back to the principal causes. All of which, lest we should seem to have left anything out, we now begin to set forth.

CAPUT II

On the General Wind: how, why, and from what cause it is born.

We call that the **general wind** which, by a perpetual motion, proceeds from East to West, accompanying the course of the Sun and the Moon. So that this may be easily understood, I should like you to note what we declared above concerning the general motion of the Ocean from East to West; for this wind exists only in the vastest seas — the Indian, and that one which they call the Pacific — subject to the Torrid Zone...

subject [to the Torrid Zone] is perceptible. And just as the motion of the ocean and seas is joined to the blowing of the winds in an inseparable partnership, so the one cannot exist without the other. Now, however, I must explain how this wind is produced.

First, then, I assume that this general wind — the Euro-Zephyrean, that is, blowing from East to West — would be perpetually unchanging if the whole terrestrial globe were covered over by the ocean. On that assumption it would meet no obstacle from any mountains, islands, or coasts lying in its path. [Margin: If the Earth were covered over by the ocean.] Having found this one unobstructed expanse, it would follow the Sun in a constant course and propagate itself perpetually around the Geocosm. [Margin: The reason why that general motion is for the most part interrupted, every time it strikes against them, and observes other laws of its course, until in the vastest expanses of the seas it spreads out its former liberty. (?)]

I assume, second, that the Sun can accomplish nothing in the production of winds without the prior dry exhalations — which I said a little earlier are imparted to the ocean by the Subterranean fire — or the moist ones that the rarefied sea itself supplies to the air.

Granting these assumptions, **I claim that the general wind is generated from East to West in the following manner.** [Margin: How the general wind is produced.] Since the Sun, beneath the Torrid Zone, perpetually strikes the ocean with rays falling perpendicularly — now on this part, now on that, according to the position of the Sun in this or that one of the twelve signs [dodecatemorion] — the result is that the sea, rarefied by the Sun's powerful bearing-down, draws up into the air a vast quantity of vapors mixed with exhalations. These rarefied vapors and exhalations, when they thrust with the greatest force against the air standing in the path ahead of the Sun, set that air in motion; and the air, driven

toward the part toward which the Sun is carried, produces — spread out in that direction — that wind from East to West which we call the general wind.

Here, perhaps, someone may object: this drawing-up of exhalations by the Sun takes place over the entire circumference of the ocean, and therefore the exhalations too, diffused in every direction, must cause a wind on every side. [Margin: An objection and its solution.] I answer that it is true that exhalations are diffused in every direction; but since on both sides — from the South and the North — they meet thicker and more vaporous air opposing them, the result is that this seething, exhalation-laden air, being of a finer substance, is thrust back and driven back by the thicker air standing around it. Pressed and confined on both sides within the royal path of the Sun, it is continually driven from East to West, while the Sun, advancing along that same path, continually elicits by its heat ever new exhalation-laden spirits. Again, since the Sun by its perpetual bearing-down dissolves an enormous quantity of water from the sea, and thereby induces a certain emptiness in that tract of the sea, to fill this emptiness — by a kind of natural necessity — the eastern waters that follow [the Sun] rush in with force, and, driven more vehemently along the maritime path of the Sun, press and thrust forward toward the West the air lodged within that same exhalation-laden path. From this wondrous attraction and repulsion of waters and exhalations there arises that perpetual Euro-Zephyrean wind which we call the general wind; and since the Sun always operates in the same way, the very reasoning of nature dictates that this wind too is perpetual. But let us confirm by experiment that all this is so.

Those who sail from Acapulco, the port of New Spain [Mexico], to the Philippine Islands must first proceed by a straight course toward the Equator. [Margin: The voyage from Mexico to the Philippine Islands.] Once they have reached it, then — whether beyond or short of it — they spread their sails and leave the ship to the will of the winds, which there beneath the Torrid Zone, both in the southern and the northern part, blow perpetually from the East. Within the space of seven months they successfully — and, what is remarkable, without changing their sails — reach the Islands *de las Boccas*, distant from eastern America by a space of nearly 3,000 miles. This would not happen if the wind, in that vastest ocean stretching out immeasurably on every side, were subject to variation and instability. But the reason why, in the ocean near the first islands one encounters — of which there is no counting in the Archipelago of St. Lazarus — the general wind takes on other laws is, first, the striking-back of the waters that drive the waves backward; second, the new and differing commotions of the terrestrial exhalations, which are elicited by the Sun from that island-nursery teeming with

seed; and third, the various conditions of the tides and currents. [Margin: Why, near the multitude of islands, the eastern wind fails. (?)] By these the general wind is disturbed, and these prevailing winds produce those whirlwinds which all who sail the Indian Archipelago experience to the great peril — indeed, the loss — of ships and men. But once these have been drawn out of the narrow straits of the islands and restored to the vast open regions of the Indian Ocean, the general wind, growing strong again, carries the ships all the way to the Cape of Good Hope, or to the island they call St. Helena.

CONSECTARY I.

And from these things it is clear why the voyage from East India to Brazil or Paraguay is easier than the reverse. For on the one route the sailors must struggle perpetually against a contrary wind, while on the other, carried by the motion of the sea and the eastern winds, they reach their destination in the western parts in the shortest space of time. But those who from the Philippine Islands seek the regions of eastern America find it impossible — because of the perpetual resistance of the sea — to keep to the path of the Sun beneath the Torrid Zone. [Margin: From the Philippine Islands to eastern America it is impossible to navigate beneath the Torrid Zone.] Instead, in order to be returned to the port from which they set out, Acapulco, they must steer their ship through the Temperate Zone to the coasts of North America, so that there, aided by northerly blasts, they may at last reach their desired destination. From this is evident the marvelous design of nature, by which it willed that the Pacific Sea beneath the Torrid Zone be driven always by one and the same blowing of the winds from East to West, as far as the islands of the Archipelago — where the ocean's...

[Top of printed p. 195 — running header "DE VENTORUM ORIGINE."]

wind, thus far continued, is driven — now striking against the islands lying in its way, packed with enormous mountains, now against the vastest regions of the China mainland — and, with new vapors stirred up there, is forced back from West to East to the shores of North America, so that it is kept moving as if in a circle, to the great mutual advantage of those traveling to and fro.

CONSECTARY II.

From this too it is clear that this general wind does not always flourish at one and the same time and place in all the regions subject to the Torrid Zone, but does so chiefly beneath the parallels of those signs through which the Sun passes. Hence sailors constantly affirm that the more closely they keep to the Sun's paths, the

easier and shorter their voyage to their destination; but the more difficult it is if on either side they have departed more than is fitting from the Sun's path, because of the new laws of the winds they then experience, contrary to the Euro-Zephyrean wind. [Margin: A wondrous constitution of nature.] For just as a river confined within its channel flows more rapidly than when spread out over a plain extending far and wide, so beneath the Sun's path the motion of the air behaves — that air being nothing other than a kind of swift aerial river, which, confined as if within a channel on both sides by the northern and southern clouds, is perpetually carried by the Sun's power from East to West, while the south-north blasts keep watch and bar it on either side lest it stray outside its channel. But I would not have you think that this wind is carried beneath one and the same parallel within an indivisible space; by no means: rather, it has its own breadth, greater in some places. Beneath the Tropics it was found to have 7 degrees toward the South and the North. And in this way the general wind is perpetually generated and preserved. But so that the reader may grasp this more clearly, I shall here add an experiment, from which you may learn the manner and reasoning more exactly.

Experiment setting forth the cause of the general wind.

Let some shallow basin two palms in diameter be filled with cold water up to the brim. This done, take an iron ball whose diameter is a quarter of a palm. When this ball has been made to glow with the strongest fire, take it with tongs and carry it across the surface of the water held in the basin, in a motion along the diameter, in such a way that it always stays a small distance from the water. You will find in the surface of the water a kind of cavity, through which the water is drawn to follow the motion of the glowing ball, continuously, right up to the rim of the basin, where, reflected, it passes off on both sides into circles, drawn back to the sides of the basin in the opposite direction. You will also discover then that a wind is born from this rarefaction of the water and the motion of the glowing iron, if you place a feather directly opposite the iron ball: for that feather will by no means bend toward the sides, but will always follow with a steady motion the advance of the glowing ball. This indeed sets forth the causes of the aforementioned wind so clearly that it seems to display the matter to the eyes.

You will ask, first: Besides the general wind, do other winds also prevail in the Pacific Sea? [Margin: Whether in the Pacific Sea, besides the general wind, others prevail.] I shall answer that, outside the path of the Sun, countless winds do indeed prevail in that ocean, but that these are particular winds, which — drawn from the exhalations and the bottom of the sea by the force of the Subterranean

fire or of the Sun — disturb the air at every time. But since that ocean is most wide open, the diffused vapors, growing as it were flaccid with time, fail together with the wind. You know that gunpowder set alight in open fields is not dissolved into vapor with the same force as in confined places; for, confined in these, it scatters everything with enormous impact and crash. The same may be said of the winds in such an ocean. It is otherwise in seas that, broken up by various islands, are checked by the enormous obstacles of the continental lands: in these the winds, variously reflected and repeatedly augmented by new exhalations, stir up enormous storms and the most furious whirlwinds of winds — as sailors report of the Indian Archipelago and the ocean lying between Japan and China.

You will ask, second: Can winds that arise in the very path of the Sun impede the general wind? [Margin: Whether the general wind can be impeded by other winds.] I answer that they cannot in the open ocean, because every vapor, every material of the winds, is so absorbed by the motion both of the air and of the sea that it can be no impediment to it. Indeed, if at any time a stronger wind should rise up, yet, when it meets the general wind, it soon yields to it as to the more worthy, and bends off to the sides, joining either the southern or the northern allies of Aeolus. I said "in the open ocean," because as soon as they have approached the shores of continental lands, or the vast districts of islands, then — behold! — with the prisons of Aeolus burst open, they feel the contrary laws of the winds, by which the general wind is not only thrown into confusion, but is even compelled, as if before the assaults of opposing enemies, to withdraw itself somewhat, until it is restored to its liberty.

CONSECTARY III.

That a wind sometimes arises from the attraction of the surrounding air.

From the foregoing it is clear that a wind too can sometimes arise not from vapors and exhalations, but produced solely by the motion of air supplying a void — as happens in great conflagrations, which a wind for the most part accompanies. But I shall explain in what way this wind is created. [Margin: A wind sometimes arises from the motion of a void.] It is certain that, by the heat of a violent conflagration, the surrounding air is supremely attenuated. Since, because of the air packed densely all around, it cannot expand to the sides, it is therefore snatched upward together with the fire, and carries the surrounding air along with it; and this surrounding air, lest a void remain, substitutes itself into

the place of the departing rarefied air. From this agitation that wind is born, which...

[Top of printed p. 196 — running header "LIBER QUARTUS, Sect. II."]

we experience in great conflagrations. And that this is so, we teach by the following experiment.

EXPERIMENT.

Which shows a wind produced by the mere agitation of air.

In the hearth of some chamber, with all the windows shut, let a fire be built; and you will find that a strong wind soon enters through the chinks and cracks of the door, drawn inward by a hidden force as it were. The cause of this is none other than that the air existing in the chamber is snatched, together with the fire, out beyond the chimney; and once snatched away, since it necessarily needs other air to supply the place of the departing air, the result is that the outside air, pitying nature in her labor, insinuates itself with great force even through the tiniest cracks, fissures, and openings, to prevent that which nature so greatly abhors — the terror of a void. [Margin: Why, in the morning, at the time of twilight, a rather gentle wind blows before sunrise.] And from this too may be gathered why in the morning, at the time of twilight, a rather gentle wind is for the most part felt before sunrise: namely because the rising Sun, by its heat and light, attenuates the air; this attenuated air, carried upward, snatches the neighboring air along with it; and by mutual consent the unattenuated portions of the western air flow toward that same part — and so that morning breeze is stirred up.

CAPUT III.

On the periodic or annual winds, which the Greeks call Etesian [Ἐτησῖαι], and on their causes.

The Aristotelians, together with their Master, torment themselves wondrously in rendering the reason for those winds which they call Etesian [Greek: Ἐτησῖαι (Etēsiai, "yearly winds")], which, about the rising of the Dog Star, used most kindly to affect Greece, seething with heat, by their somewhat cool blasts; and, evolved from the North, were found indeed to be silent by night but to breathe by day. When these ceased, there succeeded the Ornithiae [Greek: Ὀρνιθῖαι (Ornithiai, "bird-winds")], or Chelidoniae [Greek: Χελιδόνιαι (Chelidoniai, "swallow-winds")], blowing from the South, harmful to men and animals. [Margin: The cause of the Etesian winds.] And as for what concerns the Etesian

winds, they say the cause of them is the dissolution of the snows on the mountains of the Hyperborean Subpolar region: these snows, when struck by the Sun's rays and dissolved into exhalations, supplied by day the material of the winds; while by night the said dissolution of the snow, with the Sun establishing as it were certain truces, compelled the winds likewise to be silent. And this is the Peripatetic opinion concerning the origin of the Etesian winds. That it is false, I show by four arguments.

First, if from the Subpolar mountains covered with snow and dissolved into exhalations by the Sun's power that Etesian wind is born which strikes Greece in the dog-days, then surely there is no reason why the Etesian winds should not at the same time pervade Moscovia, Poland, Germany, Hungary, Gaul [France], Spain, and England with the same blasts. [Margin: The Etesian winds are not produced by the liquefaction of snows on the Subpolar mountains.] Yet in none of these regions is that continuous 40-day spell of the Etesian winds, which Greece feels, perceived at the rising of Sirius. Therefore, the explanation cannot be derived from the snows of the Subpolar mountains — since I do not see why a wind of this kind should dominate over Greece rather than over the regions listed, at the stated time, given that Moscovia, Poland, Germany, and England, in that they are nearer the Pole, ought therefore to feel it more than Greece or Egypt, regions more remote from it. Therefore, just as this wind is particular to Greece, so its cause too must necessarily be not universal but particular — not derived from the Polar mountains, but taken from elsewhere, which I shall later assign.

The second argument, which renders the Peripatetic opinion empty, is that enormous distance and interval of these Subpolar mountains from Greece, comprised within about 45 degrees, which multiplied by 60 yield 2,700 Italian miles, or multiplied by 15 yield 675 [recte: 675? — the printed figure reads "67 ½ mil-liaria Astronomica"; see Numerical impossibles] astronomical miles. [Margin: (?)] That one and the same exhalation should be propagated continuously over so great a space — obstructed by so many other mountain chains, through so many and so countless intervening vapors and exhalations, which are everywhere drawn up at the same time from rivers, lakes, mountains, and the plains of the fields — let him believe it who will. I shall prove below that no exhalation is continued for as much as 100 leagues. And besides, who told the Peripatetic that there are mountains beneath the Pole, when it is unknown to this very day whether that Subpolar region is truly a continent, or an island, or covered over with sea on every side?

The third argument, by which he proves that the Etesian winds are derived from the Pole, consists in this: that the Etesian winds are silent by night and breathe by day, and he says the cause of this is that by day the Arctic snows, repeatedly dissolved by the Sun into the exhalations with which they are filled, are dissolved — whence the diurnal wind — while by night, the dissolution of the snows ceasing, the wind too ceases. But whoever shall have rightly examined this argument will find it not only false, but contrary to the doctrine of the sphere. For who does not know that, from the Sun's entry into Aries up to Libra, there is perpetual day in the Subpolar region? Since therefore the Sun never deprives the Subpolar region of its presence and illumination for a six-month span — or, if you exempt the more remote Hyperborean or Rhiphaean mountains, never for a five-month or four-month span — surely he concludes wrongly from this that the Etesian winds, on account of the Sun's absence not dissolving the snows in the said region by night,...

[Top of printed p. 197 — running header "DE VENTORUM ORIGINE."]

are silent by night, but blow by day on account of its presence. How far these things are consistent with the principles of nature, let those who are impartial judges of natural things see.

The fourth is contrary to the nature of exhalations. For the Peripatetics say that beneath the snows lurk hot and dry vapors which, elicited by the Sun's heat, cause those winds they call Etesian. Certainly that those dry and hot exhalations should be preserved unharmed in such great measure beneath the immense heaps of northern snows — amid so great a mass of humidity surrounding them on every side, moist and cold, diametrically contrary to them — no one will ever persuade me. For I recognize no other species of exhalation than that which is separated from every mixed body, and which consists of the finest spirits clothed in a vaporous substance — which I call the material of the winds. I am not unaware that sometimes there also lurks in snows a certain vapor-laden substance, which, however, I would not call that simple hot and dry exhalation, but rather saline, nitrous, and aluminous spirits, which, elicited by the power of the Sun or evolved from the Subterranean fire, produce that vehemence of the northern winds which we marvel at. For these, having vaporized by their own substance — in which hot and dry exhalations lie mixed together — become apt material for the winds.

[Margin: Whence the Etesian winds derive their origin.] It is asked, then, whence those Etesian winds derive their origin. I say: from the natural constitution of the mountains that are spread before Greece, Macedonia, Thrace, and Bosnia. There

is that enormous chain of the Carpathian mountains, extending from the West in a long tract of lands toward the East, as far as the Euxine Sea [Black Sea], where, on the northern shore, with the mountains of the Tauric Chersonese [Crimea] — which divide it with lofty and inaccessible snowy peaks, just as the Apennines bisect Italy — and joined hence by the Coracian, Hippican, and Caucasian ridges, it stretches out toward the East in a long row, separating Poland, Lithuania, Moscovia, Russia, and Tartary — flat regions awash with lakes and marshes — from the Vistula as far as the mighty river Volga. These lofty mountains, then, covered with perennial snow, together with the said vastness of the marshy plain, cause the Etesian blasts in Greece and the other neighboring regions listed, together with the interposed Pontus Euxinus and the Lake Maeotis [Sea of Azov] — this I demonstrate as follows.

First, then, it is established — on the testimony of Herberstein [Sigismund von Herberstein] and Martin Cromer [Marcin Kromer], historians of the said regions — that about July and August, at the time when in Poland, Moscovia, Russia, and the other regions situated across the Carpathian Tauric mountains, the Pelagus and the Euxine, the southern winds begin, at that same time in Constantinople and throughout all Greece, Anatolia, and Egypt the northern winds — which Aristotle calls Etesian — begin their blasts. [Margin: Why in Sarmatia the south winds, and at the same time in the listed regions the north winds, arise. (?)] If, then, the Etesian winds arose in Greece and the other listed regions from the Polar mountains, surely the intermediate listed Sarmatian regions ought to feel them before the others — which, however, is so far from being the case that, rather, as experience teaches, at the same time, on the testimony of the said historians, opposite winds breathe upon them. So the fact that the trans-montane peoples have south winds at the time when the cis-montane Greeks have north winds — this is doubtless to be ascribed to no other cause than the natural constitution of mountains of this kind. But let us unfold the mystery.

It is established, first, by the unanimous report of the Geographers, that the mountains just pointed out, like the flat places, are of insuperable height, and so, covered with perennial snow, are likewise teeming with subterranean fires — as the innumerable multitude of thermal springs and the steaming basins of continually smoking mines abundantly demonstrate; which, lest I be too long, I have judged it superfluous to recount. [Margin: The flat places of Sarmatia.]

Second, that all the trans-montane regions stretch out in a continuous plain — awash with lakes, rivers, and marshes — from the river Vistula to the mighty

river Volga, which separates Greater Tartary from Moscovia and the Precopian Tartary [Crimean Tartary].

Third, that the Pontus Euxinus, impetuous and of unsearchable depth — both from the discharge of the Lake Maeotis and of the rivers Borysthenes [Dnieper], Danube, and others into it, and from the subterranean winds by which it sometimes swells — is agitated by perpetual surges and tempests. [Margin: The surges of the Euxine.]

Fourth, that experience establishes that the said mountains, most harsh from their multitude of snows, cause a cold constitution of the air for those dwelling on this side and that; and that the flat regions across the mountains are throughout the whole winter so bound up with snow and ice that there is no access for traders into the various regions, through pathless and devious ways, except by the help of sledges.

These things being laid down, the result is that, as soon as the Sun has entered the Equator, both the masses of Alpine snow and the trans-montane plain bound with ice are gradually dissolved. Then, as the Sun ascends higher and higher each day, the snows and ice once dissolved (which dissolution is completed in the whole two-month span, namely April and May) are wont to fill everything with floods; whence, by the Sun's heat, an enormous quantity of vapors is drawn out, which, soon insinuated into the hollows of the mountains, is dissolved into rains. After the waters, the Sun more ardently, about the middle of June, draws up the finer vapors mixed with metallic exhalations, which, unable to be contained in the narrowness of the places, by a violent eruption — the opposing vapors of the northern cold pressing upon them — are borne toward Greece, Anatolia, and Egypt, into the South, with great force. And since so great a quantity of vaporous substance has been collected, the result is that, as long as it is not consumed, just so long do the winds last. By day, chiefly about noon, dilated by rarefaction, they stir up the said winds each day; but by night, condensed by the cold, they contract themselves and suspend their blasts. And this I would suppose to be the cause of those winds which, for a span of nearly two months, [drive across] Thrace, Greece, Anatolia,...

[This page continues CAPUT III, "De Ventis periodicis seu Anniversariis, quos Etesias Graeci vocant," begun earlier.]

When they reach Egypt, these winds bring the region the most wholesome air, to the great benefit of both people and animals. They are cold partly because they are released from the thawing of snow and ice, and partly because of the icy-cold

Pontus Euxinus, which—after it has received the snow-fed and glacial waters of its mighty rivers—pours that chilled breeze across into Anatolia and Greece.

[Margin: Why the Etesian winds are cold.]

Anyone who has properly grasped these explanations will be able to assign the cause of nearly all the winds that depend on mountain positions—why here northerly winds arise, there southerly, here western, there eastern.

COROLLARY

That all winds differ according to the variety of the places from which they blow.

It is clear from what has been said that, since winds arise from a definite configuration of the mountains, different winds arise according to the diversity of the regions facing those mountains. So when the north wind [Boreas] blows here at Rome, no one would claim that the same wind blows throughout all of Italy, Germany, or France. Experience certainly confirms this: from sailors' observations we have learned that when the north wind blows in Lombardy, in Transalpine Germany the south wind blows, and the reverse; likewise, while the south wind blows along the shores of the Tyrrhenian Sea, on the opposite coast of Gaul the east wind [Eurus] blows. From this I consistently infer that a wind stirred up in one region, and arising from the exhalations of a single place, does not stray beyond its province—unless mountain chains of great size stand in the way. The flatulent exhalation of such mountains is so copious that it is carried even into more distant parts, because its height is subject to no intervening obstacles. This is what happens with the Etesian winds of Greece, with the Euxine Sea lying between, blowing from the Tauric mountains.

[Margin: The diversity of winds.]

Therefore, just as individual rivers water their own regions, so too do the winds. And again, just as we have cloudy skies here while elsewhere they enjoy clear weather, so on the very day that northerly winds blow here, elsewhere southerly, western, or eastern winds will blow. Nor do I think that winds arising from the snowy ridges of the Alps reach all the way to Rome, since the nearby ridges of the Apennines can supply us with sufficient material for winds. Hence unvarying experience teaches that Mount Gennaro [Montem Januarium], laden with snow, which at Rome causes the north wind, at the same time produces a south wind for those situated beyond the mountain, an east wind for the Sabines, and a west wind for the Vestini—all at one and the same time, according to the diffusion of the flatulent exhalations—as I have found by the observation of many years.

[Margin: Winds carrying the position of the mountains.]

[This page continues an enumeration of maritime wind-observations within Caput III; the numbered items belong to a list of pilots' observations.]

and calms. In May, vehement east winds rise, heavy with rain.

5. At the promontory which I think they call *punto Gallo* [Point Galle], on the island of Ceylon [Ceilano], on 14 March the first wind is a collateral westerly, then west-south [Zephyro-auster]. At the beginning of April it becomes steady and continuous, lasting until the first of October; when it ceases, a northeast wind [Eura-boreas] follows, continuing until March—yet such that they sometimes begin, later or earlier, by ten days or even more.

[Margin: The pattern of the winds at Madagascar.]

6. On the island of Madagascar, from the fifteenth to the end of May, the north wind [Boreas] and north-northwest wind [Zephyroboreas] blow; in February and March, the winds blow from the east and south; but in the months of March and April, at the Cape of Good Hope [promontorium Bonae Spei], the north wind and its collateral toward the east [Eurum] blow—so much so that it is unusual for the south wind or its collateral, the southeast [Euro-auster], to blow.

[Margin: In the Bay of Bengal.]

7. After the twentieth of April, in the sea of Bengal, the south wind is vehement; before that day, sometimes the west-south wind, sometimes the north-northwest wind blow violently.

[Margin: From Malacca to Macau.]

8. From Malacca [Malaca] to the port of Macau [Macaum] in China, in the months of July, October, November, and December, southerly winds dominate—the south-west [Austro-Zephyrus], and sometimes also the southeast [Euro-Auster]. In June the west winds [Zephyri] rage around Malacca and along the Chinese coast. For those bound from Java [Java] to the port of Macau, westerly winds blow in the month of May. Again, for those bound from Macau to Japan, the same westerly winds dominate in the months of June and July, though these are frequently interrupted by day by the north [Borea] and northeast [Euro-borea]; but at night the southeast wind asserts itself. For those, by contrast, bound from Japan to

China, the east wind [Eurus] and the northeast [Euro-boreas] are present at the shores of China, namely in February and March. For the Sun, driving the vapors by its heat into the northern region, finds the air there denser and unable to yield; and so it is reverberated back along the same path by which it had been driven.

[Margin: In the Bengal Sea (Ocean).]

9. Those who set out from Manila [Manila], bound for the port of Acapulco in New Spain [Novae Hispaniae], use a westerly wind in the months of June, July, and August—not through the Torrid Zone, where (as was said above) they have the easterly wind perpetually against them—but along the shores of North America, where, however, the westerly winds are weaker than the easterly; for the latter are aided by the General Wind [Generali], while the former are diminished by it, as was said above.

[Margin: From the Philippine Islands to America: which winds those bound for it use.]

10. In the Chinese Sea, the winds in July, August, and October are exceedingly variable and inconstant; for it turns now from the south into the north, and from there into the west, or suddenly from the north into the south. From this they sometimes stir up storms greater than any sailors have experienced anywhere, as will be told later.

[Margin: In the Chinese Sea (Ocean).]

11. On the coasts of Peru and Chile, almost continuously a south wind blows together with its collateral, the south-west [Austro-Zephyro]. It begins at 46° of southern latitude, and blows beyond Panama, a city lying on the American Isthmus. Hence from Chile into New

[Margin: On the coasts of Peru and Chile.]

[Continuation of printed page 199, right column.]

Spain the passage is easy, but difficult from Panama into the south. It is remarkable, however, that this wind is felt only on the coasts of Peru and Chile, and not in the more remote stretches within the Pacific Ocean away from the shore.

12. At the coasts of the Land of Magellan [Terrae Magellanicae], or *del Fuego* [Tierra del Fuego], around the Strait of *de Maire* [Le Maire Strait], westerly winds blow continually, with such force that the very trees seem twisted

toward the east by the wind's violence. If, however, you keep to the shores of the southern land within the Strait of Le Maire, you will always have the south wind blowing.

[Margin: At the Strait of Magellan.]

13. On the Malabar coasts of India [littoribus Malabaricis Indiae], in July and August, the north wind [Boreas] and north-northwest [Zephyro-boreas] blow; but from September to April, easterly winds blow from the land from the twelfth hour of night until the twelfth hour of day—yet they are not felt beyond ten miles out at sea. From the twelfth hour of day until the twelfth of night, a sea wind blows from west to east, exactly contrary to the former; and as these are weak, so too they are not so easily felt, being almost always absorbed by the northerly winds. The same occurs on the coast of America in New Spain, where by day the sea winds prevail and by night the land winds—as also happens in the kingdom of Congo.

[Margin: On the Malabar coasts.]

And these are the principal observations made by the master-pilots [Archinautis] cited above. Now nothing else remains but for us to assign the causes of each of them.

The Reason and Cause of the Aforesaid Winds.

I therefore suppose, first, that the motion of the Sun within the Tropics—by which it now approaches the northern pole, now the southern—is the remote cause of those things that are born on the outer surface of the Geocosm, as well as of vapors and exhalations. And indeed, when the Sun is placed in the southern signs, in the northern hemisphere rains, snows, and frost dominate, because of the excessive remoteness of the Sun, which cannot dissolve the thicker, raw, and undigested vapors. Hence, from the cold thus introduced, rains and showers prevail upon the earth, the mountains are covered with snow, and the plains—together with the rivers and lakes—are bound fast with frost and ice. The pores and all the breathing-holes of the earth, sodden with excessive moisture, are closed; and from this constriction of the earth, the subterranean estuaries, when they cannot exhale through their accustomed fibers, are intensified by the utmost increase of heat. But when the Sun, returning from the south, passes beneath the equator, at once the earth, animated by the Sun's warmth, opens up; and from the melting of the snows on the mountains, vast inundations are produced both outside and inside the earth—all the greater the nearer the Sun has stood to our zenith. Thus, when the Sun has advanced to a certain degree of the Zodiac, the

exhalation-bearing substance of the earth, lying precisely beneath that same sign and degree, is then first set in motion, and—once moved—is gradually disposed into the annual winds; and the estuaries of subterranean fire too...

[Margin: How the annual winds are generated.]

now, when the subterranean estuaries of fire find their channels widened, with great force they drive out through the open breathing-holes of the mountains—steeped with the earth's salt, niter, alum, vitriol, and bitumen—their fibers and veins, and exhalations made fertile with the said substances, out onto the outer face of the Earth. As soon as these have met the more fervent rays of the Sun, that spirituous substance of the exhalations, swelling and dilating itself, joins with the vapors drawn out by the Sun and is animated into those annual winds which we described a little before. These last longer or shorter in any one place in proportion to the abundance of the exhaled, flatulent material. And the subterranean fire-chambers [Pyrophylacia]—animated both by the abundance of external moisture penetrating into their deep entrails, and by the wind stirred up from the subterranean waterfalls [catadupis] of the waters—emit vast exhalations and smokes swollen with vapors, for as long as the vaporous exhalations last.

[Margin: Solution I.]

And from this it is clear why, on the Indian coast of Gujarat [Guzaratae], from March to September the northerly winds blow continually: because the snows in that great chain of the Caucasian Mountains [Montium Caucaseorum], extending through all of Greater Asia, from the melting of the snow and the openings of the mountains, exhale a vast abundance of vapors supplied from the subterranean estuaries—which, rarefied by the Sun's summer rays, spread themselves out into the south. And since the immensity of the exhaled mass is so great that it cannot be consumed in half a year's span, hence these same winds must also last for a six-month period, yet at a certain hour of the day—namely, when the material, swollen by the solar rays, spreads itself out with the utmost force. As for why, when these northerly winds cease, southerly winds afterward begin to blow as their successors—the cause is that this vast mass of vapors, driven down into the south and there compacted somewhat by the cold of the southern sky, holds back until the Sun, passing beneath the equator, dissolves it, and pours the dissolved and rarefied mass across into the northern parts—whence the southerly winds arise. And exactly the same thing then happens in the southern hemisphere as we have recounted happening in the northern.

CAPUT IV.

On the Annual Winds in the Ocean, as observed by Spanish, Dutch, Portuguese, and English Sailors.

In the course of frequent navigation around the Geocosm carried out by the master-pilots, a certain remarkable property of the periodic winds was observed: that some of them begin at a fixed and definite time set by nature, and last for half a year; some for four months, or two months; others for a month or a week; and others last only a day or an hour. The hidden reason for this matter—penetrated by no one until now—is sought. We will attempt to assign it according to the measure of our talent, as soon as we have first brought forward the observations of the said sailors.

Maritime Observations concerning the Winds.

1. In the Ocean between Africa and India, the easterly winds toward the west begin from January until the beginning of June; and when these subside around August and September, westerly winds succeed, accompanied by foul storms with the north wind raging. Hence from Ceylon a favorable navigation eastward into Java and the Moluccas is granted, on account of the westerly movement which then begins, contrary to the easterly. (But when we speak of the easterly and westerly, the south and the north wind, we do not always wish the same thing to be understood. For we form rules not only about the cardinal winds, but also about the collateral winds belonging to each cardinal—such as the southeast [Euro-Auster] and north-northwest [Zephyro-boreas], or the north-northeast [Boreo-Eurus] or south-southwest [Noto-Zephyrus].) But around the coasts of Asia and Cisgangetic India [Indiae Cisgatanae], the winds do not keep the same pattern as in the middle of the ocean. The westerly winds dominate throughout June, July, and August; with so many storms, tempests, and the violence of northerly winds do they rage that they cut off all access for merchants into these parts. Yet on the Transgangetic side of India [Transgatano Indiae Latere], at Coromandel [Coromandeliam] and Narsinga [Narsingam]—which is remarkable—at exactly the same time no storms whatsoever are felt.

[Margin: Observations of the winds in maritime expeditions made by sailors.]

[Margin: From Ceylon to the Moluccas.]

[Margin: Around Asia and the coasts of Cisgangetic India.]

2. In Gujarat [Guzurate], that is, on the coast of Cisgangetic India, from March to September the northerly winds blow, and from September to March the southerly.

[Margin: In Gujarat.]

3. The Dutch [Batavi], setting out from Java for the most part in the months of January and February, bound for Europe, after they have reached 18° of southern latitude by the easterly wind, then the south wind, or the southeast [Euro-Auster], begins, by which they are carried in continuous course as far as the island of St. Helena [S. Helenae].

[Margin: From Java to Europe: which wind they use.]

4. At the island of Banda [Bandam Insulam], the state of the winds is entirely variable; the westerly winds dominate in March, and toward the end of April variable winds and...

and calms. (continued from item 4) ...rarefied and dilated by the power of the Sun, it will therefore take no other path than that of the current. Just as a current carries off the air contiguous to it, so the air carries off the exhalation; and from this arises that diversity of the winds which many wonder at.

[Margin: The diversity of the winds explained from various motions.]

[The following resumes the explanatory discourse "Ratio & causa," left column of printed p. 201:]

[the easterly winds] of the eastern region's space, while the opposite winds, the westerly, take up [the rest]. I say, therefore, that by the Sun's motion that vast oncoming heap of vapors, gathered together within the mountains both of the island they call Madagascar [Madagascar] and within the vast hollows of the Mountains of the Moon [montium Lunae] in Africa, settles there in a suitable place until the Sun passes through the summer signs. During this halt, just as the subterranean estuaries in Africa are stirred up by the power of the Sun, so too the vast diffused abundance of exhalations revives the vapors that have been stalled and compressed there for a long time. These, gaining renewed vigor, are reverberated with the utmost force toward that quarter from which they had been driven—that is, toward the east—and they last as long as the exhalation-bearing substance lasts, and as long as the Sun rules over the place of evaporation.

[Margin: The easterly and westerly winds.]

But why these winds become now southerly, now southeasterly, now affect other quarters out of the easterlies, drawing toward the south or toward the north—no one until now has resolved. I say that the cause of this is the currents of the sea, alongside which the exhalation arising there is carried. But that the matter may be grasped, I judged that the whole must be explained by an ocular demonstration.

What the currents are, and what paths they keep in the ocean and in the other seas, we have taught at length in the preceding sections; and the Map [Mappa] displaying them teaches enough. Since, then, the currents of the Indian sea especially are most diverse—produced either by the reflection of the shores, or by the unevenness of the sea floor, or by some other cause—it comes about that if any exhalation-bearing evaporation, breathed out from the sea floor by the force of the subterranean Vulcan, meets one of these currents, it takes the same path that the sea's motion takes, drawn along as it were by the vehement flow of the waters.

Diagram. A schematic chart of the Indian Sea with its currents, rendered in flowing engraved striations that converge toward the bottom center. The currents are drawn as bundles of lines streaming inward from the corners and edges toward a central node, illustrating how exhalations follow the sea-currents.

Labels:

- A (upper left): corner of the sea, source of current A–I
- D (upper right): corner of the sea, source of current D–K
- C (top center, with arrow/compass mark above): top of the sea (the point the equator C–F passes through)
- I (center-left of node): junction point on current A–I–B–G
- K (center-right of node): junction point on current D–K
- B (lower left): corner of the sea
- G (lower center-left, along the bottom curve): point on current A–I–B–G
- L (lower center-right, along the bottom curve): point on current E–L
- E (lower right): corner of the sea, source of current E–L
- F (bottom center): the lower terminus (the equator runs C–F)

In the text: "Let the Indian sea be B A C D E; let C F be the equator; the currents are C F E, D K, E L, A I B G." Then suppose an exhalation-bearing exhalation arises at C, or at

[Continues onto right column / next page:] ...D, or at E, or at B, or at A. I say the exhalation necessarily follows the path that the sea-current takes; for the air contiguous to the sea is driven toward that quarter from which it receives the greater impression—and it can receive no greater impression than from the impetus of the marine torrent, by which it is borne off and as it were drawn along. Therefore, whenever an exhalation-bearing evaporation is led out in the same tract, it is certain that it cannot escape this impetus.

[Now the left column resumes, after the figure:] It sometimes happens that a sea-current is cut across by another current overtaking it: thus the current E L disturbs the current D K. Then I say that the more powerful current will prevail, and consequently the air and the exhalation arising in the same tract will be drawn along the path of that current. Why too the easterly wind in such an open ocean is so variable—I find no other cause than the sudden generation of vapors, now growing strong in this place, now in another; by which the general wind, as it is impeded, so necessarily too, from the interruption of the newly born wind—now blown this way, now that, as it seeks an outlet—produces various winds. Whoever has grasped these explanations: no wind will be so erratic that a shrewd observer cannot render its reason and cause. But let us prove the whole matter by experiment.

[Margin: The diversity of the winds declared from various motions.]

EXPERIMENT.

Let a bowl E be made—or any vessel you like—into which, beside the four quarters of the world, spigots A B C D are inserted. Let the bowl E be filled with water; then have a lit candle prepared. If, then, you open the eastern spigot, the water, discharged with great force, will at once stir up a wind into that quarter toward which the water rushes. If you wish to test this, apply the candle immediately above the flow of water at the place where the flowing water bends into an arc, and you will see the flame bent toward no quarter except the one toward which the water's flow is borne—namely, from west to east. Then, closing that spigot, if you open spigot A and apply the candle, you will see the flame blown, bent from south to north. If afterward as many spigots were set up as there are points on the mariner's compass [pyxide nautica rhombi], the flame of the candle will always, by its inclination, express that wind which the flow of water carries with it toward whatever point. You will experience the same if you set a feather against the flow of water: it will always be carried into the opposite quarter by the force of the wind which the water's flow brings with it. From this

truly fine experiment it appears plainly that the flow of the waters follows the wind—and that, together with the wind, the exhalation is mingled.

Diagram. A perspective woodcut of a shallow cylindrical vessel (bowl) with ribbed sides, shown from slightly above so the interior is visible. Three tasseled spigots project from its rim toward the viewer—two at left and right, one at the lower front—each drawn as a spout with a fringed/tasseled cluster of water-streams issuing from it. Labels:

- B (top, on the interior rim, with a small circular mark below): the spigot/quarter B (north position on the rim)
- A (upper left, at the left spigot): the western spigot
- C (upper right, at the right spigot): the eastern spigot
- E (center of the vessel's interior): the bowl itself, filled with water
- D (lower front, at the front spigot with tassel): the southern spigot

CONSECTARIUM. [Corollary.]

[Margin: The method to be followed for sailing to the island of Ceylon.]

From this it is clear why, according to the fifth observation, at the promontory of the island of Ceylon — the one they call *Punto gallo* [Point de Galle] — the first wind on the 14th of March blows from the west, then turns to a west-southwest [Zephyro-auster], which afterward, from the beginning of April, lasts continuously right up to the first day of October. The reason is this: as soon as the Sun has struck the mountains of the island with its rays at the right angle, it simultaneously sets in motion the hot vents [aestuaria] beneath them; and these, as they cast out an enormous quantity of flatulent vapors [halitus], if those vapors are rarefied and driven toward the quarter the evaporation moves toward — that is, from the west-southwest region into the east-northeast [Euro-borea] — produce a six-month wind, matching the six-month duration of the material. This wind, however, does not last more than ten miles out to sea, which is why it is concluded to be a land wind. For on the opposite side of the island the easterly wind begins to blow afresh. Now, as to why the wind, at first westerly, shortly afterward shifts to its collateral, the west-southwest: the cause is the force with which the first evaporation is carried, which, when later interrupted by other evaporations that arise, changes its flow into the collateral quarter, the west-southwest. When these are finished, the Sun meanwhile sets other hot vents in motion beneath the ocean at the appropriate place, and so the exhaled vaporous material follows the flow of the east-northeast current.

COROLLARIUM. [Corollary.]

[Margin: The true origin of the annual winds.]

From this it is clear that the annual winds of the various seas derive their origin from nothing other than, first, the differing situation of the mountains. For just as these mountains have, as people say, a differing aspect toward the Sun, so too, according to that aspect, are they affected by the Sun in differing ways. And since there is scarcely a mountain of any fame or name, nor any promontory so celebrated, that does not contain within itself enormous cavities, vast caverns together with water-reservoirs [hydrophylacia] — as was said in the preceding pages — certainly no one, unless wholly ignorant of nature, will deny that a great mass of vapors and exhalations lies hidden within their inner parts. The outer surface of the mountains, moreover, presents the greatest unevenness of its parts. In one part they are clothed with the thick foliage of forests; in another they are bare, consisting of nothing but rock [literally "bones"]. In one part they are arched into a circular cavity; in another they are bent into a humped surface of the ridge. Some abound in vast lakes on the level of their summits; others, by contrast, seethe with fiery craters. Since this is so, let us now see how the exhalations and vapors that are stabled within them are stirred up by the Sun.

[Margin: How the subterranean vapors and exhalations are stirred up by the Sun.]

Experience establishes that the mountains are not always illuminated by the Sun in the same way, but each day, from morning to evening, in differing ways — and indeed differently according to the place in the Zodiac the Sun holds, and according to its position. For the Sun imprints one force upon them when it is in Capricorn, another when at the equinoctial point, another when stationed in Cancer and the rest of the signs; and again one force in the morning at sunrise, another at noon, another at evening — and it pours these in

whatever twelfth-part [dodecamorion] it is finally stationed in, according to the diversity of the reflected rays, by whose action the whole business of the winds is carried out.

Third: some mountains are more porous in one part than in another; in some parts they abound in caves, which can not unreasonably be called the wombs [matrices] of the winds; in certain places they swell with sulfur, niter, alum, salt, and the other mineral juices, all of which, when dissolved into vapors and exhalations, are the origin of enormous disturbances of the air. Since, then, the

Sun illuminates the different parts of the mountains at different times and under different zones, it follows that the Sun, stationed at a different degree of the Zodiac, when it strikes the parts of the mountains opportunely with its rays, then also draws out the mass of vapor lurking within, through the pores already opened by its heat. This mass, expanded and rarefied, since it cannot exert itself beyond the rear part of the mountain, pours forth the air it meets onto the side of the mountain opposite, and so, according to the situation of the mountain, produces now a northern, now a southern, now an eastern, now a western wind, and the other collateral winds besides. But since a vapor or exhalation cannot leave the mountain unless another succeeds into the place of the one departing, there is always new air drawn in — either internally from the subterranean hot vents, or externally through the mountain's cracks and fissures — which makes up the deficit of the departing air; and this lasts as long as the Sun looks opportunely on the mountain during the day. But when the Sun is either rising or descending, just as the earlier aspect is destroyed, so it opens other storehouses of vapor, from which new vaporous exhalations are drawn out, producing new annual winds. And what has been said of one chain of mountains is to be understood of all the mountain chains of the whole world. But these matters are to be set out more fully through the Propositions.

PROPOSITIO I. [Proposition I.]

How a Wind arises from the rarefaction or condensation of Subterranean Waters.

That the bowels of the earth are full of water has been shown above in various places, from which sometimes a most violent wind is generated by the rarefaction of water lodged within the bowels of the earth. For since no water can hold together except in its own vessel, and since in the bowels of the earth innumerable water-holding cauldrons [*lebetes hydrophylactici*] are set here and there, destined by nature for receiving waters, it also happens that through the hidden flue of a subterranean hot vent an enormous exhalation is emitted, which, as it surrounds the cauldron on all sides with its most violent boiling heat, so heats the water to the highest degree. The water, thinned by the heat into an exhalation, now rarefied along with the air and requiring more room, rushes out through the opening given it and is rolled out with vast force through the narrow channels, pores, cracks, and fissures of the mountain into the external air — from which a most violent wind is born. And it lasts as long as there is water in the cauldron; when this fails, the wind too must necessarily fail. And lest in the sea a

Diagram. An aeolipile experiment. At lower left, a bellows-shaped aeolipile [*pila Aeolia*] sits in a wide shallow basin of burning coals; a jet of air (steam) issues

from its narrow nozzle and is directed against a large toothed wheel (a turbine) mounted upright on a tripod stand at center. To the right, a horizontal axle carries a roasting-spit mechanism (the *veru* and rotating drum described in the text), supported on a second stand. The figure is uncaptioned and carries no letter-labels. It illustrates the three aeolipiles Kircher kept in his Museum, whose jets could turn a spit loaded with six pounds of meat.

[Margin: Aeolian balls.] [Margin: The experiment of the aeolian balls.]

EXPERIMENTUM. [Experiment.]

The effect of aeolipiles in stirring up winds is widely known. And although I have already described this machine in the section on the air-reservoirs [Aerophylacia], I have nonetheless decided to repeat it here — this being a place very well suited for explaining the generation of winds. So let an aeolipile be made of whatever size and capacity (for the larger it is, the greater the effect it will produce), formed of compact bronze, in the end of whose neck a hole should be left so tiny that it expresses the fineness of a needle. Fill this to the middle with the purest and clearest water, by this technique: place the ball on burning coals so that it grows as hot as possible; once that is done, you will at once throw it into cold water, so that the whole ball together with its neck is covered by the waters. And since the hot and seething air within, condensed by the cold of the surrounding water, contracts itself into a smaller space for fear of a vacuum, it necessarily summons another body into the place of the departing air; and since it finds none but water, it draws this within the ball with the utmost force. By this device of nature, the water drawn in through the tiniest hole fills the ball

[Margin: The marvelous effects of the Aeolian balls.]

up to a point. Once this is done, let the ball, with the coals kindled again, be set back on the burning coals, and with the help of bellows, as before, let it be heated, and the water inside, rarefied, since no exit is given it except through the narrowest hole, is rolled out through it with a vast noise and blast. I myself have in my Museum three aeolipiles of this kind, which, when set on a vehement fire, were able by their own wind to turn, by means of a wheel, a spit weighted with six pounds of meat. And from this experiment it is plainly evident how, in the hollow water-reservoirs of mountains, an enormous wind arises from time to time by the force of the subterranean fire, from the mere rarefaction of the air — which happens chiefly in those mountains that teem with fires and hot vents.

PROPOSITIO II. [Proposition II.]

How the annual wind arises from the Subterranean Cataracts [Catadupae].

[Margin: magnam (continuation of marginal note)]

It was shown in the preceding pages that mountains are for the most part pierced by caverns and by the deepest passages, and on every side by innumerable channels — and that these, just as they are covered by perennial snows, so too supply an enormous store of material for winds, in two ways. The first way is this: whenever the snows of these mountains begin to melt from the Sun's approach, the result is that the melted water, partly spread out over the level plains of the fields below, soaks and steeps the fields with a varied mixed moisture; and this saturation, thinned into vapors by the Sun, will pour forth an abundant seedbed [seminarium] of winds.

[Margin: How the cataracts carry down a great quantity of air with them.]

The other way is this: since the mountains, as was said a little before, are full of caverns, it follows that the melted snow-water, working its way deeper through the clefts of the mountains, hurled down into the innermost recesses of the mountain over the rocks of the interior it meets, most violently agitates the air existing within by the impetuous collision of the rushing waters — which themselves also carry down an abundant quantity of air with them. From this, the air, continually stirred up by the fresh increment now of more air, now of more water, while it seeks an exit, at last bursts forth through the hidden and narrow channels of the mountain into violent winds with great force. These are sometimes driven out with such force that they lay low even the largest trees in their path — just as we demonstrated in our own Etruria [Tuscany], in the matter of the Aeolian cave [specus de Aeolia] in the territory of Volterra [Ager Volaterranus]. See too the marvels we recounted in the Third Book concerning the Aeolian mountain of the Caesii [mons Caesiorum]. But that the reasoning behind the subterranean wind may be still more clearly evident, we shall confirm it by several experiments.

EXPERIMENTUM. [Experiment.]

Let a hollow receptacle be built of bricks, of the form you see here. In its

Diagram. A cut-away schematic of the subterranean-cataract apparatus. A bell-shaped masonry receptacle is shown in section. Labels:

- A (top opening of the receptacle, at the base of the curved tube): the upper mouth from which the spiral canal descends
- E (upper rim, right of A): the receptacle's lip
- K (curved tube rising from the top): the inlet pipe through which water is poured in
- F (tube projecting from upper left): a lateral tube/spout
- L (central spiral, the cochleate canal A–L): the screw-shaped channel down which the water spirals
- I (cylindrical stone at the base): the polished marble stone on which the falling water strikes
- C (small spout/tap at lower right, with an ornamental symbol beside it): the exit channel

The water poured in at K spirals down the cochleate canal A–L and strikes the marble stone I, driving the enclosed air out through the exit at F (described in the text on p. 204).

bottom let a marble stone I be set up, reduced to a most polished surface. From A, then, let a spiral canal AL be drawn, which is open at A and below at L; and let the receptacle be so closed that it finds no other exit except at F. With these things thus prepared, water — drawn either from a spring or from some river — will discharge itself with the utmost force through K, into the canal AL, through which it falls down onto the surface of the stone I with force and noise, accompanied by a great quantity of compressed air. And from the violence of the rushing water, the air enclosed within the receptacle will be agitated in a marvelous manner; thus constricted into the narrows, while it seeks an exit, at last, having slipped out through the orifice F, it will produce a most forceful wind, one fit both to drive a hydraulic organ and to serve smiths in place of bellows. See Book 9 of the *Musurgia*, where from folio 508 up to 511 we treated at length of the Aeolian chambers [Aeoliae camerae].

By exactly the same reasoning — to return to our purpose — the same thing happens in the cavities of mountains. Within these, the water of melted snows, or rainwater, gradually penetrating to the cataracts, produces an enormous agitation of the air; and the agitated air, while it seeks an escape, at last slips out through the hidden channel of the mountain into churning whirlwinds. If indeed this wind is perpetual, it will surely owe its origin not to the dissolution of snows, but to the cataract of some subterranean river, whose fall and downpour, just as it is perpetual, so too necessarily drives the air agitated within the bowels of the mountain out into a perpetual wind. But if the wind rages through such air-holes

of the mountains only in the summer seasons, that is a most luminous sign that they proceed from nowhere else than from the subterranean cataracts of melted snows; for these winds will last as long as the melting of the snows lasts, and once that is finished, these too must necessarily cease — since, once the cause is removed, the effect is removed. Again, if a wind rages from certain mountains only on summer days, three or four hours before and after noon, but never outside these times — not at night, not in spring, autumn, or winter — that certainly cannot be attributed to the subterranean cataracts, but must be referred to other causes, which we set forth in Book 3, last chapter, on the marvels of the mountain of Casius [mons Casius]; and to that I refer the reader.

[Margin: How the winds are stirred up by the subterranean cataracts.]

[Margin: The violence of the subterranean cataracts.]

And so reason dictates that the subterranean cataracts expel enormous whirlwinds through the air-holes of the mountain. For since the water rushing with force is full of air, and carries down with it in all cataracts an enormous quantity of air (as is evident from the foam, white as snow — which is nothing other than a multitude of innumerable little bubbles puffed up with air, from whose compaction the water is, as it were, imbued with a certain bright warmth) — certainly it follows that enormous subterranean winds are born from this; and these, then, by a violent eruption both [agitate] the external air, and, from its forcing-out, produce most violent winds. And winds of this kind we assign to the number of those which arise not from exhalations or vapors, but from the simple forcing-out of agitated air.

PROPOSITIO III. [Proposition III.]

How a Wind arises from exhalations and vapors stirred up in the caverns of the Earth by the force of the Subterranean fire.

Since it is established that the Earth is filled with innumerable caverns, caves, and grottoes — in accordance with the things recounted above — of which some are filled with water, some with air, others also with fire; and since most of them, moreover, teem with mineral and metallic juices and with clods variously mixed with other matters: certainly that matter, when the heat of the hot vents [aestuaria] works its way into it through its flues, is dissolved into a flatulent and spirituous material of salts, niter, alum, vitriol, and bitumen, which is contained in them, and will without doubt cause the greatest exhalations and rapid

expirations. These, when again and again pressed and expanded by supervening heat,

[Margin: How the vaporous exhalations make their way through the porous mountains into winds.]

through the hidden passages and fissures of the mountains, at last bursting out into violent winds, agitate the Earth and the Seas with such force as mortals have often experienced to their great peril. But how that wind comes about, the following experiment will teach.

EXPERIMENTUM. [Experiment.]

Prepare AB, a vessel made of iron plates in the shape of a tube. In its bottom, B, let there be placed niter with sal ammoniac, and a portion of crude antimony — all in equal proportion and reduced to a powder, and steeped with brine. Once this is done, with the vessel set over the fire, the material placed inside, boiling up at the very first scent of the fire and dissolved into vapor and exhalation, will emit a noisy wind, one fit for laying low whatever objects you please; and unless the vessel is firmly bound to its supports with chains, you will see the whole of it snatched up into the air with the greatest astonishment. The wind that is blown out from it is so vehement that a hand placed at the orifice — or

Diagram. A schematic of the chemical wind-vessel AB. A long, curved iron tube rises from a wide, round, basin-shaped base. Labels:

- A (upper part of the curved neck/spout): the tube through which the wind is emitted; a jet of vapor is shown blasting from its open mouth at top
- B (the broad round vessel at the base): the chamber in whose bottom the niter, sal ammoniac, antimony, and brine are placed and heated over a fire (a small grate or fire-door is shown in the front of the base)

The figure is uncaptioned. It illustrates the experiment described above, in which the heated chemical mixture in vessel B drives a vehement wind out through tube A.

— or anything else — it repels with the utmost force. And it emits not only a wind with great noise and crash, but also smoke so dense that you would think yourself set in a cloud. I recall an experiment of this kind once performed here in Rome, in the forum, by a druggist [pharmacopola] not unskilled in chemistry, who had placed the said substances in a mortar to show their natural force. When the coals were kindled in it, at once, with a great crash and blast, smoke so

dense came out that, when it had covered the whole forum with a smoky murk, one man could scarcely see another — the bystanders astonished at the unusual spectacle.

We have the experiment; now let us apply it. Wherever the exhalation of the subterranean fire has penetrated crypts filled with similar material, there is no doubt that that material, dissolved into vapor, if it finds no exit, will turn everything upside down — as happens in an earthquake. But if, through the open siphons and fibers of the mountains, it obtains free power to go out, then by its impetuous agitation it produces outwardly the violence of winds, such as may overturn trees from their roots and lay low houses and towers in the utter ruin of men and animals. But of these things, more in what follows.

PROPOSITIO IV. [Proposition IV.]

How the wind which they call a Whirlwind [Turbo] or Typhoon [Typhon] is caused on land and at sea.

The wind which, from its monstrousness, they call a Whirlwind or Typhoon, dominates chiefly at sea, sometimes to the great peril of sailors. Just as the sea, wrapped in vast heapings-up of waves, it turns in a rapid eddy about the horizon, and with relentless increases agitates [the sea] with a formidable force and savage squalls in a circle. Thus, as the tenth waves [decumani fluctus] surge up and clash against one another as if butting like rams, the raging exhalation takes away from sailors every hope of safety.

[Margin: The effect of the typhoon-wind.]

Now such winds arise chiefly in those seas where vast rivers discharge themselves into the sea, or where the impetuous flow of the Ocean, dashed against the vast tracts of the continental lands, is forced to wheel into a circle, or where two opposing Oceans rush in through the jaws of straits. But let us unfold what has been said in a few words.

[Margin: The marvelous tempests of the Gulf of Lyon, which the common people call the *Golfo di Lione*.]

In the Mediterranean Sea there is found a gulf, which the common people call the *Golfo di Lione* [Gulf of Lyon], opposite the bay of the sea where the mouth of the Rhône is — through which the Rhône rolls out into the sea with a rapid current. In this gulf especially, the violence of the typhoon-whirlwind rages at fixed times, to the great fear of sailors; and it is generated in this way. For when the south

wind blows, the whole mass of the agitated sea verges toward the hollow tract of the said gulf; but the waves of the Rhône, allied with the north wind, rush in with great force from the opposite quarter. Then, behold, suddenly a great conflict of the waves arises, while these waves, not knowing how to yield to those, are agitated into violent whirlwinds. By these, the intervening water, caught between and violently pressed, while it finds no escape, is raised on high in the manner of a column or a mountain — and portends inevitable shipwreck. For a ship entangled in whirlwinds of this kind can by no art elude the inclemency of the savage element.

Diagram. A large schematic of the Gulf of Lyon, showing the whirlpool [typhoon] formed where the Rhône meets the south-driven sea. The coastline encloses an open expanse of sea; concentric circles at the right depict the great rotating eddy. Labels:

- B (top center, the inflowing river): the mouth of the Rhône [Rhodani ostium]
- H (upper, just below B): a point on the inflow
- A (left coast): a point of the gulf [the bay A B C]
- C (upper right coast): a point of the coast
- M (upper edge of the concentric eddy): outer ring of the whirlpool
- O (left of the eddy center): a ring of the whirlpool
- L (center of the concentric circles): the center/eye of the whirlpool
- N (right of the eddy center): a ring of the whirlpool
- I (lower left of the eddy): a ring of the whirlpool
- K (left, below A–G): a point in the sea
- G (lower left coast): a point of the bay
- D (lower left): the south-driven sea [mare australi vento agitatum, D E F G]
- F (right): a point of the sea D E F G
- E (lower right): a point of the sea D E F G

[Caption (verbatim, foot of p. 205):] "Sit dictus Sinus, vulgò *di Leone* A B C, Rhodani ostium B, Mare australi vento agitatum, D E F G." — "Let the said gulf, commonly called *di Leone*, be A B C; the mouth of the Rhône, B; the sea agitated by the south wind, D E F G."

I say that the sea D E, stirred up [toward the concavity of the gulf A B C], meets the waves

— against the waves B, which, being unable to resist the waves G D E, are driven off toward C. But these in turn, thrown back by the waves of the sea reflected toward the shore C, are pushed toward I; and being unable to escape the swell of the sea D E, they are forced into K M N O and whirled in a circle. When they reach L, pressed there by ever-fresh waves brought up in relays, and finding no way out in any direction, they are lifted on high in a horrible spectacle — until, the winds ceasing and the sea flattening out, they gradually subside into circular agitations and are at last restored to their natural flow. You see, then, that this Figure demonstrates beyond dispute the true cause and explanation of the whirlwinds that infest the said gulf of the sea.

[Margin: The Japanese Sea, notorious for shipwrecks.]

The nautical itineraries report that in the ocean between Japan and China, chiefly in autumn, storms of this kind arise from frequent whirlwinds, with such violence and fury that no one who has not seen them with his own eyes can conceive of them. So dangerous is navigation in this sea that a voyage is reckoned blessed and fortunate if, out of three ships, even one holds its course. The reason for this is, first, the General Wind rushing from the east, by which the sea is driven toward the shores of the Chinese mainland. At the same time this current is cut off by the south wind that comes up against it and is driven along the coast toward the north; but this northward current is in turn cut off at the same time by a north wind, and, because of the easterly wind opposing it, when it does not know how to escape, it is bent back upon itself and produces the whirlwinds we have described.

[Margin: Remarkable storms in the Strait of Magellan.]

That the Strait of Magellan is more infested than other places with whirlwinds and typhoons is established by the account of many; nor should this seem strange to anyone, since, given opposing winds and the disposition of the place, a whirlwind must necessarily be stirred up. Thus, when an easterly or General Wind is blowing in the ocean lying between Africa and America, and at the same time a westerly wind is blowing from the Pacific Sea, it happens that these two, entering the very narrow strait, agitate it wonderfully; and when the opposing winds drive opposing waves, and neither can yield to the other, the water must necessarily be heaped up into circles and piles like mountains — which we showed above also happens in this sea from the contrary ebb and flow. As for why sailors find the sea perfectly calm and as if polished smooth before a typhoon, yet a little later roughened with dreadful waves, the cause is that from the opposition of the winds the sea is at first gradually [Margin: continued below]

resolved into circular motions at a distance, and consequently the water, pressed equally on every side, is necessarily rendered level in the intervening space — as experience teaches in any pond or any fishpond, whose waters, if you stir them in a circle with a stick, you will always find smooth in the middle, free of any roughness of the waves; but if you keep up the motion, the water, soon twisted into a helix, will undergo a vast disturbance.

[Margin: Whirlwinds around Ardabil, a city of Persia.]

Yet it is remarkable, what geographers relate of Ardabil, a city of Persia: namely that there, in the months of June and July, a whirlwind is born at noon every day, lasting about one hour, by which a vast and continuous cloud of dust, hateful to men and animals, is stirred up. The reason is doubtless to be sought in the annual wind that blows in those months, combined with the disposition of the place. For this wind, bursting out from a quarter near the south, when in passing toward another quarter it meets an obstacle, twists upon itself and is whirled about, carrying off the dust with it. In this same way, as I have very often experienced, a typhoon prevails in the Roman Amphitheatre: for the wind, striking against the walls arranged in a circle, continues alongside them and is at last driven into a vortex, filling everything with stirred-up dust.

PROPOSITIO V.

Whether and how a Wind is born bursting up through the middle of the sea.

Since beneath the floor of the sea vast fire-reservoirs [pyrophylacia] are contained (as was said in the preceding Section), it cannot but be that they release from themselves a vast quantity of smoky exhalations. These, bursting up through the floor of the sea and passing harmlessly through the mass of the waters, as soon as they reach the surface of the sea, swell and dilate, and rush out wherever the gate is open; and they rage in the ways we described above.

But perhaps someone may say at this point that exhalations cannot pass through a moist medium without being immediately smothered the moment they touch it. [Margin: Whether exhalations can pass through the body of the sea uncorrupted.] To refute the falsity of this objection, it must be understood that spirits of this sort — saltpetrous and sulphurous, which the subterranean estuaries emit from themselves — are by no means destroyed by the water, but penetrate the waters without mixing with them. This is taught by experiment not only in earthquakes, but also in any waters whatever. [Margin: Observation of the Author.] I

remember that in the year 1638, when Calabria was being shaken by unheard-of earthquakes, I observed the sea — just as when it rains, and as single drops generate single bubbles in the sea, or as when fire set under a kettle excites the water into bubbles by its heat — full of bubbles and boiling, which was without doubt a clear sign of vaporous spirits passing harmlessly through the middle of the water from the floor of the sea. Again, at fixed times the water here is raised on the surface, by subterranean winds, into so unusual a swelling that to those standing on one bank it takes away all sight of the opposite bank — as Pliny relates of the river Macra. [Margin: An impromptu swelling of the river, the cause of it, and where it comes from.]

It is remarkable, among other things, what the inhabitants relate of Lake Lemane [Lake Geneva]: namely that it sometimes swells up, even in calm weather and a serene sky, so much that, while this effervescent boiling of the lake lasts, no ship can entrust itself to it safely without manifest danger of shipwreck. [Margin: A remarkable narrative of the inhabitants of this lake.] They call this swelling of their nearby lake, in French, *la vardaïse de Geneve*. The cause of this can be nothing other than subterranean winds and vaporous spirits, which—

Diagram. A perspective view of the apparatus for Experiment I : a shallow cylindrical bowl [concha] resting on a surface, with a curved tube (canal) running from below up over its rim. The labels are:

- A (left rim of the bowl): the bowl A B
- B (interior surface of the bowl, toward the right): the bowl A B
- C (where the lower end of the canal enters beneath the bowl): the open orifice of the canal
- D (the raised upper outlet of the curved tube, projecting above the rim): the orifice through which one blows, set somewhat above the water

[Following the lake-swelling passage above, the text on this page resumes the experimental demonstration.] —which the fire-reservoirs of the neighboring Alps emit through hidden passages that have their outlet in the bottom of the lake. These, with the utmost force, urge on the waters they meet, inflate them and make them swell up in the manner we have described — as is shown by the following experiment.

EXPERIMENTUM I.

Into the bottom of the bowl A B let the orifice of a canal be inserted, with its opening C left open; and let the other end of the canal C D be applied to the

outside of the bowl, its orifice D projecting somewhat above the water. In this arrangement, blow through the canal by way of orifice D, and at once the water that the bowl contains, immediately agitated at its surface, will produce violent bubbles and swellings, which are caused by nothing other than the blast passing through the bottom of the vessel and disturbing the water. But since these things are well known, they need no further exposition.

The other point presents a greater difficulty: namely, that the nitrous spirit expelled through the floor of the sea, without any mixing with the water taking place, escapes whole and entire to the surface of the water. Yet so that we may not let this pass without the support of our reasonings, I add the following experiment, from which you will learn clearly how vapor and smoke pass through a liquid without mixing with it.

EXPERIMENTUM II.

[Margin: How exhalation and vapor can pass through water without mixing — an experiment.]

Take a phial, such as the present Figure shows, filled to some level with water or some other liquid — say, up to B C — with a tube fitted onto the neck of the phial, of the kind that tobacco-smokers are accustomed to use, in such a way—

Diagram. A tall narrow-necked flask (phial) standing on a foot, with a slender tube rising from its neck (topped by a small stopper or bulb) and a second curved spout-tube emerging from the body and discharging a cloud of smoke. The labels are:

- X (at the top of the neck, where the upper tube enters): the orifice X, which is to be stopped carefully
- B (upper-left of the flask body): the water level B C
- C (right side of the flask body, near the spout junction): the water level B C
- D (at the foot of the internal tube reaching the bottom of the flask): the orifice of the syphon-tube, drawn through the water to touch the bottom of the phial
- E (at the mouth of the curved spout-tube, where the smoke issues): the syphon-orifice E, through which the smoke passes out—that, drawn down through the water, it reaches the bottom of the phial; then stop the orifice X carefully, so that neither can the air contained within slip out through it, nor can the air surrounding it flow in from outside. This done, place upon the gaping orifice of the tube some leaves of dried tobacco, or sulphur, or

something similar; and when these are kindled and your mouth is at the same time applied to the little syphon-tube E of the phial, suck out the air lodged within the phial. You will see — wonderful to tell — the smoke and breath of the kindled material pass through the orifice of tube D, in great abundance, in the form of a little cloud, and pass through the middle of the liquid without mixing with it; and you will find its exit and outflow at the orifice of tube E — the moisture being overcome, of course, by the sharpness and dryness of the smoke.

[Margin: Application to nature.]

No otherwise must we judge it to happen in the sea: through whose floor, from the fire-reservoir, a great quantity of sulphureo-nitrous spirits is raised up, passing through the water without danger of mixing with it; and soon, when it has emerged at the surface of the sea, being resolved into blasts and winds, it will agitate both the air and the sea with great force, in the manner we have described.

PROPOSITIO VI.

How a Wind arises from the pressure of clouds.

It often happens, when some storm is imminent, that a violent wind is suddenly stirred up — which occurs especially before the fall of rain, or after the explosion of thunder. The cause of this wind is sought.

I answer that this comes about from the descent of clouds weighed down with water, by which the air beneath them is violently pressed. Hence the air, once pressed, if it meets no obstacle on the sides from some other thing urging against it — whether a cloud or a vaporous exhalation — diffuses itself in a circle in every direction. But if it meets on some side a condensed vapor resisting it, the air, pressed by the cloud lying upon it, since it cannot retreat, rushes forward into the part in front. [Margin: How great a force descending clouds have.] And this wind, though it is very frequent on land and sea, does not last long, but only for the duration of the descent of the overlying, pressing cloud; and when that ceases, the wind too ceases. But let us set the matter before the eye.

Diagram. A landscape view: a dense rain-cloud massed across the top, beneath it a wide layered band of air, then a wavy surface of sea, and below that a range of mountains and valleys. The labels are:

- A (in the body of the rain-cloud at top): the rain-bearing cloud A

- B (left side of the intermediate air-band): the intermediate space B C — the air
- C (right side of the intermediate air-band): the intermediate space B C — the air
- D (on the wavy surface beneath the air-band): the surface of sea or land D
- D (again, marked lower on one of the mountain slopes): the surface of sea or land D

Let the rain-bearing cloud be A; the surface of sea or land, D; the intermediate space B C, the air. I say that the cloud A, by the weight of its waters, as soon as it begins—

—its descent, presses upon the air B C; and this pressed air, if no obstacle is set at B and C, will discharge itself there with violent force — and all the more violently, the more it has pressed the air placed below it with a swifter and more forcible descent. But if it finds obstacles on one side or the other — that is, air condensed by vapors and exhalations — then it will find its exit either at B or at C. And so the cloud A holds the function of a bellows, which by its descent expels the air between itself and the surface of land and sea, as if through a channel, with great force. From this it is clear why such violent and impetuous winds sometimes suddenly arise: namely, because if the air is surrounded on every side by the thick vapors enclosing it, and is moreover pressed by the sudden descent of the cloud overhanging it, then, since no escape is given it, [Margin: An experiment of the pressure of clouds.] it will rush, wherever the gate is open, with vast force, as if through some narrow channel.

Let L be the pressing cloud; P the pressed air; M N the surrounding dense vapors; O the gate, through which the pressed air bursts out. But these things are so easy to grasp that they need no further exposition.

Diagram. Within a ruled rectangular frame, a large ovoid mass of air (P) enclosed by a ring of rounded vapor-cloud puffs, with a fan-shaped stream of rays bursting out to the left through an opening. The labels are:

- L (top of the cloud-ring): the pressing cloud L
- P (center of the ovoid): the pressed air P
- N (right side of the cloud-ring): one of the surrounding dense vapors M N
- M (bottom of the cloud-ring): one of the surrounding dense vapors M N
- O (at the left opening, where the rays burst out): the gate O, through which the pressed air bursts out

From these things, too, it is clear why a wind is felt after thunder: because, from the bursting of the cloud, just as the air beneath it is greatly stirred, so a wind must necessarily be born. It is likewise clear why, in valleys and the fissures of mountains, so violent a wind often rages: [Margin: Why a wind is usually stirred up after thunder.] because a wind excited in open country, however gentle, as soon as it has entered narrows of this kind, there too, as if shut in and constricted, gains strength wonderfully. I myself experienced this, not without danger, on a very high mountain in the territory of Sora, to whose summit-plateau there is no access except through a narrow defile broken by crags, in which there is such ferocity of winds that no one can advance upright without danger; rather, lest he be snatched away by the wind, whoever attempts the ascent of the mountain is compelled to reach the exit by crawling. [Margin: A danger of the Author.] My traveling companion related that not long before, a whole herd of pigs had perished in this place, caught up in the whirlwinds of the winds, snatched away, and dashed against the crags of a neighboring mountain. I could adduce countless wonders of mighty Aeolus in this place, to be met with everywhere across the regions; but let it suffice to have recounted only those I myself experienced.

PROPOSITIO VII.

How the wind that the Greeks call Ecnephias and Prester is born, and from what causes.

[Margin: What the Ecnephias and Prester are.]

Ecnephias [Greek: ἐκνεφίας (eknephias, "a wind bursting out of a cloud," a hurricane-squall)] is the name given to a sudden and most impetuous wind which, when it bursts out of some cloud, turns everything upside down; and these are frequently met with in the ocean lying between Brazil and Africa, also at the Cape of Good Hope and at Terra de Natal [Natal], likewise at Guinea beneath the Equator — winds which the Portuguese sometimes call, by a corrupt term, *Travados*; and in the said places they are annual. But before we proceed to the scrutiny of the hidden cause, we must first set forth how they are born, so that, having seen their prodigious effects, we may more easily arrive at their cause.

[Margin: The ill-fated Portuguese expedition.]

The Portuguese, before they were equipped with sufficient knowledge of the ocean — while they were giving their effort to discovering new regions around the Cape of Good Hope and the promontories of Africa — more than once

experienced the savagery of this sudden wind, with great destruction of ships and men. For when India had been opened up by Vasco da Gama [Vasco da Gama], the King of Portugal dispatched a new fleet, which consisted of thirteen huge cargo ships, in the year 1500, under the direction of a Captain and Commander, to explore new regions. This fleet was the first of all the European ones to be carried into Brazil, to the great joy of the Portuguese; and when they had stayed there for some time, at last, setting sail toward the Cape of Good Hope in the month of May, they ran into the most savage storm — which our Maffei [Maffei] describes very vividly. From Brazil to the Cape of Good Hope they reckon nearly 1200 leagues [leucas] over a vast stretch; these are the chief realms of the raging ocean and the furious winds. [Margin: The apparition of a comet.] To the Portuguese, who had entered that space in May more boldly than fortunately, a flaming comet of horrible aspect appeared continuously, even to the tenth day. And as sky and sea kept changing again and again, foul clouds massed together to the north had gathered into themselves, as it were, all the wind by their reciprocating motion. The sea was sluggish — a treacherous tranquillity; the sailors, ignorant of the places and the storms, had spread all the folds of their sails to catch the breeze from every side; when, out of those clouds I have mentioned, the North Wind [Aquilò], pouring itself forth all at once with a sudden onset, in a moment so overturned and overwhelmed four ships set crosswise — whose rigging had been less aptly arranged for shortening sail — with the others looking on, that out of so great a number of men not one at all escaped. To the rest, safety was afforded either by the yardarms lowered in haste, or, where that was not permitted, by the very sails ripped apart by the wind. Then, as the North Wind [Borea] blew on stubbornly, the sea swelled again and again, the waves now borne to the stars, now sinking almost to the very depths; it terrified the very Sun, by day with a pitchy color, by night with a fiery one. For twenty whole days the storm—

—held most atrociously. So Maffei. Whether this storm can truly be reduced to an Ecnephias is uncertain, since the Author teaches that it proceeded from the influence of a malignant comet over many days. [Margin: How the Ecnephias is generated.] But the effect of an Ecnephias, just as it is sudden, so too lasts only a very short time. For my part, I can by no means persuade myself that it was a comet; rather, I would judge it more likely that a continuous effluvium of submarine exhalations, carried up into the middle region of the air and there condensed, at last caused the storm that Maffei reports. What, then, the Ecnephias properly is, must now be stated.

It happens from time to time that, with the sky perfectly serene and the sea calm, a tiny little cloud appears in the sky — which from its shape they call the Ox-Eye

[Oculus bovis] — and within a short time, taking on a vast increase of itself, it stirs up such storms as we can scarcely read of without terror. [Margin: Description of the Cape of Good Hope.] Such a portent of nature is not infrequently met with near the Cape of Good Hope, which a lofty mountain, stretched far and wide out into the sea, constitutes. The summit of this mountain is not, like that of other mountains, tapered to a point, but possesses a remarkable flatness, which, from its form and shape, the Dutch [Belgae] call *den Tafelberg* — that is, the Table-Mountain spread with a tablecloth. On the plateau of this mountain, then, in the air just above it — as the eyewitness Fr. Martino Martini [Martino Martini] related to me by word of mouth — a tiny little cloud shows itself to view, which soon covers the whole breadth of the mountain. [Margin: A sign of the imminent Ecnephias.] When the sailors have observed this, then at once, as if it were the unmistakable forerunner of an inevitable storm, they gather their sails and withdraw from the shore, entrusting themselves to the deep as to a safer place, judging that they are by no means free of that deadly banquet of the laid table — which at all times brought manifest destruction to those who approached it too incautiously. For from the mountain's summit a wind is straightway sent forth so strong that no ship, however well-built and sturdy, can endure its force; hence the sea, raised into piles like mountains, excites such great waves and squalls that the sea, with its ships, seems to be tossed about no otherwise than a feather agitated by the wind. And so, from the incredible commotion and seething of the sea, men must perish — either by the breaking apart of the ships' frame, by submersion, or by being dashed against the rocks they meet, with horrible ruin of the men. And that storms of this kind occur not only at this promontory, but also in many other places at fixed seasons, was said above: namely, at Terra de Natal [Natal]; on the maritime coast of Guinea; at the Cape Guardafui [Cape Guardafui]; at Loanda [Luanda]; and elsewhere throughout the tracts of the Indian sea. These winds, if they are discharged together with lightning-flashes, are then also called Presteres [Greek: πρηστήρ (prēstēr, "a fiery whirlwind, a lightning-storm tornado")], as for the most part happens. Having seen the horrendous effects of the Prester and the Ecnephias, we will now inquire into the cause.

I say, therefore, that all of Africa beyond the Mountains of the Moon to the south — which they call Monomotapa, Angola, Mozambique, Melinda [Malindi], and Sofala — abounds with subterranean fires. That this is true was sufficiently declared in the preceding remarks on the Volcanoes and the burnt-out Islands of the African sea. Moreover, that the whole said Region of Monomotapa is consequently riddled with caverns and crammed with abysses, dens, and caves of unexplored depth, the annual letters of our Society [the Jesuits] attest; and again,

that it is so rich in gold that the natives affirm they have not infrequently found, among the ledges of the mountains, lumps of solid gold the size of a hen's egg; and that it is therefore pregnant with metallic juices and mineral spirits. From the foregoing it was clear that wherever subterranean fires prevail, there too are found chimneys and vents (without which fire could not live), some of which, spreading far and wide beneath the sea, find their outlet in the floor of the sea, others in the highest mountains; and in these, both salts of every kind and other minerals — with the natural disposition of the Sun assisting — are digested and concocted into gold and the other metals.

[Margin: Why the Ecnephias occurs at a fixed time.]

These things laid down, I say that, at a certain position of the Sun in the Zodiac, fire-reservoirs of this kind are stirred up — whether this happens from the reciprocation of the tide of the Eastern or Western Ocean, which presses the aqueducts naturally inserted into the shores; or because of the efficacy of the Sun's rays striking the soil of the said porous, spongy region; or, lastly, because of the snowy inundations of the Lunar Mountains [Mountains of the Moon], to which the whole of southern Africa is subject. Whichever of these it is, it makes no difference: that each of the causes recounted brings about a great increase of the fire-reservoir was shown above. And that the Presteres and the Ecnephias draw their proximate origin from this, we have now undertaken to demonstrate. [Margin: The Ox-Eye, as they call it, when it is generated.] Since, therefore, the Cape of Good Hope — where impetuous and fiery winds of this kind for the most part rage beyond other regions — is set up into a very high mountain, conspicuous with its rocky summit, elevated, and on every side built up of sheer crags and cliffs, it seems not unlikely that the fire-reservoirs unload themselves through various crypts and hidden passages, partly somewhere in this mountain, partly out in the open sea. But they cannot unload themselves except through vapors and exhalations; and since these are pregnant with sal ammoniac, niter, sulphur, antimony, and similar stubborn minerals, they are soon — together with the volatile spirits of gold in which they are strong — carried up on high through the orifices of the mountain's passages. When they have reached the cold region of the air, there, condensed, they form that little cloud which they call the Ox-Eye. But since vapors and exhalations of this kind increase by continuous succession, it happens that they gradually cover over the whole plateau of the mountain in a trapezoid shape [Greek: τραπεζοειδῆ (trapezoeidē, "trapezoid-shaped")]; and the vaporous and swollen substance of the vapors and exhalations, agitated this way and that, easily kindles into fire. When this happens, then — behold! — the

spirits, impatient of their prisons, rushing downward with preceding lightning-flashes, with a fearful crash, and with incredible force, [whatever]—

whatever they strike, they level. As for why they are carried downward rather than upward, the cause is the spirits of gold, mixed together with a nitrous substance and with sal ammoniac and antimony — substances than which nothing in the natural world can be more potent or efficacious. But let us confirm the matter by experiment.

EXPERIMENT

[Margin: The remarkable power of certain minerals.]

There exist in nature certain mineral substances whose combined force is so great that the overturning of whole mountains may rightly be ascribed to them. You will discover this with the greatest astonishment if you make a compound from calcined gold, aqua regia, sal ammoniac, and oil of tartar [oleum tartari], precipitated: for at the first whiff of fire this mixture ignites and, with an enormous preliminary crash, levels whatever lies in its path — and not without grave danger to the life of anyone who handles it too carelessly.

[Margin: Experiment.]

I have seen a powder of this kind placed on the tip of a knife and set alight produce so great a noise that the senses could scarcely bear it, all those present being as it were deafened by the violence of the sound. The effect of this powder is exactly contrary to that of ordinary gunpowder [pulvis pyrius]: for just as ordinary powder, once ignited, is driven upward with force, so this one is driven downward.

[Margin: The contrary power of gold-powder to that of common gunpowder.]

For if you set alight even the smallest quantity of this fulminating powder [pulvis fulminans] placed on a plate, whether of iron or of wood, you will find the plate — of whatever thickness it may be — pierced through in an instant with a frightful crash. Its sole cause is the sal ammoniac. For just as saltpetre [salnitrum] and sulphur wage hidden quarrels of enmity, so much so that they cannot even coexist together, in the same way sal ammoniac too has its incompatibilities with tartar.

[Margin: The antipathy of sulphur and niter. The antipathy of sal ammoniac and tartar.]

So when sal ammoniac is joined with oil of tartar, its opposite, they at once break out into ferocious wars. The gold, already dissolved by the aqua regia, sinks downward; the oil of tartar strikes at the purified spirit of niter, which — stirred up by this conflict — joins itself in a contrived alliance of friendship with the sulphur of gold, the enemy of niter. Yet since the sulphur of gold is supremely purified and incomparably finer than common sulphur, it produces these astounding operations: penetrating, dissipating, boring through, and overturning everything.

[Margin: A horrid clash of minerals.]

The saltpetre, for its part — being hostile to the gold-spirits — swells up among them, and since it cannot be confined within the narrow space, together with those most powerful spirits it bursts through everything with incredible violence, amid a vast crash and roar. To these are joined the contrary pair, sal ammoniac and precipitated tartar, which enter into battles all the fiercer in proportion to the more violent hatreds with which they are at odds with one another. Therefore, whenever these violent substances are lifted into the air by exhalations and vapors, it comes about that, once kindled, they cause the very Presters and Ecnephiae [ἐκνεφίας] that we have described. Indeed, in every impetuous, turbulent, and violent wind by which even trees are uprooted, houses leveled, and horsemen and men alike snatched up through the air, it is as certain that materials of this sort, drawn out by exhalations and vapors from the bowels of the earth, are intermingled, as it is certain that all the exotic effects within the bowels of the earth — those that attend earthquakes, the overturning of mountains, the ruin of cities, and the new births of lakes — are caused by the commingling of materials of this kind.

The question now arises: why is the sea rendered so turbulent at the eruption of Ecnephiae?

[Margin: Why the sea is rendered so turbulent at the eruption of an Ecnephias.]

I reply that this happens for two causes: either through the impetuous Ecnephias rushing upon the sea, which will violently agitate the neighboring water in a moment; or, secondly, on account of the contrary waves rushing in from the deep recess of the sea, which, meeting the waves already stirred up by the Ecnephias, struggle against them with enormous effort. From this contest of the waves the sea is now raised into mountains, now whipped into whirlpools; and now, dashed in various ways against the lateral waves, it produces that disturbance which we have described.

[Margin: Why the sea is sometimes suddenly stirred up out of perfect calm.]

It also happens that the Ocean, in certain places, even in calm and tranquil weather under a smiling sky, boils up into immense swells. The only cause of this is that the aforesaid exhalations and vapors, forced up with the utmost violence through the hidden channels set in the sea floor, meet the resisting watery element and lift it on high, and in this way render it most swollen and most turbulent. These vapors, filled with the said mixture, sometimes — as we learned above by experiment — penetrate the water-substance with which they cannot mix, and slipping out beyond the surface of the sea and kindled by excessive agitation, set the whole sea ablaze at once, especially if they are bituminous.

[Margin: Why the sea sometimes burns.]

The histories relate that [Americus] Vespucci [Amerigo Vespucci] first observed this, and after him other master mariners experienced it in many tracts of the Ocean. It also happens occasionally that the water-conducting channels of the Ocean are infested by vapors and exhalations of this sort, whereupon the water, forced to recede, suddenly and violently sets in motion the entire mass of the Ocean lying above it. From this a most certain rule can be deduced: that whenever tempests of this kind arise under a tranquil sky, they take their origin either from the exhalations described or from subterranean winds. So you now have the cause of the Ecnephias set out in this place.

PROPOSITIO VIII

How the Exhydrias Wind is produced.

[Margin: What is the Exhydrias wind?]

The wind that the Greeks call Exhydrias [ἐξυδρίας, "out of water"] can be considered in two ways. Either as it arises from a vast mass of clouds dissolved into water, which falls upon the earth not drop by drop but in a total outpouring of water, ravaging everything with its flooding — and in German this is called *Wolckenbruch* [cloudburst], that is, the "bursting of clouds"; or rather as it is born from the depths of the waters, which is what remains to be discussed here.

By the long experience of those who [have plowed the vast]... ..recesses of the Ocean, it has been observed that out of a sea perfectly still and, as it were, swept clean as with a broom by calm weather, a certain vapor rises up, which, in the form of a tube or sleeve — and which the Portuguese accordingly call *la Manga* — is gradually lifted to a very great height.

[Margin: An unusual and very great storm of the sea; why it is called *Manga*.]

It then spreads out so far that it covers both sky and sea with a dense gloom, from which winds of the most dreadful and incredible violence follow. By these the Ocean is whipped into such a fury that no one can conceive in his mind the terrifying force of the waves — except one who has experienced it. The mariners' accounts record that no ship, if it ever fell into a waterspout of this kind, escaped — in those earliest times when the captains were ignorant of the force of nature in its ferocity; but nowadays, taught by experience, they are accustomed to elude the fury of this wind with marvelous skill as soon as they catch sight of the rising vapor. If you ask the cause of this wind, know that it is altogether the same as that which produces the Ecnephias, with this single difference: that the Ecnephias is produced by exhalations and vapors led out through earthen passages, whereas the Exhydrias is produced through siphons set in the sea floor, by which the said vapors are drawn out through the midst of the sea.

[Margin: The cause of the storm.]

For these, raised on high, with ever-new flatulent vapors constantly succeeding them, are at last expanded and agitated; and because of the spiritous mobility of their substance, unable to be contained, they rush out by whatever opening is given them and harass the sea with those storms we have described.

PROPOSITIO IX

What the Ecnephias is — the whirlwind that those traveling in the Mediterranean regions occasionally experience — and how it is produced.

[Margin: The Ecnephias and whirlwind in the inland regions.]

In the straits of the Arabian Gulf [Sinus Arabicus — the Red Sea], as also in the deserts of Arabia, Ethiopia, Libya, and the rest of Asia, the Ecnephias together with a whirlwind is most frequent. It first presents itself to the eyes as a dense black cloud, glowing with flame-like spirits like a kindled furnace, dreadful to behold, and teeming; by its dense gloom it brings darkness upon the day. There follows immediately upon it a stormy wind — not lasting long, however — by which the sands of the shore, both of the Red Sea and of the aforementioned deserts, are stirred up and raise sandy storms far more dangerous than those at sea.

[Margin: The storms of the sandy deserts of Africa, by which men are often buried.]

It happens indeed that a whole company of merchants, which they call a *Caravan* [Caravana], of as many as six thousand men who traverse the said deserts, is overwhelmed and buried by a sandstorm, perishing together with their camels without any human remedy.

[Margin: Why the storms of the sandy deserts of Africa, from which...]

The cause of so rare an event is sought; certainly I think there is no other than the one I have stated. Namely: nitrous-sulphurous vapors, mixed with sal ammoniac — which is gathered in great abundance in deserts of this sort, especially in the desert of Ammon in Libya, from which it even takes its name. For these, once kindled, in proportion to the violent ferocity of nature with which they are endowed, are expanded; and being of a lighter substance, striking the sandy soil they stir it up from the bottom, whence the sands, lifted up to the stars and then heaped up into sandy mountains, bury and overwhelm whatever they encounter by an inescapable fate.

[Margin: A rain of worms, serpents, and the like in Africa, from where?]

From this it is clear why in some places of Arabia and Libya a rain of worms, serpents, frogs, and similar little animals has occasionally been observed. For these — together with the sand, or even from any place where, springing up in copious offspring, they make their habitat — are snatched up by the violence of the winds, carried now into these, now into those regions according to the wind's direction; or else, from the seminal corpuscles of the said animals being lifted up and hatched by a sudden generation in the humid and warm air, they cause that prodigious rain we spoke of. And in this way no kind of rain, however exotic, is recounted by historians whose reason you could not assign — concerning which more fully in what follows.

CAPUT VI

On the Transverse Motion of the Winds, and Its Cause.

It can scarcely be told how much the meteorologists torment themselves in rendering the true and genuine account of this motion. Hence some, stretched upon the most abstract principles and neglecting the power of nature, take refuge in extrinsic and free causes and ascribe the motion of the winds to Angelic powers. And although this may sometimes be true, I do not think it becoming to a philosopher — so long as the true, real, and genuine causes of natural things are available — to take refuge in higher powers and in the power and virtues of God and the angels. For in this way, with all law of philosophizing removed, both the

ignorant man and the little woman could philosophize without any trouble about the occult and hidden causes of things.

[Margin: The motion of the winds is not established from a higher power.]

I am not unaware that Sorcerers and Witches sometimes, by the operation of demons and with God's permission, stir up the most savage storms — yet without any prejudice to natural causes, since the demons do not produce these of themselves immediately, but by means of natural causes. For inasmuch as the whole economy of nature is most thoroughly known to them, nothing is easier for them than, by applying actives to passives, to produce such an effect as the natural causes of similar things are wont — of themselves, intrinsically, and by their own nature — to produce.

There are some who, when they cannot extricate themselves from the perplexity of this motion, hold that it proceeds from nowhere else than from a Soul of the Earth — just as in animate beings the faculty of breathing out and breathing in proceeds from the lungs. But since these men philosophize as ridiculously as this, I likewise consider them hardly worth refuting. Certain others suppose that the winds are moved transversely by the rapid rotation [raptus] of the heavens — — but this too is gratuitously invented. For if, according to their opinion, the rotation of the heavens occurs from East to West, then all winds would necessarily rush forth equally from the East — which is contrary to experience.

[Margin: Various opinions on the transverse motion of the wind.]

Nor are those to be heeded who derive the transverse [λοξοδρομίαν, "oblique course"] motion of the winds from an equilibrium of motive power — relying on a false foundation, they suppose that the lighter portion of an exhalation (which they assert to be substantially earth), raised by heat, as soon as it has met the cold of the middle region of the air, is restored to its earthly nature; and while it descends, by its own weight it beats upon the lower mass of the thicker air, and since it is given no power either to return below or to rise upward, it pursues a middle, that is, an oblique motion. Whoever pleases may consult the many opinions of various authors in [Bonaventura], who in a vast volume does almost nothing else than discuss the reasons and causes of this transverse motion of the winds.

We, having sworn allegiance to the words of no Master, will set down here our own opinion, which — relying on the confidence of our experiments — we do not doubt will assign the genuine reason for the transverse motion that we call the formal cause of the winds.

It was said in the preceding pages that a wind is nothing else than a flatulent vapor expelled by heat — whether by the power of subterranean fire, or raised on high by the heat of the Sun. This granted, I say that the motion of this vapor can be carried out transversely in many ways: first, by flight from its contrary; secondly, by pressure; thirdly, by the compression of the surrounding vaporous air.

[Margin: The true and genuine causes.]

The flight from the contrary occurs in this manner: since the vapor of a most light substance, by its own nature hot and dry, drawn out from its mixture, flies upward with the greatest impetus, it comes about that, encountering in the middle region of the air a cold contrary to its nature — and since the two cannot coexist together, while it cannot, hindered by its own lightness, attempt to depart downward — being thereby repelled, it takes counsel for its flight and rushes in a middle path, driven transversely. And this is the first reason for the oblique motion.

The second, which occurs through pressure, happens in this way. It is known to everyone that vapors raised on high from the earth and sea, when they have reached the middle region of the air, are condensed there by the cold and turned into clouds; and these clouds, sinking gradually by their weight — just as they place a further obstacle to the ascent of the flatulent vapors, so too by their descent they press hard upon them. These vapors below, multiplied by the ever-new accession of rising exhalations, but pressed from above by the supervening cloud, rush obliquely by whatever way lies open; and in this way the transverse motion of the winds is carried out.

The third manner occurs through the compression of the surrounding vaporous air, in this way. It happens most often, as the vapors rise, that they are surrounded on every side — both above by the clouds and from the sides by the substance of the thicker air's pores. While thus enclosed in these narrow cells, since it suffers great violence from the ever-new multiplication of rising vapors, taking counsel for its flight it takes the way that nature offers as the easier for it; whereupon, the obstacles burst, it slips out with vehement impetus and is carried by a transverse motion into that quarter which the broken obstacle faces.

To these I add a fourth reason for the oblique course [λοξοδρομία]: namely, the fissures and clefts of mountains, from which, just as the exhalation bursts out laterally, so too it continues the lateral flow that it began from the start. And in this way it draws with full impetus into that quarter whatever other vapors and

spirits it encounters in its path, and sets the whole air in motion — which, just as it excels in marvelous mobility, so is driven in whatever direction the vapor, following its lot, is driven. And thus truly and properly that spirit acquires its strength as it goes, like a torrent or river, growing strong by the addition of new vapors, and lasts as long as the exhalation and outflow of the vaporous material lasts. Here, Reader, you have the reason for the transverse motion of the winds so combined that no other can be conceived which does not coincide with what has been said. These things being shown, nothing remains except that we demonstrate, with equal advance, the nature, property, and powers of the winds.

CAPUT VII

Whence arises the Tremor, Undulation, and the diverse degrees of intensification and remission of the impetus of the winds, and how these can be known by sound.

[Margin: The wind, striking the air, expresses its properties in its flow.]

That the wind is carried through the airy region exactly as a river is carried — this it is our task to demonstrate in this place. For just as a river, now full, now diminished, sometimes whipped up among the narrow defiles of mountains affects a certain swiftness, sometimes, restored to flatter places by a pleasing massing-together of waves, is borne along; then among the rocks it meets, as it were combed, [makes a] marvelous [murmur]; sometimes, hurled down from cataracts, strikes dread by its vehement roar; at other times among the pebbles and stones it babbles with a gentle murmur of flowing water — and thus innumerable rivers of this kind produce effects of this sort. In just the same way it happens in the wind, the motion of which, could we but attain it by the senses, we would perceive to produce exactly the same effects in these as in rivers. But lest we should seem to have omitted any of those things which [pertain to the nature of the wind]... ...pertain to the nature of the wind, we will work the matter out by experiment.

EXPERIMENT

If someone stretches out a string [chorda] made from the intestines of animals and exposes it to the wind in a place prepared a little earlier, he will observe that the string presently sounds — not with that note proper to the stretched string, but with one quite different. For now it keeps the third, now the fifth, now the fifteenth or twenty-second, then again the third, the fourth, or the sixth. Since no one has been able to give the cause of this matter, we have thought it the part of our task to disclose the genuine cause of it here.

[Margin: Why the string, struck by the wind, exhibits such diverse sounds.]

I therefore suppose, first, that the wind is not carried against the string with an even impetus, but strikes now this part of the string, now that, as it were by certain radii, with now a slower, now a swifter impetus; and that this unequal impetus of the wind — this, namely — is the cause of such diverse sounds. I demonstrate it thus.

Let the string be A E, and the wind G. If it grasps the whole string A E with a single, undivided impetus, it is certain that the string gives out its proper sound, the one that befits its degree of tension.

Diagram. A geometric construction illustrating an Aeolian string struck by wind. At the left is a personified wind (a cherub-like face blowing), labeled **G**. From the wind's mouth a sheaf of straight radii fans out toward the right, where a vertical string is marked by four points from top to bottom. The radii represent the wind's rays striking the string at different points (the apex of the fan, the bisection point, etc.) to produce different harmonic divisions.

- G (left, the blowing face): the wind [ventus]
- A (top of the vertical string): upper terminus of the string A E
- B (upper-middle of the string): point of the wind-ray G B (the trisection division)
- C (lower-middle of the string): point of the wind-ray G C (the bisection / midpoint)
- E (bottom of the vertical string): lower terminus of the string A E

If, however, the ray G C alone touches it — that is, divides it in two — it will come about that the remaining parts C A and C E sound the whole octave [diapason], just as we demonstrated in the division of the monochord. For the wind's ray will serve in place of a plectrum: when it has touched C, the trembling of the whole string in the parts C A, C E will sound twice as fast, whence the string will necessarily sound higher by the interval of one octave. But if the wind's ray G B presses the middle B between A and E, the part of the string B A — and necessarily B E — will sound the twelfth, for the reasons assigned in the division of the monochord. If again the wind presses the whole space A D, D E will necessarily sound the double octave [disdiapason], that is, the fifteenth — and so on with the rest. The wind's ray, therefore, by its various different incidences upon the string, will produce various different sounds in it. Hence, when the windy ray leaves a larger part of the string untouched, it will produce a higher

sound by that much; but when it leaves a smaller part, a lower sound by that much.

What, then, the wind does on one string, it will do on innumerable other equally-tuned strings; and this is the genuine cause of the great diversity of sounds perceived in this instrument. Sometimes a certain tremulous sound arises, marvelously affecting the ears, which certainly has its origin from nowhere else than from the undulation of the wind — which does not always come with a straight impetus, but glides upon the string in the manner of waves, and so consequently sets the string in motion with the same motion by which it strikes it.

COROLLARY

From these things too it is clear that one and the same string can give out infinitely many diverse sounds. For the wind, even though it presses the string more strongly in one place, by pressing it more weakly in other places will bring forth new and new differences of sounds. For if, for example, it presses strongly at C and weakly at B, it is certain that C A does not affect the octave entirely, but something intermediate.

From this experiment all the differences of the winds — those observed in their motion and impulse — are most clearly evident, so that one who cannot attain the flow and undulation of the winds with his eyes may perceive it in this experiment with his ears. See, if you please, what we have treated of this at length in the *Second Volume of the Musurgia* [Kircher, *Musurgia Universalis*], fol. 354.

CAPUT VIII

On the Nature and Property of the Winds.

PROPOSITIO I

Why and whence are some Winds cold, certain ones hot, and others dry and humid?

[Margin: The cardinal winds do not always possess the same faculties.]

Those are greatly deluded who suppose that all Northern winds are cold, all Southern hot, all Eastern dry, and the Western humid. For the qualities of the winds must be derived not from the regions of the World, but from the medium through which they pass. For whether some mountain covered with snows holds its position to the North, or to the South, or to the East and West, it will always be true that a wind, from whatever part of the mountain it blows, is cold on account

of the snowy medium it passes through; and so it is necessary that that wind always be humid...

there is no wind that crosses marshes and lands soaked with standing water that is not always cold and humid; and likewise the wind that blows across sandy deserts and gravelly tracts scorched by the heat of the Sun is always hot and dry — as the Greeks, the Cretans, and the Cypriots find when the Libyan or south wind, or a similar one, blows from the facing coast of Africa.

[Margin: The winds of the Romans, and their qualities.]

Experience confirms it. The north wind, which here at Rome brings us dryness and cold, that very same wind in Belgium [the Low Countries] and on the other maritime coasts brings rains and clouds. Again, the north wind, which for us is of a dry-cold quality, at Tunis [Tunisi] in Africa is reported to be of a hot-humid quality; and conversely the south wind, hot-humid for us, on the African coast is cold-dry.

[Margin: Various examples of the variability of the qualities with which the winds are endowed.]

The reason is plain. Since the north wind blows to us from the snowy mountains of the Apennines, it affects us with the same quality as the medium it passes through — that is, with cold. And since the south wind blows from the sea and from marshy tracts, it likewise affects us with the quality the medium it passes through is steeped in — that is, with humid-warmth. But at Tunis in Africa, since the Mediterranean Sea (which lies to their north) is not cold-dry but warm-humid, it will bring a wind of the same character as that medium. By contrast, from the south — both because of the mountains of Numidia and because of the intervening sandy deserts — it will breathe now a cold-dry, now a hot-dry wind. I could adduce countless examples here to demonstrate this truth, but since I touched on them in earlier passages, I have not wished to dwell on them further.

You see, then, that the nature of the winds is not everywhere the same, and that it depends solely on the medium, or on the natural constitution of the surrounding mountains, valleys, plains, seas, lakes, and marshes.

[Margin: The effects of the winds depend on two things.]

This is confirmed by reason as well. For the nature and effect of a wind depend on two things: on the very spirit of which the wind consists, and on the place through which it passes. But the spirits that breathe out from the earth to our east, and cause an east wind, those same spirits will cause a west wind for those

living in the western region — unless something else has stood in the way — a north wind from the north, and a south wind from the south, even though the wind is one and the same and steeped in the same qualities. Since, therefore, south winds do not everywhere blow from hot-humid places, and cold and dry places are not always found to the north that would produce cold-dry winds of this kind, it plainly follows that the nature of the winds is not always the same.

[Margin: The varying exhalation of one region in others.]

Therefore, in order to establish anything certain about the nature of the winds, the nature and constitution of each single region above all must be observed — for example, from what quarter a given exhalation blows, and through what medium it passes. For these two things above all constitute and vary the nature of the winds. Just as the soil and the quality of the earth of every single region differs greatly from others, so too the exhalations that rise from there [text continues at the foot of the column and resumes at the top of the next] constitute different winds as well.

Hence the diversity of winds must be reckoned according to the constitution of the horizons. There are indeed certain places that rarely admit winds, such as Egypt. Yet if winds do prevail there, they are of the kind we described above when we treated of the *Ecnephiae* [hurricane-squalls] — impetuous and violent. There are other places that are perpetually dominated by a rainless wind, as in the territory of Avignon [Avenionense], where you will scarcely ever find rain, the sky always serene, but the winds perennial, all the humidity being converted into them.

[Margin: Mont Ventoux [Montventon] in the district of Avignon.]

The reason for this seems to be none other than the windy mountain commonly called *Montventon* [Mont Ventoux], which lies near Carpentras [Carpentoractum], and which they say breathes out perpetual winds through hidden passages in its inner bowels — winds by which the vapors drawn up by the force of the Sun from the Avignon countryside are at once converted into blasts stripped of all their humidity. They say that about fifty years ago this tract used to be watered by frequent rains; but after the inhabitants had dried up a huge lake situated beyond the Rhône, about fifteen miles distant from Avignon, the sky too, stripped at the same time of the humidity it had enjoyed by the lake's benefit, thereafter denied its rain.

There are, moreover, certain places subject to perpetual floods — such are those that are crowned by great mountains. For the clouds, gathered within their

gorges, are halted and herded together, until, when a Sirocco [Syrophoenice] or Libyan wind blows from a more humid quarter, they are dissolved into waters.

PROPOSITIO II.

Whence the wholesomeness or unwholesomeness of the winds arises.

In the judgment of physicians, every wind that does not arise from a commotion of the air, but from exhalations and vapors, is not only harmful to human bodies but even deadly. To prove this, let us take up the matter a little more deeply.

In the preceding pages it was shown that the winds for the most part consist, in substance and property, of exhalations. These spirituous and vapory exhalations are not merely diffused by their own power; they also drive along any other exhalations of every kind that they encounter — from which different and exotic effects of the winds must necessarily be produced, according as they pass through various places steeped in various refuse of earthy substance. For in this way, just as they take up diverse supplies, so they marshal diverse armies with which they do not cease to assail human bodies.

[Margin: The various effects of the winds on human bodies.]

Some, with excessive humidity, immoderately distend slackened bodies; others bind them with a frost-like chill and, when the pores of the body and the soot of the vapors conceived within them are obstructed [text damaged] — when this superfluous matter is shut in [?], the inner cavities of the body are filled with humors, and they cause catarrhs of every kind, pleurisies, and apoplectic symptoms. Nor are there lacking those that, by their subtlety and dryness, [continues on next page] penetrate the inmost

[Printed p. 215 — running header: "DE VENTORUM ORIGINE." Continues PROPOSITIO II.]

economy of the body and, with the necessary humidity destroyed, dry out both the animal spirits and the vital spirits. For those saltpetrous exhalations, with their spirituous substance, not only penetrate the hidden passages of the viscera, but also, insinuating themselves among the concealed ducts of the membranes and muscles and creeping in little by little,

[Margin: Mineral exhalations, harmful to bodies.]

produce effects no less troublesome than those they bring about in the *Ecnephiae*, in *Prester*-storms [Prester: fiery whirlwind], and in other impetuous winds. For

these are followed presently by lassitude, a numbness of all the limbs, a most distressing sensation, [Greek: ῥεύματα (rheumata, "fluxes" or "catarrhs")] of every sort, a heaviness of the head with a troublesome cough, and other symptoms which it would be tedious to recount — and which commonly befall those who have caught the said winds, especially with their pores open, whether because of excessive heat or because the body was relaxed by too much exertion. But let us prove the matter by experiment.

EXPERIMENT.

Let there be made a long channel in the form of a tube, which you will so arrange that its wider opening is fastened somewhere through a wall outside the chamber, with the rest of the channel extended within a bedroom or some enclosed room. In this arrangement, let there be inserted into the said channel any kind of things you please, set in loosely and thinly — such as fragrant flowers, lilies, violets, thyme, basil, and the like.

Diagram. A woodcut illustrating the experiment. At the left stands a cube-shaped room (a chamber drawn in perspective, with a window visible on its front face). Passing through the wall of the room is a long horn- or trumpet-shaped tube (the *canalis*), its narrow end inside the room and its wide, flaring mouth outside, decorated with foliate/scroll ornament at the bell. The tube represents the channel through which the wind carries the scent (or the noxious vapor) of the substances placed in it into the enclosed chamber. No labels are printed on the figure.

It will then come about that, as soon as some wind has entered the said outer opening of the channel, the inner room (I say) will be imbued — by the wind's conveyance — with the scent that the inserted thing gives off.

[Margin: According to the quality of the things through which the wind passes, it affects bodies.]

But if into the said channel you put herbs endowed with a deadly quality — such as henbane [hyoscyamus], mandrake [mandragora], nightshade [solanum], thorn-apple [stramonium] — then you will see the whole room filled, by the wind's conveyance, with noxious vapors; and you will find that to some they bring sleep, to others the sharpest headaches, to some heartburn [cardialgia], and similar symptoms arising from a harmful and pernicious quality.

You may be convinced that just the same thing very often happens in the case of a wind. For a wind passing through places filled with wholesome things will be

steeped in such a quality of place as that from which it blows; if through unwholesome places, with unwholesome qualities, and so on. But let us demonstrate the matter by a fresh experiment.

[Margin: A history concerning the situation of certain places.]

Nautical histories report that, at the season when cinnamon is most in flower in Ceylon [Ceilano], the island spreads abroad so great a fragrance of scent that it is perceived as far as 100 miles out on the high sea — not without a weakening of one's health [text continues at the top of the right column] [and a] restoration, by the favor of the carrying wind. The same thing happens in the Moluccas, where the wind scatters the scent of cloves for many miles, especially in calm weather. By contrast, at the promontory which they call *Serra di Lyone* [Sierra Leone], long experience has taught that nearly all travelers are afflicted with exotic diseases. For their waters become charged with a wormy substance; their bodies are filled with unusual swelling; they lose their teeth; they are racked with malignant fevers; and according to each one's constitution they are beset by various symptoms. The reason for this is none other than that the neighboring mountains — which are utterly filled with arsenical, antimonial, and mercurial spirits, all of them pernicious — being thus carried by the wind into the ships, produce in the voyagers the symptoms we have described; and so it is no wonder.

[Margin: The experiment with the aeolipile.]

And experience teaches it by the aeolipile [Aeolia pila]. If you put into it waters steeped in the said lethal substances, and set it over kindled coals, you will find that the deadly vapor of the waters produces in the men shut up in that place the same effects we described — not without danger to the life of those who breathe in a vapor of this kind.

[Margin: The analogy of the aeolipile to subterranean fire.]

For just as the aeolipile stands in relation to the kindled coals, so does the subterranean ore in relation to the subterranean fire; and just as the deadly vapor of the aeolipile stands in relation to men dwelling in some enclosed room, so does the poisonous vapor of the ore stand in relation to those who have been near the source of so pernicious an exhalation. But how the plague is generated, from what causes, and how, once carried by contagion into far-off regions — since we have treated of these matters very fully in our *Scrutinium Physico-Medicum* — I refer the reader to that work, where he will find certain marvelous things bearing on this subject.

PROPOSITIO III.

On the usefulness of the winds, and on the marvelous magnetism that comes about, by the winds' benefit, in the generation of things — when each single thing, out of the exhalations filled with a varied mixture of seminal matters, draws to itself, conveyed by the winds, whatever has been most suited to it.

That Nature carries out her operations by a kind of perpetual *pericyclosis* was shown in the preceding pages. Now we shall begin a new *pericyclosis*, by which — through the benefit of the winds — the several bodies of mixed things draw to themselves the nourishment that has been most congruent and necessary for their sustenance, conferred by the winds out of the exhalations, both subterranean and elementary, filled with a varied mixture of seminal matters. How this comes about, we shall teach with God's inspiration.

It is well known that the Sun, sending down its rays into the Geocosm, as soon as it has met with anything humid and dissolvable, draws it up on high after the heat has rarefied it. But since there is almost nothing [text continues on next page]

[Printed p. 216 — running header: "LIBER QUARTUS, Sect. II." Continues PROPOSITIO III.]

that is not rarefied by the Sun (except for those metallic and mineral bodies which have already attained the firmness of their solid consistency, and which need a more efficacious fire for their dissolution), so likewise there is nothing that is not resolved by the solar rays into its elementary parts.

[Margin: An analogy.]

Just as the subterranean fire stands in relation to the hidden crypts of the mineral mixture, and the artificial fire to the alembic in which mixed bodies are separated by means of exhalations, so does the Sun stand in relation to all the dissolvable bodies of the Geocosm. Such are: first, all humid things — the sea, rivers, lakes, pools, ditches, springs, places teeming with mineral spirits; second, plants, trees, and shrubs; third, the mixtures of seminal matters; fourth, animals of every kind.

[Margin: From all natural things certain exhalations are drawn by the Sun.]

From all of these the Sun draws out certain exhalations or spirits (which afterward are drawn back again, by a kind of marvelous magnetism, by those very things which have a certain proportion or consent — what the Greeks call

[Greek: συμπάθεια (sympatheia, "sympathy")] — with the seminal mixture hidden in the exhalations). This, I have thought, ought here to be treated with care.

And first indeed, as concerns the humid nature: it cannot but happen that, when struck by the burning rays of the Sun, it is at once raised up into vapors —

[Margin: Every humid thing being heated emits a vapor with heterogeneous corpuscles.]

which vapors are nothing but an infinite multitude of watery corpuscles, which, since they are most highly rarefied and made subtle by the heat of the Sun, are by reason of their extreme lightness carried up into the airy region. But since we have shown elsewhere that the watery element is everywhere filled with a certain panspermia [panspermia: universal seed-mixture], it can happen that, together with the watery corpuscles, heterogeneous or spermatic corpuscles — far removed from all sense-perception — are raised up as well.

[Margin: The scents of plants are nothing but their diffused effluvia.]

Again, that plants and trees emit the exhalations proper to each one as soon as they are struck by the Sun's rays is so well known that no one could doubt it; and scents bear sufficient witness that they are nothing but the effluvia of certain corpuscles, each one of which is imbued with the quality of the whole. Moreover, the Sun, striking the mineral surface of the earth, draws out the saline, nitrous, and sulphurous spirituous exhalations of the other minerals. And I would have you understand that the same thing happens in like manner with animals of every kind.

[Margin: The panspermia of things is carried into all the regions of the world by the wind's conveyance.]

This panspermia of things, then, raised into the air by way of vapors in the manner we have stated, and carried by the wind's conveyance into all the regions of the world, founds a new economy of seed-beds. For since all things consist of a twofold matter — one fixed and consistent, the other thin and volatile —

[Margin: The twofold matter of spirit: fixed and volatile.]

hence it comes about that the fixed, sluggish, sluggish [doublet in source] matter clings to the ground, while the other, of a thin and volatile nature, flying so high aloft, once it has been drawn off from its substrate, can never again be joined with the fixed — except when, carried about by the benefit and ministry of the winds, it at last falls into a place where it finds a fixed thing congruent and

proportionate to itself. When this happens, then at once it is seized — like iron by a magnet, like flame by naphtha — so that, just as the subterranean fire stands in relation to [text resumes mid-sentence at the top of the right column] [the things that are dissolved by it], that which had been separated from a thing by the heat of the Sun is restored to it as fixed.

[Margin: The marvelous magnetism of nature.]

Hence comes that marvelous *palingenesia* [palingenesia: regeneration, rebirth] — a *pericyclic* one — by which the several things are restored, by a kind of magnetic attraction, to the mixed bodies from which they are dissolved. In ores, the saline, nitrous, sulphurous, aluminous, and bituminous spirits, which had flown off from there by the force of the subterranean heat, are by the reciprocal commerce of the winds brought into the fissures and veins of the mountains, and by a kind of natural attraction each is restored, one to one, to the fixed bodies appropriated to it. For since these spirituous exhalations evaporate in every place, it comes about that the laboring fixed bodies, which cannot be preserved in their being without the volatile spirits, are always provided for out of the common storehouse of the exhalations by the ministry of the winds. The seminal broods of plants, together with their seed, snatched away by the force of the winds, are scattered everywhere for the propagation of the species.

[Margin: In the Roman Amphitheater all kinds of herbs are found to be born.]

This may also be seen in the monuments of the ancient Romans — aqueducts, amphitheaters, walls, temples, and other half-ruined buildings — on whose summits all kinds of plants and shrubs are born. And how they reached there, or who planted them in those places, only the man can fail to know who is ignorant of the nature and property of the winds. The wind has its hidden vehicles, by which it conveys the imperceptible seeds of plants there; and these seeds, joined to the saline and nitrous spirits of the lime and mortar in which they are strong, and then fermented by rains and dew, at last produce the very kind of plant from which they came. And just as experience teaches that this is true on the driest, most parched walls and partitions, so it must be believed to happen much more in all those places to which seed-beds of such things have been carried by the wind's vehicle. For those spirits of mixed bodies — which, dissolved by heat, are set in motion and carried about by the winds — are vaporous spirits of diverse species, with which are mixed at the same time spirits issuing from the vegetable, animal, and mineral economy. So when they are roused by motion and pass through various places, if they should reach proportionate matrices of this kind, each single matrix (or each single material and fixed body) sucks up and as it

were imbibes, from the spirits flowing past, the part more proportionate to itself, leaving aside the part that is, as it were, incongruous to it.

[Margin: Like attracts like.]

This is no different from what happens with the various kinds of food taken in: once digestion has been carried out in the stomach, the heart draws what suits it, the liver what is its own; and the brain, spleen, lung, kidneys, and the other members each draw the things congruent to them.

[Margin: An analogy to the human body.]

Hence the more secret physicians, the Iatro-mystae [Iatro-mystae: mystical physicians], assert that the members of animals, as soon as they have been taken as food and digested by the heat of the stomach, presently flow together, each to the members that symbolize with it: brains to the brain, heart to the heart, liver to the liver, lung to the lungs, and so on — so that from the hidden likeness and proportion of nature they may be able to benefit the member which they express in their figure. And from this was born that more arcane [text continues on next page]

[Printed p. 217 — running header: "METEOR. IMPRESSIONES SUBTERRANEÆ." Continues PROPOSITIO III.]

[Margin: The characteristic science of natural things from their signatures.]

characteristic science, by which sagacious physicians, through the hidden characters of things, teach how to recognize the healing power proper to each member of the human body — the power belonging to a plant or to the other mixed bodies which reproduce that member by their figure. Of this we have treated very fully in the *Ars Magnetica*, in the *Musurgia* [*Musurgia Universalis*], and in the second volume of the *Oedipus* [*Oedipus Aegyptiacus*], in the treatise on the hieroglyphic medicine of the ancient Egyptians; and so in this place we do not wish to be longer. But we have thought it worthwhile to illustrate the matter by another comparison.

[Margin: The magnetic experiment.]

Suppose someone, having reduced countless kinds of things to powder and mixed them together, were to spread out the whole powdery mass upon a table. I say that, just as the iron dust, whole and entire, can be separated out from so great a heap of confused things by the mere application of a strong magnet, by its attraction, so too among confused metallic powders, mercury (or quicksilver),

first reduced to powder by amalgamation, as the chemists call it, can be separated out whole and entire from the rest in a retort by the force of fire alone. And if someone now knew of a magnet that attracts gold, he could in the same way separate the gold-filings from the rest of the chaotic mass with little trouble — and so on with the rest. But concerning this secret we shall perhaps, in the following books, disclose some things hitherto unseen and unheard of, so that we may give the curious explorer of hidden things a handle for advancing the inquiry further.

What, therefore (to return to the matter we have proposed), I say about the confused heap of powders, you should know is to be understood likewise of the spirits of the various bodies, which, mingled together, are diffused through the air. For these are the true and fecund seeds, and as it were certain souls, that give being to all things.

[Margin: The air is full of the diverse spirits of natural things.]

For no one can deny that mixed in the air are the spirits of innumerable things, which both breathe out from the earth and, in the dissolution of things, are separated from one another. I speak of those seminal spirits which are extracted by the spagyric art from roses, violets, wine, and countless other things. What art can do, then, nature does far more excellently, in the resolution of the said things accomplished by the heat of the Sun. For these spirits, scattered abroad by the wind, when in the motion of the air they strike against bodies, then the fixed things that cling to the earth — each one of them — at once draw to themselves the spirit most congruent to themselves and their nature, and retain it, so that out of it the compound may again coalesce into its former state. And accordingly fixed bodies of this kind are nothing but certain magnets, appointed by nature to separate out those confused spirits.

[Margin: The marvelous pericyclosis of nature.]

Again I say: by nature, once it has become perfect, the seed of the living thing is elaborated; and that seed is, as it were, the magnet of that nature. For when the seed has become complete and perfect, it is separated from the living thing; and once separated, it at once begins, by the magnetism implanted in it, to join to itself proportionate parts — both from the gross things clinging in the earth, and from the spirituous things flying through the air; and by the hidden characterisms of things [text resumes at top of right column] it is in this way increased and perfected, its roots ever extending themselves toward new soils, so that from them they may seek new fixed parts; while the rains and winds breathe

fresh spirits upon it, by which at last, once compounded, it attains its ultimate perfection.

In this way we have amply taught — both here and in our *Iter Hetruscum* [*Iter Extaticum*, the "Etruscan/Tuscan journey"] — that mines of gold, silver, iron, and stones, after they have been exhausted, grow again. So that, even from these things, the ineffable providence of God, Best and Greatest, may shine forth, while things thus grow together and serve one another so studiously that, although one may seem to stand toward another in a wholly contingent relation, yet the one can neither exist nor subsist without the other. For unless the winds dispersed those spirits pregnant with their spermatic mixture, the generation of things would not be perpetuated usefully in every place. For that supreme Architect of nature knew how so to conceal his art that this most divine artifice should seem to be devoid of all art, and all things to have come about by random chance.

COROLLARY.

Hence the final cause of the winds is made plain, and the immense benefit they bring with them.

[Margin: The final cause and the greatest usefulness of the winds.]

For these dissolve into rains the clouds compacted with humidity — without which the nature of things would become wholly barren; yet, lest they should harm the earth with immoderate humidity, winds of a drier nature at once rise up to oppose them, to dry out the earth dripping with excessive moisture. On these depends all the fruitfulness of the fields and the fecundity of the trees, since the seminal forces flow abundantly to all things. By their help, lakes and seas, lest they putrefy, are kept agitated by continual motion. Journeys are accomplished by every wind around the terraqueous globe, so that nowhere is lacking what is so greatly necessary for the preservation of the nature of things. For what is more marvelous than, by the ministry of the winds, to traverse in so brief a time the immense spaces of the Ocean and the seas — to discover new worlds — to bless the human race with vast treasures of riches — and, the chief thing of all, to carry the light of the most holy Gospel along all the paths of the world, into the unknown tracts of the most remote lands, with an incredible gain of souls?

But you will perhaps object: that cannot be good which fills the world with so many calamities. For the winds, besides the countless harms they bring to men, also sometimes carry deadly exhalations — breathing out from the bowels of the earth and from the cadaverous refuse of putrid things — to the utter ruin of men

and animals, when they scatter the plague abroad by their contagious blasts. Therefore the winds [are evil].

[Margin: Why nature has permitted such pernicious winds.]

I answer: It is true. Nevertheless, by these evils of nature the same thing is done as in bodies overburdened with pernicious humors by purging medicines, by which bodies are to a certain extent purged, so that, freed from the virulent humors, [text continues into the following pages]

[Margin: That which purges the body of harmful humors.]

[restored] to their former health with the greater profit. In the same way, even when winds occasionally rise up that are destructive — winds that infect the air and steep both plants and animals with virulent qualities — they nevertheless have this good bound up with them: by venting their deadly breath, they restore to its former wholesomeness the diseased earth. And to keep these winds from troubling the earth with any longer annoyance, it has been arranged by nature's great wisdom that soon afterward other winds of a more wholesome character rise up and, like so many brooms, sweep clean the malignant impressions made in the air. Whatever danger the pernicious breaths had brought, these winds wipe away by their own kindness — so that nothing in the whole order of nature is so destructive that nature does not labor to draw from it some signal good.

[Margin: Art the imitator of nature.]

It also happens from time to time that the gracious God, to chastise the perversity of the human race, permits such evils of nature by his own just judgment, for the good of souls: that pressed down by these whirlwinds of calamity, men may turn back through repentance and the amendment of their lives to the God of all good things, from whom they had fallen away.

CAPUT IX.

On the production of artificial winds, which serve men both for recreation and for advantage.

So as not to seem to have left out any of the curious matters in this work, I have decided that the production of artificial winds too should be treated here. Man, nature's ape, observing the marvelous effects of the winds — and unable to command them at his own pleasure — contrived by his own ingenuity, after nature's model, something similar that might serve his needs. For when he saw that winds, passing through narrow places and shut-in walls, or against

interposed mountains and valleys, or struck against obstacles, acquire enormous force, he at once turned his attention, on rivers, lakes, and seas, to the construction of ships, and fitted them out with sails. In the spreading of these sails the wind is caught as if in a net, and being unable to escape, drives both sail and ship along with itself. On land, mills driven by the force of the winds were built for grinding grain, so that those who were without the current of a river might obtain by the help of the winds the necessary supports of life. Craftsmen, moreover, to rouse their fires with greater vigor — finding by experiment that wind grows wonderfully strong under the slightest pressure — invented bellows, in which air is drawn in and enclosed on the upstroke, and on the downstroke, being compressed, escapes with the utmost force. Since nothing is more common than this device, I have thought it superfluous to say more about it.

Nor shall I speak either of hydraulic contrivances and wind-guns [sclopiis ventosis], which I have demonstrated very fully partly in the *Ars Magnetica* and partly in the *Musurgia* — on which see also Fr. Gaspar Schott [Gaspar Schott], once my partner in literary leisure, who treats them ingeniously in his *Magia Pneumatica*. I pass over the ingenious construction of wind-vanes [anemoscopes], which I set forth in Book 20 of the *Ars Magnetica*. I will add here only, in what follows, how a certain Æolian chamber [conclave Æolium] may be fitted out that, in the summer months, will supply continuous winds of any desired temperament — designed both for the delights of princes and for cooling liquors and fruits.

Let a brick receptacle A B C D be built, of the size commonly used in constructing living-quarters. Beneath its floor C G H D, let two receptacles be made, separated by the partition L M; in the first of these, C D L M, let there be a syphon Q, whose arm-mouth X is to be left open. The other arm Y, the longer one, likewise open, is to be led through the partition L M — to which it is to be well cemented — into the receptacle L M N O. In this last there is another syphon R, whose longer arm, inserted through the bottom N O to the outside, projects out and is meant to discharge the water. Into the receptacle C D L M, from outside, let a rather wide channel be led, fitted with a stopcock T; when this is opened, water is hurled with violent force into the vessel P, whose bottom V is open. Furthermore, through the partition C D — which is the bottom of the floor G H C D — let there be led, below the place marked with the letters G H, leaden syphons; these are to be led

Diagram. An uncaptioned engraving of the Æolian (air-conditioning) chamber, shown in cutaway. The upper portion shows the room itself in three-quarter perspective as a box-shaped enclosure (the living chamber), with the inner back

wall pierced by numbered outlets through which jets of air (drawn as fan-shaped sprays) issue. The lower portion shows, in cross-section, the two stacked underground water-receptacles with their syphons, the inlet channel with its stopcock, and the discharge syphons. Two coiled tubes (the leaden syphons running up behind the chamber walls) loop up the sides of the room. Labels (read under magnification):

- A (upper-left corner of the room): corner of receptacle A B C D
- B (upper-right corner of the room): corner of receptacle A B C D
- E (upper-left of the inner back wall): top corner of the pierced inner wall
- F (upper-right of the inner back wall): top corner of the pierced inner wall
- 1 (left side of inner wall, upper): air-jet outlet
- 2 (left side of inner wall, lower): air-jet outlet
- 3, 4, 5 (center of inner wall, in a row): air-jet outlets (sprays drawn)
- 6 (right side of inner wall, upper): air-jet outlet
- 7 (right side of inner wall, lower): air-jet outlet
- [The text names outlets 1–8; outlet 8 is not separately legible in the figure — presumed paired on the right. [?]]
- G (lower-left of inner wall): bottom corner of inner wall / floor edge
- H (lower-center of inner wall): bottom corner of inner wall / floor edge
- C (left edge, at floor level): corner of floor G H C D
- K (right edge, at floor level): floor-level corner [K appears in figure though text reads C D L M; [?]]
- D (right edge, at floor level): corner of floor
- T (left side, below floor, on the inlet channel): stopcock
- S (left side, below T): lower end of the inlet channel
- P (basin/vessel at lower left): vessel P with open bottom V
- V (within/below basin P): open bottom of vessel P
- L (lower-left corner of the lower receptacle): corner of receptacle L M N O
- M (lower-right corner of the lower receptacle): corner of receptacle L M N O
- Q (syphon at lower center-right): syphon Q
- X (mouth at upper arm of syphon Q): open mouth X
- Y (longer arm of syphon Q): arm Y leading through the partition
- R (syphon at bottom, with discharge): discharge syphon R
- N (bottom-left outer corner): corner of receptacle L M N O
- O (bottom-right outer corner): corner of receptacle L M N O

are led up behind the walls A E C G, F B H D, and E F G H, with their lower mouths pointing into the receptacle C D L M, and their upper mouths inserted into the wall at the places marked with the numbers 1 2 3 4 5 6 7 8 — so that the mouths open into the chamber. And you will have your Æolian chamber prepared.

Its use is this. In summertime let the cock of the syphon S P, set into the wall, be opened, so that water drawn from outside is precipitated into the receptacle C D L M, and there drives out, through the mouths of the syphons opening into that same receptacle, the air standing within it. This air, driven out through the mouths 1 2 3 4, etc., of the syphons inserted behind the walls of the chamber, issues with great force and refreshes the chamber and those staying in it with a most pleasant coolness. And the wind will last as long as the precipitation of water made through the channel S P lasts. But since the receptacle C D L M is filled in the course of time, we have therefore arranged the syphon X Q Y — which Hero [Hero of Alexandria] calls a "bent diabetes" [diabetes inflexus] — by which the water is discharged into the receptacle L M N O, and from there, overflowing, is emptied outside through the bent syphon R. And in this way, since the syphon X Q Y discharges just as much as the channel S P precipitates — and since the air within the water and the structure of the receptacle is always in motion and turbulent — it will, through the mouths of the syphons 1 2 3 4 5, etc., continuously and with renewed force supply the chamber with windy, cold air.

But let this suffice concerning the nature, property, and use of the winds.

CAPUT X.

That there is no meteor which does not derive its origin from the subterranean world, and that within it meteors of every kind are produced, just as on the outer surface and in the airy region.

That the subterranean fire is the cause of all meteorological impressions, we have suggested above. But by what manner it produces these things, by what art it accomplishes them — whether it fabricates them in its own workshops and inmost recesses and then, when they are finished, expels them; or whether, like a diligent steward and nature's viceroy, it visits its several territories in person and disposes its business; whether it prepares them by a voluntary motion; or whether it is summoned by the Sun, which holds high dominion, to render an account of its husbandry? When all these modes are reviewed, it will become clear from what is to be said shortly that the fire disposes its operations in each of these ways. For above all it works upon the nearest matter at hand, and either masters it or sets in motion various kinds of mixture; according to the measure of

these a new form is drawn out, to lay down the law for the new compound; and then, by the deputy-work of its own heat, it advances and fosters the whole economy of the mixtures. Sometimes it happens that this subterranean fire-lord [pyrodynasta], having obtained compliant matter and an abundant supply, pours out new stations along long routes and leads forth colonies. It never hurries unwillingly, nor is it summoned against its will; but, by nature's instinct, it does not so much venerate the light of the stars as cross the bounds of the earth in order to enjoy the fellowship of the friendly heat — about to pay homage to the king of light for the subterranean revenues faithfully administered. But, setting aside this analogy of words, let us now press on more closely to our subject.

The subterranean fire, then, tireless and robust in its powers, applies itself to simple generation in such a way that meanwhile it does not refuse a rich brood of mixtures. In the work of its operations it employs two attendants: vapor and exhalation. The former is, as it were, water in potency; the latter, fire in potency. These are truly the all-seed-bearing [omniseminarium] of the mixed bodies, and by their working all the generations that take place on high are promoted and perfected. But lest, with its benefits poured out into the airy region, it could be said to have deprived its own realm of them, I will first treat of the impressions of meteors that take place in the subterranean world; and then I will set out in order, paragraph by paragraph, the causes and explanations of those things which, by its benefit, become known on the outer surface and in the airy region.

§. I.

All the meteorological impressions that occur on high outside the earth — these same occur in the subterranean world.

In the preceding pages we have shown abundantly that the Geocosm, besides its innumerable receptacles — which we call pyrophyllacia, hydrophyllacia, and aerophyllacia — is also crammed with crypts, caverns, and spaces stretched out to an immense extent; and that it is finally pierced through with passages, tunnels, syphons, clefts, and fissures, in which, by the perpetual constitution of law, vapor and exhalation hold sway — the former drawing its origin from the waters, the latter from fire. And concerning the rivers, water-conduits, and the immense lakes and seas beneath the earth, we have spoken amply in the preceding Book, and will speak again in what follows; so let us proceed to explain other matters.

Subterranean Rains.

And first indeed, that there are subterranean rains, only the man can be ignorant who is unacquainted with the construction of the distiller's alembic. For when a

vast vapor has been continuously drawn out, by the force of the internal heat, from the hydrophylacic storehouses into the hidden crypts of the mountains, here, condensed in the colder places and dashed [imp-]

[Margin: Subterranean rain comes about by the resolution of vapor by the force of heat within the crypts.]

[Margin: Subterranean rivers.]

[—dashed] against the vaults, resolved into water, it falls drop by drop in the manner of rain. And it was for this reason that Aristotle asserted that the origin of springs comes from nowhere else than from the resolution of vapors carried out within the subterranean crypts — a view which we, however, in our *Sectio de Origine Fontium* [Section on the Origin of Springs], demonstrate to be not a universal but only a partial cause. About subterranean rivers, then, there is no controversy.

[Margin: Subterranean snow and hail.]

Whether snow and hail are likewise generated in subterranean caves ought equally to be in no one's doubt. For if vapor has fallen into cold crypts charged with niter-bearing spirits, the foamy substance of the vapor, before it turns into water, is drawn together by the cold of the surrounding air into snowy flakes; but if it has been resolved into a drop-like watery substance, then, with a violent cold wind coming over it, it must of necessity be condensed into hail and ice. I myself saw on Mount Sorano [Monte Sorano] a crypt encrusted as it were with ice, with huge icicles hanging here and there from its vault, from which the inhabitants of the neighboring mountain make, in summertime, drinking-cups most fit for cooling the water and wine poured into them — the extreme cold being turned into the highest delight of the drinkers.

[Margin: The Sorano crypt.]

Subterranean Winds.

[Margin: Subterranean winds.]

I come to the subterranean winds, which not only hold sway in the hollow districts of the earth but rage with incredible force — a thing as certain as the furious and violent gusts of the Æolian mountains, which are everywhere commonly observed. See what we have set down in Book 3, in the chapter *On the Æolian Mountain of the Castori*, and in our *Itinerarium Hetruscum*, concerning the *Ventosa spelunca* [windy cave] in the territory of Volterra. Not long ago there

reported to us a man as noble as he was most learned, Pierre Guisony [Pierre Guisony], a Frenchman, Doctor of Laws and of Medicine: that near Noviodunum — commonly Nions [Nyons] — there lies a most famous Æolian Mountain, from which perennially blow forth winds of such force that the inhabitants, impatient of its fury, when they had several times blocked up the mouth of the cave with brickwork of stones, were never able to set against the violence of the wind obstacles robust enough but that the wind soon, casting back and prostrating the barriers, claimed back its former liberty for itself by redoubled rage. See what we have reported about similar mountains in the place cited.

[Margin: The Noviodunum windy cave.]

The cause of such subterranean winds is inquired into. I say, then, that the origin of these winds can be manifold. **First:** salt-niter spirits [spiritus salnitrosi], rarefied by the force of fire; for while they are pressed by the narrowness of the places and passages, and then, now endowed with greater freedom, enter the more spacious caverns, the air enclosed in the caves, violently agitated by the onrush of the invading spirits — finding an exit only through the most narrow passages — thence rolls itself out, together with the spirit, with that rage which we have described. And this is the first cause of subterranean wind.

[Margin: The cause of subterranean winds.]

Second: the cause of winds is the cataracts of subterranean rivers, which, when they have hurled themselves down through rocky and precipitous places, soon, within the cavernous tract of the cataract, produce by their fall a huge wind; and this, rolled out afterward through the hidden passages and then through the air-vents of the mountains, makes such havoc as we have described. **The third** cause of winds can be the liquefaction of snows on the mountains, whose dissolved waters, penetrating the hollows of the mountains, by their fall sometimes cause great winds within the bowels of the mountains; and this cause does not differ from the one that arises from the subterranean cataracts of rivers, except that the latter rage perennially, the former only at certain seasons of the year. There are also other causes of subterranean winds, which, because we have explained them in the place cited, we will not dwell on here; let it suffice meanwhile to have demonstrated subterranean winds by these few adduced reasons.

§. II.

The earthquake, the proper effect of subterranean conflagrations.

That the earthquake is not so much a meteorological as a subterranean impression, reason itself dictates, since the earthquake performs its accustomed catastrophes not outside but inside the earth — in which nothing more terrible and fearful, nothing more deadly to the human race, can occur in the whole order of nature. It is the greatest scourge of God, by which God the Best and Greatest is wont to chastise above all the men who are his enemies and the despisers of his commandments. What cities have we not read of as overthrown by these, what lands devastated, what mountains cast down?

[Margin: The frightful earthquake.]

[Margin: Histories displaying the marvelous force of earthquakes.]

Pliny [the Younger] [Plinius], in the Vesuvian conflagration of his own time, writes that the tremors of the earth were such that the earth seemed not, I will not say to move, but to be turned utterly upside down. Scipione Mazzella [Scipione Mazzella] and others relate that the commotions of the earth were so great at Pozzuoli [Puteoli] in the year 1594 that the sea was observed, to the great astonishment and dismay of the onlookers, to draw back some 200 paces. The earthquake that preceded the Vesuvian conflagration in the year 1631 is said to have been so great that, the floor of the sea being broken open, men came upon fish partly cast out onto the sea, partly left on the shore as the sea receded, together with ships; and these were followed by horrid bellowings, smoke, a rain of ash, eructations of huge rocks, fiery torrents, and gushings-forth of new springs and of bitumen — all of which display the incredible and most violent force and power of nature when it rages. But the explanations of all these things, the order now requires that we assign.

It is well known how much warlike artillery and the subterranean tunnels charged with gunpowder are capable of. Surely there is nothing so solid, nothing so well founded, that they do not hurl it skyward and lay it flat in the twinkling of an eye. And if indeed we examine the cause of so great a driving power, it is nothing

[Margin: That what warlike artillery does on the surface of the earth, that the force of gunpowder does.]

[Margin: How an earthquake comes about in subterranean tunnels.]

else than what you will find to be the origin of such great destruction: namely, a powder compounded of niter, sulphur, and charcoal. For the powder, kindled from the charcoal, rarefies the niter; and this, once rarefied — since it cannot remain together with sulphur, its enemy, nor be contained by the narrowness of the places — by its violent eruption, all obstacles being burst, works the havoc we have described. If, then, artificial powder is so strong, how much greater strength shall we judge a greater abundance and multitude of combustible matter to have — of sulphur, I mean, of niter, alum, sal ammoniac, bitumen, and the rest of the mineral and metallic spirits, of gold, copper, iron, arsenic, mercury — with which the inmost cores of the Earth are crammed? Who, then, does not know that fearful earthquakes issue from this source? And they come about, as appeared in the preceding pages, in the subterranean crypts, in the manner that follows.

[Margin: How an earthquake comes about.]

The subterranean fire, by the violence of its heat, having opened and burst somewhere the barriers of the mountains, where it has built itself a way into a cavern stretching far and wide — then, behold, the air within is at once stirred up with violent motion; and because it is furnished with an abundance of combustible matter, from the sudden ignition of the matter it rouses a great quantity of exhalations. Since these are given no place anywhere to escape, in the horrid battle thus joined such commotions arise as the power of nature, being greater, cannot endure. The exit therefore being cut off on every side, now they batter the inmost walls of the mountains, now boring through the channels of the softer earthy fibers — while they strive with fruitless toil — from the excessive impulse of the laboring nature an earthquake must of necessity be caused thereby. At last, driven by the dread and threats of that sworn enemy of nature, the void, the obstacles of the overhanging crags and earthy masses being undermined, they do the same thing that gunpowder does in the artificial driving of mines — that is, they shatter everything: they overthrow cities and fortresses, they make horrible chasms, they produce new lakes, and the like things which the records of the historians recount to us, they accomplish.

[Margin: The transfer of a mountain by the force of an earthquake.]

Egidio of Naples [Egidio Neapolitano] reports, in his treatise *On the Conflagrations of Mount Vesuvius* — whom Pietro Castelli [Pietro Castelli], a physician, cites on the last leaf of his work on Vesuvius — that in his own time a frightful event befell in Basilicata, a province of the Kingdom of Naples. From a formidable earthquake that arose there, an entire mountain, noble for its cultivation of vineyards, was carried from its own place into another, three miles distant from

there, without leaving any trace of standing in the intervening places. And he says that to this very day a long-standing suit hangs, between the possessors of the said mountains, in the Neapolitan court — what they commonly call the *Vicaria* — as to whether the returns and money-payments which the royal treasury is accustomed to exact are to be sought from the prior site, where the mountain stood before, or from the latter, into which it was cast. And it is truly a wonder that an event of such kind, if it is true — unheard of in all the ages — was not described by more historians. Be that as it may, that mountains are not only overthrown by the violence of earthquakes, but also born anew, suddenly, even in the midst of the sea, was demonstrated in the preceding Books.

From these things, unless I am mistaken, it is brilliantly clear how earthquakes are born among the subterranean caverns, and how, through various branching tunnels, exhalations — now running here, now there, as they seek an exit and do not find it — powerfully shake the earth; until at last, the foundations of the mountains being burst, they either, with the force thus made, hurl the superimposed mass elsewhere, or, if it is too heavy, force it to subside into a deserted place. But as to the fact that, when cities or mountains are swallowed up, a lake for the most part emerges in the place of what was swallowed, this comes about in this way: that the swallowed earthy mass below falls into some hydrophylacium; and since these cannot subsist together, the water, lighter than the earthy substance, thus squeezed out through the gaps, takes the place of the swallowed-up city or mountain. And experience teaches this: for if you put a stone of proportionate size into a basin full of water, that stone, sinking to the bottom, necessarily makes the displaced water brim over outside the basin.

Subterranean Thunder.

From so great a clash of subterranean exhalations with the air — from the most violent collision of bodies — a sound must of necessity arise. Hence all who dwell near fire-vomiting mountains testify that, before these begin to rage, for many days they have perceived, as it were, huge bellowings and noises not unlike thunder or the discharge of warlike cannon — certain forerunners, as it were, of the deadly tragedy soon to follow. I myself, indeed, while I was present in the year 1638 amid the unheard-of earthquakes that were reducing Calabria almost to a wasteland, remember that always, before an imminent earthquake — which often repeated itself by day and by night — I perceived a horrendous murmur and incredible crashings, like the sound of many drums. And on a certain day, when I had noticed that Strongylus [Stromboli] was raging, with an eructation of fiery masses, more than usual, I heard too a dull murmur, I know not what, from

a mountain 60 miles distant, which kept seeming to grow toward us; and when it reached us, it gave forth within the earth such horrid thunderings that the senses scarcely sufficed to bear them. Joined to this was so fearful a shaking of the earth that no one could any longer stand on his feet, all my companions being prostrated by the force of the raging nature. And at last, a truce being established, when we rose up and beheld the town of S. Eufemia [Sant'Eufemia] (from which we were no more than three miles distant) covered with a vast cloud — as this gradually vanished — [we saw] the city swallowed up with no trace any longer left, and a lake, which it had previously lacked, risen up in its place.

[Margin: A frightful earthquake observed by the Author.]

with a terror of spirit I could scarcely put into words.

CONSECTARIUM I.

On Subterranean Thunders.

From these observations I concluded, by an inescapable inference, that Calabria communicates through hidden channels both with Etna and with Stromboli [Strongylus] and the other Vulcanian islands, and that subterranean sounds and bellowings of this kind arise from the clashing of tumultuous spirits within those hollows and from the reciprocal struggle of effervescing exhalations. Since these share the very same mechanism as the thunders of the upper air, they may rightly and deservedly be called—and indeed must be called—subterranean thunder [tonitru subterraneum].

CONSECTARIUM II.

On Subterranean Lightning and Flashing.

[Margin: Lightnings, thunderbolts, flashings, and burning heats rage perpetually in the subterranean passages.]

From these same facts it is also evident that when exhalations are kindled in the subterranean crypts—packed together with sulfur, niter, coals, and other combustible kindling of like sort—dreadful thunderbolts too are forged there, far more savage and far more frequent than those of the upper air. For the aerial exhalations draw the whole matter of their lightnings from nowhere else than the subterranean vapors, which are carried aloft out of the earth together with the rising vapor and there are wrought into a thunderbolt. Wherever the same causes converge, there the same effects must necessarily be produced. For the

same reason, that subterranean caverns do not lack their flashes and lightnings is known only to one who has rightly grasped the causes of each. Thunderbolts, therefore, are born in such abundance in the subterranean regions that those cramped recesses, unable to contain them, sometimes thrust them out into the open; and a number of mountains demonstrate this plainly—mountains that, under a calm and serene sky, rage with such fury from time to time that scarcely anyone can remain safe from them. Such is Mount Tola in the Mauritian Islands [Insulae Mauricae], as may be seen in Orazio Torsellini [Horatius Tursellinus], in his *Life of St. Francis Xavier*, from whose chasms at certain seasons fires are hurled forth with great destruction of men and animals. And as many as have written of the eruptions of Vulcanian mountains testify to this—Pietro Bembo [Petrus Bembus] and others on Mount Vesuvius and on Etna, which (they aptly describe) when stirred by subterranean fires has cast lightnings shot through with black smoke far and wide. All these things I have judged ought to be described here at greater length than was strictly fitting, in order to show that the subterranean regions are not only fertile in meteoric impressions, but are the sole cause of those meteors that are generated on high.

An Experiment by which we demonstrate what has been said.

If someone fills a vessel beforehand with boiling water and then seals it so that every exit for the air is blocked off, and exposes it to the cold air in wintertime, it will come about that the water in it, rarefied and then condensed by the surrounding cold air, contracts into a smaller space; and since no body can be substituted in place of the departing one, the vessel—through too great a dread of the impending vacuum—shatters into the tiniest fragments with a dreadful crash and noise.

[Margin: The wondrous power of the vacuum operates.]

The same thing happens in artillery [tormentis bellicis], which often burst apart with a powerful report from the excessive straining of the kindled exhalation.

[Margin: Experiments.]

I have little globes made of fused glass, the size of cherries, which I first fill halfway with niter-water. When these are set on burning coals, the steam from the water rarefied within seeks an exit and, finding none, bursts its barriers in a most violent eruption and stirs up so great a crash that the booms of fired muskets seem—if not surpassed—at least matched by it; all present are astonished and as it were thunderstruck at so unwonted a sound. With this festive applause of sounds I am accustomed to receive distinguished visitors in

my Museum. In the very same way, then, that an earthquake occurs with a noise from the tumult of confined spirits, this is so certain that no controversy can be raised about it. But as for what Aristotle hands down concerning the timing of earthquakes, concerning islands in the middle of the sea that are immune from them, and concerning a forty-day duration—since experience cries out against these, no general credence is to be given to them. For not only in coastal places and in islands near the mainland, but also in the most remote islands, and indeed in the Mediterranean inland regions of great continents, earthquakes have been so confirmed by experience to occur at any time of year that no further room is left for doubting it.

[Margin: Earthquakes occur chiefly in those places under which the seething basins of the pyrophylacia rage.]

Earthquakes therefore occur chiefly in those places beneath which the seething basins of the pyrophylacia rage, whether these lie beneath coastal shores, or beneath the most remote islands, or beneath inland tracts; and finally beneath all those places below which subterranean channels are situated—channels that sometimes extend themselves over 200 miles, branching far and wide.

[Margin: The earthquake which it exerts on the regions within the channels.]

This I observed with the utmost diligence in Calabria in the year cited just above, in which, along the stretch from Sicily as far as Belvedere [Bellevederium], over a tract of two hundred thousand paces and more, earthquakes had wrought enormous ruin of cities and towns through the subterranean channels. These channels, as I was able to gather from the sound, took their origin from Mount Stromboli; from there they extended through submarine chasms to the Vatican Promontory [promontorium Vaticanum], and from there beneath Tropea [Tropeam], Monteleone [Monteleonem], Lopidium, and Sant'Eufemia [S. Euphemiam]; and from there, with a turning course, they struck at Nicastro [Nicastrum], Amantea [Amanteam], and Cosenza [Confentiam], and from there at Paola [Paulam], and at last at Belvedere—where, whether because the passages were blocked or the spirits failed, they brought their fury to an end. They had, however, some collusion also with Mount Vesuvius

when, after my arrival at Naples, I examined it more carefully. (On this, see the *Epistle to the Reader* prefixed to the work.) From these channels mentioned it became clear that those cities above all are liable to earthquakes which stand directly over one of the said tunnels, while the neighboring towns indeed feel a tremor of the earth, but only through the sympathy [consensus] of the

surrounding parts—as happened in the great earthquake that arose in the Soranian territory [Agro Sorano] on 2 July in the year 1654, by which we felt even Rome itself, nearly three days' distance away, tremble through this sympathy. I also gathered, as from a most evident sign,

[Margin: The places in this region liable to it are those abounding in waters, rivers, and lakes.]

that those places are least liable to earthquakes which either lie above hydrophylacia or abound in great moisture from a multitude of lakes, pools, and marshes—as does Etruria [Hetruria]. For although Etruria abounds in combustible matter and its whole soil is encrusted with sulfurous clods, earthquakes are nonetheless not so frequent there as in dry regions, because the abundance of moisture, when the subterranean exhalations are at any time kindled and drawn out by dread of a vacuum, is extinguished and suppressed by the neighboring moisture. Were this not so, I should believe that all hope for Etruria would long since have been given up for lost.

CAPUT XI.

In which all the meteorological impressions that are born on high are shown to draw their origin from the subterranean fires.

I shall not speak here of springs, rivers, lakes, medicinal waters, and waters of various flavors, nor anything of minerals, fossils, and metallic bodies, since it is known to all that these acquire their origin from the subterranean recesses as their true and proper offspring. But intending to treat in this place of the watery, aerial, and fiery impressions, I shall demonstrate through several Paragraphs that they derive their entire existence from the fiery exhalations of the subterranean world.

§. I.

From watery impressions are formed clouds, and from these rains, hail, snow, ice, hoarfrost, dew, mist, and the like.

Since the subterranean caverns are perpetually agitated by the force of Vulcanian fire in a continual exhaling motion, and since the whole earth too is spongy, pierced through by countless vapors—both in the plains and in the mountains and at the bottom of the sea—it cannot but happen that these vapors, continually breathing forth and steeped and mingled with the moisture (whether of sea, or of

lakes and rivers, or of the moisture-soaked earth), are exalted into the form of vapors. And once exalted, when they have reached the middle region of the air,

[Margin: How snow and hail are generated.]

they are condensed by the cold into clouds—clouds which, though heavy with moisture, are not yet converted into rain, but only become rain when, separated and dissolved by the breezes that play upon them, they are turned to rain and restored by right of return [postliminio] to their origin, from which they had emanated. But if the clouds, made pregnant with nitrous and saline particles, take on a foamy character, then very soon, when a colder wind comes on, they flake out into a snowy substance. And if a cloud has already been resolved into drops, those drops, overtaken in their very fall by the vehemence of the surrounding cold acting through the power of niter, are frozen together into hail; and in this way hail is formed.

But you will perhaps object: the Sun is by no means idle in these operations of nature, but is the principal cause. I reply that it is true the Sun, the Moon, and the stars cooperate greatly besides; for the Sun at once attenuates in itself the vapid, niter-salty, sulfurous, aluminous, and bituminous exhalations which the subterranean fire has sent forth, and draws them aloft once attenuated—whence by their innate power they are converted back into those things from which they arose. But the subtler vapor, while it breathes out from the bowels of the earth—being nonetheless composed of its own niter-salty particles—is, in the nighttime, condensed by the cold caused by the Sun's absence, and returning to the earth by its own weight becomes dew, a fitting nourishment for all growing things. This dew, settling upon trees that are strong in nitrous power and suited to it, is by a certain wondrous magnetism and reciprocal attraction boiled down into manna.

[Margin: How manna and dews arise.]

In this way—since the leaves of certain trees contain in their innermost recesses an aluminous (or, if you prefer, nitrous and unctuous) substance—it comes about that when these leaves are struck by the burning rays of the Sun, the nitrous force is led from the center to the circumference; and when night falls and they are as it were softened by the descending dew, then, as the nitrous particles of the dew are joined to the sweetish chalices of the leaves, at the next heat of the Sun, with all moisture cast off and excluded, they blossom out into a snowy substance, which we call manna. Again, if the vapor has been mixed with impure refuse, then—being still crude and unripe and sooty—near sunrise, rarefied by the warm air, on account of the intermingled particles of scorched sulfurous-bituminous

matter and the crude matter mixed in, it turns into a mist most pernicious by its caustic force, not to men only but to plants as well. If this mist, when the Sun's heat comes on, has flown up on high, it produces rains; but if, with its moisture consumed, it descends through the weight of its particles, it will bring fair weather to a sky now likewise free of that troublesome soot.

But you will object: this whole birth should rather be referred to the sea, swollen as it is with spirits of this kind, than to

the vapid and flatulent subterranean exhalations. I reply: whatever the sea possesses that is spirituous and exhalation-laden, it possesses entirely either from the sucking-up of the earth or from the subterranean exhalations with which the sea is perpetually imbued; and so, through hidden water-channels [hydragogos], it partly restores to the earth what had been drawn off and imparted to it, and partly transmits it—raised on high by the force of the Sun—to the air, to be further wrought into clouds, rains, snows, and hailstones. And thus whatever exhalations the subterranean fire breathes out directly are all, by means of the sea, drawn up and sublimated by the celestial fire (I mean the Sun) and destined for the said births, and diffused over immense tracts of sea and land by the power of the winds.

[Margin: The fire-powers of the world: Phoebus and Vulcan.]

For these are the two fire-lords [pyrodynastae]—Phoebus, I mean, and Vulcan, or what amounts to the same, the celestial and the subterranean fire—so joined in their operations by an inviolable bond of friendship that the one cannot operate without the other. Since we have pointed this out in many places in this work, we shall not dwell on it any longer.

§. II.

On the aerial or fiery subterranean impressions, and first on Lightning.

The fiery impressions are: lightning, flashing, coruscations, burning heats [caumata], will-o'-the-wisps [ignes fatui], Castor and Pollux [St. Elmo's fire], aerial comets, and the like, which the meteorologists treat of—all of which we have shown to draw their origin from the subterranean realms. Since the subterranean world perpetually sends forth on every side breaths joined together and confederated from a medley of various mineral particles, it comes about that these, by their subtlety penetrating all moisture, are drawn aloft by the Sun together with the vapors; and there, impatient of the cold,

[Margin: Whence the motion of lightning.]

they are wrought into lightnings. This happens if, enclosed in denser clouds, the breath—pregnant with the spirit of a certain sulfur, of arsenic, and the spirit of gold—begins to clash with the hostile substance of a nitrous breath: for then, in a violent catastrophe arising either from the tumult of opposing spirits or from the narrowness of the clouds in which they are enclosed, the several portions are kindled; and at the first clash, when the bars of their intolerable prison are burst with the greatest force, they are borne headlong on an oblique path and an aerial rolling, about to present a horrible and deadly spectacle to mortals. Hence, as the sulfurous breath strives upward while the earthy portion of nitrous character sinks downward by its weight, there arises that turbulent descent of the lightning.

[Margin: Why it liquefies metals while leaving soft things unharmed.]

But as to why it liquefies every metal it meets by its penetrating force, and lays low and consumes hard things alone while leaving soft things unharmed—this happens on account of the fiery ray and the sulfurous spirit of gold of incredible efficacy, and because of its supremely penetrating power. Have you ever seen craftsmen fusing glass at the lamp, who drive the flame

[Margin: A comparison of the flame with which glass-workers fuse glass with lightning images.]

(I mean, by the blast) into the utmost length and fineness? If you have seen this, you will discover with wonder that what without the blast the flame could not accomplish is accomplished by the blast-fed flame [*conflatoria flamma*]*—that is, glass and every metal are melted in a moment, the instant the flame touches them. These effects are so aptly fitted to those of lightning that there is nothing in the nature of things which better expresses the nature of lightning. Many wonder why lightning consumes a sword while leaving its scabbard unharmed, and wine while leaving its cask unharmed. You will discover most clearly how this comes about if you interpose, before the blast-fed flame, a piece of leather or a thin wooden tablet. For you will see the flame—wonderful to say—by its penetrating power pass at once through these unharmed, and act only on the metallic and glassy bodies on the opposite side. But if in a spoon you catch up water or wine, exposed to the fiery ray, you will see the whole liquid consumed and evaporated in the time it takes to recite a single *Pater noster*. By these effects we arrive at a knowledge of proximate causes better than by a thousand metaphysical speculations, which contribute nothing to the matter.*

But if the blast-fed flame has so great a force, how much greater shall we suppose the flame of lightning to have, especially since it is pregnant with mineral spirits, the most subtle and penetrating of all? But why (lest I omit anything necessary to the intimate knowledge of this matter) a flame stirred by a blast obtains such great powers—you may judge the cause of this to be the following:

[Margin: The cause of these effects.]

that the fiery spirits, stirred by the blast, since they cannot free themselves from the subject to which they cling, are driven with the greatest force together into the very tip of the flame's apex; and there, pressed and condensed and reduced to the tiniest space, while they cannot escape further because the flame prevents them, they are increased there by an ever new and renewed accumulation of spirits, and seethe with an incredible heat. It is no wonder, then, that they cause such unwonted effects of combustion and liquefaction.

EXPERIMENT.

Into a lamp filled with oil, set a thick wick steeped in melted sulfur together with the oil of sal ammoniac and niter; and when it is kindled, blow the flame through a tube of glass or any other material. The apex of this flame is of such efficacy that there is no metal so stubborn that it will not melt it; for in fiery spirits of this kind, made from sulfur and antimony and niter, nothing more efficacious in the nature of things can be found. But of these matters fuller material for discussion will be given in Book VII, on minerals.

§. III.

On the remaining fiery subterranean impressions.

[Margin: Falling stars.]

The impressions which the meteorologists call falling stars come about in two ways. First,

sulfurous breaths exalted into the upper reaches of the air, if they meet no obstacle, ascend as far as they can, seeking out the region most agreeable to their nature; and being by their own nature easily inflammable, they are kindled even at the nearest opportunity. For when spirits of this exhaled kind are extended lengthwise, then that smoky band, as soon as it touches the cold of the higher air opposing it, has its outermost tip kindled by the excessive struggle and friction; and this, creeping swiftly along, sets the whole of that vaporous sulfurous matter on fire to the end by a kind of successive ignition. And thus that fire, depending

on the disposition of the smoky band, seems to rush from on high either downward or into an oblique part of the world.

[Margin: Experiment.]

An example for us can be the smoke rising from an extinguished candle: if you bring another lighted candle near it, then at once that smoke, catching fire, runs back to its source from which it exhales, and rekindles the already-extinguished candle at the same time. The experiment is as well known as it is most certain; and the smoke exhaling from the candle is nothing other than the sulfurous breaths extended lengthwise in the region of the air, through which the flame is propagated successively—and thus you will have a falling star. This is equally evident in gunpowder laid out and scattered in a line upon the floor: if you bring fire to it from one end, you will see the powder catch flame successively, so that the flame seems to run along, although there is no local motion backward there, but only a successive new production of fire in the successive parts of the underlying material.

[Margin: Fiery missiles imitate falling stars.]

In the second way it can happen by exactly that mechanism by which the fiery missiles we call *pyroboli* [rockets]—kindled and rarefied by the violence of the fiery body—ascend with the utmost force on high, as far as they can, in the form of a luminous line, where, the impetus failing, they descend again, until at last, the fiery vapor being consumed, they vanish. But the meteors which the Greeks call κάύματα [Greek: kaumata, "burning heats"]—that is, kindlings [accensiones]—happen in this way:

[Margin: How burning heat is generated.]

sulfurous exhalations gathered in scattered clouds, when they have been kindled, seize now these portions, now those, the earlier ones being extinguished; and from this arise those coruscations which—appearing in the form of contending hosts—are gazed upon by those ignorant of the cause with great astonishment, as though some portent significative of evil omens; whereas they occur in exactly the same way as in scattered and dispersed gunpowder, whose portions, dispersed here and there and so separated from one another that they nevertheless always remain continuous through the interposition of the intervening grains: for one grain, once kindled, runs at once to the next, and this to others and still others successively, until all, the fire being caught up, finally cease. Whoever makes a trial of this matter by night will produce a perfect representation of κάύματα [kaumata] in a finely interrupted illumination.

The will-o'-the-wisp [ignis fatuus], and the fire that is detected on the oars and rudders of ships, we likewise declare to be nothing other than a subterranean exhalation mixed with sulfur and bitumen, which, having rolled out beyond the sea and clinging to wooden bodies, is at last kindled either by the motion of the sea or by the agitation of the sea. But since we have reasoned about these matters more fully elsewhere, we have not wished to be longer here. There remain comets and beams [trabes], concerning which the Reader may consult our *Itinerarium Exstaticum*, where we have set forth their true mechanism and origin.

From these things—deduced perhaps more fully than was fitting—it is plainly evident that there is no effect in the nature of things so exotic that it does not obtain its origin from the Subterranean World.

LIBER QUINTUS

DE LACUUM, FLUMINUM, FONTIUM

On the Nature and Properties of Lakes, Rivers, and Springs, and Their Origin from Subterranean Sources

[Of the origin of lakes, rivers, and springs (Liber V, "De Lacuum, Fontium, Fluminumque origine").]

SECTIO I.

On the origin of springs, rivers, and lakes, and their diverse nature, powers, and properties.

PRAEFATIO.

That divine pronouncement of *Ecclesiastes* is most true: "The sun rises and sets, and returns to its place; and there, being born again, it circles through the south and turns toward the north, surveying all things; the spirit moves on in its circuit, and returns again upon its circles. All the rivers run into the sea, yet the sea does not overflow; to the place from which the rivers come, they return again, so that they may flow once more." [Ecclesiastes 1:5–7] These things are so certain that no interpreter of this sacred text has ever raised any doubt about them. But the manner and means by which it happens has at all times seemed so hidden, so difficult and impenetrable, that down to the present day the true reason for the origin of springs has seemed to hang in doubt. This subject has been so confused

— by a multitude of monstrous opinions, by countless inventions of the philosophers, by endless difficulties, and finally by a labyrinth of conflicting doctrines — that scarcely anyone has been able to extricate and disentangle himself from them.

Seeing the nearly hopeless difficulties of the subject, and wishing to bring at least some light into such great darkness, I have resolved in this work to bring the whole matter back to the anvil. Taught and guided by the experience of many years, I have perhaps achieved this much: if I have not arrived precisely at the principles intended by nature, I have at least come close enough to them that I may seem to have brought forward something more exact, more plausible, and more probable on this subject than others have — leaving the judgment to more learned men. And so that this may be done as well as possible and to good effect [εὐμεθόδως [Greek: eumethodōs, "in good method," methodically]], I will first set out my Suppositions, and then turn my pen to the causes of the individual effects.

DISQUISITIO I.

On the origin of springs, lakes, and marshes.

SUPPOSITIONES.

I suppose, first. That the whole Geocosm — as was most amply demonstrated in the preceding books — is pierced through with innumerable caverns, hydrophylacia, pyrophylacia, and aerophylacia, with passages, siphons, and water-conducting channels, with fissures and pores, and this not only on the external surface of the Earth but also in the bed of the sea and the Ocean. This was established and confirmed by various and diverse examples and histories.

I suppose, second. That the continuous ebb and flow of the sea, caused by the Sun and Moon, together with the most violent motion of the perpetual winds by which it is agitated, has been so arranged by the admirable disposition of divine wisdom that, with the incredible pressure of its mass, it drives water out through all the passages of the Earth — much as a pump, by pressing water, hurls it upward and disperses it. This too was very fully shown in the preceding books, as well as in the *Iter extaticum terrestre* [*Subterranean Ecstatic Journey*].

I suppose, third. That the fiery channels of Vulcan [the subterranean fire] produce remarkable alterations and metamorphoses in the subterranean waters that come up from the sea, when it sublimates them as they pass through the passages and fire-conducting siphons — now rarefying them, now thickening and

condensing them, now tinging them with mineral exhalations, and working in similar ways, which will be brought forward in what follows.

I suppose, fourth. That nature, established within the hidden and everywhere-enclosed subterranean caverns, produces wondrous effects in drawing water up into higher places, by reason of its dread of any vacuum arising anywhere.

I suppose, fifth. That the subterranean water-conducting channels [canales hydragogos] are not everywhere of the same width, but — according to the constitution of the various places — are now dilated to an immense breadth, now constricted into a narrow strait, now held to a moderate span. From this irregular distension proceed wondrous effects in the natural world, as will be said later.

These things being supposed, let us now begin the argument we have undertaken.

CAPUT I.

DISQUISITIO

On the manifold cause of the origin of springs.

It cannot be that their origin should be traced back to a single universal cause. Therefore, according to the variety of the effects, diverse causes too must be established. Of these I will here assign ten, on which depends the origin first of springs, then of rivers and lakes, and I will explain them all in order.

The first is the opinion of Aristotle and of all his followers, who reduce the origin of springs to two heads: namely, to the resolution of vapor condensed by the cold of the place within the inner vaults of mountains; and, secondly, to rains, which — when they penetrate the passages of the earth and find an outlet somewhere — produce a spring. Thus indeed Aristotle philosophizes [*Meteorologica* I.13, Text 52]. His words are these: "And therefore the streams of rivers seem to flow from the mountains, and the largest and greatest rivers flow from the largest mountains and from those near high places. By contrast, in the plains, away from the rivers, very few rivers arise at all. For the mountainous and other high places, like a sponge suspended above, in a small measure indeed but in many places, trickle and let drip water; for they take up the great abundance of descending water, and they cool and condense the ascending cold vapor again into water — and therefore, as I said, the greatest of rivers seem to flow from the greatest mountains." [Margin: *Aristotle's opinion on the origin of springs.*] These are the words of Aristotle.

[Margin: *Exposition of the opinion.*] Since these opinions are most obscure, they have stirred up various disputes in the Schools as well. For my part, I declare the true sense of Aristotle's opinion on the causes of rivers and springs to be this. First, he says there is water that is collected from the earth from rains coming down out of the clouds, and is absorbed as if by a kind of sponge; then, little by little, the earth gradually releases the water distilling within it through springs and rivers. This sense is plain, as is clear from the words quoted. The other cause he hints at is by the ascending vapor — vapor that is cooled and condensed into water. Here I would not have you understand the vapor existing in the air, but rather that which lurks within, and which, striking against the cold vaults of the caverns, is there resolved into water.

[Margin: *The cause assigned by Aristotle is shown not to be the universal one.*] And although I would not deny that springs can arise from the resolution of vapors — as I will demonstrate later — yet what excites those vapors, and how the absorption of rains and the distillation of droplets could supply so great a mass of water as we see rolling out of the mountains afterward, cannot be conceived. Much less can it be grasped how, in the lakes of the very highest mountains — lakes that pour out whole rivers on every side in perennial flow, and that are not necessarily covered by any vault for the resolution of vapors into water — the water can ascend. Nor does that claim hold, that springs are found only on high mountains, but few in the plains away from the rivers. I, on the contrary, hold that in the plains a greater abundance of water is born from time to time through subterranean springs than what rolls out of the mountains — as the vast lakes abundantly demonstrate, as I will show below.

Since, therefore, Aristotle has philosophized about the causes of springs in a very abstract way and, in his manner, metaphysically, we — proceeding to the nearer causes — are confident, God granting it, that we shall overcome all the reefs of the difficulties that occur, which lie hidden in Aristotle's obscure opinion.

That springs, then, arise from vapor resolved in the vaults of the subterranean caverns is false, if we consider it universally. For we see, and most frequent experience confirms, that in countless places where huge streams and rivers obtain their origin from the mountains, the water bursts forth not in the manner of a bubbling spring, but like a vast river, and is at once found fit for navigation — as may be seen in the sources of the Ganges, the Nile, the Po [Padus], the Rhône [Rhodanus], the Rhine [Rhenus], and the other rivers of the whole Geocosm.

[Margin: *Objection from the Peripatetics.*] But someone from the Peripatetic school will say: it is true that they do not roll out in the manner of a bubbling-up, but

there are without doubt huge reservoirs of water within, which — from the resolution of vapors in the vaults of the caverns, just as in the glass vault of an alembic — supply this abundance of water in the hydrophylacium beneath; and this water, then seeking an outlet through the fissures of the mountains, bursts out into a river. These things are indeed rightly and skillfully said, and I am not opposed to this opinion, as was clear from what preceded.

Yet from the mere distillation of the subterranean crypts, that so great a mass of water should be collected as to immediately constitute a vast river thrust forth — that I cannot be brought to believe; and he will find many companions for his opinion.

There is added to this a second difficulty concerning the vapor condensed in the subterranean vaults and resolved into drops, which the Philosopher posits. For I do not see whence such a vapor could be produced in the coldest caverns, to which neither Vulcan nor Phoebus [neither fire nor sun] has access. [Margin: *In cold places no vapor can be generated.*] For neither in cold places, where there is no heat to attenuate the water, nor in the coldest places where there is no heat to draw water out into vapor, can a vapor ever be conceived to come about. But let us suppose that subterranean heat is introduced through the fire-conducting channels [thermagogos] ordained for it by nature, into caverns thus enclosed on every side. Yet who does not know that the heat would then take such an increase over time that — just as it heats the mountain's enclosure — so it would heat the water contained within it with incredible fervor? And thus, just as happens in hot springs [thermae], a river not cold but hot and steaming would issue forth, discharging its hot exhalation together with the water through the water-conducting channel common to both.

[Margin: *The Peripatetic opinion is refuted, because many mountains never receive rain at their source.*] Therefore this opinion, if rightly considered, cannot be true. For since it does not always rain on the mountains, and the mountains of many regions are not even capable of rains — as the sacred text testifies of Gilboa [de Gelboe; cf. 2 Samuel 1:21], and as the Geographers record of very many mountains both within and beyond the Torrid Zone, which nevertheless pour forth very many waters — so likewise the dry earth in the inner caverns of the mountains cannot supply by a perennial flow so great a mass of water as we know the mountains to disgorge.

To the second difficulty I say this: it can indeed happen that the distillation of resolved vapor produces some streams; but that so great a mass of water as the mountains repeatedly pour out in the manner of rivers could be supplied this

way, I deny. And I demonstrate it in this fashion. First, take the experiment known to all, concerning the Alembic. Let it be marked with the letters A, B, C. Its lower, bulging vessel is A, containing the moisture;

Diagram. A woodcut of a distillation apparatus (an alembic), used as an analogy for the subterranean generation of springs. At the left stands a tall, bulbous flask (A) set over a fire of flames upon a square brick or grid base; rising from its neck is a rounded dome or head (B). From the head, a curved tube or spout (D) leads down and to the right into a smaller rounded receiving vessel (C), which stands upon its own square base. Per the surrounding text: A is the lower receptacle of moisture (representing the floor of the cavern), B is the vessel in which the vapors are collected (representing the vault of the cavern), C is the vessel that receives the water resolved from the vapor in B, and D is the channel through which the resolved water descends.

- A (lower flask, over flames): the lower bulging vessel containing the moisture — the receptacle of moisture and the floor of the cavern
- B (upper dome/head): the vessel in which the vapors are collected, representing the vault of the cavern
- C (right-hand vessel): the vessel that receives the water of the vapor resolved in B
- D (tube/spout from B to C): the channel [canaliculus] through which the resolved water descends

—containing the moisture; B is the vessel in which the vapors are collected, and it represents the vault of the cavern, just as A is the receptacle of the moisture and the floor of the cavern; while C is the vessel that receives, through the little channel D, the water of the vapor resolved in B.

[Margin: *That water cannot be raised without heat by vapor alone.*] Having established this, I argue thus. Either A is filled with moisture, or it is empty of it and is filled by vapor alone, insinuated into it through the cracks of the mountains. If you grant the former, then it cannot happen without an attenuating heat that the water be driven into vapor — just as, in vessel A when it is filled with moisture, the vapor will not rise without fire. If you say the latter — that the vapor, condensed in the cold vault, is resolved from whatever heat finally penetrates the cracks of the mountains — it will indeed be resolved, but in so small a quantity that, descending through the channel D, it will constitute only a rivulet and can never present a river. And just as, when the vapor in vessel A ceases, I say that all distillation will consequently cease, so likewise, when the vapors — and from these the rains — cease upon the mountains, I assert that the

caverns, deprived of moisture, will be deprived equally of their outflow. And this happens above all in the summer months, when, with all the matter of rains consumed by the Sun, the showers cease and the mountains dry up. And yet, notwithstanding these failures, that the mountains nevertheless always pour out their rivulets is too well known to need stating.

[Margin: *A similarity demonstrated by the Alembic: that the resolved vapor cannot supply a continuous flow.*] Indeed, experience confirms that the drops in the vault either of the mountains or of the alembic, just as they take long delays before they fall, so the water collected from the falling of the drops, as soon as it finds an outlet, glides away, while the flow ceases for a time, until the basin is refilled with a new increment of water. This appears clearly in the preceding figure, at B and C: when the vapor in vessel B has been resolved into drops, as soon as it has insinuated itself through the channel D into vessel C, it is collected there again; then, as soon as it has reached the orifice by its own increase, it at once discharges itself through the channel E; and so, after a certain delay has intervened, the flow of water ceases until the new accumulated water refills it. And thus the flow of water always, through interrupted turns, takes certain delays. The same thing must necessarily happen in the caverns of the mountains, since the resolution of vapors into drops can never supply so great a mass of water as the perennial eruption of any stream or river from a mountain requires by its own nature — for the reason that it can never, by its dripping, replace the quantity of the gliding water. From which it would also follow that rivers and streams should sometimes cease and at other times run again — which, besides being repugnant to experience, is also contrary to the intention of nature.

It is therefore clear that the opinion of Aristotle concerning the origin of springs and rivers, taken universally, does not hold. And so another universal cause must be sought out, one that may provide the origin of springs and rivers from the resolution of vapors — which now, God granting it, we will set forth.

SENTENTIA AUTHORIS

On the Origin and Rising of Springs from Subterranean Vapors.

In some springs arisen from the resolution of vapors, as to their substance indeed

I subscribe, not unwillingly, to Aristotle's view — yet not as to the manner. How, then, we hold that springs can arise from the said vapors, we explain in a few words.

Supposing first that the earth, as has been very often shown, is furnished partly with hydrophylacia, partly with pyrophylacia and aerophylacia: that these may serve the operations of nature, nature, by great design, willed that various siphons, passages, openings, fissures, and clefts be inserted into them, for carrying on the hidden commerce of its business. If these are led from the pyrophylacia, we have judged them to be called thermagogi [heat-conductors]; but if they are derived from the hydrophylacia, hydragogi [water-conductors]. If, then, a water-conducting channel has carried a great abundance of fiery spirit somewhere into one of the hydrophylacia of the mountains, the water — at once stirred up and roused, as if by the welcome arrival of a guest, and raised into vapors — will cling to the vault of the hydrophylacium. There, condensed and resolved by the cold of the place, flowing down through the walls of the cavern and collected in its cavities, it will at last burst through a channel into a spring. And since these exhaled exhalations are perennial, and consequently the resolution of the vapor and the stream issuing from it are perennial, it is necessary that the spring, pouring out its waters in perennial flow, be perennial too.

[Margin: *How Aristotle's opinion can be defended.*] The other mode is this. If into the moist subterranean cavern of some mountain, one not so thickly packed with water, those fiery exhalations have entered, it will happen that, mixed with the moisture of the places through which they pass, they take on the nature of vapor; and these vapors, insinuated into the cavern and dashed against the cold vault, condensed there and resolved into water, flowing likewise through the little water-conducting channels ordained by nature, will turn out equally into a perennial spring and stream. And in this way the opinion of Aristotle can conveniently be defended. As for those who say that springs derive their origin from rains and snows collected in caverns — about which we will treat later — they speak well; but for the reasons indicated above, they will indeed have springs, yet not perennial ones, but springs deprived of water at certain times (namely, when both rains and snows cease) and abandoned by their flow, as we will afterward confirm by various examples.

CAPUT II.

DISQUISITIO

On the principal and general cause both of springs and of rivers.

§. I.

MODUS PRIMUS.

The Peripatetic, against the sacred utterance of *Ecclesiastes*, denies that the origin of springs and rivers proceeds from the sea, and affirms that it is born solely from the resolution of air condensed into vapor, as we showed a little above. But just as we showed a little before — standing on the inquiry into the general cause — that this is false, so it will be our part, with a varied apparatus of experiments, to explain in this chapter the contrary: that is, that all springs and rivers go out from the sea and return into it.

The only difficulty, which prevents my adversaries from persuading themselves of this matter, consists in this one point: that they cannot conceive how water, contrary to its own natural inclination, can be raised even to the highest peaks of the mountains, when the sea is much lower than they. If I overcome this difficulty, surely I think no one is of so senseless a mind that he will not — as the saying goes — come over, hand and foot, to the side of my opinion.

I say therefore, in accordance with the first and second supposition of this Section, that not only the earthen body but also the bed of the sea is perforated with innumerable passages — which was abundantly demonstrated in the preceding books by an induction of the seas and lands. This being granted, it is also certain that it was not without the admirable design of nature that the sea — according to the second supposition — is pressed by so many storms, so many blasts of winds, so many masses of descending clouds, and finally, by the perpetual reciprocation of its ebb and flow, is most constant in its perennial inconstancy. These things assuredly argue a great institution of sagacious nature, which, just as it willed nothing in vain, so directed all these things toward the admirable ends of nature.

[Margin: *What the manifold motion of the sea contributes to the origin of springs.*] It is known from hydraulics how contrary even the slightest force is to water by which it is pressed — inasmuch as it cannot bear to be contained in a place: for either, when pressed, it immediately overflows, or, if it finds an outlet somewhere, it soon flees through it, as if fleeing a violence inflicted upon it, and pursues paths set beyond the limits of nature. This is evident in a stone thrown into water; it is evident also from the manifold experiments of the hydraulicians, which we will adduce later. This being established, I say that water can, with no trouble, be brought up from the sea even onto the highest peaks of the mountains — as is clear from the perennial mountain lakes, which are found here and there in them.

EXPERIMENTUM I.

Pressed water, where it finds an outlet, ascends on high beyond its natural inclination.

Let there be two bellows, A and B, made of thick leather and foldable, into the bottoms of which let two channels, G and F, be inserted, which extend into the receptacle D, C, E, F of the supposed living water. And let there be, at the inner orifices of each bellows, two valves [platismata], so constituted that, when one bellows is raised, the one valve opens and the other closes as that bellows falls. Let the receptacle of the water be divided by a certain diaphragm, G and L, lest of the one

[Continued from the previous page: "...lest the operation of one bellows hinder the operation of the other."]

the operation of one bellows hinders the operation of the other.

[Margin: The apparatus shows graphically how sea-water rises into the mountains.]

This done, run two channels, H L and N O, fitted to the side of the receptacle C D E F, in line with the two orifices of the two bellows. Let the channels H I and N O be equipped with their own valves [platismata], so arranged that they open at the thrust of the water, and let them be led off into receptacle K. So if you wish to operate the device: when bellows B is raised, water is drawn from receptacle D C E F through channel E into the bellows; but as soon as the bellows descends, the water drawn in and pressed inside is driven through channel H L into vessel K. Meanwhile, as bellows B falls, the other bellows A is raised, and in the same way water is drawn from receptacle D C E F through the appropriate channel G; as A descends, it presses the water through channel S, upward into vessel K. Thus by the alternate drawing and the violence of the pressure, water is driven into receptacle K, which has an orifice at X, through which the water discharges itself in as great a quantity as the bellows have expelled into vessel K. In this way vessel K will always be full of water and will last with a perennial outflow at X — especially if the water of the receptacle is living water, and if the bellows are raised and lowered in alternate turns, by some commonly known mechanism, as you see in the figure, set in motion by the water itself.

Diagram. A hydraulic machine demonstrating how sea-water is forced up into the mountains. On the left stands a large rectangular receptacle (the "sea," labeled C D E F at its corners) built up of stacked horizontal slats, with two accordion-

pleated leather bellows (A in front, B behind) seated on top of it. Channels run from the bellows: G and F at the base of the receptacle, with E and the side-channels feeding the discharge. On the right a tall vertical receptacle (vessel K) receives the pressed water; its discharge orifice would be at X near the top. A large spoked drive-wheel (with hub N and a peg O on its rim) stands at lower right, geared to raise and lower the bellows alternately; above and behind, a curved drive-arm or crank arches over to the bellows. Readable labels:

- A (top left, front bellows): the front bellows [follis]
- B (top left, rear bellows): the rear bellows [follis]
- C, D, E, F (corners of the left receptacle): the receptacle representing the sea/Ocean
- F (lower mid-left): channel into the receptacle
- E (mid-left): channel between receptacle and bellows
- G (foot, center): channel G
- K (right): vessel K, receiving the pressed water
- N (hub of wheel): axle/hub of the drive-wheel
- O (rim of wheel): peg on the wheel's rim

Application of the hydraulic machine to the operations of nature.

[Margin: Application of the hydraulic machine to the operations of nature.]

Now that we have the machine, let us apply it to the operations of nature. Imagine that the water contained in receptacle C D E F is the sea or Ocean; that the bellows are the ebb and flow of the sea, which — pressed by the alternating increases of the waters drawn up by the Moon — expel water through the water-bearing channels [hydragogi] inserted by nature in the sea-floor, up into the water-reservoirs [hydrophylacia] of the mountains, which vessel K represents. And in just this way we say that the waters, pressed by the enormous weight of the accumulated waters, are raised with no difficulty from the sea to the highest peaks of the mountains.

[Margin: What the ebb and flow of the sea contribute to the origin of springs.]

For just as the bellows are now lowered, now raised, by alternate motions, so the ebb and flow of the sea, in the space of twenty-four hours, twice in alternating succession, renew the laws of their reciprocation. They are distributed into six-hourly stations, so that at opposite points of the Ocean — which is the same as saying, with the Moon set at opposite points — the sea is always raised at the same time in two quarters and lowered at the same time in the two opposite

quarters. This rise and fall we call the ebb and flow [fluxus et refluxus], as was said in the preceding Section. That the water suffers this violence not only from the ebb and flow of the sea, but also from storms and the whirlwinds of the winds, and indeed is pressed and squeezed out by the very descent of the overlying air and its vapors — this we shall show by the following experiment.

EXPERIMENTUM II.

Pressed air presses the water and expels it to the desired height.

Let there be made a lead pipe A C B, which at each end has small cups A and B. Let cup A have a little channel C projecting from its center; and let cup B be somewhat deeper, and have at its center an open hole, into which the pipe C B is fitted. And you will have the instrument ready. Let cup B represent the sea, lower than the mountains into whose peaks the water is raised; and let cup A represent the mountains themselves, higher than the sea. First let the whole pipe be filled with water through cup B. I assert that, from the mere pressure of the air lurking within the hollow capacity — pressure produced by the flat of the open palm of the hand — the water contained within pipe B C A, likewise pressed, will be expelled with great force past A, into C, up through the little syphon C, to a great height. You may judge that exactly the same thing happens in the sea, since...

Diagram. A small U-shaped (siphon) apparatus illustrating Experiment II. At the right stands a cup B (raised on a short stand), the deeper cup representing the sea, with the pipe descending from its center. At the left rises a narrower vertical tube ending in cup A, from whose center a little channel C projects upward; a jet of water sprays up and out of C at the top. The two cups are joined below by the lead pipe bent in a U. Readable labels:

- A (upper left, twice marked, with a small cup): cup A, representing the mountains, higher than the sea
- B (right, deeper cup): cup B, representing the sea
- C (top of the left tube): the little channel/syphon from which the water spurts; also marks the foot of the U-bend
- H (lower left): point on the rising pipe

[Printed p. 231 — running header "DE FLUMINUM ORIGINE."]

[Margin: The apparatus shows graphically how the sea-water rises into the mountains.]

that the water — whether pressed by the impulse of the air, that is, of the winds set in motion, or by the gravity of the cloud-waters charged with moisture and descending — necessarily yields through the water-bearing passages [hydragogi] (which must always be kept full of water), and discharges itself beyond its equilibrium-level A, up into the cup-shaped hollows of the mountains, far higher, against its natural inclination. And just as the ebb and flow of the sea — and likewise the air, whether stirred by the wind or descending from heavy clouds — is pressed almost everywhere and continually, so from this pressure of the sea, yielding through the syphons fitted to it, there must be a perennial discharge into the water-storing cup of the mountains [concham hydrophylacticam]. For it is now commonly known that perennial effects follow upon the cause of perennial operations. This is indeed a remarkable experiment, which we are accustomed to display in our Museum to the great delight of spectators: for water, pressed in cup B by the motion of the air and squeezed out through the little channel C, into cup A, and from there through another small syphon, e, discharges itself like a river. The experiment is so clear that it seems to set the very cause of our undertaking plainly before the eyes.

But someone will object that the sea-water is not pressed with such force that it could set in motion the whole, almost infinitely weighty, mass of water standing within the water-bearing channel. To this I reply: the water held within the water-bearing channel is not only easily moved, but is also thrust beyond the limits of its equilibrium with almost no effort. For since the water within channel B C H is balanced at H and at B, it has no other space to traverse beyond the limits of its own nature than from A or H into cup C A. Again, since the heap of surging waters in the sea — or even the pressing force of the winds — is far more powerful than the water contained between A and H, or between H and C, it is certain, from our hydrostatics, that the water is powerless to resist so great a mass of agitated water. Hence, necessarily compelled to yield to a more powerful principle, that is, to a greater force, it will insinuate itself into cup C A, through the channels joined together for it by nature. In the same way, the gusts of the winds, by which the sea is pressed, possess that same power to raise the water contained in the water-bearing channels beyond the limits of its equilibrium — since we shall show by the following diagram that the mass of waters to be raised above equilibrium is, as it were, imperceptible compared to the mass of those pressing down in the Ocean.

First, I suppose — following the common reckoning of geometers, although some judge otherwise — that the semidiameter of the Earth is no more than 3,600 miles, of which 60 correspond to one degree of the heavens; and that this

semidiameter is taken from the surface of the sea, that is, from the mathematically spherical Earth. But since the mountains, whose base is the said surface, are higher than it, it must now be demonstrated how much higher the sea must reach beyond its natural limit in order to raise the waters into the cup-shaped hollows of the mountains.

[Margin: The highest mountains are scarcely perceptible relative to the semidiameter of the Earth and the periphery of the Ocean.]

Let the semidiameter of the Earth be A B, 3,600 miles long, terminating at point H, on the surface of the sea or the spherical Earth, the line A T. Now let us suppose the highest mountain of the whole Geocosm — than which none greater or higher can be found on the globe of the Earth, as is clear from the heights of mountains shown in the Table of Book 3. Add this to the semidiameter of the Earth, B A, and the line A C will result, which expresses the summit of the highest mountain in the Geocosm. And so, as the semidiameter of the Earth stands to the height of the mountain, A O — 30 miles — which, in respect of the vast and immense Ocean, holds a portion of the Earth so small that it is scarcely rendered perceptible. And the proportion will always be rendered the more imperceptible, the smaller the height of the mountains. So the Peak of Tenerife [Pico de Teide], Olympus in Asia, Etna in Sicily, Caucasus in Asia, Athos in Macedonia — in respect of the vastness of the Ocean — seem in a way to vanish.

[Margin: As B A is to A C, so...]

From this I infer that the waters of the Ocean — whether pressed by ebb and flow, or by storms and the force of the winds, or by the descent of the clouds — can with no difficulty be cast up even onto the highest summits of the mountains; and that the whole error is a mockery of human imagination. For people, accustomed to things present, when they behold mountains so high before them, marvel how the water can be raised to so great a height — not having considered the vastness of the Ocean poured around the terrestrial globe, relative to which the mountains, as has been shown, obtain scarcely anything of perceptible magnitude.

[Margin: Error of human imagination.]

To this is joined another deception of fancy, when people imagine that some small mass of waters is pressed in the Ocean. Not at all: for the swelling produced by the accumulation of the waters pressed by the Moon is so great that it extends — not to say to several miles, but — to many thousands of miles. For the swellings of the sea that are caused in the Ocean by the Moon, since they are always

opposite to one another, each swelling occupies a whole quarter of the Ocean, as is clear from the Figure, in which...

Diagram. A tall vertical scale-diagram at the upper right of the page, illustrating the proportion of mountain-height to the Earth's semidiameter. A vertical line is graduated with the values 1000, 2000, 3000, and (at top) 30, against a horizontal scale-bar marked C — 30 at the top. Near the top, a small jagged/hatched triangular profile represents the highest mountain (line A C) rising above the surface; the letters H, A, and others mark the surface-point and the foot. At the very bottom the line terminates at H. Readable labels:

- C, 30 (top scale-bar and apex): summit of the highest mountain; $A C / A O = 30$ miles
- 3600 (near top, beside the surface): the Earth's semidiameter, 3,600 miles
- A, H (top, at the surface): A = base/surface point; H = surface of the sea
- 3000, 2000, 1000 (descending graduations on the vertical line): the scale of miles toward the Earth's center
- H (foot of the line): the Earth's center / opposite terminus
- T (top right): terminus T on the surface line A T

[Margin: The summit rises along the axis to a height of 30 miles.]

[Margin: The highest mountains are scarcely perceptible relative to the semidiameter of the Earth and the periphery of the Ocean.]

[Margin: Error of human imagination.]

[Printed p. 232 — running header "LIBER QUINTUS"]

the swellings of the sea, A B C and D E F, opposite to each other, occupy precisely two quarters of the Geocosm; while the pressure of the sea occupies just as many, namely B D and C F. But this is set out very fully — see Book 3, Section 1, on the motion, that is, on the ebb and flow of the sea. For these swellings travel, in the space of 24 hours, around the whole globe of the Earth, by this design of nature: that, by the weight of the accumulated waters, they may agitate the sea and expel it through the water-bearing channels inserted by nature into the Earth, up into the water-reservoirs [hydrophylacia] of the mountains. And since these swellings are perennial, there must likewise be a perennial influx of waters into the said reservoirs; nor, as long as the world endures, will they cease to drive the watery element. Since, then, these swellings are so vast, and are violently accumulated, and each separate portion of the swellings presses the waters equally, it plainly appears that they discharge themselves into all the mountains of the Earth not

through one water-bearing channel alone, but through innumerable ones, whose waters they perpetually drive. And this discharge will be the easier, the more oblique the water-bearing syphons are — which I also set forth by this experiment.

Diagram. Top left of the page: a vessel of lead or iron plates showing a bent and a vertical channel, set over a landscape of small hills. A box-like reservoir A (lid marked A, with a corner marked D) sits at the upper right; from it one channel descends obliquely from B toward C (running down across the hills to the left), and another descends vertically from E to D. A short cylindrical stand-pipe with a domed top (the perpendicular tube) rises at center, marked H below. Readable labels:

- A (top of the box-reservoir): the vessel of plates, to be filled with water
- D (upper right corner of the reservoir): perpendicular channel E–D
- B (left, head of the oblique channel): start of the oblique channel B C
- C (lower left, foot of the oblique channel): outflow of the oblique channel
- E (center): head of the perpendicular tube
- H (below the central stand-pipe): point on the perpendicular channel

[Margin: Experiment.]

Let there be a vessel of lead or iron plates, A D, whose channel is led obliquely from B to C, and another perpendicularly from E to D. Let the water, with which the vessel must be filled, be pressed either with the flat hand or with some pestle. It is certain that the water will be driven much more easily from B to C than from E up the perpendicularly erected tube E D — because the weight of water in an oblique position weighs less than in a vertical position, as we demonstrated in our Hydrostatics. Hence shrewd Nature seems to have had regard to this principle, when she chose not to bend channels of this kind straight down perpendicularly into the earth, but with an oblique course, for the easier propulsion of the waters, as is clear from channel B C.

[Margin: Objection.]

There is this further point: not all the water-bearing channels are inserted in the sea-floor, but very many are also implanted by nature in the walls of the land-mountains that have their position toward the sea, or in the flanks of islands. And just as the former are driven by the pressure of the mass of water, so the latter — pressed both by the dashing of the waves and by the force of storms and winds, and by the ebb of the surging sea — most easily carry the water up onto any

mountain-peaks whatever. Perhaps here someone will object that the motion of the sea ought to be in no way violent, but natural — which, on our hypothesis, it is not.

[Margin: The motion of the sea is not violent.]

I reply that nature has always intended to join something of the violent to natural motion — something which, properly and simply, ought not to be called violent, but [arises] from a certain necessary concomitance, as is clear from all the operations of nature. In this way the whole sea, perpetually restless and turbulent, is not so by some natural force, but by the agitation both of the winds and of the ebb and flow of the sea, which impress a certain violence on the waves. This is also evident in meteorological impressions: as when the wind lays low the trees and casts down towers; an earthquake too overturns cities, drives the sea backward, and turns everything upside down — things which, although they are doubtless natural operations, nevertheless cannot occur without violence, and that the greatest, inasmuch as it follows from them. In the same way, from the impulse of the sea made into the water-bearing channels, the water is necessarily, by violent pressure, compelled to raise itself beyond the limits of its own nature; and it is a certain impulse, which follows from the operations of natural things. Therefore, just as these operations are intended by nature, so they are also perpetual. For if they were simply something violent, they would certainly by now have wholly failed; but they endure and will endure, as long as the world shall stand — as so many ages of Etna, so many burning places, so many and so varied kinds of hot springs attest. We are therefore compelled to admit that these things ought by no means to be called simply violent, but to be natural effects bound up with their natural cause.

[Margin: The exposition of St. Thomas.]

The exposition of St. Thomas [Aquinas] on that passage of Aristotle, "no violent thing is perpetual," supports this view of ours; there he expressly says that no violent thing is perpetual unless its cause be perpetual — as if he were to say: if anything should seem violent in natural operations, it nevertheless cannot properly and simply be called violent, since a perpetual effect of nature necessarily follows upon a perpetual cause of nature. This operation, therefore, does not belong to the genus of the violent, but of the perpetual, just as the other species are perpetual and intended by nature — just as, in the circulation of human blood, the ascent of the heavier blood from the foot to the head is not called violent, but intended by nature, and so perpetual as long as the person lives.

These things explained, we shall now set forth the mode and the manner by which the water is raised from the sea up to the highest mountains, and into the other water-reservoirs of the mountains.

[Margin: How the sea-water is raised above the mountains.]

And first, indeed, I suppose that the natural water-reservoirs [hydrophylacia], and likewise the syphons, that is, the water-bearing conduits [inciles hydragogos], were inserted not by chance or accident, but by a great design of nature — indeed by no less industry than were the veins and arteries in the human body, that is, the Microcosm, inserted into the vessels of the humors. And just as eternal Wisdom established all things in number, weight, and measure, so too it equipped the inner Economy and fabric of the Geocosm with those supports, without which...

[Printed p. 233 — running header "DE FLUMINUM ORIGINE."]

it [Wisdom] foresaw from eternity that the causes of things could produce no effect.

Many marvel, and cannot grasp, how it comes about that — for example — the Alps, comprehended within France, Germany, and Italy, pour forth so many rivers, so many streams, which by their perennial flow have never ceased from the very beginnings of things until now, nor will cease while the world stands. From where, I ask, do the Danube [Danubius], the Rhine [Rhenus], the Moselle [Mosella], the Meuse [Mosa], the Rhône [Rhodanus], the Saône [Arar], the Po [Padus], the Ticino [Ticinus], the Inn [Oenus] — besides innumerable lesser rivers and streams, as well as lakes — draw their origin? If anyone should say that they take their origin from the distillation of drops within the subterranean caverns of the mountains — as the Peripatetics do — he will, in everyone's opinion, be asserting something ridiculous, since all the drops collected here and there through the vaults of the mountains could scarcely make up a single river. Some other secret of Nature, therefore, lies hidden here, which I have judged ought to be made plain in this place.

Let the Reader call to mind what we said in the Third Book about the water-reservoirs [hydrophylacia] of the mountains; and he will find that, just as in the Alps, so in all the other chains of the vastest mountains, the said water-reservoirs were established, from the beginning of things, by the singular providence of God, Best and Greatest [Deus Optimus Maximus]. From these, rivers are channeled off into the various parts of the world, both for the watering of the surrounding regions and for the benefit of mankind and the convenience of

navigation. But rivers so great and so many could not be channeled off in a perennial flow, unless the said water-reservoirs were continually replenished with ever-new supplies of water. And this cannot come about from the resolution of vapors within the caverns of the mountains; for, as was said above, if all the vapors of the whole air were resolved into water, they could not suffice for so great and so continuous a mass of water. Nor [can it come about] from the resolution of rains and snows, since that is not perpetual, but at certain seasons ceases from moistening — and consequently the rivers too would necessarily have to cease from their flow, which is contrary to experience. Nothing else, therefore, presents itself, except that the said water-reservoirs are replenished daily from the Sea or Ocean, through subterranean passages. How this happens, I now show.

Let there be one or more water-reservoirs [Hydrophylacia]...

Diagram. A large engraved landscape plate occupying the lower two-thirds of the page, illustrating the system of mountain water-reservoirs feeding rivers. Across a panoramic countryside, several mountains rise; two of them are shown in cutaway, revealing cavernous interior reservoirs (vaulted chambers with water) from which streams issue. Rivers wind down from the mountains through the plain, branching and joining, past towns and settlements (a walled city at lower left) toward a broad body of water in the foreground, where sailing ships and small boats are shown. Concentric ripple-rings in the open ground at center-right may indicate a spring or whirlpool / a subterranean inlet. The plate bears no engraved letter-labels visible at this resolution.

set within the cavities of the mountains like basins, [these are] A B C D I. Their water-channeling [hydragogi] subterranean siphons are G L M, G L B, E O, Q P, H I, and their openings on the sea floor are G E Q. I assert this: by the continual force of the ebb and flow [of the tide] and of the winds, the waters pressed at the bottom of the sea will discharge into these reservoirs the entire mass of water with which the subterranean passages, all the way up to the hydrophylacia, are filled. As a result, the hydrophylacia, being always full, will at last burst out into rivers through the fissures and passages of the mountains — just as it appears in the Figure. In this way, from this very visual inspection, the origin of rivers may shine forth more clearly than the noonday light.

You also see how, at the loftiest summit of mountain D, the subterranean passage Q P makes lake D pour forth rivers. You should not say that this lake arose from any increase of rains or of melted snows, since on that account it would surely dry up in time. Rather, lakes of this kind are perfectly clear — like the lake on the

summit of Mount St. Gotthard, which hurls down the river Ticino [Tessin] through manifold cataracts here and there, in perpetual motion, into the deepest valleys. [Margin: The lake on Mount St. Gotthard.] This is the clearest sign that it is continually enriched from elsewhere by a fresh supply of water. Nor will you say it is born from the dissolution of vapors, since, lacking any vault [overhead], it enjoys an open sky.

It should also be noted that in Alps of this kind there are various hydrophylacia, some higher, some lower, which nevertheless always correspond to one another through a certain communication. Some indeed are roofed over by mountains, while others — as nearly all mountain lakes are — display their station under the open sky: such as, in Switzerland [Helvetia], Lake Lemman [Lac Léman / Lake Geneva], the Lake of Lucerne [Lacus Lucerninus], the Lake of Zurich [Lacus Tigurinus], and the Lake of Constance [Lacus Acronianus]. That these arise from a single hydrophylacium parceled out into various stations and stretched out within the vast recesses of the mountains can be in no doubt to anyone who has rightly understood what precedes. For if, by divine power, the said mountains were cut through along the surface of these open lakes, you would surely find immense lakes within — furnished with countless water-channeling canals [hydragogi] discharging water, and these not only communicating with the external and open lakes, but also continued within beneath one level plane.

You would moreover find some basins [Lebetes] set into the higher vaults of the mountains, which, finding an exit through the flanks of the mountains, turn into various springs and streams. And lest you think we attain these things by conjecture alone, the histories of hydrography confirm by the clearest testimonies that they are in fact so. [Margin: Histories concerning the hydrophylacia.] Among other things they report that in Nicaragua, a province of America, there is, beside an enormous lake, a most vast cavern; and the barbarians [natives] who penetrate into its innermost recesses assert that a most vast lake, like a sea ...

without end, is found within, and that in it so formidable a sound is perceived that — unless they at once turn their feet [back] — they are deafened by the noise of the dreadful waterfalls [catadupae] of the waters. The same is attested by Olaus Magnus concerning the Cavernous Shores of Bothnia [the Gulf of Bothnia], of which more fully in another place.

The same has been confirmed; the same is observed within certain mountains of the Kingdom of China [Regnum Sinense], which are filled with subterranean lakes and rivers — as Father Martino Martini [P. Martinus Martinius] told me

more than once, and which he afterward made public in his *Atlas* [the *Novus Atlas Sinensis*]. And concerning certain mountains of Upper Austria [Austria Superior], Father Lorenz Andreas Eissert [L. Andreas Eissert], a priest of our Society, reports — about which [I shall speak] in its proper place. It is also said that in Lake Fucino [Lacus Fucinus] an enormous cavern is found, which, if anyone enters it, he perceives — besides the immense lake which he finds, continuous with the external lake — also the sound of rushing waters, with great dread at entering. And since I always inquired of those who related such things to me whether they perceived any distillation of waters within the said caverns, they solemnly affirmed that they had never observed either a distillation, or that subterranean cobweb [?] which the Peripatetic school invents for itself, or any rain.

Therefore the sound of the rushing waters plainly teaches that somewhere, through the water-channeling canals [hydragogi], water hurls itself down through immense precipices into a subterranean lake. I could adduce countless examples of this matter in this place, but because they have already been set forth in other places, I do not wish to dwell on them. Let the reader consult the interior constitution of a hydrophylacium, graphically delineated, from the figure here appended. There you see a lake situated within the mountain, into which, from the flanks of the mountain, water is hurled down through subterranean canals into the said lake; this water, afterward flowing out from the subterranean lake through other channels worked out [for it] into the outer fields, produces rivers and lakes — as the diagram shows. Meanwhile, let these things suffice for demonstrating the argument we have proposed.

Diagram. A large engraved landscape plate occupying the lower half of the page, depicting the interior constitution of a hydrophylacium (mountain water-reservoir). The central feature is a great cavern opened within a mountain massif, revealing an internal lake or pool of water from which several jets and cascades of water spurt upward and outward. Streams issue from the flanks of the surrounding hills into outer fields and valleys; the rolling mountain landscape with scattered trees frames the cavern. The figure illustrates how subterranean water collected within the mountain bursts forth through openings to feed the external rivers and lakes. No engraved point-letters or caption are legibly present on the plate.

CAPUT III.

DISQUISITIO

Concerning the remaining modes and methods.

[De reliquis modis & rationibus.]

§. I. MODE II.

How, by natural attraction arising from the fear of a vacuum [metus vacui], water may from time to time be drawn upward to a height?

EXPERIMENT.

Let there be made a bowl [concha] of lead, *d e*, covered over with glass B X C. Let this bowl have, between the columns B H and C I, another bowl, F, from which a small channel [canaliculus] *F d* is inserted into bowl *d e* and set open at E. This done, let another small channel E G be inserted into the bottom of bowl *d e*, with a stopcock S, beneath which another bowl H L is placed. Let the columns B H and C I support the whole machine. Once it is constructed, you will fill the upper bowl *d e* with water through the open screw [cochlea] X, which is then to be closed in such a way that air cannot get under [into it]. Let bowl F also be filled with water.

These things accomplished, if you open the stopcock S of the small channel S G, the water, descending by its natural flow ...

will draw the air in vessel A B C [after it]; and this air, when drawn off, finding nothing to put in the place of what is departing, is at once seized by the fear of a vacuum [vacui formido] and will allure the water contained in bowl F through the small channel E *d*; this water will burst out with the greatest force through the opening E into a fountain [jet]. Once this [water] has fallen back into bowl *d e*, it will discharge itself through the channel *e G* into bowl H L, always drawing new water from bowl F — so that, if bowl F be perpetually refilled from some fountain, I assert that the flow of water in bowl *d e* too will go on perpetually, the bowl never overflowing; for as much as it draws from bowl F, that much it sends down through the siphon *e S*. We have the experiment in our Museum, proven by daily use. Now let us apply it to the subject of our undertaking.

Imagine for yourself a certain bowl existing within the hollow of a mountain — which the glass B A C represents — into which air cannot penetrate from outside. Let this bowl have another, neighboring it, joined to it on the side, which is F, and which gushes with waters from some perennial stream, however and in

whatever manner it arose. Let it [F] correspond through a passage of the mountain — like a certain small channel F *e* — to bowl *d e*. And since a bowl of this kind has another channel *e S* extending into the depths of the mountain, it is certain that bowl *d e*, with the waters flowing together through the fibers [veins] of the mountain, will — as soon as it is filled — discharge itself through channel *e S*; and consequently, lest the hollow of the mountain suffer the fear of a vacuum when the water departs, it will draw from bowl F as much water as it had let go through channel *e S*. And thus bowl *d e* will gush perpetually with waters.

Diagram. A schematic woodcut of the vacuum-attraction apparatus described in the experiment, set into the lower left of the page's left column. It depicts a tall composite vessel standing on a footed, baluster-turned pedestal base. At the top is a domed glass cover from which an arrangement of fine jets or sprays rises (the fountain produced at opening E). Below the dome are tiered bowls supported between two columns. Readable point-letters on the figure:

- X (at top): the screw / filling-aperture [cochlea] of the upper bowl
- B (upper left, on the glass cover): left side of the glass dome B X C
- d (upper right, on the bowl rim): right end of the lead bowl *d e*
- H (mid-left): foot of the left column / lower bowl H L
- L (mid-right): right side of lower bowl H L
- V (at base): the footed pedestal / lowermost vessel [?]

Several additional small letters around the tiered bowls (the channel-labels E, G, F, S referenced in the text) are present but too finely engraved to resolve individually at this resolution.

[Printed p. 236 — LIBER QUINTUS]

[Continuation of MODUS II, the vacuum-attraction experiment from the prior page:]

and so it will pass from bowl *d-e* through channel *e-S*, finding another hollow space, and from there into a perpetual spring or stream. But the mouth of the channel *E-Z* must project somewhat above the surface of the water in bowl *d-e* — whether that mouth is set in the middle of the cave or in its walls — so that the water in bowl *d-e*, which ought to discharge through channel *e-S*, does not instead discharge through channel *d-F*. You see from this experiment, then, how springs and streams can sometimes be produced by the fear of a vacuum [vacui formido], through the continual drawing-off of water gathered from elsewhere.

[Margin: Art takes its working principles from nature.]

Perhaps someone here will object that this is an excessive and superfluous exertion on Nature's part. But let him understand that nothing can be accomplished by art in hydraulic motions whose working principles art does not derive from Nature, the all-creating exemplar, and from the reasonings of eternal law. Let him be assured that the wisdom of the Cosmic Architect [sapientia Cosmotecnilis], working its art through nature, has established nothing in vain, but has set everything up with the highest providence — as in all else in this theatre of the universe, so above all in the Subterranean World, with unspeakable craftsmanship. Man, the ape of nature, then strives in his own operations to imitate this as far as he can, by whatever means.

MODUS III. [How Springs and Rivers can be formed from rain and melted snow.]

That springs and rivers are sometimes formed from rain and melted snow I would not readily deny, since experience plainly teaches it; but I can hardly be brought to believe that springs and rivers of this kind are perpetual. Springs and rivers are formed in this way. On the flat tops and slopes of mountains, the snows heaped up in winter melt little by little as the Sun passes into the northern signs, by the Sun's heat and by falling rains. Once melted, they partly seep through the clefts of the mountains and partly, through winding falls, work their way little by little into subterranean caverns or crypts. If rains and showers are then added, these caverns, weighed down by the excessive increase of water, discharge themselves through the gaps and fissures of the mountains; the discharged water turns into springs, and from the running-together of these springs at last into a river. The flow lasts as long as the melting of the snow lasts; once that is finished, the river, its bed dried up, ceases from its flow.

Innumerable examples of this could be cited, but let one stand for all — one I recall observing with the greatest care in Gallia Narbonensis [Narbonne / southern France] in the year 1631, at the spring (or rather river) of the Closed Valley, which is commonly called Vaucluse [Vallis clausa / *Vaucluse*].

[Margin: The Vaucluse Spring [Fons Vauclusii], in the territory of Avignon.]

Between Carpentras [Carpentoractum] and Cavaillon [Cavallio], four leagues distant from Avignon, there is a certain valley altogether wild and formidable to behold for its overhanging crags. In it there is to be seen, down to this very day, a house — though ruined by the injuries of time —

[Margin: The house of Petrarch.]

within which Francesco Petrarca [Petrarch] once, whenever he was seized by the poetic frenzy of the studies to which he was accustomed, would withdraw, carried away by his love of solitude; and they say he betook himself there so that, far removed from all the noise and tumult of the court, with a freer and more unencumbered mind, he might bring to completion what he had conceived in his mind. Not far from this house there is to be seen a cave, made by nature in the rocks, within a valley shut in on every side; which — wonderful to tell — for half the year is always dry, showing not even a trace of moisture. But on entering the cave — as I myself observed most carefully — one meets various passages running this way and that, in the larger of which no end is to be found. They say it extends for many leagues into the recesses of the Alpine mountains, and is moreover divided into so many branches that you could swear you were entering a labyrinth.

[Margin: Description of the Vaucluse Spring.]

At the said season — in winter, that is — this whole tortuous passage, formidable for the manifold spreading of its branches, is seen to be dry, strewn with the finest sand and with various scraps of mineral matter. Yet soon, at the time when the snows in the mountains of the Dauphiné [Delphinatus], or in the Cottian Alps [Alpes Cottiae], are wont to melt, then behold, the said passage erupts through the mouth of the cave with a mighty roar, belching out such a quantity of water that by its force it at once turns six mills, set no more than fifty paces from the opening. And — what is more wonderful — the river is soon filled with trout and other fish, which the subterranean cavity (into which they had been swept by some force through the chasms of rivers or lakes) brings along with it. But as the snows are gradually consumed and the water-cisterns [lebetes] emptied, the river too, settling into a truce until its own season, ceases, the fish vanishing — fish which, no doubt by some instinct foreseeing the failure of the water, in good time withdraw into the rivers that lead to the Island [Insulam], a place situated not far from here. And in this way springs and rivers are formed from melted snow.

In like manner, springs and rivers are sometimes formed from rains and showers in this way:

[Margin: How rivers are formed from rains.]

On the ridges of the loftiest mountains, either at the summit or near the summit, flat or concave places are found, filled with rainwater collected there and gradually stagnating into a lake. From this it comes about that the water, having

seeped through the fissures of the mountains into the subterranean basins and overflowing as it increases, at last bursts forth into a river. An instance of this kind can be seen in the plain of the ridges of the Apennines: for one traveling from Rome to Loreto [Lauretum], it lies enclosed between the hill called "Colle Fiorito" (the Flowering Hill) and Serravalle [Seravalle], where that whole plain in winter turns into a marsh, formed entirely of rain and melted snow; but in summer and autumn it blossoms into a most flowery meadow and rich pastures. Often passing this way, while I marveled how so great a mass of water could so quickly vanish — and since wonder spurs one to inquire into the cause — I consulted men experienced in the locality on the matter. They led me to a spot where they showed me a huge chasm, through which the water unburdened itself; and they added that the waters, through subterranean passages —

[Printed p. 237 — DE FLUMINUM ORIGINE.]

not far from the Tiber [Tyberis], discharge themselves into the river from a huge cave in the mountain; and this river, which runs while the lake stands, dries up when the lake is dried out. I have found similar places in the Apennines of Tuscany [Appenninus Hetruriae], concerning which consult our *Iter Etruscum* [Our Etruscan Journey].

Of the marvelous Field in Carniola [Carniolia].

In which, through the course of the year, the inhabitants — in the stations destined for them by nature — sow and reap, hold their hunts, and at last, when the whole field has been turned into a lake, go fishing.

There is in Carniola, not far from Ljubljana [Laubacum], a place truly most worthy of admiration, which we have thought fit to describe here. This place, first, in summer and autumn, counterfeits a meadow heavy with the manifold yield of its sprouts; but in November it presents the appearance of standing water far and wide, and through the whole winter is found locked in ice; while in spring, as the water drains off, it becomes a field most fit for sowing — so that one and the same place, now a field, now a shrubby meadow, now a lake, discharges the triple office entrusted to it by nature, and not without remarkable benefit to the public good. With its abundant harvest of both grain and pulse and hay, it not only blesses the homeland, but in summer also affords its managers no small help by the hunting of hares and wild boars; and likewise, toward the beginning of winter, it provides the territory with an abundant catch of fish, a remarkable supply indeed.

Having seen the prodigious effects of this place, let us now inquire into their causes. The first question, then, is this: From where does so great an abundance of water come to this place, so as suddenly to become a vast lake? I answer that this happens because, in the Pennine Alps [Alpes Penninae], a huge quantity of snow, with which they are covered, melts continuously over the course of summer; whence it comes about that the Alpine hydrophylacium, by the increase of the melted snow, gradually overflows around the end of October, and by its overflow discharges itself, through some hidden subterranean passage, into this place. For, as the inhabitants have observed, at a fixed time, amid the greatest cold, [the water] rolls forth both from the bowels of the nearby rocky cliff and from the center of the field, and converts the whole plain into a lake.

The second question: From where does the lake get so great an abundance of fish? I answer: from some hydrophylacium or external or internal lake stocked with fish, which, overflowing with great force, sweeps the fish along with it into this place — as happens in many other similar places. As for the fact that in spring the lake vanishes together with the fish, not one surviving — the reason is that the fish, gradually following the outflow, return through the subterranean passage to the place from which they had come. And in this way the place, freed from the tyranny of the waters, is turned into a field and farmland of rich and fertile soil, and thus most fit for sowing. The harvest over, growing wild with the manifold sprouting of plants and shrubs, it offers a place most fit for the stabling of hares, boars, and wolves — until, overwhelmed by a new inundation, the field, turned once more into a lake, is subjected to Neptune's jurisdiction. And this truly admirable [marvel?] of nature, this [Greek: ἀντικίνησις (antikinēsis, "counter-movement" — alternating reciprocal change)] [?], lasts year by year, and will doubtless last forever.

MODUS IV. [Of the origin of Springs and Rivers that arises from the confluence of subterranean waters.]

It cannot be otherwise: from so many yearly floods and from the convergence of melted snows, an enormous mass of water must from time to time be heaped up in the subterranean hydrophylacia, in this way. Since the mountains are extremely porous and lie open with countless fissures and chasms, water, insinuating itself through these, when it finds a hydrophylacium or some cistern [lebes], fills it by its confluence; then, pressed by the narrows of the vessels, it must necessarily overflow, and once overflowed, it bursts out through other chasms and channels into rivers.

[Margin: The various differences of rivers, and why some now overflow, now [run low?] — from where?]

From this it is clear why at certain times rivers shrink so low that they can be forded without any trouble, while at another time they so swell up that they bar passage to all who try to cross — because, when the confluence of waters ceases, the rivers diminish, whereas while the increase of water lasts, they must necessarily swell. Now there is no small difference among rivers of this kind: some, entirely dried up, leave off from their flow, and no other cause can be assigned for this than the single confluence of rainwaters within the basins of the mountains — while that lasts, the river lasts; when it ceases, the river ceases. Others, however, endure with a perennial flow, but not at the same level of fullness — now diminished in water, now swollen with water. The reason for this is that within the hydrophylacia, which draw their origin from the Sea, are from time to time replenished with other occasional waters, whether of rain or of snow; by the increase of these they consequently pour forth a greater abundance, with which the river swells. I am speaking here not of torrents, which are constituted solely by the confluence of waters gathered within the folds of the mountains at the time of rains, but of that increase of water in rivers which sometimes arises suddenly even when the sky is clear, calm, and subject to no rains. See what we have pursued at length in the Third Book on the Origin of the Nile [*Tertio Libro de Origine Nili*].

MODUS V. [The Lakes of the higher Mountains pour their waters into the hydrophylacia of the lower mountains; from which arise springs and rivers.]

It happens not infrequently that in the loftiest mountains huge lakes are observed which, just as they lift their summit beyond all the bounds of the rains, so they cannot be augmented by the rains — as they report of Mount Athos. And thus they obtain their origin only from the Sea, in the manner already stated above...

[Printed p. 238 — LIBER QUINTUS]

[which they] doubtless obtain. Lakes of this kind in the mountains, just as they are perpetually filled, so too are drained off through subterranean conduits into the cisterns [lebetes] of the lower mountains; from which cisterns of this kind, enlarged and enriched by the benefit of the waters,

[Margin: How the waters in the lower mountains are poured out, by the correspondence of the mountains.]

springs and rivers are poured out along the passages destined for them by nature. This kind of thing seems to occur chiefly in the Alps, in which not infrequently great cataracts [catadupae] roll down from inaccessible mountain peaks; yet these, soon absorbed in the deep valleys and the closed-off ledges of the mountains, prepare an outlet for themselves elsewhere. I myself have seen, from the lake of Mount Cimino [mons Ciminus] in Tuscany — which they commonly call *il Lago del Vico* — set in a most lofty place, [water] burst out through subterranean passages at Ronciglione [Roncilio] into a most rapid river; and we have shown at length, in our *Iter Etruscum*, that three other neighboring lakes are derived from it — which I would have you consult.

MODUS VI. [That springs and rivers can sometimes also be born from subterranean winds.]

Whoever penetrates the hidden ways of sagacious Nature will openly confess that nothing has been denied to it in the production of marvelous effects. For just as it uses wondrous art in conveying waters from the sea up into the storehouses of the loftiest mountains, so too it is mighty in wondrous industry in raising those waters on high by means of subterranean winds and exhalations — which I now set about to demonstrate. Since Art is nothing other than a kind of imitation of nature, it is certain that whatever is accomplished by art has previously existed in nature as its prototype — which I demonstrate by the following contrivance [technasma].

EXPERIMENTUM I. [Showing how water is raised on high by the force of subterranean winds.]

Let there be made two adjoining vessels A-B of lead or iron plates, separated by a diaphragm C-D. This done, let three channels be drawn, in the manner you see them set in the figure. The first, E-F, open at both ends, [running] from the upper floor E, to which it is joined, let it be led down through the diaphragm C-D into F. The second, I-K, open at both ends, let it be led from the floor I up into K. The third, G-H, led from G through the upper floor into H, let it project somewhat — and you will have the machine ready.

[Margin: How water is raised by the force of the winds.]

To watch the effect, then: let vessel A be filled with water through the opening V; and, the opening V having been stopped up, let water be thrown into the crater V-H-E, which, descending through channel E-F, drives out the air lodging in vessel B through channel I-K. The air thus expelled from there will press upon the water

in vessel A; and the water, being pressed, since it finds no escape except through channel G-H, will discharge itself through that channel into a most limpid spring, as you see. We have the experience; let us now apply it to our purpose.

In the preceding Section we taught that winds, on account of their abundance of exhalations, perpetually hold sway in the subterranean crypts. For since, being checked by the obstacles of the mountains, they seek a wider space and do not find it, they escape with the utmost force through even the finest chinks and fissures of the mountains, like so many siphons; and where they find water within some cistern, they will doubtless press upon it; and if the crypt has another siphon, it will force the water out through it. But let us show the matter by an example.

Let there be a mountain F-G-H having within it a hydrophylacium

Diagram. A pair of figures forming a single composite woodcut across the foot of the page. At left is the apparatus of Experimentum I: an hourglass-shaped twin-vessel device standing on the ground, with the upper vessel narrowing to the lower. At right is a cross-sectioned mountain (the Modus VI / Experimentum II illustration) showing internal cavities, channels, and a stream issuing from its flank, with trees on the slopes and a wavy water-line at the base. Readable labels:

- V (top of left apparatus): filling/throwing opening of the crater V-H-E
- X (center, on the mountain): the internal cistern / cavity marker
- A (left apparatus, upper vessel): vessel A
- B (left apparatus / mountain interior): vessel B (the lower cistern)
- C (left apparatus, mid-body): the diaphragm point C
- D (left apparatus, base): point D
- F, G, H (mountain): the mountain's labeled points (interior cavity and outlets)
- Small water/ground hatching and tree figures along the base (decorative, unlabeled)

The full label set on the composite woodcut is A B C D E F G H I K V X (left apparatus: A B C D E F H I K V; mountain: A B C D H V X).

EXPERIMENTUM II.

The experiment of the tortuous siphon is well known: when you have filled it with water, and have placed one end at the bottom of a vessel filled with water, while letting the other, directed outward, flow, the whole vessel will be drained

out; and if the vessel teems with living [i.e. spring-fed] water, [you will see] the flow through the siphon likewise

[Printed p. 239 — DE FLUMINUM ORIGINE.]

[lasting] perpetually as well. In just the same way, you may persuade yourself, the like happens from time to time within the subterranean passages.

Let there be a cistern [lebes] within the bowels of mountain A, and another within mountain C; from the bottom of C let a passage C-E be directed by nature into cistern A; and from the bottom F let another passage, longer than the first, be led into channel B. When, therefore, the water flows out of cistern A through channel F-g into bowl B, then necessarily, by the fear of a vacuum, water is drawn from cistern C through channel C-R and substitutes itself in the place of the departing water — namely, into cistern A. And just as the water in basin C is perpetual, so too the flow through channel F-g into basin B will be perpetual; where it will also discharge itself outward, either into a spring or into a stream.

Diagram. A cross-sectioned mountain landscape at the top of the column, showing two interior cisterns connected by curving channels, with streams issuing from the slope and a hatched ground-line below. Readable labels:

- A (upper interior of the mountain): cistern A
- B (interior, lower right): basin B, where channel F-g discharges
- C (interior, the deeper/source cistern): basin C, the perpetual reservoir
- E (channel from C): outlet of passage C-E into cistern A
- F (lower interior): origin of the longer passage / channel F-g
- Faint channel-tracings (C-R, F-g) curving between the cisterns; the small letters g and R are engraved faintly. [?]
- Outlet streamlets at the mountain's flank (unlabeled)

By these arts the sagacity of nature plays within the subterranean economy [Oeconomia]; which arts, though most remote from our senses, reason itself nonetheless dictates do happen in this way from time to time.

[Margin: All things in nature are accomplished by attraction and repulsion.]

Since the whole operation of nature consists in nothing other than a kind of attraction and repulsion, so too in the leading of waters it employs now expulsive force — as appeared in the first experiment — now attractive force, as appeared in this second experiment.

MODUS VII. [How springs and rivers are born from the attraction of moisture.]

As we have often urged, all the fibers of the porous Earth draw moisture — from the sea, and from lakes and rivers — into their own nourishment by a certain natural appetite. For since the earth is composed of countless fissures, fibers, and pores, the sea, through these, as through certain veins, insinuating itself, supplies the whole Earth with its due nourishment through countless other veins, not unlike the capillary veins in the human body.

[Margin: The earth is not [free?] of water [Terra vena... non si... fossis locis].]

For just as, when the skin is cut at any place whatever of the human body, blood immediately comes out, so there is scarcely any place in the Earth where, if you dig deeper, you would not at once find water —

[Margin: The earth naturally draws water as if [for] its own nourishment.]

except in certain desert and sandy places, which are not inaptly compared to the callous parts in the human body; and just as you dig those deeper, [you find] blood, so those at last supply water. The whole terrestrial globe is therefore pierced with fibers and fissures, as we have said, not otherwise than the human body with veins and the capillaries propagated from them; and through these, just as flesh, so the terrestrial body draws the necessary nourishment by an innate appetite.

Now this attraction comes about in many ways. First, the parts of the mountains, after they have been dried out by fiery vapors, by an innate force, as a remedy for their dryness and aridity, draw the nearby veins of moisture by suction, and in this way restore themselves, lest they be utterly destroyed. Secondly, among the earthy clods there are sometimes found gypseous or chalky materials, which, just as they are mighty with a marvelous power for sucking, by their innate dryness, so too, raising water from a low place on high, form it into a little pool [lacuna] in their outermost part. The matter will become clearer by an experiment.

EXPERIMENTUM.

Let a column A-C be made of gypsum, on the top of which let a crater B be formed; place it [resting] on its center C in a bowl D filled with water, and leave it for some hours — and you will find that the water, sucked up little by little by the gypseous column through its successive parts, at last reaches up the column A to

the crater B, and there persists even to the point of overflowing; and when the crater is emptied and the column dried out, by a new suction the crater is filled again with water. The same thing, you may persuade yourself, happens also in gypseous or chalky mountains.

Diagram. A turned, vase-like apparatus standing in the lower middle of the right column: a slender gypsum column rising from a broad, footed dish, with a small cup (crater) at its top. Readable labels:

- B (at the top, the small cup): the crater B formed at the column's summit
- A (on the column shaft, just below the crater): the column A
- C (at the foot of the column / its base in the dish): the center C on which the column rests
- D (the broad dish): bowl D filled with water

The column rises from the center of dish D; the whole stands on a turned circular foot. (No labels flagged.)

But perhaps you will say: these gypseous fibers of the mountains, as soon as they have imbibed moisture, cease from further attraction of water. I answer: they do cease for a little while, but as soon as they have been dried out again by fiery vapors, the craters are refilled by ever-new suction —

[Margin: Gypsum naturally seeks water.]

by such a moderation of nature that, by the suction of the water, the gypseous matter neither turns entirely to mud, nor, being utterly dried out by fiery exhalations, is reduced to powder; but it keeps to a certain mean, compounded equally of moist and dry. Such gypseous mountains, moreover...

[Printed p. 240 — running header: "LIBER QUINTUS"]

[Continuation of CAPUT III, MODUS VII — springs from moisture-attraction.]

such mountains—as both the Apennines and the Alps amply demonstrate—from which flows water charged with gypsum [aqua gypso scatens]; and those who drink it become afflicted with goiter [strumosi]. But more of this in what follows, where I shall treat fully of the powers of waters.

MODUS VIII.

How new springs, lakes, and rivers are at times fed by an earthquake.

[Margin: How springs are at times fed by an earthquake.]

The historians relate—and among the rest Seneca and Pliny [Pliny the Elder]—that amid the symptoms of great earthquakes, springs and streams sometimes break out in places where none existed before. I shall now show by what process this happens.

How an earthquake occurs I explained at length in the preceding pages. When the fire [Vulcanus], or as the chemists [Chimici] call it, the *Archeus* [Archaeus], rages with conflagrations in its subterranean realm, the result is that through its flues an immense quantity of fiery exhalations is driven through the fire-conducting channels [canales pyrogogos]. These, struggling within the subterranean passages with incredible force, seek an exit and find none; at last, impatient of the narrow confines, they make an exit for themselves. The foundations of some hydrophylacium are thereby shaken and shattered, its vault thrown down, and the whole mass resting upon that vault necessarily collapses. When that mass falls into the hydrophylacium beneath, since the mass and the water cannot subsist together, the water is violently compressed and forced to yield to the intruding newcomer. Squeezed out through the hidden channels it meets, it either bursts forth into springs, or at least, pressed outward, takes the place of the overlying mass and is shaped into a lake—as happened in my presence in the year 1638 at Saint Euphemia [Sant'Eufemia], a town of Calabria, which was swallowed up by an earthquake and left a standing pool in its place. I could adduce many examples of this kind, but since I have dealt with them in the preceding pages, it is superfluous to repeat them here.

[Margin: Many causes of changes arise from the interior of the earthen parts. [Ex interiori partium terrenarum lapsu multæ causantur mutationes.]]

MODUS IX.

How springs and rivers can be born from condensed air and from the blasts of winds.

There is sometimes generated in subterranean places an immense quantity of vapors and exhalations. Drawn out through the porous and tube-like tracts of the mountains, these at once, upon meeting colder air, condense into clouds; and these clouds, dissolved by the cold of the airy region, return outward as rains. But when the subterranean vapors cease, and there is no body to supply in place of the departing vapor, then—through fear of a vacuum [metu vacui]—the mountains draw in the surrounding air mingled with the vaporous clouds through those same fissures. The vaporous air, drawn within, upon contact with the warmer air is at once resolved into a subterranean rain, which, gathered

among the caverns, gives in turn a fresh origin to springs and streams. Many wonder

why the peaks of the mountains, at the time of impending rain, are almost always veiled in clouds. Let them reckon that the reason is none other than this: that the vapors, as soon as they have breathed out through the fissures of the mountains, condense into clouds upon contact with the cold of the surrounding air, and stand there; and lest they be dispersed, they are checked, as by obstacles, by the cold vapors of the airy region raised on high from elsewhere. For the nature of things so delights in such sports of attraction and repulsion that without them it seems to attempt nothing in the reciprocation of elemental matter, nothing in shaping the forms of meteorological impressions.

[Margin: Why mountains covered with clouds are forerunners of rains. [Cur montes nubibus tecti, pluviarum prodromi sint.]]

MODUS X.

The circulation [pericyclosis or circulatio] of the blood through all the veins of the human body is a discovery of our own age, confirmed by countless experiments, so that no one but a man ignorant of these matters can any longer doubt it. You may marvel that this portion of blood, which a moment ago stood in the veins of the feet, after a few hours travels by its ascent to the veins of the head, and from there descends again, only to repeat by a new ascent the station it had left—an arrangement established, surely, by an admirable design of nature. Since I have treated of it very fully elsewhere, I have chosen not to repeat it here; so let me return to the subject I set myself.

[Margin: An example of the circulation of the blood in the human body. [Exemplum circulationis sanguinis in humano corpore.]]

I say, then, that these principles of cyclic motion are observed by nature not in the human body alone, but in the watery element—or what amounts to the same thing, in the *pericyclosis* of the Ocean. See what I have set forth, with ample reasoning, in Book IV, Section I, Chapter 6, concerning the circulation of the Ocean through the northern and southern poles (*Mundus Subterraneus* IV.1.6). If, therefore, anyone of a more stubborn disposition should be unwilling to accept these arguments of mine concerning the origin of springs, rivers, and lakes, I trust that he will at least not despise this tenth mode; for what nature accomplishes with such wonderful sagacity in the circulation of the blood would seem in no way to be denied to her likewise in the circulation of waters from the

sea over the peaks of the mountains, since the principle of both is one and the same. As to how she carries out this circulation, consult Harvey [William Harvey], who skillfully demonstrates that it comes about through the valves set in the ducts of the veins, with the heart as the first author and mover of this motion. So if anyone duly compares the valves of the veins with the subterranean waterways [aquaeductibus subterraneis], he will find that the same thing happens in those places, as the experiments hitherto reported clearly demonstrate. You see, then, reader, that in this treatise I have so combined the causes of springs and rivers that no effect about this matter, however exotic, can be assigned whose cause you may not reduce to one of these ten. Therefore let this suffice concerning the origin of springs and rivers.

[Printed p. 241 — running header: "DE FLUMINUM ORIGINE. 241"]

CAPUT IV.

DISQUISITIO

On the origin of lakes in the plains.

[Margin: There are four kinds of lakes. [Quadruplicis generis lacus sunt.]]

In the preceding pages I consider that I have said enough about lakes on the summits of mountains and their origin. It now remains for me to say something about the lakes, pools, and marshes that occur here and there in the level expanses of the plains. They are of four kinds, according to a fourfold mode of combination. For first, there are certain lakes that receive no river and emit none, but persist in a perpetual constancy of their existence. Second, there are some that do indeed receive rivers but emit none. Third, there are others that do not receive a river but emit one. Fourth, there are, finally, those that both receive and emit. Apart from these modes, no other can easily be assigned. Therefore, once these have been duly set out, I shall rightly seem to have settled the whole disputed question concerning the origin of lakes. And so:

MODUS PRIMUS.

Whence and how arise those lakes that neither emit nor receive any river.

Lakes of this kind can again be considered under a fourfold class. First, some of them are made by art. Second, some are left behind by an inundation of the sea and of rivers. Third, some are collected within the basins [lebetes, "cauldrons"] of

mountains from rains and the melting of snows. Fourth, finally, some are established by nature herself through subterranean springs. Of the first three I shall forbear to speak, since they are not perennial, and in summer—unless preserved by the labor and industry of men in need of water—easily dry up. But let me turn my pen to investigating the origin of lakes of the sort that endure perennially without the emission or reception of any river. I am not speaking here of the rivulets channeled into some lake from the nearby veins of springs, but of rivers that pour themselves out into certain lakes.

Very many lakes of this kind are found here and there, especially in regions ringed by a vast plain—as in Muscovy [Moscovia], Holland, and the other places of Europe, Asia, and America. In Etruria [Hetruria] there is the Thrasymene [Thrasymenus, Lake Trasimeno]; among the Vestini, the Fucine [Fucinus, Lake Fucino]; in Latium, the Regillus [Lake Regillus], and the like. But among all the rest, the greatest in the whole world is the Parime Lake [Lacus Parime, Lake Parime] of America, lying immediately beneath the Equator, about 300 miles in length and about 100 at its greatest breadth, marvelous in having neither any increase nor any emission of a river.

[Margin: The vastness of Lake Parime in America. [Lacus Parime in America vastitas.]]

These lakes, and the like, since they are enormous

and neither emit nor receive a river—except for streams collected from rains or the melting of snows—it rightly falls to me to examine their origin. I say, then, that lakes of this kind, on whose outer surface no trace appears of any river either received or emitted, cannot subsist without some hidden commerce of subterranean rivers. For on this account they would otherwise—just like those that arise from rains and melted snows—dry up in the summer season through the exhalation of vapors and in the course of time be wholly consumed. Yet experience contradicts this in the case of the said lakes; for although in winter they are increased by rains and showers, and in spring by the melting of snows, nevertheless in summer they enjoy their native increase at an ever-uniform rate, subject to no diminution.

[Margin: How a lake without an apparent river receives a river. [Quomodo lacus absque apparenti flumine recipiat flumen.]]

For since they receive, through subterranean channels, water drawn off from some hydrophylacium, then—lest with time, as the mass of waters grows, they overflow—they discharge through another subterranean passage just as much

water as they had received through the former. And in this way lakes of this kind subsist under an ever-uniform tenor. And although in summer, through some attenuation by the solar heat, they pass in part into vapors, the deficiency is nonetheless always so restored by the subterranean influx of waters that there is never any cause to fear total dryness. It is therefore plain that the same thing happens to these lakes as to those that on their outer surface both receive and emit lakes [recte: rivers], with only this difference: that the former are filled and emptied by subterranean rivers, the latter by surface rivers. Hence it is no wonder that Lake Parime in America endures forever, since it is doubtless connected—whether by the hydrophylacia of the mountains they call the Andes, at whose roots it lies adjacent, through subterranean recesses; or by a perpetual influx of subterranean rivers—so that, as it is filled, it is likewise emptied through other similar passages into the innermost abysses of the earth. See what I have set forth copiously concerning the origin of Lake Thrasymene, which discharges itself through subterranean channels into the Clanis [Clanim, the river Chiana], in the book entitled *Iter Etruscum* [*Etruscan Journey*], where I have confirmed this opinion by experiments of my own, so that no further room for doubt is left.

Second, all those lakes that adjoin the sea, being salt, are constituted only either by an inundation of the sea or through subterranean passages by which they correspond with the sea—as I have abundantly demonstrated in Book IV, On the Mexican Lakes (*Mundus Subterraneus* IV).

[Printed p. 242 — running header: "LIBER QUINTUS, SECT. II. 242"]

MODUS II.

Whence and how arise those lakes that do indeed receive rivers, but emit none.

Lakes of this kind are observed in great number by the geographers, among which the foremost place is rightly held by the greatest lake of the whole world, which they call the Caspian Sea [Mare Caspium]: it receives huge rivers, yet emits none apparently, being closed on every side by a rugged chain of mountains. Concerning it, consult Disquisition 9 of the preceding book, where I have treated of its origin professedly. Second is the Asphaltite Lake [Lacus Asphaltites], which they call the Dead Sea [Mare mortuum], which—except for the Jordan—evolves no river apparently, as I discussed in detail in the preceding pages. Among these lakes may be counted Soram [recte: the Sura?] in Muscovy; in Persia, Calgistan; in Africa, Cytur; and several others.

[Margin: The Caspian Sea receives huge rivers, emits none. [Mare Caspium ingentes fluvios recipit, nullum emittit.] The Dead Sea, that is, the Asphaltite. [Mare mortuum sive Asphaltites.]]

The cause of this effect is asked, in the first place. I say, then, that the cause of these is this: that lakes of this kind, even though they apparently admit perennial rivers, nevertheless—lest they overflow with time—are emptied through another, non-apparent subterranean passage. These things are so consonant with reason that no one, unless perhaps a man without sense, could doubt of it.

MODUS III.

Whence and how arise those lakes that do not indeed receive any river, but emit one.

Lakes of this kind occur everywhere in great number. Among them stands out Lake Chiamy [Lacus Chiamy], on the eastern side of the Ganges, which pours out four rivers of remarkable size that perpetually bless the regions of Siam and Pegu with their flooding; the Cyacuyhay [recte uncertain], an elongated lake in the borders of China, which, joined to another, flows down into Chiennam [recte uncertain]; the third is Lake Titicaca [Titicain, Lake Titicaca] in the province of Charcas [Charcea] in America, 80 leagues in circumference, which gives birth to a huge river that nevertheless, a little later, mingled with another lake, vanishes—doubtless seeking an outlet for itself elsewhere through subterranean passages. In Nicaragua of America [the lake] which, distant from the Pacific Sea by only four miles, emits a river that, winding through a hundred miles of meanders, at last evolves into the Atlantic Ocean. This one doubtless draws its origin from the Pacific Sea through hidden passages.

[Margin: Lake Chiamy emits 4 huge rivers. [Lacus Chiamy 4 fluvios ingentes emittit.]]

Of this same sort are: Lake Iroquois [Lacus Iroquois] in Canada, from which the river Saint Lawrence draws its origin; in Italy, such are Lake Vulsinius [Lacus Vulsinius, Lake Bolsena] in Etruria, which sends forth the Marta [Martam] from itself; Lake Bracciano [Lacus Braccianensis] or Sabbatinus [Lacus Sabbatinus], which evolves the Arona [recte: Arrone]; and several others, which I pass over.

[Margin: Lakes that do not receive rivers, but emit them. [Lacus qui flumina non recipiunt, sed emittunt.]]

The cause is the opposite of the prior one. For just as those lakes that receive rivers and do not emit them discharge themselves elsewhere through hidden passages, so too these that do not receive rivers but emit them are filled, as it were

through hidden conduit-channels [hydragogos inciles], and so are emptied through a manifest river: which is sufficiently clear.

MODUS IV.

Whence and how arise those lakes that both receive and emit rivers.

Lakes of this kind, again, are to be considered variously. For either they have their consistency from the increase of rivers, without any other subterranean spring—and in this way they obtain the name of pool [stagnum] rather than of lake; or, besides the intromission and emission of rivers, they are increased also by a subterranean spring. These in turn have various attendant conditions. For either they receive more water from the influx of a river than they emit; or they receive less than they emit; or they receive just as much as they emit. The first two repair the deficiency of water, both in reception and in emission, through the influx or efflux of other subterranean waters. Lakes of the last kind, on account of the quality of their waterways [aquaeductuum], distribute the laws of the influx and efflux of waters in equal measure—as happens in artificial fountains.

[Margin: The various attendant conditions of lakes that both receive and emit a river. [Variæ conditiones lacuum, qui flumina recipiunt & emittunt.]]

Another difference among these lakes is to be noted: that some discharge outside the lake, in an unmingled current, the river which they receive, passing through the middle of the lake—as happens in Lake Léman [Lacus Lemanus, Lake Geneva], through which the Rhône passes; in the Acronian [Lacus Acronianus, Lake Constance], through which the Rhine; in Lake Zaire or Bed, through which the Nile passes unmingled. A certain river of Muscovy is said to traverse ten lakes; and the like is told of other lakes of China and Brazil, which I omit for brevity's sake. But certain lakes take in rivers which, at once mingled with the lake-waters, leave no trace of their flow. Now, the reason that some are not mingled is none other than this: that since river-waters are much subtler and finer than lake-waters, they consequently delight—by an innate force and with an unmixable current—to float upon the latter as upon something coarser. But those that seek mingling are convinced to be of the same nature. Hence it is plain that all lakes of this kind are indeed increased from rivers, showers, and melted

snows, but, as to their origin, obtain the whole rationale of their essence through subterranean waterways and springs.

[Margin: Rivers that pass through the middle of certain lakes without mingling. [Flumina quæ per medium lacuum quorundam sine commistione transeunt.]]

COROLLARY [CONSECTARIUM].

From what has been said thus far it is plain that this fourfold mode-classification can easily be reduced to one. For what occurs in lakes that receive and emit rivers, that same thing occurs in lakes that show no river either received or emitted, by means of the hidden rivers beneath the earth, by which they are filled and emptied,

[Printed p. 243 — running header: "DE FLUMINUM ORIGINE. 243"]

and so they do not differ from the outer ones, except that the latter are detected by the manifest judgment of the senses, the former by an inference drawn beyond the senses [ultio (recte: ultra) sensuum iudicio].

If a lake A receives the river B and emits the river C, then the result will be that, if the rivers B and C are conceived as covered and subterranean, the lake A will appear to exist alone, as is seen in lake N. Again, let there be a certain lake that receives river B but emits none; then you will imagine to yourself a subterranean river C, and so you will conceive the lake to be manifestly increased by river B, but not apparently diminished by C. The same holds of a lake that receives indeed no river yet emits one: then you will conceive, by the contrary reasoning, that lake A is filled by the non-manifest subterranean river B, but apparently discharged through the river C. Whoever has rightly understood these things will, beyond doubt, assign without difficulty the rationale of the proposed difference of lakes. Therefore let this suffice concerning lakes arising in the level plains. The figures follow. Note that the black which is seen here denotes the subterranean.

Diagram. First of a row of four landscape schematics across the top of the page, each a cross-sectional mountain-and-lake profile illustrating one of the four lake types. This first panel shows a lake at left fed by an incoming river B (flowing from the lower left) and emitting river C through a mountain mass at right.

Labeled points:

- A: the lake basin (center-left)
- B: the river entering the lake (lower left, "B")
- C: the river emitted (toward the right, "C")

- [Several small interior letters within the lake basin are too small to resolve — [?]]

Caption (verbatim): *Lacus A recipit B, & emittit C, flumina.* — "Lake A receives B, and emits C, rivers."

Diagram. Second panel of the row. A lake (V) within a mountain valley that receives river L but emits nothing externally; the black (subterranean) outflow is shown beneath. Labeled points:

- V: the lake (center)
- L: the incoming river (left, "L")

Caption (verbatim): *Lacus V recipit L fl. & nullum extra emittit.* — "Lake V receives the river L and emits nothing outside."

Diagram. Third panel. A lake (S) that receives no surface river but emits one (Y); the subterranean feed is shown in black. Labeled points:

- S: the lake (center)
- Y: the emitted river (lower, "Y")

Caption (verbatim): *Lacus S flumen non recipit, sed emittit, uti Y.* — "Lake S does not receive a river, but emits one, as Y."

Diagram. Fourth panel of the row. A lake (labeled N at center) that neither receives nor emits any river apparently — the self-contained type — with the subterranean connections shown in black on either side. Labeled point:

- N: the lake (center, "N")

Caption (verbatim): *Lacus flumen non recipit, neque emittit apparenter.* — "The lake neither receives nor emits a river apparently."

SECTIO II.

DISQUISITIO

DE VARIIS AQUARUM DIFFERENTIIS

On the various differences of waters

and their qualities—or what amounts to the same thing, on thermal springs [Thermae], that is, on medicated and compound waters, and their nature, property, and origin.

CAPUT I.

On simple spring water, and on its goodness and its harmfulness.

[Margin: The pure element of water does not exist in the nature of things. [Non datur aquæ elementum simplex in rerum natura.]]

I suppose, first, that a pure and simple element cannot exist in the nature of things, and consequently that the water we use—and which we cannot do without—is not simple nor pure, but a substance mingled and confused with various corpuscles of heterogeneous mixed bodies. Since I have shown this elsewhere by the induction of various things and experiments, and shall demonstrate it more fully below, I will not dwell on it here. And although in this place I call spring water "simple," I would nonetheless have this understood not of absolute simplicity, but of relative—namely, insofar as, compared to other waters, it exhibits the greater marks of simplicity; yet that it is not absolutely simple, the great differences among springs sufficiently show. And although I have treated of these matters more fully in my *Iter Etruscum* [*Etruscan Journey*], it has nonetheless seemed good to treat here, more precisely, certain points there omitted.

[Margin: Six differences of potable, that is, sweet, waters. [Sex differentiæ dulcis aquæ.]]

Six differences of potable or sweet water are for the most part laid down.

First, **Spring water** [Fontana], which gushes from the inmost vitals of the earth in a living vein. Second, **Lake or marsh water** [Lacustris sive palustris], standing and stagnant. Third, **Rain water** [Pluvialis]. Fourth, **Cistern water** [Cisternarum]. Fifth, **River water** [Fluvialis]. Sixth, **Well water** [Putealis].

[Margin: The differences of potable waters. [recte: the six kinds — corresponds to "...por... ut plurimum statuuntur"] Spring water. [Fontana.]]

Which of these is the most healthful for drinking, the best fitted for quenching thirst and aiding digestion, and the most convenient vehicle for the blood as it is poured out from the liver into the whole economy of the body—about this there is no slight dispute and controversy among the physicians. Some prefer spring water on account of its supreme clearness, sweetness, lightness, and coldness. Others, on the testimony of Plutarch [Plutarcho teste], prefer the water of showers or rains, because it is light and airy. Some set cistern waters above the rest, because they are nothing other than rain water, and the most thoroughly purified of all dregs. Nor are there wanting those who hold that the waters of rivers are the healthiest—induced, perhaps, by the most healthful waters of certain rivers, of the kind that Solinus [Solinus] says the waters of the river Choaspes [Choaspis] of Persia to be: of such perfection that the King

[Margin: Which water is more healthful. [Quænam aqua salubrior.]]

than these waters he would put to use for drinking; just as the same is reported of the water of the Nile [aqua Nilotica], being the sweetest and most fertile, and of countless others. [Margin: What waters are renowned for their wholesomeness and goodness.]

At Puteoli [Pozzuoli] the water is heavy and is digested only with difficulty, nor can it even be determined whether it is wholly free of putrefaction. Yet it will be the less to be condemned in proportion as it is improved more and more by the frequent stirring of those who draw it, or if it gushes up from a subterranean spring. As for lake-waters [lacustres], finally — that is, standing or stagnant waters — since these are struck from the roll of the wholesome kinds altogether, let me now show what is to be concluded about the remaining kinds enumerated. [Margin: The condition of the water at Puteoli.]

And first of all it must be laid down as certain that there is no water anywhere on the face of the earth that is not, at least in some part, polluted by the foulness of earthy refuse, with which it necessarily mingles. For if you consider the origin even of the clearest spring, it cannot but be that, passing as it does through subterranean channels [cuniculi] on its long journey, it is tainted by the tincture of earthy juices and stones endowed with various properties, and by the scrapings of their particles — just as was shown in the preceding Book in the chapter on the saltiness of the sea [de salsedine maris]. [Margin: That there is no water free of an earthy admixture.]

Rainwater [aqua pluvialis], as it arises from the dissolution of various vapors steeped in various supplies of mineral spirits, cannot avoid contamination when these become associated with earthy matter and are turned into water. Hence cistern-water [aqua cisternarum], because it is a kind of mixture both of the different waters collected in the cisterns at different seasons of the year and of the hail and snow melted on the roofs in winter, is condemned everywhere by the physicians — as Matthiolus [Pietro Andrea Mattioli] reports — on the ground that snow and hail contain in themselves some noxious and deadly thing, the seedbed of many diseases.

Again, since river-water [aqua fluvialis] is the receptacle of various minerals, of brooks, and of all filth and carrion, surely no person of sense would assert that it conduces to health — unless, kept over a long stretch of time in large earthenware vessels and clarified by settling, it grows clear and is thoroughly purified. [Margin: River-water is unwholesome.] The same is to be thought of lake and stagnant waters, which are judged to be worse than river-waters in proportion as, lying foul in their motionless state, they are nearer to putrefaction. [Margin: Marsh-waters are the worst.]

And so, of these six kinds of drinkable water, if you set aside the stagnant ones, there is scarcely any that does not suffer some loss of its purity; and none, equally, that cannot be improved by various filterings, boilings, and settlings. Hence the signs of the goodness and wholesomeness of waters must be gathered from elsewhere — which signs we now set down.

The first and universal sign of the goodness of waters, then, is this: that they be clear, translucent, thin, pure, light, of their own color, free indeed of any taste, and agreeable to the palate; and that they both grow hot quickly when set to the fire and grow cold again as soon as they are removed from it; and finally that they do not linger even the briefest moment in the upper digestive organs [praecordia], but pass by an easy course without any distress to the stomach. Waters that come together under this complex of qualities and signs you may hold to be the most highly praised for drinking and the most fitting for preserving health — on the testimony of Galen, Dioscorides, Cardano [Girolamo Cardano], Matthiolus, and others. [Margin: Universal signs of the goodness of waters.]

The second sign: if you find that people who use the common water of some place are robust in strength, glowing in color, subject to no ailment of the legs and no blariness of the eyes, and live a long and healthy life, then know that those waters are most thoroughly approved.

The third sign: if water set over the flames in a cauldron quickly comes to a boil, and with like speed cools down when the fire is drawn away, count those waters good and of the better sort — especially if little or no sand or mud settles at the bottom of the cauldron.

The fourth sign: if legumes cooked in it cook through quickly, with no hardness left, let that be for you a sure indication of a most wholesome water.

The fifth sign: if you observe a spring around which neither moss nor rushes grow, and that place is fouled by no filth — while the water itself is translucent and clear and passes over a bed of pebbles and fine sands coated with no slime — you will have sure signs of the thinness and wholesomeness of that water.

But how the heaviness and lightness, the goodness or badness of any water may be recognized, and may be detected by means of hydrometric instruments, we shall teach in what follows by many and various methods.

CAPUT II.

De Aquilegiis sive de Signis, per quæ, ubinam Aqua alicubi sub terra lateat, cognoscere quis possit.

(On Water-Finding, or the Signs by which one may know where Water lies hidden somewhere beneath the earth.)

These experiments are of great importance in those places where strongholds, or country villas, or the like are wont to be built; since the mere lack of water removes every enjoyment of comfort. And since there is no piece of ground that does not somewhere underneath have either moisture or the vein of some spring, the water-finding architects [Aquileges Architecti], anxious for so great a benefit, rightly make it their business to inquire whether there is any hope of a hidden source. Hence, intent with unbroken effort, they have discovered certain signs by which they have at last reached the hidden vein of water — signs that Vitruvius (*Architecture* VIII), Pliny, Palladius, and Cassiodorus have handed down to the memory of posterity. They are as follows. [Margin: Signs of water lying hidden beneath the ground.]

1. If you see a place green with grasses, and also luxuriant with an abundant crop of leaves on tall trees, you may convince yourself that somewhere beneath there lies, for certain, a quantity of water. For in lands beneath which sweet moisture is not far off, there is, as it were, a perpetual smile of

plenty in certain growths — such as the water-rush [*juncus aquaticus*], the light reed [*arundo*], the sturdy bramble [*rubus*], the pliant willow [*salix*], the green poplar [*populus*], and the remaining kinds of trees, which nonetheless luxuriate with a thriving increase beyond their natural measure.

2. The marks of hidden waters are the wandering willow [*salix errativa*], the alder [*alnus*], the chaste-tree [*vitex*]; and among the herbs, the buttercup [*ranunculus*], the water-lily [*nymphaea*], the fleabane [*pulicaria*], the galingale [*cyperus*], the water-mint [*mentastrum aquaticum*], and the like, which both love water and can neither be nourished nor preserved without it. To these is added a not uncertain indication: stationary troops of croaking frogs.
3. It is gathered from the quality of the places and from the nature and property of the soil and clod. Where the soil is chalky, corrupted by a varied mixture, there you may hope for neither abundance nor good-tasting water. By contrast, in clayey earth scoured clean of all rubbish, the water is always sweet, and colder where there is tufa [*tophus*]; for both make the water light and, by filtering it, hold back the dirt. [Margin: Chalky earth produces unwholesome water.] Gravel [*glarea*] promises uncertain water, but of good taste. Sand from coal-bearing grit [*arena carbunculosa*] pledges water that is sure and stable and — what matters most — wholesome. Red rocks too promise the best water and of the most certain hope; beneath the rocky roots and flints of mountains it is more plentiful, colder, and more wholesome. [Margin: Good water, which veins it loves.] And these are the chief signs of hidden waters; now let us see how they may be explored by other methods and experiments.

EXPERIMENTUM I.

Let some spot be dug down to a depth of about five feet. Then, around sunset, let a copper or leaden basin smeared with oil be set in it, turned upside down so that its hollow looks toward the bottom of the pit; and let the mouth of the pit meanwhile be covered over with reeds and foliage, with earth heaped on top. The next day let it be opened; and if any moisture has trickled down upon the copper or lead in a copious sprinkling of drops, you may be sure of an abundance of water lying hidden there.

EXPERIMENTUM II.

If into a pit like the foregoing you set an earthenware vessel, still raw and unfired, and a tuft of wool loosely bound — and if the next day you find the vessel broken and dissolved by the evaporating moisture, and the wool also soaked, so that water can be squeezed from it — that will indeed be a sign of abundant water hidden there. The same will happen if a burning lamp full of oil is set out in the same pit covered with foliage: if the next day you see it gone out, with no failure of the oil or wick, you may convince yourself for certain that waters are lurking there, not far distant from the lamp. Likewise, if you kindle a fire in it, the scorched earth will breathe out a misty vapor — an indication of hidden water.

EXPERIMENTUM III.

Let the water-diviner [aquilex], in the morning facing the East, but before the rising of the Sun, lie prostrate flat on the ground and observe whether anywhere moisture curls up into a thin little cloud and strikes the air with a tremulous motion; and where he has detected this, let him dig, assured of stored-up water.

Some, driven by I-know-not-what superstition into a perverse persuasion, think this can be accomplished by means of a sieve, in which a suspended pair of shears, by its points, will — as soon as it has come over a hidden vein — point out the water by an infallible sign. I remember having seen at Viterbo a ridiculous experiment of this kind performed by a certain stone-mason; but just as it rested on no principles of nature, so it was deservedly exploded by the laughter and jeers of all. [Margin: The superstition of certain water-seekers.] To these I will add several methods far more recondite, yet most certain, with which I once used to explore the hidden springs of waters.

EXPERIMENTUM IV.

Let there be made, from some wood that has a sympathy with water — of the kind that alder and willow might be — an arrow C B, more or less in the manner in which the needle is usually mounted in magnetic compass-boxes [magneticæ pyxides], yet fashioned with this skill: that the half C A be made of any other wood, as dry as can be, while the other half A B be of green wood of alder or willow; let the two, joined together at the hollow middle A by a brass cone, be tied so as to make a perfect equilibrium. This done, let a foot be made on which the instrument can be steadied, and let it have in its upper place a spike [obelus], which, fitted into the brass cone of the arrow, not only supports the arrow but renders it so finely balanced that the arrow may, with no trouble and no

impediment or resistance, be set in motion by the easiest and gentlest motion, just like the needle this way and that in magnetic compass-boxes; and you will have the instrument made ready. Or, if that hollow little cone can be made only with too much difficulty, you will balance the arrow upon a turning axis, and the same effect will result, as appears in the Figure.

Diagram. A water-divining instrument of the sympathetic-needle type. At the top, a long horizontal balanced arrow runs left to right, lettered C at the left tip and B at the right (arrowhead) tip, pivoting at a central hub. The hub is drawn as an oval (compass-box) carrying the small letters of the pivot mechanism — L at the top of the hub, O to its left and T to its right along the arrow shaft, and P below at the supporting pin. Below the arrow, two further views are shown: at lower left, the complete instrument mounted on a flat rectangular foot/base with an upright post bearing a short balanced arrow at its top; at lower right, the bare upright pivot-post (the spike/obelus) standing on a splayed three-pronged foot.

- C (left tip of horizontal arrow): one end of the arrow (the dry-wood half, C A)
- A (center, at the hub): the hollow midpoint, joined by the brass cone (boundary of halves C A and A B)
- B (right tip, arrowhead): other end of the arrow (the green alder/willow half, A B)
- L (top of central hub): pivot-point marking on the compass-box
- O (left of hub, on shaft): point on the arrow shaft at the pivot
- T (right of hub, on shaft): point on the arrow shaft at the pivot
- P (below hub): the supporting pin / spindle of the pivot

Therefore, when you intend to inquire somewhere for a vein of hidden water, set up the instrument in a spot conspicuous by the preceding signs and shady, in the early morning before the rising of the Sun; and then, after some hours, inspect the part

A B of the arrow made of alder-wood. If it has dipped downward, you may be sure that in that place water is stored. For since the said wood has the greatest sympathy with water, and eagerly draws to itself the moist vapor from the earth, it must necessarily, being soaked and weighed down with moisture, leave its equilibrium and incline downward. It will gain greater force if you cover the alder-rod over with tufts of wool, because of the great thirst for moisture that is in wool. [Margin: The sympathy of the alder-rod with water.] But here I will not omit to mention how the veins of springs sometimes dry up.

Now the veins of springs are wont to vanish or disappear from a fourfold cause. First, from a collapse of earth and rocks below the ground, arising from an earthquake, or from rains, or from melting snows — by which the water, prevented from running by its usual path, is forced to seek new outlets. Second, from a new blocking of channels or an opening of others. Third, from the recent digging-out of some well, or foundation, or mine, or the like, by which the path of the flowing water is cut off and opened elsewhere. Fourth and finally, from a new sprouting of woods and groves, or from their uprooting; for the roots of trees draw water to themselves. Hence it comes about that some spring either dries up at a new growth of plants or flows forth at their being grubbed out. See what we have treated of these matters at greater length in our *Iter Etruscum*. [Margin: How the veins of springs vanish or are newly generated.]

CAPUT III.

De Aquis mixtis seu compositis medicatis in genere earumque causis, & de mixtionis cum mineralibus diverso modo & ratione.

(On mixed or compound medicated waters in general and their causes, and on the diverse mode and manner of their mixture with minerals.)

Those waters that are called mixed or compound — which are composed of various earths, metallic bodies, juices, and the remaining kinds of minerals — are without number; and so too the variety of differing waters has no end. For just as in man no face, no voice, no natural bent of disposition, no temperament can be assigned that does not differ from another's temperament, so I say there is no water, whether simple or compound, that does not acquire a special difference from all other waters whatsoever. [Margin: No one water is altogether like another.] And so I would venture to say that there are as many differing kinds of waters as there are differing kinds of earthy clods, of minerals, of metals, and of juices both liquid and solid. Since these do not fall under number, there exist likewise innumerable kinds of waters — especially when single kinds are aptly combined with single kinds by mixture — so that it is consequently difficult to pass firm judgment on medicated waters.

Two most noble philosophers, Seneca and Pliny, saw this. Hence the former, in *Natural Questions* Book III, when about to discourse on waters, says: *Let us*

approach a serious, weighty matter; let us do what is wont to be done on a journey — those who have set out later make up for the delay by speed. Let us hasten; let us undertake a work, I know not whether surmountable, yet great certainly, without making excuse of my age. And the latter, in Book XXXI, chapter 1, having gazed upon the very many powers and differences of waters, exclaims: *What mortal could enumerate them all?* — Why should level-headed philosophers be afraid? for the matter cannot be exhausted by examination. [Margin: The difficulty in discerning the powers of waters.] Yet, these difficulties notwithstanding, we are not so deterred as to have any mind to throw down our spear:

It is something to advance thus far, if it be not granted to go beyond.

I judge that I must do the same as the physiognomists, who, amid that infinite diversity of temperaments, do not so far go astray from their forecast of the predominance of these temperaments as not, ever and again, to touch — as with a needle — the inmost nature of men and their inclination to virtues and vices, and to determine it most truly. That I may do the same in this judgment of waters, and with so much the happier outcome [?], I will here recount only the principal mixtures of things by which water is infected; from these the curious reader will easily find the way to explore the rest, since they are discovered, not with difficulty, from the predominance of the qualities, by the service of the senses, and with the help of experiments. The mixtures, then, of all waters, in whatever way they are at last compounded, I reduce to five Heads. [Margin: The examination of the mixtures in waters.]

1. For either they are mingled with various clods of earthy matter, under which all kinds of earth are comprehended.
2. Or with the various kinds of salts — which are called concrete juices — and there arise as many differing kinds of mixtures as there are differing kinds of salts.
3. Or they are joined with the various kinds of juices, or liquid fluids, under which are contained both the oily — such as bitumens — and the non-oily — such as the strong and caustic waters [aquae fortes & causticae].
4. Or they are mixed with metallic bodies, and take on the nature of the metals with which they are tinged.
5. Finally, or they are mixed with the various kinds of stones, under which all the differences of rocky substances are contained.

And to these five Classes, whatever lies hidden in corporeal and subterranean nature

is recalled; and from the mixing of them flows the series of qualities that follows — those qualities which shine forth in that diversity of waters which we have just reviewed.

The following synopsis is presented in the source as a two-column brace-diagram: on the left, the **Waters** classified by the substance that infects them; on the right, the **qualities** that arise from these, joined by the central caption "From these arise qualities, such as are...".

Waters [Aquæ] (infected by / consisting of)	→ From these arise qualities, such as are:
Infected with earths [Terris infectæ]	Acid [Acidæ]
Salty [Salsæ]	Bitter [Amaræ]
Nitrous [Nitrosæ]	Salty [Salsæ]
Aluminous [Aluminosæ]	Hot [Calidæ]
Vitriolic [Vitriolataæ]	Cold [Frigidæ]
Sulphurous [Sulphurosæ]	Oily or fatty [Oleaginosæ seu pingues]
Verdigris-bearing [Æruginosæ]	Poisonous [Venenosæ]
Of lime and gypsum [Ex calce & gypso]	Colored [Coloratæ]
Metallic [Metallicæ]	Effervescent [Ebullientes]
Bituminous [Bituminosæ]	Transformative [Transformativæ]
Infected with mercury [Mercurio infectæ]	Purgative [Purgativæ]
Iron-bearing, copper-bearing [Ferratæ, æratæ]	Wholesome to whatever members [Quibuscunque membris salubres]
Petrifying [Lapidescentes]	

From the combination of each of these single kinds with each single kind there arises that admirable variety of waters which the above-cited philosophers were unable to conceive. For if you conjugate these twelve species according to the principles of our combinatory art [ars combinatoria], there will be born 479001600 — that is, four hundred seventy-nine million, one thousand six hundred — differing species of waters. [Margin: The admirable power of combination.] If you again resolve these into the differing combinations of the species of earthy clods, of salts, of niter, of alum, of vitriol, of sulphur, and of

metals, you will have a number that exceeds the whole number of the sand of the sea. But since, in the twelve species set forth, a predominance always presents itself to the senses, content with that, it is now time for us to treat of each in order.

§ I.

De fontibus seu aquis auriferis, gemmiferis, aliisque terra infectis.

(On springs or waters that bear gold, bear gems, and are otherwise infected with earth.)

A threefold mode of mingling must be considered in all of these. First, there are certain medicated waters that are constituted not by a perfect but by a confused mixture — that is, those that teem with the perceptible particles of various minerals and can be separated from them with no trouble. [Margin: Improperly mixed waters, what they are.] Second, those that consist of a perfect mixture, such that the individual particles of the water are mingled with the individual vaporous spirits intimately, by a kind of union separable only by a long boiling; and so they constitute one body with the waters, one substance, one form — such as salt water, vitriolated water, and so on. [Margin: What waters perfectly mixed are, and how they contain a perfect mixture.] Third, finally, there are certain waters that consist partly of a true mixture of the things they contain, partly of a confused, or rather true, mixture: and these are compounded from the first and second modes of mixture. In this way there are many thermal springs [thermae] that emit calcareous stone — imperfectly mixed with them by reason of what is imparted to them, while with true salt they are united in a perfect mixture. [Margin: Certain perfectly and imperfectly (mixed).] But let us explore all these things more deeply.

Gold-bearing springs and rivers [auriferi fontes & flumina] are found almost everywhere, namely where mines of gold are dominant. [Margin: Gold-bearing springs and rivers.] More renowned in name than the rest are: the Tagus in Spain; in Italy the Padus [Po]; in Germany and Hungary innumerable brooks; in Asia the Padrotus [Pactolus] and Chrysorrhoas; in Bactria the Oxus; in Carmania the Hyramnis; in Africa the Nile, the Niger, and the Zairus [Congo]; in America, beside Potosí, all the rivers teem with golden grains. But concerning these, see the writers who treat of them: Aristotle in *On Marvellous Things Heard*, Pliny, Solinus, and very many Geographers of this age. It is our task to set forth the causes of this golden flow [Chrysorrhoia].

If, then, anyone should ask whence the gold-grains of this kind draw their origin — whether from the nature of the river mingled with the earthy clods, or from elsewhere? — I dispatch myself in few words in a matter by no means recondite. [Margin: The cause of the gold-bearing rivers.] If gold-bearing veins lie beneath a river or lake, surely they can, according to the opinion of some, be said to be generated in the waters themselves; yet we shall speak more fittingly if we say that the gold, having sprung up in the native veins of mountains, is from there scraped off by the flow and force of the streams and brooks, carried along, and brought down into the channels of the rivers, and mingled with their sands and waters. And experience teaches — in the Principality of Tirol, in Bohemia, Saxony, Hungary, and finally in all those regions in which the womb of the mountains is laden with gold — that there, in those very brooks and rivulets, the gold-grains scraped off from the gold-bearing veins and mixed with the sands show themselves. [Margin: How gold is generated in rivers.] Mariana, the historiographer of Spain [Juan de Mariana], relates that the inhabitants once, having broken and split the mountains, let water in, which by washing would convey away the gold; and so the gold scraped off from the veins settles in the sands, but is not begotten in them — for sands lack the little veins in which moisture, from which gold is made, can be contained, nor does the maturing heat reach there.

Our Fathers report that the rivers around the region of Potosí in America are so productive of gold that the annual revenues of our College at Potosí are nil, except what the gold-bearing river supplies to them; and they operate thus. [Margin: The causes of Potosí. The revenues of the College of our Society, which (come) from gold assigned to them.] At fixed and appointed times slaves [mancipia] are sent out to extract the sand; and the extracted sand they cleanse on slightly inclined boards by the frequent washing of water poured over it from filth and dirt; and in this way the remaining

LIBER QUINTUS, Sectio II — CAPUT III, §. I (continued): De fontibus seu aquis auriferis, gemmiferis once the earthy material has been carried off by the affusion of water, the heavier gold particles are left behind. These particles are then placed in crucibles and melted by a fierce fire; the melted gold is afterward beaten with a hammer, drawn into sheets, and put to use. As for how much gold the Nile, by its cataracts, supplies to Egypt from this precipitate, I have shown it in the second *Syntagma* of the *Oedipus Aegyptiacus*, in the discourse on the alchemy of the Egyptians, to which I refer the reader.

[Margin (p. 248): The cataracts of the Nile supply Egypt with gold.]

Since, then, innumerable rivers of this kind are found throughout the Geocosm, one might reasonably ask whether these rivers do not also share something of the power of gold — or, what amounts to the same thing, whether gold is perfectly mixed with the water. I answer that it is not. For if you were to keep water in a golden cup for a hundred years, it would still draw out no virtue from it. Gold, being indissoluble and compacted by the strictest laws of nature, cannot yield the desired effect unless it is first dissolved by strong waters [aquae fortes — the acids of the alchemists]. It does happen from time to time, however, that veins of gold, dissolved by some corrosive and caustic liquor, pass off into spirits; and water impregnated with these takes on some virtue. Even so, I do not think a perfect mixture of gold with water is possible, but only a confused and lightly tinged one — as I shall explain at length in the proper place, in treating the nature of potable gold [aurum potabile]. As for gold-bearing waters and places that yield gems [gemmae aquae], I shall philosophize about them elsewhere.

[Margin (p. 248): Gold cannot be perfectly mixed with waters.]

§. II. De Fontibus et Aquis terreno luto infectis.

(On springs and waters tainted with earthy mud.)

Whenever water passes through places tainted with mud of various earthy substances, it is tinged with the quality that the mud itself contains. Such mud is formed from chalk, clay, sand, gypsum, ochre, sandarac [sandaraca — red arsenic

sulphide], red ochre [rubrica], ash, lime, and the other sands and powders of mineral bodies, as soon as these are mixed with moisture. Chalky and clayey waters are found in great number in Etruria [Hetruria]; they are heavy and by no means conducive to health. If water passes through sand and a harder gravel, it is reckoned the best and most wholesome of all — for the whole virtue of waters depends on what tinges them.

[Margin (p. 248): The whole virtue of waters depends on what tinges them. The virtue of waters depends on the earthy materials they pass through.]

Waters tinged with gypsum are likewise found, not infrequently, in Etruria. While they contribute much to the external washing of the body, when taken by drinking they are thought not to be free of danger, on account of a certain caustic virtue they possess. Waters that abound in ochre, sandarac, and the like are extremely harmful to drink; yet many who use them as a bath are freed from many infirmities. This class of stones varies a good deal according to place: the stone is found ash-colored, livid, pale, or reddish. In some places a kind of stone is found which, when dug up, is converted into a very tenacious gypsum — as in Cyprus, on the testimony of Pliny [Plinius]: if waters pass through the veins of this stone, they are rendered white.

[Margin (p. 248): Gypsum-waters, where chiefly found.]

Gypsum waters [aquae gypseae], accordingly, are found everywhere in great abundance — for instance, in Italy among the Camertes [the people of Camerino], at the river Callis [the Chienti? — Latin "Callim fluvium"], so that those who drink from it become afflicted with gravel [stramosi — "stone-bound," i.e. afflicted with calculi]. The water of certain wells at Bologna [Bononia] is gypseous and exceedingly noxious, having a certain suffocating power; the same is found among the Helvetii at Eugesta [Augst?], at Pozzuoli [Puteoli] in Campania, and in innumerable other places.

§. III. De salsis Aquis et Fontibus.

(On salt waters and springs.)

Since in the preceding Book I philosophized at length about the saltiness of the sea [salsedo maris], and in the following Book I am going to treat of the nature of salt [natura salis], here I shall not so much describe the salt springs as touch on them only in passing. It is established, then, that among the other medicated waters nothing is more frequent or more numerous than salt springs. For no water — I do not say medicated or compound, but not even a pure and simple one — can be

designated which does not have at least a little salt mixed in. This has been so confirmed by the chemical art that no room is left for any further doubt. For just as salt is a kind of seed of nature, and an earthy element that goes into the composition of all mixtures, so too nature has willed that it be lacking nowhere — being so necessary to the preservation of things.

[Margin (p. 248): There is a little salt mixed in all waters.]

Hence scarcely any kind of thermal spring [thermae] will be found that does not have some salt mingled in it. Yet in those waters in which salt has the predominance, these too are called salt waters. Some of them are born from the innermost salt-bearing caverns of the mountains; some are tinged from the very banks of rivers that are charged with saltiness; others from subterranean waters abounding in the native saltiness of their locality. The springs and rivers of Hungary, Poland, Tyrol, and Saxony; in Italy at Volterra [Volaterrae], in Emilia, Picenum, Etruria, Gaul, Spain — and, finally, throughout the whole globe of lands, met with everywhere — bear sufficient witness to this. But I shall treat of these more fully in what follows, God willing.

§. IV. De Fontibus Nitrosis.

(On nitrous springs.)

What niter [nitrum] is, and how many species of it there are, see in the following Book, in the chapter on niter. Here I shall only adduce waters infected with niter. To do so, I would first have you know that the earth in some places produces niter most abundantly — as does Egypt near Memphis (today Cairo), where it is even, when baked by the heat of the Sun, converted into a stone most apt for making vessels. Water flowing through places of this kind is therefore tinged with a nitrous quality, to the great advantage of medical practice.

[Margin (p. 248): Niter, where it is chiefly found.]

In the territory of the Sabines, at the place now called the Well of Retina [Puteus Retinianus], the said authors point out the Catilian Waters [Catiliae Aquae] — most celebrated in the records of the ancient writers, indeed from the very times of the Aborigines [the legendary aboriginal inhabitants of Italy] — as being very full of niter; of which [I shall treat] more fully in the following Book, in the chapter

[§. IV continued:] on niter. Such are the waters about the floating islands [de Insulis natantibus]. Of this kind are several waters in Emilia near the Maldula [river], and in the Valley of St. Martin near the Flaminian Way; in the Bajan

[Baiae] territory of Brachula and Sucullaria near Lake Avernus, and that which is on the island of Aenaria [Ischia]. In Etruria the waters of Borra and Volterra; in Germany, the most highly praised ones near Strasbourg [Argentina]; in Helvetia [Switzerland] at Zürich [Tigurum]; in the Duchy of Württemberg at the Marcian Forest [Sylva Martiana — the Black Forest]; in Alsace, and innumerable other places. The virtue of all these, just as it has detergent or abstersive force, is likewise held by all physicians to be cathartic or laxative — unless the admixture of other waters makes them produce different effects.

[Margin (p. 249): Places where there is plenty of niter in the waters.]

For the predominance of niter makes waters potent; and when drunk they correct a bad constitution arising from phlegm, loosen the bowels, and benefit ailments of the nerves — which is attested by distillations [i.e. catarrhal discharges] — and the chest. They heal disorders of the skin and the itch; instilled into the ears, they remove ringing. In a word, they produce effects equivalent to salt, except that salt yields a restraining, cleansing power, while niter yields a cleansing power. But of the nature and properties of niter expressly elsewhere.

[Margin (p. 249): When [such waters are] harmful.]

§. V. De Aquis Aluminosis.

(On aluminous waters.)

Whenever water passes through places filled with alum, it becomes aluminous, tinged with the powers of alum. Now alum is imbued, as it were, with contrary qualities: moderately hot and supremely dry, and besides cold, and powerfully astringent; the signs of these are its taste. For at first taste it is somewhat sweet and thin, pricking the tongue; from which it gradually passes into a bitter and markedly astringent flavor. Water perfectly mixed with it shares these powers.

[Margin (p. 249): Aluminous waters.]

It is indeed remarkable that I have seen no stream tainted with alum which allows any herbs to grow on its banks here and there. For — as Theophrastus too noted — aluminous water neither nourishes nor generates any plant, a most evident sign of its truly powerful dryness, which predominates in it. Hence they are wonderfully suited to curing diseases that take their origin from excessive moisture or cold. Such are the waters near Tolfa, flowing forth from the aluminous mountains; such is the Albula in the Tiburtine countryside [the territory of Tivoli]:

[Margin (p. 249): Why aluminous waters do not let herbs grow on their banks.]

One goes to the cold citadels of Hercules, where the Tiber flows, and where white Albula steams with sulphurous waters.

And innumerable others, as is clear from the *Catalogue of Thermal Springs* [*Catalogus Thermarum*].

§. VI. De Aquis sulphureis et bituminosis.

(On sulphurous and bituminous waters.)

These can be considered here in a threefold way: some are sulphurated [sulphuratae], some sulphurous [sulphureae], and some of both kinds. We call "sulphurated" the pure ones, which contain much sulphurous substance in an unmixed state. "Pure sulphurous" we call those which, as long as they boil, are mixed with and tinged by sulphurous vapors and spirits; but once cooled, and again removed from the fire, they are found to have lost all sulphurous tincture — the vapors and spirits that existed in them having flown off — so that they display neither odor, nor taste, nor any further mark of a sulphurous character.

[Margin (p. 249): Sulphurous waters.]

But if the waters have been intimately and perfectly mixed with sulphurous corpuscles together with the exhalations of [sulphurous] spirits [the text reads "fpiritibus... bilium," apparently "spiritibus sulphureosis" — sulphurous spirits], then they truly and properly obtain the name of sulphurous waters, and always exhibit sulphurous effects, whether they be hot or cold. Of the former kind are the Albula Waters, which abound in sulphurous lumps but are nevertheless not mixed with them — having, as I said a little earlier, the predominance of alum. Of the second kind are all those sulphurous waters which, when cooled, put off their sulphurous character. Of the third kind are the waters in Etruria at S. Cassiano, and the water of Caia near Viterbo [Viterbium]. For since they pass through long windings, through sulphurous veins filled with sulphurous vapors and exhalations, and are perfectly tinged with the scrapings of sulphurous substance and the spirits mixed in with them, they are mixed in an intimate and inseparable union.

As regards bituminous waters, it is certain from experience that all fatty and bituminous liquors, though at first sight they reject all mixture with waters, are nevertheless overcome by long delay and confusedly mixed with them — as all bituminous springs show. Indeed, they are so filled with bituminous vapors (as Fallopius [Falloppio] reports of certain springs in the territory of Parma) that they

are kindled by a flame scarcely even brought near them; nor can a flame, once kindled in the water itself, be extinguished by any pouring-on of water, but only by wind, or by cloths thrown over it.

[Margin (p. 249): Bituminous waters.]

Such bituminous waters arise from the many bituminous spirits and vapors which are continually raised up from the boiling vein of bitumen in those subterranean places. But of the nature, species, and origin of bitumen, see in the following Book, in a special chapter.

§. VII. De Aquis succo lapideo, sive petrifico pollentibus.

(On waters endowed with a stony juice, or petrifying power.)

By "stony juice" or "petrific [power]" I here understand a certain humor, very well elaborated and concocted, generated from stony matter — a humor or juice which, on drying out, turns into stone. Medicated waters imbued with this juice are called petrifying [petrificae], because anything placed in them, in the course of time, they either coat with a stony crust or even convert entirely into stone. This juice is found chiefly in thermal

[§. VII continued:] waters. With some it is mixed in a twofold manner: sometimes by a true and proper mixture, sometimes by a not-true but confused mixture. We give an example of the former mode in a plant: for if you give some plant a petrifying water drawn in as nourishment, then the petrific juice must also at the same time be drawn in, whereupon the plant turns entirely to stone. But if the juice has not been mixed with the water but only confused with it, then the plant, avoiding the juice and drawing in only the water, will never turn to stone, but will only clothe its stem with a stony covering.

All of this I learned by experience on my journey through Etruria. There, near the town of Roncolano [Roncolano] in the territory of Siena [Senense], I observed two hot springs, whose water was carried through channels to turn millstones. In these channels, sedge, rushes, buttercup [ranunculus], and similar herbs grew up with such fertility that every year they had to be rooted out lest they disturb the motion of the water. And once rooted out and thrown into a neighboring spot, I beheld, not without astonishment, all those herbs turned to stone.

[Margin (p. 250): An observation on the petrifying nature of herbs.]

When I asked the millers the cause of this, they answered that waters of this sort have the virtue that whatever herbs have grown up among the channels, or in

the water itself, turn to stone as soon as they are rooted out; but whatever herbs have grown outside the water, in the open fields, never turn to stone once rooted out. The cause of this can be none other than the following. Since with waters of this sort the stony juice — or petrific spirit — is intimately mingled, and the herbs draw in, as nourishment, the water swollen with this spirit, it necessarily comes about that the herbs, as long as they are nourished by this moisture, cannot turn to stone; but as soon as they are deprived of it, then the moisture of the petrific juice, drawn into the herbs and left, as it were, to its own liberty within them, gradually drying out, by the inborn proneness of nature, is at last converted into that from which it first proceeds — that is, into a stony substance, similar to the one from which it took its origin. This is a manifest sign of a perfect mixture with the water.

[Margin (p. 250): Why herbs do not turn to stone while they are in the water.]

But waters which are mixed with a petrific juice or spirit of this sort not perfectly but by a certain confused manner do not turn to stone throughout their whole substance, but are only coated as it were with a certain stony crust. There is in Etruria, near the Castle which takes its name from a Hill [a castle called "del Colle"], a very limpid little river, which, a short distance after its source, flows down into a torrent commonly called the Sena. This torrent gushes forth with a stone pregnant with a certain petrific spirit. Hence the little river, as soon as it is mingled with it, is at once imbued with the petrifying quality. Indeed, all things that remain in that water — such as wood, herbs, fronds, and the like — do not turn to stone, but are merely coated with a stony crust, the substance of the wood and herbs remaining intact. This indicates that the petrific juice is mixed with waters not perfectly but, as we said, only confusedly. But on this marvelous petrefactive quality, fuller occasion for discussion will be given in the following [Book], in the chapter on petrifications [Cap. de impetritis].

§. VIII. De Aquis metallicis.

(On metallic waters.)

Waters are called metallic which exhibit the properties of gold, silver, copper [aes], iron, tin, and lead. But whether metals can be truly and properly mixed with waters is a matter of great controversy among the metalloscopist philosophers [Philosophi Metalloscopi — those who investigate metals]. The principal ground of the negative opinion is this: first, that on account of their indomitable hardness they cannot perfectly communicate themselves to waters;

for if you were to keep cold water for even a hundred years in a golden, silver, or leaden cup, etc., you would still find no indication of any mixture.

[Margin (p. 250): Metallic waters.]

But we subscribe to the affirmative opinion. As regards gold, it is certain that it undergoes some mixture with the liquor — if not a perfect one, at least a confused one. This is plain from strong waters [aquae fortes], in which gold is wholly resolved into imperceptible atoms; and plain too in chalybeate and iron waters [aquae chalybatae et ferratae], which are imbued with the virtues of iron or steel, most wholesome for hypochondriac obstructions. Let us therefore explain how waters can be mixed with metals.

I say that metals which are solid and already brought to perfection by the purgation and refining of fire scarcely — if at all — admit any mixture with waters, unless decoction is applied. For by this means the metallic spirits are roused and communicate themselves in some way to the waters, as experience teaches in chalybeate waters. Secondly: since in the subterranean veins metals are not so solid and hard, and do not have their due perfection — being still endowed with much moisture, and soft after the manner of earthy clods — it can happen from time to time that, with caustic waters flowing in, the gold-bearing spirits are separated, and together with the scraped-off particles of gold, as soon as they insinuate themselves into the hot waters, communicate to them by some mixture, of whatever quality it may finally be, their own virtue. And in this way I judge that the Baths of Bipera [Thermae Biperinae] in Helvetia, and any others found elsewhere, possess the faculty of gold.

[Margin (p. 250): Whether gold can be mixed with waters.]

Since in some places silver thermal springs are found, it may reasonably be asked whether silver can truly be mixed with waters. Fallopius denies that it can be mixed with waters, on account of the supreme viscosity and hardness it possesses. We say that cold waters — or those which from time to time flow together after the manner of streams in silver mines — are incapable of mixture; but if the silver spirits, dissolved in their proper veins by the heat of subterranean fire or by the virtue of caustic waters, are mingled with thermal waters, I have no doubt that these too are tinged with the virtue specific to silver. And silver reduced to a calx and mixed with water, [I have no doubt, abundantly]

[Margin (p. 250): Whether silver can be mixed with waters.]

[§. VIII continued:] proves it more than sufficiently. But of these things more in the chapter on silver and its tincture.

Whatever has been said of gold-bearing and silver waters is likewise to be said, in the same way, of waters bearing brass [aeratae], iron [ferratae], tin [stanneae], and lead [plumbeae]. These, as has been said, are not mixed with any waters as to their substance, but as to the power communicated by the spirits existing in them. For thermal lead-waters [thermae plumbales], which are found here and there in Germany and Lorraine [Lotharingia], are not called "leaden" from lead because traces of leaden substance are found in them, but because they exhibit the power and property of lead — and thus contribute greatly to driving off Saturnine diseases [Saturnini morbi — disorders associated with lead, the metal of Saturn]. To which is added that, the softer the metals are, the more easily they communicate their power to the waters. And let this suffice concerning the mixtures of waters.

[Margin (p. 251): On lead-waters in Germany and Lorraine.]

CAPUT IV.

De Mixtura Aquarum Medicatarum

ID EST, Quomodo et qua industria, quatenus Mineralia ac Metallica corpora cuivis Aquae medicatae insint, per varia Experimenta cognosci possit. (*On the Mixture of Medicated Waters — that is, by what means and what skill it can be recognized, through various experiments, which Minerals and Metallic bodies are present in any given medicated water.*)

It is indeed a matter of great moment in medical practice to pass an exact judgment about medicated waters, since on this depends the whole well-being of the sick who use them. And although many writers have prescribed various ways of recognizing them, it has nevertheless seemed good to me to set down here some new experiments, not observed by others, so that on this point our reader may find nothing in this subject not most exactly discussed on every side.

[Margin (p. 251): Of great moment is the knowledge of what each medicated water contains as its mixture.]

Now since the virtues and properties of thermal waters consist especially in that tempering which the waters themselves have acquired from the mixtures of earthy clods and minerals, the first method of recognizing the mixtures must be by way of experiment, together with an exact knowledge of minerals — a method

that must necessarily be ready at hand for anyone approaching this Corinth [adeunti Corinthum — alluding to the proverb "not everyone may go to Corinth," i.e. this is no easy undertaking]. The method is accomplished in a twofold way. The first is carried out by the whole ministry of the senses; the other — which natural philosophers call *a posteriori* — is gathered from the quality of the residues that the channels leave behind them. We shall set forth both in a few words.

[Margin (p. 251): The virtues of waters must be sought by sense and by reason.]

There is implanted in the nature of human beings a power of knowing from things evidently apparent and sensible, through which they not only track down the causes of things but seem plainly to know them, when reason agrees with the senses. Therefore the substance of waters whose mixture — and consequently nature and property — you desire to know must be explored: namely, how much it seems to differ from simple water in weight, color, taste, odor, and finally the quality of touch. This substance for the most part prides itself in a twofold endowment. One is elemental, by which each thing operates by its qualities — hot, cold, dry, moist; the other is specific, which some also call celestial, superior to all the powers of the elements and to all the conjectures of the senses, inasmuch as it betrays itself only in marvelous effects.

[Margin (p. 251): The virtues of things [are known] by sense and by reason. The specific virtues of things.]

If [this specific virtue manifests itself] in any class of mixed things, it certainly exerts itself most of all in medicated waters, as will afterward be shown; and indeed it extends so far that — not to say any [mineral] spring, but not even a simple-water spring — can be met with which some ray of celestial favor has not breathed upon and endowed with some singular benefit. Yet the investigation of these is the more difficult, the more inaccessible are the inmost chambers of their causes. Added to this is a certain infinite variety of the mixtures shining forth in waters, in which — just as the faculties do not consist of one single degree, nor have the same efficacy in one spring as in another — so the difficulties are doubled.

Physicians, for the most part content with the knowledge of the primary qualities, distributing the use of the discipline through certain degrees, as it were, of heat — from the first to the second, from the second to the third, and thence to the fourth — estimate by a quite fallacious conjecture to what action and efficacy each one attains. Then, having learned the connection of the primary qualities

among themselves, they proceed in the order of nature to the compound and consequent operations: namely the effects of heating waters — rarefaction, fusion, digestion, and attenuation; of moistening waters — softening and soothing; of cooling waters — repletion and distension; and finally of drying waters — astringency and condensation, and other such things, they investigate.

[Margin (p. 251): The difficulty of estimating the virtues of waters. The degrees in the powers of waters.]

From these, finally, they proceed to the third class of operations — those, namely, which result from the secondary qualities among themselves and from the virtue of the primary ones — which, taken inwardly, cleanse, lubricate, loosen the bowels, provoke vomiting, and stir up the viscera of the body by similar means. Thence, advanced to the fourth class of operations, they discover indeed notable powers; but on account of hidden reasons and the almost inexplicable connection of the parts, [a power] deduced from a likeness of the whole substance, scarcely thus far — except by a few, whom Divine Goodness with excel-

[whom Divine Goodness has endowed by their] surpassing subtlety of mind with knowledge of them. Of this kind are the waters whose powers operate through the hidden signatures of nature. [Margin: The wondrous effects of certain waters.] Some of these break up stones in the bladder and kidneys; some cure epilepsy; by some occult property others act on particular organs; some induce madness, bring on forgetfulness, and dull the wits; some provoke sneezing, hasten baldness, draw tears, and stir laughter; still others make women who suffer from sterility fertile. To this same class we may refer all waters of a deadly quality. The reasons for these effects I shall set out, God willing, in what follows, so far as the weakness of my own understanding will allow.

This, then, is the procedure physicians usually follow. But amid the great perplexities of the physicians one must hold fast to some sure rule that sheds undoubted light on the matter. Most of the Peripatetic philosophers attach great weight to sense-experience. By touch they classify waters as hot and cold; by weight as light and heavy; by taste as sweet, bitter, acid, or sharp; [Margin: Knowledge by the primary qualities is not sufficient.] by color as clear, turbid, blue, bright, black, and tinged with various other colors; by smell as sulphurous, bituminous, and the like, of a most fetid stench. Yet no one should follow this as a sure and infallible rule. For although many waters can be recognized by their color, we still cannot be certain whether the color derives from one mineral mixture rather than another — there are many substances that tint water with a similar color. [Margin: The intimate qualities are to be known.] If you consult the

taste and detect a certain sharpness, you still cannot tell whether it derives from salt, from alum, from niter, or from vitriol, or from all of these mixed together, unless you look into their inmost properties. For although they all bite the tongue with their sharpness, they must be distinguished by the differing faculties they possess. Salt waters, when drunk, strengthen the stomach, whereas nitrous waters by contrast upset the stomach and rather forcefully stir up phlegmatic humors. The former make the hands rough after washing in them; the latter, by their detergent or cleansing power, leave them smooth and soft. But just as the judgment from roughness is deceptive here — since many minerals roughen the hands by their washing — so too the softness and smoothness of the hands that niter produces by its cleansing power belongs to many other substances as well, such as lime, ash, and lyes. Aluminous water is told not by smell but by taste: it has an astringent power without bitterness, yet it bites the tongue and palate remarkably and sets the teeth on edge. But since many other substances produce the same effects, no firm judgment can be formed from them either. Vitriolic and bituminous waters are recognized by taste and smell: the taste strikes the tongue with a certain sharpness, the smell with a most foul stench. And so, unless waters are recognized from the whole complex of qualities proper to each thing mixable with them,

EXPERIMENT I.

To recognize the mixture of waters by boiling.

Take a glass vessel, or at least an earthenware one coated with glass inside. In this vessel let medicated water — of whatever kind it may be — be boiled down to the consumption of a third part, then let it stand for three days, until it is separated from all its dregs, leaving only the sediment. But take care not to move the vessel in any direction, for in that way the dregs would be mixed up again; and by this care the water will be separated from the dregs that have settled.

[Margin: A method of recognizing the mixture of waters by experiment.] Take from a coarser filter a cloth, which you will fashion with scissors into the shape of an inverted pyramid; dip the apex of this for some distance into the boiled water, but let the remaining end of the cloth, wetted beforehand, hang outside the vessel. In this way it will come about that the wetted end hanging outside draws the water up the other end of the filter, which we immersed in the water, and so the whole and only the water will gradually pass of its own accord through the run of the filter outside the vessel, with the sediment alone remaining behind. This sediment, exposed to the rays of the sun, will soon reveal the various mineral admixtures, in the manner to be explained a little later.

EXPERIMENT II.

To recognize the mixture of waters by evaporation.

Take a glass vessel with a widely open mouth, of the kind that urinals usually are, coated with a lute made of flour and egg-white according to the rules of the art. Let this be immersed up to its middle in another earthenware vessel filled with sand, and being filled with medicated water, together with the earthen[ware vessel]...

[continuation on p. 253, second part — Experiment III] ...[let it be set] either in the sun, or in some other warm place not exposed to any powders, with the mouth open during the day, but at night or when the sky is rather cold, lest through lack of heat any separation occur. Once the water has been evaporated by this means, let the dregs or sediment be dried in the sun, and you will gather a mixture from the scrapings of the various minerals, as we shall explain later. This experiment has this attendant difficulty: that along with the water a great quantity of the mineral spirits also flies off — which does not happen in the preceding experiment.

EXPERIMENT III.

Chemical.

To recognize the mixture of waters by distillation.

I shall set down here the most certain and reliable experiment of all, by which not only the particles of the individual minerals mixed into the waters, but also the spirits and vapors dominant in them are discerned by a truly fine method and by the infallible balance of judgment. Proceed as follows.

Diagram. A distillation apparatus for the chemical analysis of medicated waters. At the lower part is a cylindrical brick furnace (A) with a draft-hole or vent at its base. Standing within the furnace is a sand-bath vessel; above it sits a flask containing the medicated water, surmounted by an alembic head whose beak conducts the distillate through a tube. The tube passes through a wooden cooling-vessel filled with cold water, and the condensed water with its spirits descends into two receiving flasks at the right, set on a bench. The figure carries the letter-labels keyed to the text below.

- A (lower body of the furnace): the furnace itself, with its fire-chamber and a small arched stoke-hole at front

- B (lower left of furnace): the draft-hole or air-vent that animates the fire
- C D E F (mouth of the furnace / sand-bath): the earthenware vessel set immediately over the fire, filled with sand
- G H (within the sand-bath): the vessel holding the medicated water
- I (upper, the still-head): the alembic head ("capitellum") fitted over vessel G
- K (the beak/spout of the still-head, "nasus")
- L (the bend of the conducting tube)
- L M (the run of the glass tube carrying the vapor onward)
- N (the wooden cooling-vessel filled with cold water, through which the tube passes)
- O, P (the two openings of vessel N, tightly closed)
- M (the receiving flask at the right, into which the condensate descends)

Proceed thus. With the little furnace A prepared, its fire animated by the draft-hole B, into its cavity let there be placed an earthenware vessel C D E F, filled with sand up to a certain point; into this sand let there be immersed, up to its middle, another vessel of narrower neck, which we have marked with the letters G H, filled with medicated water. Over this let there be set the still-head I, fitted with a beak K, joined to vessel G at the point H with lute and bandages, so that nothing can escape from it. Into the beak K of the still-head I let another glass tube be inserted at L, sealed with the same care, so that nothing can evaporate from there either. Finally let this tube L M pass through a wooden vessel N filled with cold water; and with both openings O and P of vessel N exactly closed, you will have everything prepared for investigating the mixtures of the waters. For the fire kindled in the furnace A, once the sand of the vessel C D E F (which is set immediately over the fire) has been heated, will heat the medicated water enclosed in vessel G; whereupon the water, thinned into vapors, as soon as it has entered the still-head I, will be condensed by the cold into water,

EXPERIMENT IV.

How it may be discovered that a metallic tincture is present in medicated waters.

Since metallic species can be recognized only from the corruption of the sediment — so that any metal present in the waters is turned into its own characteristic residue, from which it is then known that this or that metal is present, and in this way iron, silver, gold, chrysocola [borax/copper-green], copper, and the like become known — and since, to make each of the enumerated metals turn into its

own residue, a certain medicament is needed, that is, a corroding liquid, such as the corroding waters of the chemists [aquae erodentes] or the strongest and sharpest vinegar: the method of proceeding is as follows. Let the metallic sediment of the water be poured into the said vinegar, or into water endowed with caustic power; and once you have inspected the water, if you observe that a rust has formed upon the sediment, you may be sure that the medicated [Margin: A method of recognizing whether metals are present in the waters.]

CAPUT V.

Description of the Hydrometer

By which the heaviness and lightness of waters is investigated.

A German craftsman, Johannes Toldenus [Johann Tölde], once used a similar instrument for the mixture of salt water, and from him Cabeus [Niccolò Cabeo] received it. But since there has scarcely been anyone who rightly understood its principle, I shall teach here, with all the brevity I can, the manner of constructing it. Its use is only in those waters that have something salty mixed in, and also in investigating the lightness or heaviness of fresh waters, arising from whatever cause.

[Margin: Construction of the hydrometer.] 1. Let there be made a glass phial, paunchy in the manner of a sphere, with a very thin neck, which nevertheless should not exceed a hand's-breadth in length. In the center of its base insert a hook, from which you may hang a weight when needed, and you will have the instrument ready. Its figure is A B.

Diagram. A graduated glass hydrometer in the shape of a wide-mouthed goblet — a bulbous phial with a very thin neck rising up its center, a small bulb at the bottom of the neck, and a hook below for hanging a weight. The central neck-tube is divided into graduations marked with a sequence of letters from top to bottom.

- A (top of the central neck): the mouth/top of the graduated tube
- (descending the neck, the graduation marks lettered in sequence): d, e, f, g, h, i, k, l, m, n, o, p, q, r [the small graduation letters read top-to-bottom; lower letters faint — q, r [?]]
- B (the bulb at the foot of the neck): the spherical body/float
- C (below B, at the hook): the point where the weight is appended

2. Choose for yourself, as far as you can, the clearest water, thoroughly cleansed of all the dross of salt and earthy impurity. Immerse the phial in this water; this will be done if you always pour the water into it little by little, until, by sinking beneath the water, it leaves only the mouth A uncovered. This done, weigh as exactly as possible the whole of the water contained within the phial, and whatever weight the water weighs, that much weight you will hang on the hook at the bottom of the phial at point C. Then you will divide the neck or tube N A into its degrees by this method.
3. Take a basin, as capacious as possible, which you will fill with the purest water, as before, and whose bottom should be a little deeper than the length or height of the phial C A. Weigh this water beforehand as exactly as possible — for in this lies the whole crux of the business — and let it be, for example, 100 pounds. And since one pound consists of 12 ounces, 12 multiplied into 100 gives 1200 ounces of water.
4. This too being done, take a quantity of the best-prepared salt, dried and reduced to the finest powder, suited to the operation about to follow. From this salt set aside ounce-portions in proportion to the water just weighed — that is, first weigh out one pound of salt in a balance, placing the water in one pan and the salt in the other, until they balance; then likewise weigh one ounce of water against one ounce of salt; finally set aside separately as many ounces of salt as you judge you will need in the operation. With these things set out, you will begin the graduation of the phial thus.
5. Place the phial A C, fitted with its weight C, into the basin, and it will be submerged, according to the second operation, up to the mouth. This done, throw into the basin's water 1 ounce of the salt set aside, and when it has mixed, it will make the water heavier, whereupon the phial, lifted, will rise somewhat — for example, to d; mark that point carefully. [Margin: A method of graduating the phial by the lightness and heaviness of the water.] Again throw another ounce of salt into the basin's water, and the phial will rise higher — for example, to e; mark that point. Then again throw another ounce of salt into the basin's water, and the phial will rise to f; mark that point likewise. And in this way you will always throw further ounces, one after another, into the water, until the phial has emerged with its whole neck, marking with particular care the points where the neck touches the water; and with the several points assigned their numbers in order, you will have the instrument prepared — whose mouth had to be closed at first, lest any water penetrate.

Use of the Instrument.

If you wish to know how much salt any salt water — whether it be sea water or spring water — has mixed in it: then immerse the phial together with its weight in it, and at once the point where the water touches the neck of the phial will show in numbers the quantity of the salt mixture contained within the salt water, of a bulk as great as the water of the basin was, and of a weight as great as the said water weighed. For what [holds] of a fixed and determined weight of any...

COROLLARY.

From this you will learn, first, how much excess or deficiency of salt a salt medicated water has. Second, given a hundred pounds of water of this kind, you will know how much salt you can extract from it. Third, whether sea water is saltier than spring water, or the contrary. Fourth, from this you will learn, given whatever sweet and drinkable waters, how much one is lighter than another: for that one will be lighter in which the phial has sunk more deeply, and heavier the one in which it has risen higher. [Margin: The heavier the water, the more easily a body settles in it; the heavier, the more difficultly.] For the heavier the water, the more the phial will sink; and the lighter it is, the less it will resist the sinking body. For the heaviness of drinkable waters depends on the quantity of salt mixed into them, which, though it may deceive the taste — since one does not perceive the salt mixture — nevertheless cannot deceive our instrument.

Another Hydrometric Instrument.

Diagram. A glass-tube hydrometer of the form described, marked A B C. It is a long, narrow graduated tube (open at the top at A, neck A B divided into parts numbered 80, 70, 60, 50, 40, 30, 20, 10 descending), terminating below in a large spherical float B, beneath which hangs a small bulb C marked with the alchemical symbol for mercury (☿, argentum vivum / quicksilver), into which the mercury is poured.

- A (top of the divided neck): the open mouth
- (neck graduations, descending): 80, 70, 60, 50, 40, 30, 20, 10
- B (the large lower sphere): the major globe/float
- C (the small bulb below B): the globule into which quicksilver is added
- D E (marks low on the neck, just above the float): the depth-marks to which the tube is to be submerged

Let there be made a glass tube of the form you see here, and let it be marked A B C. Let this tube be open at A, its neck A B divided into any number of parts you like. Into this tube you will pour quicksilver [argenteum vivum, mercury], until you see the globe B sink beneath the water. But if the quicksilver should depress the whole hydrometer by its weight to the bottom, then you will always pour in less quicksilver, until — with the smaller globule C, affixed to the larger globe B, filled — you will keep on thinning [the charge] until the whole globe is submerged beneath the water down to D E, and you will have the hydrometer ready for weighing and testing water. But you should first test this in the lightest water; for if the hydrometer is placed in somewhat subtler water, it will be submerged still further — and indeed the deeper, the subtler the water is — and at the same time it will show on the neck the differences of heaviness and lightness. The quicksilver serves no other purpose than to keep the instrument always at equilibrium within the water.

EXPERIMENT.

Raphael Magiottus [Raffaello Magiotti], a most distinguished mathematician, in his little book *On the Heaviness of Waters by Compression* [*De renisu aquarum per compressionem*], devised something of this kind for investigating the heaviness and lightness of waters. A latticework cylinder is constructed of brass wires, conical in the form of a cage, or rather of a fisherman's creel, as appears in the present figure. Within this cage let there be placed several glass globules, perforated underneath, whose size is in arithmetical proportion.

Diagram. Magiotti's instrument: a domed, beehive-shaped wire cage (a latticework conical cylinder, like a fisherman's creel) standing on a flared base, with a ring at the top for lifting. Inside, several small glass globules are visible suspended at a level within the cage. The figure is uncaptioned and carries no letter-labels.

Into these globules thus arrayed [the creel], immerse the cage equipped with such globules into waters of differing heaviness, and the more globules rise upward, the heavier the water is in kind; the more it is lighter, the fewer rise; lightest of all when none rises. But an experiment of this sort has its own difficulties; wherefore we find the preceding instrument both more apt for use and subject to no errors. Others place an egg in the waters: if the water is of a heavier condition, it will float; if of a lighter, it sinks. But neither does this determine the precise difference of waters.

[Margin: Another hydrometric instrument.]

[Margin: Another method, used by the Grand Duke of Tuscany.] The Most Serene Grand Duke of Tuscany, Ferdinand II [Ferdinando II de' Medici], showed me another way of investigating the goodness and badness of waters, and it is as follows. He set out in order, in glass cups, waters of every kind fit for drinking — spring, river, well, lake, and the like. Then in a certain glass vessel he kept another liquid, which he poured into the glass cups set out in order; and at once, in waters of poorer condition, the water would be seen to turn to a dusky color, and in the worst even to black, whereas in the purest water it produced no change at all. From this one could at once gather the cause of so sudden an alteration: for since in the purest water there is scarcely any mineral admixture present, the liquid...

[The continuation of the preceding chapter (Caput V), which discusses the precipitation of liquids into other liquids — by which precipitation waters are turned now into a milky color, now into red, now into blue, green, purple, and similar colors.]

it could not find anything on which to act. But in the remaining waters, which were imbued with some admixture of the said mineral species, the liquid, once poured in, acted upon the various waters just as it acted upon the mixture native to it, and so likewise produced the necessary change. But just what this liquid was will be told in the following books. [Margin: The precipitation devised by chemistry.]

[Margin: See on the precipitation of liquids, where you will find certain remarkable secrets, in the Corollary, the Reader.]

CAPUT VI.

On the heat and warmth of the thermal springs and its cause, and how they are blended from minerals of such differing tincture.

Since in the preceding book, *On Subterranean Fire*, we discussed this subject most fully, nothing remains here except to lay out the knot of the matter: how the thermal waters are heated, and how they come to be steeped in so many and such great differing properties. Experience establishes that some thermal springs are cold, some lukewarm, and some so boiling hot — yet still bearable to the touch — while others seethe so violently that they instantly strip the flesh, pulp, and bones from the bodies of animals thrown into them, and consume them utterly.

[Margin: The varied differences in warmth of the hot waters.] One asks the cause.

I answer briefly, then, that all of this depends on the situation of the fire-chambers [pyrophylacia]. For if some Vulcanian workshop is placed immediately beneath the cauldron of the waters — that is, beneath the water-reservoirs [hydrophylacia] — I say that, on account of its nearness to the seething fires, which continually breathe out from the fire-chamber A through channel A B, the waters contained in basin B will take on the highest degree of heat, as happens at the Bullicame near Viterbo [Bullicame Viterbiense]. But if the said exhalations make their way through the fire-conducting channel [canalis pyragogus] L R S into the water-reservoir V, the increase of heat will likewise be less in the thermal water S, and less in W, and least in X and the adjacent thermal springs, until they are so far removed from A that, at last wholly stripped of heat, they grow cold. The same is to be said of the fire-conducting channel D G H, through which the fiery spirits, passing across, discharge themselves into the water in which it is mediately laid beneath the channel L. It is no wonder that this water should seethe. But B, since it is farther from the fire-chamber P, has this result: that as the heat gradually slackens, the water grows cold — especially if the channel V has approached through the cold waters of the water-reservoir X. For in this way, in the spring B, it will discharge itself with a notable sensation of cold. It can also happen that the cold water from some other recess Z discharges itself into B without any access of more distant fire.

Here I cannot pass over what is being reported to me as I write this. In the year 1660, in the month of June, when a vast earthquake afflicted that whole region of France that extends from the city of Bordeaux [Burdigala] toward Narbonne — [Margin: History of a terrible earthquake.] there was near Bigorre [Bigornium] a vast and lofty mountain which, by the force of raging nature, is said to have been so swallowed up that, apart from the huge lake it left behind, no further trace of it appeared. They add that the district around the Pyrenees mountains had been thickly furnished with many thermal springs; and that in one set of these, after the collapse of the mountain, waters that had previously been most fiercely boiling drew on so much cold that no one could any longer use them. The question is asked: whence that violent change of boiling waters into the coldest ones? I say that the fire-conducting channel was blocked by the fall of the mountain, and opened another channel which conducted cold waters; or, if not this, then that the waters, deprived of all heat once supplied through the fire-channel, finally passed over into their native cold.

Diagram. A large cross-sectional view of a subterranean region, drawn as a mountainous tract cut away to reveal the underground network of fire-chambers (pyrophylacia) and water-reservoirs (hydrophylacia) and their connecting

channels. At lower center the great fire-chamber A blazes; from it fire-conducting channels branch out across the section — the principal ones lettered, with reservoirs and thermal outlets distributed through the body of the earth and discharging at surface springs marked *Thermae* at the right and lower right.

vessels E, F, H, G, I — fitted with channels and filled with water. Experience teaches that the waters of the said vessels, as soon as the vaporous spirits of the seething fire reach their concave interiors, are warmed by them, and indeed all the more effectively the nearer they are to the furnace. In this way F and G will seethe more than H and I, and E most of all. All of this experience has taught me in the chemical furnaces, of which I treat expressly in the seventh book. That the same thing occurs within the earth was clear from the preceding experiment. It is therefore no wonder that some thermal springs are nearly cold, others lukewarm, and some most fiercely seething — the reason for which is plain from what has been said.

Diagram. An apparatus illustrating how vessels of water set at increasing distances from a furnace are heated to differing degrees. At the base stands the furnace **A**, its fire visible at the mouth. From its dome the vapor rises through point **D** into the bulbous head **E** above; from the lower part of the furnace a horizontal channel runs out from **C**, passing through a series of round-bottomed vessels **F**, then **H**, and on toward **I** — each successive vessel farther from the heat source and thus less strongly heated.

- **A** (base): the furnace [fornax], with fire at its mouth
- **C** (lower left of furnace): junction where the horizontal channel leaves the furnace
- **D** (above furnace dome): vapor passage upward
- **E** (top): the bulbous distilling head / vessel directly above the fire (heated most)
- **F** (right of **C**, first vessel): round-bottomed vessel
- **H** (farther right, second vessel): round-bottomed vessel
- **I** (far right): the most distant vessel (heated least)
- [The companion labels **G** are paired with **F/H** in the text; the figure shows the lettered series **E, F, H, G, I** as the channel runs out]

COROLLARIUM.

From what has been said it is also clear why in some waters springs are found of which one is the coldest and the other the most boiling hot. The channel of the colder water is farther from the fire than the other, hotter one. Moreover, it happens that the water-conducting channel [hydragogus] sometimes runs on through another cold water, and, the heat being thus extinguished, afterward pours out cold waters.

Let there be two springs **A** and **B**; let **A** be hot and **B** cold — just as in the territory of Viterbo [Ager Viterbiensis] I recall having observed them, no more than two palms' span apart. For since the fire **S**...

Diagram. A cutaway of a hillside showing two surface springs very close together — one hot, one cold — and the underground channels that account for the difference. At the left, near the surface, the fire-chamber **S** burns; its heat reaches the channel feeding the **hot spring** (labeled *Calidus fons*) at **A**, while the neighboring **cold spring** (*Frigidus fons*) at **B** is fed by a channel that runs down from a far reservoir at the upper right (point **Z**), passing through points **X** and **V** and emerging at the pebble-lined basin **P** at lower right, without taking on the fire's heat.

- A (upper left): the hot spring, captioned *Calidus fons* ("hot spring")
- B (upper center): the cold spring, captioned *Frigidus fons* ("cold spring")
- S (left, underground): the fire-chamber [pyrophylacium], shown as flames
- Z (upper right): the far reservoir feeding the cold channel
- X (right of center): channel point along the cold conduit
- V (lower right of center): channel point along the cold conduit
- P (lower right): the pebble-lined basin / outlet

is, I recall, only two palms' span distant; for since the fire S...

EXPERIMENTUM III.

Exhibiting the Mixture of Waters.

The mixture of waters is either simple or compound. It is simple when the water is mingled with only one of the minerals; compound, when with several. And the mixtures come about in the manner that follows.

From what has been set out above it is established that the earth teems with countless mineral species, so that one and the same combination of substances is never found in all places; rather, according to the variety of the differing veins, it is altogether manifold and beyond telling — with the exception, however, of sulphur and salt, which are absent from no waters, present in some with greater excess, in others with less. [Margin: The earth teems with countless mineral species.]

Now, just how mixtures of this kind come about in the subterranean womb of the Earth, I shall show by a geodetic example. Imagine, then, a vast district of the subterranean region divided by the courses of water-conducting channels [hydragogi] into various branches; within these the water runs down and is tinged by the filings and scrapings of various minerals, together with their properties. It is certain that there arises from this a vast medley of differing things and mixable species, which then, bursting out into a spring, reproduces the character of the very properties in which the species it was mixed with are strong. But let us demonstrate the matter by a model.

Diagram. A geodetic model of the subterranean water-distribution. At the center lies a single great water-source (the "hydraulicum") **A**, a roughly oval reservoir. From it channels radiate outward in all directions, each running through a vein of a particular mineral (the channel-courses are labeled with mineral names) and emerging at a peripheral spring lettered **B** through **H**. The surrounding terrain is drawn as ranges of hills.

- A (center): the central water-source [hydraulicum]
- B (lower right): a spring fed by a channel of plain (sandy/flinty) ground — yields *fresh* water
- C (upper right): spring on the *Sal* (salt) channel — yields salt water
- D (top): spring on the *Nitrum* (nitre) channel — yields nitrous water
- E (upper left): spring on the *Alumen* (alum) channel — yields aluminous water
- F (left): spring on the *Vitriolum* (vitriol) channel — yields vitriolic water
- G (lower left): spring on the *Ferrum* (iron) channel — yields chalybeate (iron) water
- H (bottom center): spring on the *Sulphur* (sulphur) channel — yields sulphurous water
- Channel labels (running across the section): *Alumen* (alum), *Vitriolum* (vitriol), *Nitrum* (nitre), *Sal* (salt), *Ferrum* (iron), *Sulphur* (sulphur), and a channel marked *Aqua dulcis* (fresh water)

Let there be some water-source A which bursts out in every direction, through the various passages of the Earth, into the various springs B, C, D, E, F, G. Now let the water pass through the passage or channel A B, which teems with gravel and sandy matter, or with very hard flints. I say that the spring B that issues from it will furnish fresh water, since the channel contains no matter, apart from those mentioned, that could tinge the water with some predominant mineral property. [Margin: The matter of some mineral tinges the water passing through it with the property in which it itself is strong.]

But let the water pass from A through channel A C, which is filled with salt: I say the spring C will be salty — that is, such as the vein is through which the brine passes. Again, let it go out from A through channel A D: I say the spring D will be nitrous, that is, tinged with nitre, by that property in which the channel it passes through, filled with nitre, is strong. And in the same way, if it has passed through A E into an aluminous vein, and through A F into a vitriolic one, and through A G into an iron-bearing one, and through A H into a sulphurous one, the springs E, F, G must likewise be steeped in that property in which the channels they pass through are strong.

You see, then, the source from which the simple mixture of medicated waters draws its origin — namely, from a simple vein of some mineral mixed with no other. From this it is also clear why sometimes, in one and the same place, medicated waters of differing properties are found gathered in different springs. So once, I recall, I saw at the town of Urb [Urbâ oppido — Orb (Urberach)?],

subject to the jurisdiction of the Elector of Mainz [Elector Moguntinus], six springs endowed with the most diverse properties, set no more than four paces apart from one another. The cause is that the water, as it passes through different channels filled with different mineral species, is tinged by them, and in the different springs displays such a property as the channel — that is, the ore — through which it passes presents.

You see, then, the mode of simple mixing. Let us now proceed to the compound. And first I would have you know that subterranean waters make their way not through a single water-conducting channel only, but — just as on the outer surface of the Earth some principal river is made up of various streams — so this underground flow is divided branch-wise into various streams of water and forks apart. These branches, just as they are tinged by the various species of the various minerals they pass through, are likewise, when they are channeled together into some single spring, filled with a manifold progeny of differing properties. [Margin: How the medicated waters come to be pregnant with so manifold a progeny of properties.]

To prove the matter by an example: from A, passing through the sulphurous channel H, the flow forks into K and I — there through a salt-bearing vein of the channel, here through a nitrous one. Hence the sulphurous matter of the channel...

[Margin: How a manifold mixture arises in the waters.]

channel H, mixed, will make with the channels K and I a mixture of salt — namely, and of nitre — yielding sulphureo-salt-nitrous waters. Again, channel K, forking into L and M, will, striking a vitriolic vein on the one side and an aluminous one on the other, produce in springs L and M (tinged by the confluence of the preceding waters) — in M indeed a sulphureo-salt-aluminous water, and in L a sulphureo-salt-vitriolic one.

Diagram. A larger, more elaborate geodetic model of the compound mixing of waters. A single source **A** at the left feeds a branching network of channels that fork and cross through veins of many different minerals (each channel-segment labeled with a mineral name) and finally gather into the great collecting spring **R** at the right, which thereby holds all the mineral species and properties combined. The terrain is drawn as encircling hill-ranges.

- A (left): the source [hydraulicum]
- H (center-left): the sulphurous main channel leaving A
- K (center): fork junction

- I (lower center-left): fork junction
- L (right of center): spring/junction (sulphureo-salt-vitriolic)
- M (center): spring/junction (sulphureo-salt-aluminous)
- N (center): junction
- O (center): junction
- P (upper center): junction
- S (lower center): junction
- T (lower center): junction
- R (right): the great collecting spring, holding all properties combined
- Channel/vein labels: *Sulphur* (sulphur), *Sal* (salt, appears twice), *Vitriolum* (vitriol), *Alumen* (alum), *Ferrum* (iron), *Nitrum* (nitre), *Aurum* (gold), *Bitumen* (bitumen), *Plumbum* (lead), *Cadmia* (cadmia / calamine), *Calx* (lime, appears twice), *Ochra* (ochre), *Aerarium* (copper-ore / "brass-vein")

vitriolic. Again, the subterranean stream L, forking, passing into an auriferous vein at L on one side at O, and into an iron-bearing vein at P on the other, will produce in spring P a sulphureo-salt-vitriolato-ferruginous water, and in spring O it will bring forth a sulphureo-salt-vitriolato-aureous mixture. And what is said of these is to be understood of all the remaining streams — K, M, N, and H, I, Z, S, T — until, all of them being channeled together into R, they constitute, out of all the minerals they pass through, the spring R, compounded of all the species and powers of minerals.

You will achieve the same by art as nature does, if you channel together the waters from some spring, through different channels, into some single spring. For if you fill the individual channels with different ores — salt, nitre, alum, bitumen, vitriol, and so forth — the water diffused through these channels and mingled with the minerals will at last constitute a spring stocked with all the said species. So that from this it may be plain even to the eye what art and industry nature shows in producing the mixtures of waters.

From this, too, the reason for the colors with which different waters are imbued is clear. For the water will take on such a color as the mineral clod is which it passes through [Margin: The waters take on the color of the mineral they pass through]: if yellow, yellow; if red, red; if black, black; blue if it is blue; green if green; and finally, if white, it will yield a milky color. Each single mineral will give its own color in the simple medicated waters, but in the compound ones a variegated mixture. But let this suffice concerning the mixtures of waters.

SECTIO III.

DISQUISITIO

DE THERMIS

And On Medicated Waters, and Their Marvelous Powers and Properties in Particular — All of Which Are Shown to Take Their Origin from Subterranean Sources.

CAPUT I.

On the principal thermal springs, or medicated waters, that occur here and there on the surface of the Geocosm.

Since the diversity and variety of the mineral bodies of the earthly clods is not better understood than through the diversity of the medicated waters which nature everywhere produces, I judged that it would certainly be worth my while if, in this place,...[the principal...] ...of the more celebrated thermal springs, leaving out countless others that have not come to my notice, I might attach a catalog. For from this it will become plainly evident, beyond what we have already so laboriously demonstrated in the preceding pages: **First**, that there exists a certain perennial subterranean fire which, by its heat, suffuses such an innumerable multitude of thermal springs, and that this fire holds dominion over the Earth. **Second**, that there are likewise innumerable subterranean reservoirs of water [hydrophylacia], which—heated by that inseparable companion, the fire—break out everywhere throughout the body of the Earth, which is everywhere pierced by channels both for conducting water [hydragogis] and for conducting fire [pyragogis]; exactly as the human body, a microcosm, is pierced by the innumerable ducts of veins and arteries and by the recesses of its principal members. In this the wonderful, ineffable, and incomprehensible variety of all things—a variety hidden within minerals—shines forth most especially. And just as these things everywhere present themselves to view, so they display a certain marvelous administration of the subterranean economy. With these points established, let us now at last take up again the web we have begun.

§ I.

On the Thermal Springs of Europe, and first on the Springs and Thermal Waters of Portugal and Spain

Europe contains Portugal [Lusitania], Spain, France [Gallia], Italy, Germany, Hungary, Poland, Illyricum, and Greece, together with the adjacent islands of Sicily, England, Scotland, and Ireland [Hybernia]—all of them everywhere packed with innumerable thermal springs, as will be clear from what follows. In Portugal there are 8; in Spain 40; in France 45; in Germany 120; in Italy 86; in Hungary and its neighboring places 9; in Poland near the Carpathians several; in Illyricum 16; in Greece and its neighboring islands 22—all of which correspond to one another through the hidden passages of the earth, and are animated and preserved by one and the same fire distributed through its various fire-reservoirs [pyrophylacia], exactly as in the human body the animal heat, through diverse channels and the branching ducts of the veins, animates, directs, and stirs all things toward the effects intended by nature.

And to begin with the thermal springs of Portugal, let the reader know that nearly all the islands of the Atlantic Sea—such as the Canaries, the Madeiras, and those they call the Azores—are most abundantly stocked with thermal springs, as the annual reports of our Society [the Jesuits] amply attest. Nor is this surprising, since they are rich in the most copious sulphur, salt, niter, alum, and bitumen, and nourish enormous fire-reservoirs beneath them, by which they are perpetually agitated. But on these matters see the fuller account in the preceding pages, and likewise what was treated in our *Itinerarium Submarinum* [*Submarine Itinerary*].

Among the other marvels of Portugal there is, first of all, that wonderful lake admirable on the summit of Mount Erminius [Serra da Estrela], which, as Antonio Vasconcellos [António de Vasconcelos] testifies in his *Descriptio Lusitaniae*, is theologian of our Society, is of such a nature that when the Ocean swells, it too swells and heaves up at the same time—a clear sign that it is connected to the Ocean by hidden water-conducting passages. [Margin: Mount Erminius in Portugal always heaves.] The same may be said of the wonderful well next to the Monastery of St. Jerome, cut entirely with cells and dwellings into the living rock on Mount Sintra, in which the waters swell at the rising of the sea. Only the lake of Interamna [Lamego region?] in Portugal is no more than 18 leagues long, as Vasconcellos again testifies, and contains twenty-five thousand perennial springs—an abundance comparable to none in Europe. [Margin: 25

thousand springs in Portugal.] For they have wonderful powers on account of the golden sands that the Tagus pours forth, and it shares these riches with the neighboring lands on every side. [Margin: The gold-bearing Tagus.] Among these, too, there are many thermal springs, noted by name throughout all Portugal for the celebrity of their fame. [Margin: Thermal springs of Portugal.] Such are the Caldas near Óbidos, memorable for the hospital [Xenodochium] built for the use of the sick by Eleanor [Leonor], wife of King John II [João II]. Next come the Baths of the Algarves [Algarbii] near the town of Alvor, in which King John II is said to have perished while seeking a remedy for a lethal poison. [Margin: Thermal springs of the Algarves.] But leaving aside the others—those in Beira and in the Convent of Lafões, and still others met with here and there—one prodigy must be set forth in this place, which shines out in a spring four leagues from Coimbra [Conimbrica], near the towns of Cantanhede [Cutanhedum] and Cadima. The spring is no more than a foot deep, sandy and somewhat turbid, called in the vernacular *Fervenças*, so named from the perpetual boiling of its waters and sands, by which it seethes. Its nature is such that whatever you throw into it, it swallows up; and it cannot sufficiently be made apparent where it rolls away the tree-branches thrown into it, since more than once a whole tree, applied for the sake of experiment either by its lowest roots or only by its topmost foliage, has been so greedily devoured by the trunk or by any branch whatever that it could not be torn out by any force, and within a brief space of time not even the tiniest twig appeared. [Margin: Marvelous properties of the spring.] It also happened that when a pack-animal's foot slipped, the water in a brief space so powerfully drew the beast to itself that it could scarcely be dragged away by any skill or strength from the force of the devouring water. This is from Vasconcellos, whose explanation we shall disclose in what follows, in the section on miraculous springs.

The chief thermal springs of Spain are the *Caldas del Rey*—so the village is called, beside which they boil up; situated beside the road that leads from Compostela [Santiago de Compostela] into Portugal, it is renowned for the distinction of its baths, of a warming and digesting power. [Margin: Thermal springs of Spain.] From here, at the town of Tralus [Caldas de Reis area?], 30 stadia distant, another most celebrated bath occurs, of all the greater usefulness in that, owing to the natural mixing here and the confluence of various springs, each person can prepare and temper the waters at his own discretion: they warm, dry, and digest. Again, beside the city of Orense [Ourense] there bubbles up a water hot and exceedingly rich in a vein of cinnabar [minium]; and although it smells somewhat of sulphur, yet when it has cooled... [Margin: Thermal springs rich in cinnabar.]

[printed p. 261 — header "DE THERMIS"]

and settled, it presents itself so pure, clear, and limpid that it is fit not only for that purpose but also for the use of food and drink; and the ancient remains of baths sufficiently show that it was employed by the old Romans for luxurious use. This too is remarkable: that from the very middle of the river Minho [Minus]—on which the thermal springs lie—the hottest waters burst forth in great quantity. These prove that the waters have their outlet from the deepest bowels of the earth, in the very bed of the river, and that they penetrate the river's waters in an uncommingling abundance. There are also other springs in this Kingdom of Galicia, near the city of Viana and in the mountains of Suidae [the Sil region?]. From here, as you set out toward Castile and Baetica, you will find everything full of thermal springs. Between the borders of the Tarraconensian region and Navarre, where the Ebro [Iberus] flows not far off toward the village of Fitero, baths of great virtue are found here and there—as also everywhere along the roots of the Pyrenees. In the territory of Seville [Ager Hispalensis] in Baetica many spring up, which are perhaps those called Caeparia or Anthetana by Pliny [*pace Plinius*].

[Margin: The mountain commonly called Sierra Morena, and its marvels.]

In the middle of Spain there is a very high mountain which, by its long course westward, divides Castile from the Kingdom of Granada; from its upper side the river Guadiana [Ana] flows, while from its lower side the Guadalquivir [Baetis] flows out more openly into the Mediterranean. In this mountain I judge there to be the workshop of Vulcan, from which both metals of every kind are forged, and which, pregnant with a wonderful variety of waters, washes all of Spain with beautiful rivers. That the metals there bring forth abundant offspring, the barrenness of the mountain sufficiently shows, inasmuch as in it trees are condemned to perpetual exile, and only rough and rocky retreats hold sway; livid in color and dark of face, the mountain seems as it were to mourn the reproach of its own sterility—not unfittingly called the *Sierra Morena*, so named by the natives from *Mauro* [Moorish], that is, from its black color. In the rock-base of this mountain there are seen very deep entrances, and among others, next to the village of Almadén, a huge cavern stretching back into a recess of nearly 50 miles, in which a great many very deep wells are seen. [Margin: Wells of quicksilver, or of mercury.] From these an immense quantity of quicksilver [argentum vivum] is drawn up by a teeming throng of workmen and diggers, who—either hired at a great price, or condemned to these mines to expiate the punishment of some great crime they have committed—dragging out a wretched existence with

trembling bodily frame and convulsed nerve-tendons, at last redeem the brief span of their life by a calamitous death. The earthen clods that are dug, and that exude quicksilver, are for the most part stony and of a reddish color; but on the outside, scorched by the heat, the clod blackens, and to those looking from afar it appears of a livid or iron-rust color.

There are also seen four springs of acid waters, all of different power, around the rock-base of the mountain—a sign of the diverse mixture of other latent metal-and-mineral veins within the mountain. These waters, however, having laid aside through filtration the malignant faculties of the salubrious clods, are used by the natives with great benefit in stubborn diseases of the stone [calculus] and the bladder.

Another spring of acid water is observed near the town of Almagro, whose water is excellent and so agreeable to drink that—as Baltasar Ruiz, a native of the place and describer of this spring, testifies—of the roughly fifteen hundred families of that village, the greater part live in perpetual abstinence, all drinking of wine being excluded, and delight in the drinking of this spring alone; and with so great a concourse of men that around midday, from the frequent drinking, the whole spring appears as if drained dry. [Margin: Spring near the town of Almagro.] A similar spring is seen near Bolaños [Bolegnum], a town not far distant from the preceding. There is also a spring of similar condition three miles from Toledo, differing in this from the preceding, that the water drawn at the surface of the spring is exceedingly sweet, but if anyone lowers a bucket to the very bottom of the well, he will draw up a most acid water. The reason for this is not difficult to discover: since both sweet and acid waters perpetually flow into this spring or well, it happens that the acid ones, on account of the abundance of various salts, with their innate heaviness immediately sink to the bottom, while the sweet ones, being lighter, seek the surface.

Departing from here through the remaining tracts of Spain—whether to the north, or to the south, or finally to the eastern tract of the Pyrenees mountains—everywhere you will find a multitude of baths, so that you can scarcely move your foot ten leagues without ever finding new and ever-new spectacles of thermal springs. These indeed I would set forth here in order, but lest I should stuff my account with matters already treated elsewhere, I have deliberately resolved to pass them over in silence; for they take their origin alike from the Pyrenees and from the mountains of Galicia, Castile, and Asturias—mountains crammed with minerals—through subterranean passages.

[printed p. 262 — header "LIBER QUINTUS, Sect. III"]

§ II.

On the Springs or Medicated Waters of France

That whole part of France bounded by the Pyrenees mountains so abounds with the waters of thermal springs and medicated springs that there is scarcely anyone who could count them. [Margin: The immense multitude of medicated waters at the Pyrenees mountains in France.] Indeed, from Bayonne all the way to Narbonne a continuous vein—or sulphurous channel [cuniculus]—constituted out of mountains pregnant with sulphur, niter, alum, bitumen, and vitriol, runs through various subterranean ducts and branches; and the immense earthquake that arose there this year, 1660, and afflicted the region with horrible disasters, amply demonstrated this. As a result, besides the deepest chasms, dried-up rivers, and mountains partly cut down and partly swallowed up, the thermal springs themselves degenerated—their former channels either changed or blocked—and in a sudden metamorphosis the most boiling-hot waters turned into the coldest. But, leaving aside countless others, we shall here recount only the more important and more celebrated thermal springs.

The thermal springs at the village of Dax, situated among the Pyrenees mountains, are sulphureous-bituminous, so tempered by nature that there is no disease of those they call arthritic [the arthritics] that they do not cure. These nonetheless sometimes grow so hot that not only the waters themselves but also the surrounding fields seem to burn—which plainly hints at the traces of a fire-reservoir latent somewhere beneath the mountains.

These are followed by others, commonly called *Orentaine* [Ourentaine?], most celebrated thermal springs, and most salutary for driving out diseases of the kidneys and liver. There are also, at Mount Balaruc [Balarva] near Béziers [Biterrae], a singular remedy against spasm, paralysis, dropsy, and arthritic diseases. Then there occur, at the roots of the Pyrenees mountains, the baths commonly called *de Montferran* [Montferrand], of the same virtue and faculty as the preceding. Near these accede the thermal springs commonly called *de Baignaires* [Bagnères] at the village of the same name, and others called *Dencausse* [Encausse], celebrated for the great concourse of people, of admirable virtue—even on this account, that they confer fecundity on women laboring under sterility, and most effectively cure the other infirmities with which women are commonly wont to be afflicted; the reason for which we have set forth elsewhere. Not far from here, new baths occur in a pathless and deserted place, commonly called *Barèges* [Baregues], which—though they are approached with

great inconvenience to the sick—nonetheless easily make up for it by their faculty of expelling all diseases. And these are the more celebrated thermal springs in this sub-Pyrenean mountain tract, which, as they draw their origin from subterranean passages, so they seem to propagate it further still into the mountains of Auvergne [Alvernia].

There are seen, moreover, in the mountains of Auvergne and their district, six especially celebrated thermal springs; the first of which are those commonly called *de Vic-le-Comte* [Vieleconde], which—precipitated from an immense rock with great roar and heat, and as it were through two spigots—prepare a suitable bath below for all who are weighed down by a stubborn filth of humors. This spring consists of vitriol; the sign of which is that, when distilled, it leaves pure vitriol at the bottom of the vessel, and if anyone places gallnut [galla] in the waters, he will at once find the water itself turned into ink [atramentum]. It is of such acidity that, unless it is tempered by mixture with another water flowing past, it would—owing to a certain too-violent and caustic faculty—cause ulcerations of the intestines, induce dysentery, and bring on other diseases; yet when properly tempered it is useful and fruitful for driving out every disease. After these follow, at the said Auvergne mountains, the thermal springs of *Mont d'Or* [Mont-Dore], and those commonly called *Aygues candes*, that is, "warm waters," likewise of wonderful virtue, whence they are thronged with a great concourse of men. After these follow the *Nivernenses* [springs of Nevers] and *Bourbon* [Bourbonnes/Bourbon-l'Archambault], most celebrated of all France; since their power and natural constitution have been described by others, I do not dwell on them.

There remains at last a wonderful prodigy of nature in waters, to be set forth, which the noble town of Clermont [Claremontium] in Auvergne presents to us. Wonderfully has the prodigy of this spring tormented the minds of philosophers. It issues here from a rock, and in the very issuing it produces rock and the whitest stones. The stream, which flows out from the spring, builds little bridges by its own power for its dwellers, so that it can be crossed, by this contrivance: they make the stream flow over planks arranged in the shape of an arch, and—wonderful to tell—within the space of 24 hours they find a little bridge constructed by the continuous and laborious industry of the water. For the water of this spring, being most limpid, is by a perceptible operation changed into stone by a natural flow never interrupted; and since it is distinguished from other springs neither by color nor by taste, the very brute beasts, deceived, while they drink it too greedily, soon fail and perish—for when they are cut open, their stomach is found filled not with water but with a stony mass. The inhabitants of

this place, intending to display to curious spectators the wonderful efficacy of the petrifying faculty in this water, pour the water into a glass, and immediately it is turned into stone, and—the glass being broken—reproduces its figure so exactly that it would be believed to have been cast in a plaster cup within a mold. In the same way, into whatever vessel of whatever shape you pour the water, it is soon, as it were like a kind of curd, by a perceptible condensation changed into a stony mass entirely similar to the figure of the vessel. Hence some of the more curious, having poured it into the molds or forms of statues, find a stone statue within—the mold being broken. The reason for this prodigious metamorphosis—since it requires deeper principles—we shall unravel in what follows, in a chapter of its own. And let these things said about the thermal springs and medicated springs of France, countless others being omitted, suffice.

§ III.

On the Springs and Thermal Springs of Germany

Since nearly all of Upper Germany is especially mountainous and bubbles with abundant metallic veins...

[printed p. 263 — header "DE THERMIS"]

there is scarcely a place that does not somewhere produce either thermal springs or medicated waters; and indeed the number of acid springs in Germany is as great as in any other region. Thurnheuser [Thunhauserus/Thurneisser] asserts that they run up to a thousand, besides the thermal springs met with everywhere, which—because it would be tedious to describe them—I shall here set down only the names of the places and their composition, extracted from various authors.

Table of the Thermal Springs in Germany

N

o

Spring	Location	Mineral composition	Medical virtues
1 Curienses or Piperinae [Chur, Switzerland]	—	golden-sulphureous-ferruginous-nitrous mixture	heal all infirmities. These springs, beyond all others, have this remarkable feature: that they burst forth on the third day of May,

N

o

Spring	Location	Mineral composition	Medical virtues
			the feast of the Finding of the Holy Cross, but withdraw and dry up on the fourteenth day of September, the feast of the Exaltation of the same Holy Cross; the reason for which see explained below, in the section on miraculous springs.
2 Thermae plumbariae [the "lead springs"] in Lorraine [Lotharingia]	—	leaden mixture, whence they also have their name	heal all diseases that bring on ulceration
3 Badenses of the Swiss [Baden, Switzerland]	—	sulphureous-aluminous	warm and dry; opportune for cold diseases
4 Badenses in the Margravate of Baden, near Argentina [Strasbourg / Baden-Baden]	—	sulphureous-saline-aluminous	aid cold diseases
5 Badenses in Austria [Baden near Vienna]	—	sulphureous-nitro-aluminous	heal cold diseases
6 Ferinae in the Duchy of	—	same mixture as the preceding	(as preceding)

4 3 .	The springs of Spiegelberg [Spigelbergenses] near Hameln [Hammelia], in Lower Saxony [inferior Saxonia].	alum, vitriol [vitriolum], and ochre [ochra]	Tinged with ochre, they are good for arthritic disorders.
4 4 .	The springs of Teplitz [Teplizenses], in Bohemia [Boemia].	sulphur, nitre, alum, bitumen, and calcareous stone	There is scarcely any kind of disease they do not help.

N
o

Spring / Place	Minerals	Virtues
	[saxum calcarium]	
4 The springs of 5 Wolkenstein [Wolchensteinenses], in Meissen.	—	About these, the distinguished physician Augustus Hauptmann [Augustus Harptman] wrote learnedly and elegantly in German; consult him.

These, then, are the medicated springs and thermal baths famous in Germany, with countless others left unmentioned. From them it is clear that nature most of all delights to display her sport with waters of this kind in mountainous and Alpine regions.

§. IV. On the Thermal Baths and Medicated Springs of Hungary, Transylvania, and the Other Adjacent Northern Regions

The Carpathian range [Carpathus Mons], which divides Transylvania from Hungary and Poland, teems with every species of metals, minerals, and waters. Accordingly, it produces everywhere innumerable springs and thermal baths stocked with prodigious virtues, for the Pyrophyllacia [fire-storehouses] beneath it vigorously drive nature's machinations. Fire, by its own nature inclined to rise and confined within the innermost caverns of the earth, is constantly driven toward some outlet. When it finds one — where there are springs of nascent water somewhere — it heats those waters to the highest pitch of fervor. Neither water nor wind can check its force, and least of all can fire itself construct any barrier against it. Indeed, the more it once gathers its onrush, the more strongly it presses, and when it meets an obstacle it bursts beyond bounds to produce the symptoms we observe — marvels both in nature and in certain works of art. Confined, it creeps along little by little, and at last produces astonishing conflagrations. Thus wherever it penetrates and does not exhale, it first converts into itself the air it meets — which is more alterable — then the earth it passes through, and not only the waters it encounters but also the rocks and tunnels, all of which it sets ablaze, especially where it is drawn by its natural appetite toward an outlet and passes through places heavy with sulphur, where it is nourished and fed. In this way it acquires for itself the powers needed for that extreme

fervor we see and feel in thermal baths. As this has been evident in all the thermal fervors so far surveyed, so it shines forth most of all in the thermal baths of Hungary and Transylvania.

But since we have reserved the marvels of springs of so varied a nature for the following chapters, we will not dwell on them here. On hot waters and lakes, and on those that are never frozen even by extreme cold, see Olaus Magnus, who describes them exactly. On the thermal baths and boiling waters of Iceland [Islandia] and Greenland [Gronlandia], see what we discussed above, at length, concerning the marvelous effects of Subterranean Fire. For Scotland, England, and Ireland [Scotia, Anglia, Hybernia], read, if you please, Hector Boece [Hector Boetius], Buchanan [Buchananus], and also Father Eusebius of Nuremberg [P. Eusebius Norimbergus] on the miraculous effects of nature in Ireland. Since I have found these accounts wrapped up with many falsehoods, I have thought it best not to set them out, but to confine myself to what is both well attested and confirmed by experiments — partly by myself, partly by other trustworthy and learned authors.

§. V. On the Springs and Thermal Baths of Italy

Italy, enclosed by the Alps and divided down its middle along its whole length by the linked ridges of the Apennines, and walled off by the Upper and Lower Seas [the Adriatic and the Tyrrhenian], has obtained from nature a situation to which she has made no other in the Geocosm like. Since nature has girded it with so great a natural rampart, it cannot but be that she has also joined to it all things at once — not only those necessary for the sustenance of human life, but the most abundant resources for an abundance of delights. Among these, the multitude and variety of thermal baths offers itself most of all to view. If their number were to be reckoned exactly, neither paper would suffice to describe them, nor wit to explain the impenetrable virtues and properties that shine forth in them.

Tuscany [Hetruria] alone triumphs in the glory of twenty-five most celebrated thermal baths, besides countless spectacles of medicated springs; but since we have surveyed these in a special work entitled *Iter Hetruscum* [*The Etruscan Journey*], we do not repeat them. Rather, I shall first turn to noting those that, in Transpadane Italy [Transpadana Italia], are foremost in the celebrity of their name; but in the...

In the territory of Padua [Patavinum] alone there are reckoned six [thermal baths], and these are: the Bath of Abano [Balneum Aponotanium]; the Bath of Mount Ortone [Balneum Montis Osthoni]; St. Peter's [S. Petri]; Domus Nova [the New House]; St. Bartholomew's [D. Bartholomaei]; and finally the one they call St.

Helena's [S. Helenae]. I shall briefly run through the nature of all of these in order.

The Bath of Abano [Balneum Aponotanium] — in Greek ἄπονον [Greek: aponon, "without pain"], because it heals without pain — was celebrated not only by present-day writers but also by the ancients, Suetonius, Claudian [Claudianus], and Pliny. It is situated in the middle of a valley; on the side facing north it is ringed by mountains, while on the side looking toward the city of Padua it is surrounded by a vast plain. A hill rises up, compacted as though of crude pumice, from which, through what are like stone pipes, that most praised water flows in a rich and perennial stream — the mother of the Aponian thermal baths.

Concerning its composition there have been varied opinions among physicians. Fallopius [Fallopio], who undertook the scrutiny of the spring by a thousand modes of experiment and left nothing undone in order to reach the innermost mixture of this spring, seems deservedly to have wrested the palm from all the rest. Taught by an irrefragable knowledge of experiments, he at last determined that there is in those waters salt, indeed, as the predominant element; then calcareous stone [lapis calcarius] (the kind that, when heated, turns to lime); and finally a sulphureous vapor. From this he inferred that the water heats in the second, remitted degree, and likewise dries in the second, but intense, degree — which he confirmed, on the principles of iatric [medical] science, against Savonarola [Savanarola], so that no further room for doubt remains among physicians. The use of these waters is carried out in a fourfold manner: namely by drinking, by sitting-bath [infessio], by sprinkling [embrocha, that is, by dripping/stillicidium], and by the sweating-room [laconicum]. By these means all diseases arising from inveterate cold and humidity are cured, except the French disease [lues gallica, syphilis]. But concerning the diseases that the water cures, see Claudian's most elegant encomium of it, where he adduces some remarkable properties of these waters.

Proceeding westward from Abano, after 150 paces one comes upon a very lofty hill named Ortone [Ortonus], at whose base is seen a shrine sacred to the Mother of God [aedes Deiparae], renowned for many miracles; in its vestibule is seen a cavern, within which a descent lies open by a brick stairway. Here flows a purer water, called the Virgin's Water [Aqua Virginis], somewhat tepid and seasoned with a most mild salt, fit to heal by drinking alone. Not far from the Virgin's Water is seen a spring of most fervent water, salty and sulphureous, very well suited to healing subcutaneous diseases. Not far from here two baths are seen, filled with tepid and medicated vapors, an excellent remedy for softening the limbs. But in that pool where the boiling water springs up there is a clayey and

rich mud, whose power is such that it dries, disperses, strengthens, and binds together loosened parts. Yet take care not to apply it to the affected part while it is hot; rather, first warm it with that water, smear it with cold mud, set it out in the sun, and only then use it.

Setting out from Padua [Patavium] across a plain of twelve miles, one comes upon a most pleasant hill, from whose depths boil up those most fervent waters, which take their name from a little chapel built and consecrated there to St. Peter [Divus Petrus]. They consist of abundant salt and a certain juice not unlike ochre [ochra]; they heat moderately, dry, and gently strengthen. Going on four miles from these, one comes upon a hill which from its northern side spews out most fervent waters, while from its other side it is famous for the abundance of medicated springs that gush there. From a new house built there by the Carrara family [Carrari], patricians of the city of Padua, these are called the Thermae of the New House [Thermae Domus Novae]; yet through neglect of cultivation they are today nearly obsolete and squalid. Descending about 500 paces from here, one comes upon a mountain which, from the throng of the sick who flock there, is called the Mountain of the Sick [Mons Aegrotorum], corruptly "Monte Grotti." From this mountain flow the most celebrated thermal baths, composed of sulphur, salt, and gypsum [gypsum], whence they dry vehemently, heat moderately, and are especially conducive to ulcers of the skin. Proceeding farther, in a certain valley girt on all sides by steep hills, two miles distant from St. Peter's bath, one comes upon the Bath of St. Bartholomew [Balneum S. Bartholomaei], so named from a chapel consecrated in his honor — the most celebrated and most frequented of all the thermal baths, not indeed by reason of the water, but on account of the most fervent and bituminous mud upon which that water floats, very well suited by anointing to softening the rigor of the joints and nerves. This mud conceives its heat from the fiery and bituminous exhalation that the infernal fires breathe out. Two miles from here is seen the chapel dedicated to St. Helena [S. Helena] on a hill, from which the bath also takes its name. In it, besides charming sweating-rooms and twin sprinklings and a spring of boiling water and a medicated mud, the water — filled with sulphureous vapors — has, besides salt, a little sulphur and some clayey matter inclining to the color of ochre; whence it heats moderately and dries. But the mud, when cooled, is deprived of its medicated power. Something marvelous lies hidden here, and different from the mud of St. Bartholomew's Bath: this mud dries powerfully, that one softens.

And from this multitude of thermal baths that shines forth in the Paduan territory, it is plainly evident that this whole tract is filled with subterranean fires

and consequently with every kind of mineral, which spreads its veins far and wide into the surrounding regions. For in the territory of Verona [Veronensis], ten miles distant from Padua, the Calderian thermal baths [Thermae Calderianae] are at once encountered, which physicians use not only for drinking and sitting-baths, but also for various purposes — even for cooking food for the sick and for diluting wine. Their mixture consists of red ochre [rubrica synopica, Sinopic red earth] with a little salt and sulphur. Corresponding to these, through subterranean channels, in the Cispadane region [Cispadana Regio], are the thermal baths of Aquaria [Thermae Aquaritanae] and of Reggio [Regienses]; for from the territory of Modena [Mutinensis Ager] there gushes, at the village of Aquario near the city of Reggio...

of Reggio [Regionsis] city's village, in the judgment of skilled physicians, it consists of salt, nitre, and marble lime [calx marmoreus]. Its remarkable property is this: that outside the spring it remains uncorrupted for the space of a hundred years; whence it is carried not only through the neighboring provinces of Italy but also into France [Gallia] and Spain [Hispania]; it has all the [virtues] that the use of the Aponian water possesses.

Closely corresponding to this, in Flaminia [the Flaminian region], is the Bath of St. Mary [Balneum D. Mariae], distinguished by three thermal baths — namely those of the Lords [Dominorum], of the Middle [Medii], and of the Tower [Turris] — whose waters all hold a most clear, gem-like salt with a portion of nitre, [conducive] to sulphureous vapors, and are tinged with marble lime. Near these are other thermal baths: those of St. Martin [S. Martini], St. Christopher [S. Christophori], and Meldola [Meldula]; about which read Fallopius and others.

§. VI. The Thermal Baths of Tuscany [Thermae Hetruriae]

In no region of Italy do I recall having found more abundant thermal baths than in Tuscany [Hetruria]. If anyone wished to bring them to a count, he would easily run up to fifty of them; but since we have set them out in order in our work entitled *Iter Hetruscum*, I have thought it best not to repeat them here. For there are, first of all, those which [the region] pours forth: the thermal baths of the territory of Lucca [Lucensis], of Pistoia [Pistoriensis], of Pisa [Pisanus], of Volterra [Volaterranus], of Viterbo [Viterbiensis], and of Bracciano [Braccianensis] — each one of which is again divided into diverse and manifold other thermal baths, which we display at a single glance in the following Table. The virtues and properties, situation, and composition of each, let the reader see in our cited work on Tuscany.

Table Containing the Thermal Baths of Tuscany

Tuscany [Hetruria] contains thermal baths in the territory of:

Lucca [Lucensis]:

- Florentiola
- Malapetra
- Corsenas
- De Ducciis
- S. Joannis [St. John's]
- Villenses

Pisa [Pisano]:

- Bal. Reginae [the Queen's Bath]
- S. Juliani [St. Julian's]
- De Aquis

Volterra [Volaterrano]:

- Bagno al morto
- Balneum casei cocti [Bath of cooked cheese]
- Ducciae
- Balneum Planitici
- S. Michaelis [St. Michael's]
- With diverse kinds of waters

Siena [Senensis]:

- Thermae S. Philippi [St. Philip's Baths]
- Thermae S. Cassiani [St. Cassian's Baths], distributed into ten springs
- Aquae Borrae
- Balneum de Avenione
- Bagno bello
- Balneum Clusinum
- Bal. Ruffellanium
- Bal. Rapolanum
- Bal. Saturnium
- Bal. Montis Alceti

Viterbo [Viterbiensis]:

- Bullicamum
- Bassetum
- Cruciatum
- De Palatiis
- Jasellinum
- Castrense
- Balneoregium
- Ad Lacum Vadimonis [At Lake Vadimon]

Bracciano [Braccianensis]:

- Vicarellum
- De Styliano
- Cere veteris [of ancient Caere]
- Centum cellarum [of Centumcellae / Civitavecchia]
- Et complura ad maritimam oram [and many more along the maritime coast]
- Nepesinum [of Nepi]

§. VII. The Thermal Baths of Campania [Thermae Campaniae]

Tuscany, sporting with Campania through subterranean passages, produces innumerable kinds of medicated waters and thermal baths — especially in the Pozzuoli territory [Ager Puteolanus], the Baian [Bajanus], and the neighboring islands of Ischia [Ischia] and Procida [Procyta], which have the same origin throughout that whole tract of land and lie subject to it: partly from the sulphureous [region] at Pozzuoli, partly from Vesuvius at Naples — the workshops of Vulcan [Vulcani officinae], drawing their nature from burnt earths and ashes. Some of these are not only sharp and unpleasant, but the most agreeable ones spring forth from those very ashes, now already extinct — as once, so now, most celebrated. Some, in which a certain sharpness thrives, are most useful in drinking-cures for many infirmities, being of an abstergent [cleansing] power, and are either nitrous or salty. The waters once Cicero's [Ciceronian], now called Bagno del Prato, are situated in the Baian district; about which Pliny speaks thus: "There is a villa worth recording, set on the shore for those going from Lake Avernus toward Pozzuoli, celebrated for its portico and grove, which Marcus Cicero called the Academy; in which, after his death, while Antistius Vetus possessed it, hot springs broke out — most salubrious for the eyes

— which were celebrated in an elegant epigram by Laurea Tullius, his freedman." Today they have the same virtue and make a most excellent eyewash [collyrium], consisting of the virtue of cadmia [cadmia, calamine], by which they are tinged.

There are also in this place — though now nearly obsolete from age — other baths: of the Sun [Solis], others of the Moon [Lunae], others Imperial [Imperatoria], so called from ancient superstition, which consist of sulphur and iron. Proceeding three miles from here, beneath the Misenum promontory [Promontorium Misenum], one comes upon the most celebrated Bath of Cantorelli [Cantorelli Balneum], renowned for the marvelous effects it produces in extracting iron splinters — which they wrongly suppose to be effected by an infusion of magnetic tincture, as, taught by our own experiment, we have noted in our *Ars Magnetica*. Adjoining this, in the Lucullan territory [Lucullanus Ager] near the Grotto of Posillipo [Crypta Pausilippi], two springs of great virtue flow: on the right a most limpid one; on the left one of a milky color, whose waters grow tepid in winter and are cold in summer — the reason for which we explained above. It consists of a mixture of lime, sulphur, and iron, just as it is formed from the clods and rocks of an iron-bearing [ferruginous] mountain. In this same Baian gulf, at the Monastery of St. Anastasia [S. Anastasiae Monasterium], one comes upon the bath of Petreolus and another, which they call Cuma, of the same nature, consisting of a cleansing virtue. When, in the year 1638, I was examining this tract, I was indeed amazed at the abundance and variety of medicated springs bubbling up in it, since one can scarcely cover a hundred paces without coming upon some new spring or pool of differing virtue. Here I saw a spring which they call Gilleroso, well-suited to purging the kidneys. Nearby are waters which they call Bracchulae, of a sulphureous-nitrous nature; the thermal baths of St. George [S. Georgii], which consist wholly of nitre; another, now called "by the handful" [pugilli], well-suited to the flow of hemorrhoids, of an astringent power; another, Succellaria, emanating at the edge of Lake Avernus, seen diluted, whitish and in taste, fit for expelling urine [and] the stone, both of the kidneys and of the bladder. Joined to these is Juncana near the Grotto, so called because it bubbles up among the rushes [junci]; taken by drinking, it fattens, and excites Venus [sexual appetite] in the cold-natured. There are also in this district other spring-waters. The little bath called "De Petra" and "Plaga" [Plagam] is especially prized by the Neapolitans for its strengthening power. At the Monastery of St. Anastasia, from even a small dug pit, a most limpid water springs out, both pleasant to drink and most potent in medicinal powers. And so this whole Baian tract gushes with waters so salubrious that Horace [Horatius] not undeservedly sang of them:

No bay in all the world outshines fair Baiae. [Nullus in Orbe locus Bajis praelucet amoenis.]

Pliny says: "Medicated water bubbles forth here, kindly and everywhere, in very many lands; yet nowhere more lavishly, nor with more kinds of aid, than in the Baian gulf — some of sulphur, some of bitumen, some of salt, some of nitre, some of alum, and some likewise profiting by an acidic and varied mixture, and some by the very vapor." To these is added the incomparable pleasantness of the place, which Martial [Martialis], once admiring, wrote thus to Flaccus:

Baiae, golden shore of blessed Venus, Baiae, proud and gentle gift of nature: Though I should praise Baiae, Flaccus, with a thousand tongues, I should praise Baiae as it deserves — yet not enough. [Littus beatae Veneris aurum Bajae / Bajae superbae blanda dona naturae / Ut mille laudem Flacce Bajas / Laudabo digne, non satis tamen Bajas.]

Yet — such is the inconstancy and vicissitude of human affairs — most of these, in the conflagration of the Pozzuoli territory in the preceding century [the 1538 eruption that formed Monte Nuovo], buried and submerged under ashes, ceased to flow; but those that survived such a disaster are today frequented as most useful, of the kind we have surveyed. So full, then, are all the places of this region with the gushings of bubbling springs and thermal baths, that in the very Cave of the Cumaean Sibyl [Cumana Sybilla] nature has produced a thermal water that heals human infirmity. And all places are likewise full of fires, as the Phlegraean Fields [Phlegraei Campi], or the Forum of Vulcan [Forum Vulcani], which we described above, abundantly attest — so that in these places Nature, the bridesmaid [Paranympa Natura], the supreme craftsman-mind of all things, seems to have established a marvelous wedding of water and fire. From here, moreover, through the winding mazes of subterranean tunnels, the neighboring islands of Ischia and Procida — which they once called, joined into one, Aenaria — have conceived so great a breeding of most diverse waters and fires that there is scarcely a place in them that does not abound with these. But whoever desires more about these, let him consult Scipione, Mazzella [Mazella], Pighius, and the other describers of these places. We, who have seen and explored them, have thought it best to bring forward here only these things.

§. VIII.

The Thermal Springs of Sicily and the Lipari Islands.

[Thermae Siciliae & Liparitanae]

(printed p. 268)

I will say nothing here about the thermal springs [thermae] and medicated fountains that occur, scattered in great number, along the maritime coast of the rest of the Kingdom of Naples, in Calabria. Instead I will turn my pen to Sicily, where nature seems to have gathered together — as into a small epitome — the riches she has displayed elsewhere only piecemeal. It is from Sicily, then, that one ought rightly to draw the examples of every kind of difference and alteration that shines forth in medicated waters.

[Margin: The great wealth of thermal springs and of medicated waters in Sicily, and their variety.]

Consider the kingdom of Vulcan, where fire openly reveals itself in its nature and its effects. Those effects are: flame, vapor, combustion, smoke; its material is sulphur, oily clay [gleba pinguis], ash, pumice, stone-coal [lichanthrax], bitumen, salt, vitriol, and metals of every kind. From this variety of material arise marvelously varied operations of the fires. And so on every side spring up countless sweating-chambers [sudatoria]; waters hot, lukewarm, cold, salt, acid, white, black, blood-red, oily, bituminous, putrid — waters that yield not only veins but whole rivers, lakes, fountains, and baths. No one should wonder at this: whoever knows the immense power of Etna will easily grant the cause and origin of all these things. For the power of Etna, diffused through transverse fire-channels [pyragogi] in every direction out of its innermost depths, raging through the whole circuit of the island with perpetual smoking vapors, acts according to the degree of heat these channels contain. Either they boil up through their caverns and make sweating-chambers, or, where they encounter waters, they alter them, and by their tinctures produce as many kinds of thermal springs as are perhaps not to be found in all the rest of the world.

[Margin: The materials of the fires in Sicily.]

Among the rest, famous are the thermal springs produced amid the ruins of the city of Selinus [Selenuntina Urbs], today called Sciacca, of marvelous variety. For in the middle of a very high mountain dedicated to St. Calogerus [S. Calocero], there occur here and there various labyrinths of caverns: some open in straight passages, others in transverse ones; still others stretch down into the deepest Tartarus by an unfathomable abyss. These always resound with a dreadful and terrifying roar — whether from the enclosed multitude of hidden fire, or from the violence of the winds rushing this way and that, or from the impact of the sea-waves driven with great force into the mountain's passages. Certainly, at fixed

times, the cave emits sounds not unlike claps of thunder: a dreadful thing, striking fear into everyone.

[Margin: The thermal springs of Selinus.]

[Margin: The mountain of St. Calogerus, marvelous in the variety of its waters and vapors.]

Among the rest there is one vast cavern, in the middle of which is a well of immense depth, dark and dreadful to look down into. Here it teems with several warm veins on every side, which flow back from the channels of various caverns, and at the same time it emits vapors that excite wholesome sweats in those who enter, up at the cave's highest vaulting. To this very day one can see, cut into the living rock by the ancients from time immemorial, seats adorned with various inscriptions — which, however, since they have been eaten away by the injuries of time, snatch from the curious every hope of deciphering them. There are also in this cavern siphons [syphones] — made, I know not whether by art or by nature's industry — filled with hot vapors. Those who suffer from disorders of the head, ringing in the ears, and deafness, by applying their ears to these siphons for a short time are freed from their infirmities; they are also good for strengthening the nerves. Hence they are visited with notable benefit by great numbers of the sick who throng there, especially on the feast of St. Calogera, a hospice [Xenodochium] having been built there at public expense for that very purpose.

[Margin: The astonishing cavern of the mountain.]

On the plateau of this mountain other kinds of thermal springs presently rise up, and among the rest a most clear water of marvelous power to loosen the bowels. Whoever drinks it without knowing this will surely expose himself to the great mockery of the bystanders, since the effect follows so suddenly upon the drinking that there is scarcely time and place to withdraw decently. Hence the local jokers often put on a ridiculous spectacle with foreigners, deceitfully enticed into drinking.

[Margin: Other springs of various powers.]

There is no lack of abundant thermal springs at the foot of Etna, which, however, out of so great a number of better ones, are neglected. That there were once most noble springs at Syracuse — the lakes Pismam and Cianon [recte: the springs/lakes Pisma and Cyane[?]] — and that the latter undergoes waning and waxing with the Moon, Mirabella teaches. At Catania too there were once two thermal springs famous for their great display of columns, as Pietro Carrera

[Petrus Carrera] shows in his description of Catania. To those who travel by land from Catania to Palermo, on the side there occurs a town commonly called Miheo [Mineo], on whose plain there lies, a little within the interior, that most celebrated lake of the Palici [Palicorum lacus] mentioned by the ancient writers. Of immense depth, in hidden correspondence with Etna, with its waters rising up some three cubits high, it seems as it were to sport, when blasts press upon them both from the neighboring sea and from overhanging Etna. The waters are sulphurous and ashy, and have the same taints as Etna — of fire, sulphur, ash, and stench — so that they send up exhalations deadly not only to birds but dangerous to men, since, no differently than Etna, they hurl up globes of flame as well. Of these Ovid writes thus, *Metamorphoses*:

[Margin: The lake of the Palici, near Mineo.]

And he is carried past the deep lakes, and the pools of the Palici reeking with sulphur, where the earth has burst and boils. (*Ovid, Metamorphoses* V.405–406)

Today, from the mephitic exhalation [Mephitis] they breathe out, they are called Naphtae ["the Naphthas"] by the inhabitants; and although they bubble up with three fountains, they nonetheless do not exceed the rim of the pool, doubtless discharging themselves elsewhere through subterranean channels, as we showed above concerning the property of lakes. A lake of this same kind is also seen between Agrigento [Agrigentum] and Divona, of unsearchable depth, which hurls up sulphurous waves from its source some three cubits high, to the utmost wonder of those who behold it. Again, in Pelorus [Peloro], near the Mamertine strait [the Strait of Messina], there occur three lakes, celebrated in the superstition of the ancients; not far from these lie the springs of the city Thermae [Termini Imerese], which, from the ancient city of Himera [Hymera]...

[Margin: The lake of Agrigento.]

[Margin: In Pelorus, near the Sicilian strait.]

(printed p. 269)

built in the most ancient ruins — Cicero and Pliny [the Elder] being witnesses — has baths well suited both to pleasures and to driving off diseases. Near Enna [Henna] too — at the place today called Castrum Ioannis [Castrogiovanni] — there appear pools famous for the rape of Proserpina, whom the poets imagine to have sought the underworld in this place, leaving behind her an abyss filled with the most foul and stinking waters.

[Margin: Lakes famous for the rape of Proserpina near Enna.]

There are also in the diocese of Palermo [Panormus] waters sulphurous by nature and most fervently hot, celebrated for their use in baths and no less in sweating-cures. Drepanum [Trapani], which was formerly called Segesta, at the foot of Mount Eryx [Eryx], teems likewise with a diversity of waters as of metals. Although these are most hot and sulphurous, yet because they do not pass through any vein of salt, when they have cooled — Strabo being witness — they become drinkable. And to this day three baths endure, of which the first is hot, the second hotter, and the third hottest; below these — as Fazello [Fazellus] reports — at a stone's throw of the foundation, there is a huge sulphurous lake which, made turbulent by sudden eruption, is called by Solinus the Herbesus, and today by the inhabitants the Gurgus ["the Whirlpool"].

[Margin: Drepanum, formerly Segesta.]

[Margin: Baths, and the turbulent lake called Gurgus.]

Time would fail me if I were to attempt to enumerate all the lakes, fountains, rivers, Charonian pits [charonticae scrobes], and sulphurous pools in the inland places of Sicily. But let what I myself have seen, here told to the reader, suffice.

The Lipari Islands — also called the Vulcanian or Aeolian Islands — teem so with thermal springs that they scarcely leave room for drinkable water, so much do they abound in medicated fountains and in fires. But since we have spoken of them among the preceding matters, I will not dwell on them.

[Margin: The Aeolian Islands teem with thermal springs.]

Between Africa and Sicily lies interposed an island by the name of Pantelleria [Pantalaria]. Wherever you set foot, the soil is dry, red, and hot, so that it can scarcely be endured by those walking barefoot. It takes its origin (for the most part out of the depths of the boiling vents which, by Vulcanian fires, correspond through subterranean passages to the workshops of Etna and the Lipari Islands), and it is evident from the caverns of the mountains, which, agitated by waters and vaporous blasts, are felt to growl with a continual and perpetual sound within. The greatest natural prodigy in it is discerned — Fazello being witness. For since the land, thirsty from excessive heat, suffers the utmost lack of fresh water, by a truly wondrous plan of nature these inconveniences have been provided against. In the middle of the island is a huge cavern, vaulted on every side with rugged rocks; in the very navel of this cavern is found a chasm of immense depth, out of which perpetual smokes of exhalations and vapors,

condensed in the vast vault, are resolved into streams of fresh water — in such abundance and quantity that, drawn off thence into siphons made partly by art and partly by nature, it suffices abundantly for the whole island, for drinking and for other uses.

[Margin: The island of Pantelleria, marvelous.]

§. IX.

On the Thermal Springs of Asia, Africa, and America.

[De Asia, Africa, Americae Thermis]

That the whole Geocosm abounds in boiling vents [aestuaria] was shown in Book IV, the truth of which we demonstrated by the present account of the Vulcanian mountains, which are seen everywhere across the entire surface of the Earth, in no region lacking. We also set out the mountains in order on a geographical map, from which it necessarily follows that there is an abundance of metals and minerals; and since at that same place we described, in the greatest mountains, the cauldrons of the hydrophylacia [hydrophylacia — subterranean water-reservoirs], hence there follows the necessary consequence that we have gathered: that waters heated by fiery vapors, and tinged with the power of minerals lurking everywhere, supply the abundance of thermal springs, sweating-chambers, and medicated fountains — since nature always acts the same everywhere, and arranges all the effects of natural things to one and the same standard.

[Margin: Where the Vulcanian mountains are, there the water is medicated; that is necessary.]

These things being premised, I declare:

That the same abundance of thermal springs and mineral fountains which we have seen in Europe exists in the other parts of the globe; and this could be doubtful only to one who is ignorant of the marvelous laws of nature. But lest we seem to have said this gratuitously, we will now record some of them, both from the records of historians and from the report of various men who have studiously traveled over the world.

Asia Major and Minor, together with the Greece it embraces, teem so full of thermal springs and the miracles of fountains that a whole volume would be needed to describe them all. Let whoever wishes read Aristotle's *On Marvelous Things Heard* [*De admirandis*], Pliny, Solinus, Theophrastus, Aelian, and countless

others. Let him consult besides the *Itinerary* of Marco Polo of Venice [Pauli Marci Veneti Itinerarium], who mentions them here and there in Tartary and the other regions; Hayton the Armenian [Haithon Armenus] too, *On the Thermal Springs at the Caspian Sea*; concerning Persia, the itineraries of various men who set forth that nearly the whole of it abounds in marvelous fountains of waters. The *Annals of the Society of Jesus on Indian Affairs* commemorate them everywhere, and among the rest most exactly Father Martino Martini [P. Martinus Martinius] in his outstanding work, which he entitled the *Atlas Sinicus*: Japan is forever boiling with most hot waters, as Luis Fróis [Aloysius Froes] testifies. The Philippine Islands so teem with them that scarcely out of the eleven thousand islands which are counted in that archipelago does there occur a single one that does not produce something singular and marvelous in its waters. Africa, chiefly along its shores, abounds in countless medicated waters.

[Margin: Greece teems with thermal springs and other miracles.]

[Margin: Asia, China, Japan abound in thermal springs.]

[Margin: The Philippine Islands teem with thermal springs.]

[Margin: Africa.]

I will not speak here of the provinces of America, which are so filled with them that — as the historians relate — they not only supply the inland region with an immense abundance of them, but in some places pour forth most fervent rivers, as it were, from the loftiest crags; and if somewhere they find no exit, they pour themselves out through the very floor of the sea, into the outermost surface of the sea with great force, all of them potent with wondrous powers. I pass over here the most frequent thermal springs of the Kingdom of Mexico, established by benign nature both for delight and for the cure of diseases. The day would fail me if [I were to attempt to recount] those which were shown in Guatemala [Quatomata], Peru, Chile [Chili], Quito [Quato], Cusco [Cusco], Potosí [Potosi]...

[Margin: In America the great multitude of thermal springs.]

[Margin: The Mexican region.]

(printed p. 270)

[if I were to attempt these things of] nature in the waters. Let this therefore be the Catholic [i.e. universal] Rule: Wherever the workshops of Vulcan are found together with metallic mines, there the miracles of thermal springs are beheld; nor can it be that the thermal springs, as it were their inseparable companions,

are absent. But that everywhere the Vulcanian workshops, the sulphurous pits, and the nitrous, saline, aluminous, and vitriolated fountains are to be found, was shown in the preceding pages. Rightly therefore do we infer that thermal springs, and fountains of marvelous faculty, are nowhere lacking. But let this suffice concerning thermal springs.

[Margin: The friendship of fire and water in subterranean places.]

CAPUT II.

Whence the Medicated Faculty of Thermal Springs Flows Forth, Against So Many and So Different Diseases.

[Unde medicata facultas Thermarum, contra tot ac tam differentes morbos, profluat.]

Since in the whole contemplation of natural things nowhere does the Majesty of Nature appear more marvelous than in the wondrous variety of waters, it must certainly be demonstrated by every means: who the craftsman of such great effects is, and what is that mastery by which elements otherwise most diverse and utterly contrary in their qualities are nonetheless united, in such great concord and such harmony, in the hot waters of the thermal springs — so that the water with its moisture does not extinguish the fiery power, and the power of fire, with its own most efficacious force, does not injure the contrary moisture. On the contrary, by a certain natural ambition of friendship, they strike pacts of peace which seem unable to be dissolved by any power. Thus fire moves all things through all by its activity, and nourishes all things through all by water; and so, according to the Philosopher's [Aristotle's] dictum, the first participation of life is from heat, and its preservation is in the moist. How, then, water conceives heat was very fully stated in the preceding pages; but how it attains so great an increase of marvelous powers — how, and by what bridesman [paranympus], the confluence of the most diverse powers is tempered into so close a wedlock, in so exact a proportion, in so precise a measure and symmetry — that surely is a matter for deeper scrutiny. Come then, let us attempt something; and if we do not seem to have satisfied the reader on every side, at least we shall deserve praise for having attempted something in a difficult matter.

[Margin: The marvelous arrangement of divine Providence, ordained for the good of mankind.]

The most wise Creator of things, GOD, the Best and Greatest [Deus Optimus Maximus], as He produced all things for the sake of man, so He willed that man

be furnished with all means of every kind for preserving him in a perfect state of health. Hence there is nothing in the nature of things which does not possess some peculiar medicinal power; nothing which does not regard with its power some one part of the human body, and bear before it, by a certain marvelous character, that for whose cherishing it was created — indeed, that it is borne, as it were by a certain weight, toward that to which it corresponds by the law of natural friendship. And since the constitution of the human body consists of many sulphurous, nitrous, saline, vitriolated, and oily parts — the very same, namely, of which every compound consists — hence it comes about that the hot water of thermal springs, with which they are exactly mixed, when used, produces those marvelous, wholesome effects that we wonder at in the symptoms of the sick. For I would not have you suppose that all the causes of these effects depend always on the primary qualities, but rather, for the most part, on the specific powers and qualities of the things mixed with the thermal waters, as we shall later disclose concerning the causes of prodigious waters.

[Margin: Salvation is in all things, just as it is found everywhere.]

Now the things that are usually mixed in perfect union with medicated baths are: salt, niter, alum, vitriol, sulphur, bitumen, together with the tinctures of the seven metals — which, as by I know not what magnetism, are borne to the principal parts of the human body entrusted to them, and so make that very power of which we are speaking marvelous, and preserve [the body] in a perfect state of health. But let us at last show the matter, beginning with medicated salt waters.

Every land partakes of its own salt — here more, there less is found — and as the lands are found to be, such grades of salty quality do the waters themselves obtain: hence they are smoky, dry, brackish, bitter, sharp, slightly bitter; and where the soil is exactly salty, [the waters] are exactly salty. Hence rarely is there in waters any impression from some mineral or metal which does not also partake of the quality of salt, for every land partakes of this flavor. Hence again it is evident that scarcely any pure and simple water is to be found — as we taught above too — that does not contain something of salt, even if in an imperceptible quantity. But the diversity of grades of sharpness depends on the subterranean places through which [the water] flows: if it has gone through mineral veins richly filled with salt, it is most salty; if through places endowed with rarer salt, it is less salty; if it has flowed through gravel and sand, having deposited its mass of salt by straining-through, it issues forth insipid. As to why hot brackish waters [aquae salsugineae] are saltier than the rest: this happens from the scorching produced by the power of the subterranean fire, by which, the spirits flying off,

the fixed salt remains; by this the waters are rendered saltier the more perfectly the dissolved salt has been mixed with the waters. The same thing, therefore, happens in brackish thermal springs by nature as in waters most thoroughly dissolved with salt prepared by art: just as these dry violently, heat less, bind, contract, cleanse, and purge — which are the proper faculties of salt — so too they cleanse the skin, and restrain all excrementitious and putrescent moisture, and [reduce] the excessive grossness of the body...

(printed p. 271)

they attenuate over time. So then, the fact that salt thermal waters are of such great benefit to the scabby, the leprous, the elephantiac [elephasis-sufferers], the spotted [maculosi], and those with vitiligo, is for the most part to be ascribed to the powers of salt. For since by nature it has been digested within the waters in a marvelous mixture, symmetry, and proportion, hence, penetrating through the open pores by the power of the heat residing in the water, it produces those effects we marvel at. And just as there is no particle of our body that does not consist of saline corpuscles, these — if they are either scorched by a preternatural heat, or have otherwise acquired pernicious qualities from the corruption of the humors — bring it about that, within the hot baths of salt, they are attracted by a certain natural appetite to particles like themselves, introduced into the water as a vehicle; and so they free the body from its troublesome guest, by the evacuation of the corrupt putrefaction and of the diseased subcutaneous humor [humor intercutaneus].

[Margin: Why it is of such great benefit in subcutaneous diseases.]

As to why it is of such great benefit to the spleen-afflicted [lienosi] and the hypochondriac, and to the other diseases which take their origin from flatulence — this happens in the manner that follows. The saline corpuscles, together with the hot water with which they are mixed, introduced through the pores and attenuated by the heat, presently pervade the whole body with their subtlety; they unblock, by their acridity, the obstructed pathways to the spleen, the intestines, the womb, and the other members. Wherever they encounter corpuscles like themselves, depraved by the fault of the humors, they draw these into themselves by a certain attraction, and at last, together with the cleansing power they possess, they soften the members, render them fit for their accustomed functions, and carry off with them the dregs — the causes of the obstructions — through the discharging gates of nature. From this it is evident why some thermal springs confer fertility on the barren: because the saline corpuscles mixed in the waters dry up by their power the foul collection of

vitiated humors in uterine diseases, dispel it, cleanse it away, and open the closed passages; and once these things are accomplished, fertility must necessarily follow — provided a natural defect of the womb does not stand in the way. And in this manner the medicinal powers of salt thermal springs operate in driving off the said diseases.

[Margin: Why & to the hypochondriac.]

[Margin: The waters of salt thermal springs.]

Nitrous thermal springs differ in few respects from the faculties of salt. For they heat, attenuate, digest, cleanse, bite, thicken, dry, and ulcerate; on account of the greater efficacy in which they exceed the saline, they are also more bitter than the salt ones; and on account of the airy, subtle, and spirituous corpuscles of niter that are mixed with the waters, they cut, and attenuate much more powerfully than the salt ones. Hence they draw out viscid humors, loosen the bowels, provoke urine, induce sweats, cleanse the kidneys, expel gravel, break the stone. For whatever they find in the body of the impurity of nitrous dregs and of malignant quality, they dissolve it — united to itself as it were by a certain attraction, by their acrimony, all phlegm and viscosity being consumed. Yet I do not know what hidden agreement they have with disorders of the eyes and blariness [lippitudo]; for it has been observed by long experience that in nitrous mines no one is afflicted either with blariness or with any disorder of the eyes — which is doubtless to be ascribed to its supreme subtlety and its incisive faculty, by which it cleanses all things. Hence among physicians niter has always been held one of the most excellent of the few eye-salves [collyria]. See what we set forth more fully, in the following Book, concerning its nature and property.

[Margin: The powers of nitrous thermal springs.]

[Margin: The flavors of niter do not cause blariness, nor do those afflicted with blariness undergo it.]

Aluminous thermal springs, besides the faculties they have in common with the nitrous and saline, are endowed chiefly with an astringent power. Hence the parts of the body which, by their thinness, they relieve of excrements, these same they strengthen, and render more robust; they check a flux of blood arising from any cause whatever; they stay the flux of gonorrhea; they soothe burnings of the urine; they remove obstruction of the bladder and the ureters; they strengthen the relaxed retentive power of the kidneys; and they produce countless other effects, to the great help of the sick. The reason for this can be no other than a certain power which, just as it partakes of a mixture of salt and niter, so operates

much more efficaciously than the aforesaid; since from the predominance of water they have the property of refrigerating, but from the fiery acrimony the property of moderately drying and astringing.

[Margin: Aluminous thermal springs and their powers.]

Vitriolated or atramentous thermal springs — in Greek χάλκανθον [chalkanthon, "copper-flower," i.e. blue vitriol] — from Calcanthum, as if you would say "the flower of copper" and the superficial recrement of the material [of copper]. And so, just as it takes its origin from copper, so it is produced only in those places that teem with copper mines. Hence the thermal springs that flow through vitriolated places of this kind partake of the power proper to vitriol, which is a vehement astringency joined with a notable heating power; nor do they any less dry, constipate, contract, and gnaw. Hence, unless they are aptly tempered, they are not only useless for drinking but even dangerous. Yet they are most useful in baths or fomentations [embrochae], suited to healing the same diseases as the aluminous, nitrous, and saline ones — with this added, however, that they penetrate and cleanse more readily. Hence scarcely any acidulous springs [acidulae] are found that do not partake of something from vitriol — not indeed as to their sensible being, but as to the spirituous and vaporous substance with which they are subtly and perfectly tinged.

[Margin: Vitriolated thermal springs.]

And these are the four species of saline bodies which, unmixed and operating each by itself, indeed afford the same effects to the waters with which they are mixed — differing only in diverse degrees of intensity, and in that property proper to copper which accrues from vitriol as well. But mixed among themselves they obtain effects utterly different; and if we trace these back to the rules of the combinatory art [ars combinatoria], we shall find that they obtain twenty-four most diverse effects.

Liber V, Sectio III — De Thermis

Caput II — Whence the medicinal power of thermal springs flows (*continued*)

Table of the combination of a mixture of the four saline bodies — salt, niter, alum, and vitriol.

The table lists, for each predominant species, the binary, ternary, and quaternary combinations of the four saline bodies, the overall complexion of the resulting mixture, and the predominant qualities (effects) it produces. The Latin verbs are: *siccat* (dries), *attenuat* (thins), *penetrat* (penetrates), *incidit* (cuts), *calefacit* (heats), *dissipat* (disperses), *densat* (condenses).

Predominant	Combination	Mixture (complexion)	Effects
Salt predominant	Salt with salt	A warm, moist mixture	dries
	Salt with niter		dries, thins
	Salt with alum		dries, penetrates
	Salt with vitriol		dries, thins, cuts
	Salt with niter, alum		dries, thins, penetrates
	Salt with niter, alum, vitriol		dries, thins, penetrates, cuts, heats
Niter predominant	Niter with niter	A dry, warm mixture	thins, disperses
	Niter with salt		thins, dries
	Niter with alum		thins, penetrates
	Niter with vitriol		thins, cuts
	Niter with salt, alum		thins, dries, penetrates
	Niter with salt, alum, vitriol		thins, penetrates, dries, cuts
Alum predominant	Alum with alum	A dry, cold mixture	penetrates, condenses
	Alum with salt		penetrates, dries
	Alum with niter		penetrates, thins
	Alum with vitriol		penetrates, cuts
	Alum with salt, niter		penetrates, dries, thins
	Alum with salt,		penetrates, dries,

Predominant	Combination	Mixture (complexion)	Effects
Vitriol predominant	niter, vitriol		thins, cuts
	Vitriol with vitriol	A moist, cold mixture	cuts, heats
	Vitriol with salt		cuts, dries
	Vitriol with niter		cuts, thins
	Vitriol with alum		cuts, penetrates
	Vitriol with salt, niter		cuts, dries, thins
	Vitriol with salt, niter, alum		cuts, dries, thins, penetrates

We could not set down here all the qualities that can belong to each of these four, but only the primary and predominant ones. For if we had wanted to list every quality proper to each individual case, the combination would rightly grow to infinity. Since each of these is for the most part equipped by nature with a fourfold endowment of qualities, twelve multiplied by twenty-four [12 in 24 ducta] will yield 288 different mixtures, and consequently different species of effects. And if I were to extend these through the four degrees of the primary qualities, there would result 1,152 mixtures, and just as many different effects. I therefore pass over in silence the diverse species of salts, niters, alums, and vitriols — for if I tried to combine these among themselves as well, the matter would run off very nearly to infinity. And who could describe in adequate words the combination of things if bitumen, sulfur, and the remaining metallic and mineral species were added in? See what we have very fully taught about these matters in our *Ars Combinatoria* [Combinatory Art].

CONSECTARIUM I. [Corollary I]

From this it is clear that no medicated water can exist that does not obtain a mixture of minerals and metals different from another's, and consequently different ratios of properties. For these mixtures behave no differently than numbers, to which the addition of a single unit essentially changes the number — as Aristotle teaches in *Metaphysics* IV [l. 4. *Metaph.*]. Even though the senses cannot reach these mixtures, that they lie hidden, blended in their secret chambers by the marvelous shrewdness of nature, reason itself teaches *a priori*, and experience *a posteriori*. And so we cannot sufficiently admire the wondrous providence of divine wisdom in the arrangement of natural things, when we look

more closely at that admirable marriage of the most diverse things conspiring into one — so disposed by a certain harmonious temper, proportion, symmetry, and measure that, in the use of these waters, the sick and diseased condition of mortals obtains an infallible effect.

But it could rightly be asked at this point how this confused little blend of so many species of different things can operate in the waters without confusion, and how it can exert its powers in the bodies of the sick. To this I answer in a few words. Since God [DEUS] and nature do nothing in vain, and all their works proceed from the best and most perfect intention, a certain marvelous attunement was surely necessary to him, lest one thing should retard or weaken the powers of another. Rather, by a certain unanimous conspiracy they should aim — by preserving the human race, for which they were created — at congruous and necessary medicinal effects. Hence it has come about that, just as the individual species of the said mingled things look toward the individual members of the human body, and by a certain magnetic and sympathetic affection toward them —

— are carried and drawn there: whether taken inwardly by drinking, or outwardly by sitting-bath, washing, smearing, fomentation [embrocha], or by trickling-drip [stillicidium] of the said waters, the individual species flow together to that member which they regard with a friendly natural affection. And since the saline species are filled with the most subtle spirits, nature uses them as a kind of forerunner [prodromus] — both to open the gates and to scour out the obstructed passages, and to prepare, direct, and ripen the mass of humors.

[Margin: "The beautiful analogy of the humors in the human body to the properties of the metals."]

These [saline spirits] are followed at last by the sulfurous spirits, like Tetrarchs in the same analogy, which by their innate heat moderate all things — namely the entrances of the best humors in the body. These [sulfurous spirits] are the spirituous substances of the metallic bodies, each of which seeks its natural station and dwelling-place. The golden substances, as if heaped with royal virtues, occupy before all others the metropolitan seat of the heart, and strengthen it. The bronze substances, and those consisting of much sulfur, flow together to the citadel of the breast and the station of the lungs. The iron substances hasten to the workshop of the spleen and the hypochondria, to purge the melancholic dregs. The leaden, tin, and nitrous-saline substances, prevailing toward the blood-making kitchen of the Microcosm, gird themselves to strengthen the liver and to dry out the dropsical phlegm. The sulfurous,

bituminous, and nitrous substances combine to loosen the intestines by their evacuating faculty. The stony mixed substance performs its parts excellently to relieve the kidneys and the bladder. Others, by their cutting and resolving faculty, are suited — applied by fomentation [embroche] — to the diseases of the brain and nerves: to paralysis, tetanus, tremor, opisthotonos, and apoplexy.

You see, therefore, that nature does with the same multiplicity of species mingled in the waters what is wont to be done in the perfect administration of a democratic state: while each individual performs the office committed to him, in this or that place, in this or that condition of office, in the best way it can be done, all nonetheless ever aiming at the same goal — which here is the common good and the single welfare of the commonwealth, and there the perfect health of the Microcosmic economy and the temperament of the humors.

CONSECTARIUM II. [Corollary II]

From this it is evident that most cases produce the marvelous effects which we sometimes see them yield in the cure of the sick — not by the primary forms of the qualities (whose sole office is to heat, to dry, to moisten, to cool), but rather by the specific properties of the minerals, arising from the likeness of the whole substance. And this specific property is nothing other than a certain sympathy, a hidden agreement of nature, by which one [water] exerts its power on this member of the human body rather than on another — as we shall show most abundantly in what follows.

And so you see, Reader, how the medicinal faculties operate in the thermal springs, and by what power they accomplish the effects we have recounted. These things accomplished, nothing further remains except that we now descend a little more deeply into the inner recesses of nature, and examine with all study and diligence from where, and from what causes, are born those astonishing prodigies which shine forth in certain springs, to the great wonder of the philosophers.

SECTIO IV

DISQUISITIO — DE MIRACULIS AQUARUM

On the Miracles of Waters, and the Prodigious Nature and Property of Certain Springs.

PREFACE [PRÆFATIO]

If in any natural compound the majesty of nature shines forth, [and] if she has assuredly placed her throne in the watery Realm, only that man could fail to know it who has nowhere beheld it. And so Pliny [Plinius], gazing up at prodigies of this kind that are almost beyond human credence, and forestalling as it were the goodwill or belief of his readers, says: *"If anyone judges that some of these things are not to be believed, let him declare that in no quarter are the miracles greater."* Some of these prodigies are referred back to heat, savors, odors, weight, lightness, thickness. Certain ones contain a wonderful power of healing; certain ones a deadly power. Nor are there lacking those which, by a kind of metamorphic virtue, turn everything to stone, iron, or copper, hasten gray hair, or are powerful with a divinatory force. Others, at the rising of the Moon, rival the tides of the sea; others are powerful with marvelous properties. Treating of these individually, in order, as far as can be done and as the weakness of our talent permits, we shall try to search out their causes.

Liber V, Sectio IV — De Miraculis Aquarum

Caput I — On the Color, Savor, Odor, and Mephitis [noxious exhalation] shining forth in certain springs and thermal waters

There are innumerable differences of colors in the waters. Since these differences are as it were manifest, we shall not dwell too long on them — especially since we have discussed this subject sufficiently and more than sufficiently, both in the preceding pages and in our *Hetruria* [Iter Hetruscum / our work on Etruria]. Who does not know that waters take on the color of whatever sort the mine or gallery is through which they have flowed? Now the channel through which the water flows can be considered in three ways: as belonging to the vegetable kind, or to the mineral, or to the metallic juices.

[Margin: "Waters are tinged by the juice of plants."]

Waters of the first kind are tinged by the juices of grasses and trees. For example: we see that the waters in which the alder [alnus] luxuriates with abundant growth are tinged a reddish or rather a lye-colored hue. If they wash over grasses such as celandine [chelidonia], chrysanthemum, and other similar plants, they are imbued with a saffron color. If they lick over white, gleaming, or chalky earth, they flow a milky color. If they have flowed through red ochre [rubrica], they are stained a red color. If through ochre or sandarac [realgar], a yellow color. If through verdigris-bearing places, they are blended with a green color — and so on with the remaining metallic juices, as we have taught above. But let us confirm these statements by experiment.

EXPERIMENT [EXPERIMENTUM]

Let there be a basin B A, into whose concave [interior] the little channels C D E F G H I K are inserted. These you should first fill with powders of various colors, namely: C with red, D with yellow, E with blue [caeruleo], F with brown [fusco], G with ash-gray [cinereo], H with green, I with white, K with black color.

Diagram. A perspective view of a round, shallow basin (concha) seen from slightly above, so the interior cavity and the rim are both visible. Eight short tubular spouts (canaliculi) project radially outward from the basin's side-wall, each connected to a small lettered opening; the basin as a whole is labeled A, and its near rim / front is labeled B. The lettered channels are arranged around the basin.

- B (top center, on the rim/interior): basin marker B
- A: the basin (concha) itself
- C (interior, upper left): channel C
- D (interior, top center): channel D
- E (interior, upper right): channel E
- F (lower right, projecting spout): channel F
- G (lower right rim, spout): channel G
- H (front center, spout): channel H
- I (front left, spout): channel I
- K (left side, projecting spout): channel K

When this is done, let the basin be filled to the brim with spring water; and the water, seeking an exit and issuing through the little channels, will be tinged with the color proper to each channel. You will thus see the water flow out tinged: red through C, yellow through D, blue through E, brown through F, ash-gray through

G, green through H, white through I, and finally black through K. I would have you suppose that the same thing happens in subterranean places. In these, imagine to yourself a water-reservoir [Hydrophylacium] A B, which discharges itself through diverse channels furnished with diverse minerals. I say that the water, in the spring of its own reservoir, is pure and simple; but as soon as it has entered the said channels — filled with veins of variously-colored minerals — it will present to the outside different species of springs in color, savor, and odor.

And this for the most part happens when they share in the corporeal substance of the earths. But if they are tinged only by the most tenuous vapors and exhalations of the minerals, or effervesce only by heat without any admixture, then they are discharged with the natural color of water — that is, limpid, clear, and translucent. And this indeed presents no difficulty; so let us proceed to other, more recondite effects.

It is asked, then, in the first place: why does the sea, to those viewing it from some mountain, display so great a diversity of colors? For in one part you will see it appear red, in another crimson [puniceum], in another yellow, in another now green.

[Margin: "The diversity of colors appearing on the surface of the sea."]

I say that colors of this kind are by no means real, nor arisen from any admixture, but only apparent (as we have amply demonstrated in our *Ars Magna Lucis et Umbrae* [Great Art of Light and Shadow]) — and that they arise either from the diverse reflection of the clouds and mountains, or, most of all, from the varied disposition of the sea-floor. For where the sea is deepest, there the sea is black and as it were pitch-colored; if it teems with the green sprouting of seaweeds, it will appear green; if with red pebbles and sand, it will appear red. In this way, in the first navigation of the Dutch [Batavi] to the Strait of Magellan [mare Magellanicum], not far from the mouth of the river della Plata [Río de la Plata], when they observed the sea stained an utterly blood-red color, they lowered a bucket and, inspecting the drawn water more exactly, found an innumerable multitude of little reddish worms mixed in the waters. These, taken up by hand, leaped here and there like fleas — and so they called them sea-fleas. Some think they are vomited up by whales at a certain time of year; others say they come from an infinite supply of small crabs, which stable themselves in the said tract of sea, and, being of a red color, present the sea, to those looking from afar, as imbued with a blood-red color. Elsewhere the whole Ocean is seen green, on account of the multitude of the plant they call Sargasso [sargasso], with which the sea is covered for many thousands of miles — about which plant, since we

have treated of it elsewhere, I have not thought it should be repeated here. Moreover, some waters appear blue (whether from the erosion of metals) or green (from a certain contagion), according to the marvelous attunement of the subterranean fire. For it is so disposed by heat that it sometimes makes juices from white turn red, from red turn yellow, from yellow turn green or black — no otherwise than as from sweet phlegm comes blood, from blood yellow bile, from yellow [bile] green or black — through certain degrees of color heightened, while from cooking [coction] —

— it [the color] proceeds, namely, into an excess of heat, and from this into a scorching. This is evident too in the diverse species of amber [succinum] — white, yellow, black — of which the first is produced from a moderate heat into white; the second from white into yellow by an intensifying of heat; from yellow, black is produced by a scorching heat. And this is the reason why rivers and springs sometimes change their native color: namely, on account of the confluence of various other rivers which enter some river, since these, taking their origin from diverse minerals, communicate the tincture they have acquired to the larger rivers which they enter — especially after great deluges of rain, by which water, imbued with the various dyes of the earthen clods of the land, rolls itself with a great load into another river. Hence the rivers are at first rendered turbid; and then, with the mud subsiding, the mineral spirits which remain infect the limpid water with various color and savor. The river Hypanis [Hypanis], most wholesome to drink — on Pliny's testimony — becomes most bitter after admitting the gush of a most bitter spring, which he calls Exampaeus [Exampaeus]. But let us now draw nearer to the miracles of the springs.

§ I. — On the Spring of the Sun [De Fonte Solis]

Pliny relates that among the Troglodytes there is a Spring of the Sun, which around midday at the new moon is extremely cold, then little by little begins to grow warm up to the middle of the night, at which time it is troubled by heat and bitterness. If the things Pliny says are true, I would readily ascribe the reason for it to the constitution of the subterranean channels. The first of these is filled with sweet water by a perennial flow, through a channel proper to it, like the other sweet springs.

[Margin: "The reciprocation of the Spring of the Sun, whence it comes."]

The other [channel], drawn from the Ocean by a long tract of ways, and heated by the subterranean fires, discharges itself into the same spring at a fixed hour. Now since the water of a channel of this kind is agitated by the ebb and flow of the sea,

it happens that for six or more hours it gradually insinuates itself into the spring; but with the sea subsiding, it too, drawing itself back, ceases from its flow, nor is it again urged by the inflowing of the sea. The bitterness of the water, moreover, results from the nitrous places through which it flows; and as the nitrous corpuscles gradually settle out from these, the limpid water prevailing, it is little by little restored to its former coldness and sweetness — which is said to happen around midday. But with the channel again stirred up by the surge of the sea, the spring, now grown cold, must necessarily grow warm and bitter again. And that the surge of the sea seethes most of all at midday, when the Sun is joined to the Moon, has been shown above. But of this prodigy [I shall say] more below.

§ II. — On Wine-Like Springs, that is, those carrying the odor of wine [De Vinosi Fontibus]

The kindly liberality of Nature has not only sported in wondrous ways in the waters, but has also wished to use mortals with delights in liquors of a wine-like savor — not, however, except when mixed with wine. The Lyncestian water [Lyncestis aqua], which is called *acidula* [sour-spring], after the manner of wine

— makes [men] drunk; which prodigy Ovid [Ovidius] elegantly described in *Metamorphoses* XV [Ovid. 15. *Metam.*]:

Differing in effect from this flows the Lyncestian stream, Which whoever
has drawn with little-moderated throat, Staggers no otherwise than if he
had drunk pure wine.

And concerning a wine-like spring on the island of Naxos, Propertius [Propertius] [says]:

And for you, Naxos, through your midst [flow] sweet-smelling rivers,
From which the Naxian throng drinks your unmixed wine.

And lest we be compelled to attribute some exaggeration to the fabulous poets: it is established that in very many regions of Germany and Gaul springs of this kind, which are said to recall the savor of wine, are found. Among these the most famous is that spring, celebrated by the confluence of men, in the County of Katzenelnbogen [Comitatu Cazenelobogensi], situated not far from Mainz [Moguntia], called Schwalbach [Sualbach] after the town it adjoins. Another is near the confluence at Andernach [Andernacum]. Another, in the Lyonnais territory of Gaul [Ager Lugdunensis] at the town of Saint-Galmier [S. Baldomani], called the Strong Spring [Fons Fortis], *fontaine fort*, supplies the lack of wine: if a

quarter-measure of it is mixed with wine, nothing of the wine's savor is lost; if it is poured onto flour, it immediately ferments, like any sour [liquid]; it is so wholesome that the townspeople rarely use a physician — by which virtue the aforementioned springs too are powerful. Such a one is also found in Aquitaine, not far from the city of Bazas [Bessa], a sour, wine-like spring: if you pour even a little of it into wine, you would believe you had drunk pure wine diluted with no water. In Spain, near Valencia [Valentias], it was shown above that similar ones are found. Since these things are so by the common estimation of men, the cause of this savor is rightly inquired into: namely, whether there is in the water itself something resembling the odor and savor of wine, or not?

I say: since all sour-springs [acidulae] have some unaccountable friendship with wine, and marvelously excite and exalt the savor of wine and the spirits lying hidden in it through their native sharpness — hence I think it comes about that —

[Continuation, left column, printed p. 275 lower:]

— [the springs are wine-like]. Now since this kind of channel-water is agitated by the ebb and flow of the sea... [this passage belongs to § I above; the columns interleave].

The Lyncestian water, which is called *acidula*, after the manner of wine, tinged with wine, while they titillate the tongue and palate with a pleasing tickling — and so, deceived by the odor and savor of wine (as we have also said in the preceding remarks) — [people] suppose that that odor and savor which is in wine is present in the sour-springs themselves. For since all sour-springs take their origin from alum or vitriol, mixed together with niter, and these are devoid of odor, it is certain that they cannot exhale that wine-odor of themselves. Rather, the sour water itself, joined to the agreeable sharpness of wine, produces in the imagination of the drinkers such an effect as they experience in the savor of wine. All these things, long and much explored in springs of this kind by various experiments, have at last become known to me. And so waters of this kind are not called wine-like because they share in the nature of wine, but because, sharp and joined and mixed with wine, they make a more pleasing draught of wine. For separated from wine, you would perceive as much of its odor as of any other sweet waters which we use everywhere in drinking. Let us therefore leave this opinion to those who, just as they always reek with a wine-like breath, so dream of nothing but wine-like liquors and their drinking — or at most of the first savor of the sour-springs.

[Note on page order: the PDF pages of this opening are bound out of sequence. By printed page number the reading order is 276 → 277 → 278 → 279, i.e. → 1 → 4 → 3. The translation below follows the printed-page order.]

CAPUT II.

On the gravity and levity of certain waters, and their marvels.

[Body heading reads "C A P U T II." — this opening begins Chapter II of Section IV, not Chapter I.]

The Peripatetic school refers the causes of gravity and levity in waters to the primary qualities, heat and cold; others refer them to density and rarity. For just as waters draw savors and odors from the material they pass through, so from that same material — and from its various mixtures of mineral particles, such as salts, niter, alum, vitriol, and the rest of the minerals — they acquire gravity in proportion to the abundance of what is present, and levity in proportion to its scarcity. From this arise those remarkable spectacles in waters: some of them buoy up whatever is thrown in, while others submerge whatever is thrown in. The cause of this is nothing other than the gravity and levity of the waters.

[Margin: Why some waters are heavier than others.]

But to proceed gradually from the better-known to the less familiar: many people wonder why ships unloading from rivers into the sea ride deeper in the rivers than they do in the sea. I myself have noticed this more than once and observed it carefully: as soon as ships are carried down from the Tiber [Tybri] into the sea, they rise about two palms higher and lift up above the water. The cause of this is nothing other than the salt mixed into the sea, which, just as it makes seawater denser and heavier, likewise holds the ships up higher.

EXPERIMENT.

Take two cups, one filled with spring water and the other with water diluted with salt. Once this is done, drop an egg into the first cup filled with spring water, and you will at once see it sink; drop the same egg into the water saturated and diluted with salt, and now you will find it floating on the surface. For the lighter the water is, the more easily the egg sinks; and the denser the water is, the more easily it floats.

COROLLARY.

From this it is also clear why certain fresh waters sometimes flow on top of others — why, for instance, the Rhine [Rhenus] flows over Lake Constance [lacum Acronianum / Lake Acronius], the Rhône [Rhodanus] over Lake Geneva [Lemanum], the Mincio [Mintius] over Lake Garda [Benacum], the Ticino [Ticinus] over Lake Maggiore [Verbanum], the Adda [Addua] over Lake Como [Larium], the Oglio [Ollius] over Lake Iseo [Sevinum], and the Marcia over Lake Fucino [Fucinum]. There is no other cause for this — as we have explained in earlier passages as well — except that the rivers, purged by their continuous flow and motion and having deposited the heavier mixture, are rendered lighter than the waters of the lakes, which are contaminated with various mixtures of subterranean matter. These lake-waters necessarily become heavier: partly because they are weighed down by bituminous matter, partly through the absorption of earthy juices, and partly too because the Sun draws off the finer parts of the water, leaving the dreggy substance behind. It is likewise widely established that oily, greasy waters float on top of fresh waters.

[Margin: Why some waters do not mix with others.]

And from this is also clear the cause of the spring of Panchaea [fontis Panchaei] in Thrace, of which Plutarch [Plutarcho] reports that a vessel filled with its water weighs twice as much in winter as in summer. This is because in winter, when the pores of the earth are closed, subterranean vapors entering through the openings in its bed fill the water with various mixtures of mineral matter — whence it is heavier; but in summer, when the Sun's heat opens the pores of the earth, these same vapors exhale and leave the spring free of any admixture of vapors. Hence it comes about that, for the reasons stated, the bottom of such springs is warm in winter and cold in summer.

Pliny [Plinius] records that in a lake of Sicily near Agrigentum [Agrigentini], in the Asphalt Lake [Asphaltitico] of Palestine, in the Acuscidamus [Acuscidamo] of Africa, and in the Arethusa [Arethusa] of Greater Armenia, everything floats and nothing sinks — not even bricks. In others, by contrast — as in a certain lake of Ethiopia [Aethiopiae] — everything sinks the instant it is thrown in, so that the lake does not even hold up the leaves of trees but they immediately sink. Into the Alcyonian Lake [Lacum Alcyonium] at Lerna [Leonam], if anyone enters, even a skilled swimmer, he sinks at once whether he wills it or not, dragged down to the depths with great force.

[Margin: Waters in which nothing sinks.]

The cause of each of these prodigious effects is asked. I say, then, first: in lakes in which nothing sinks — as in the Asphalt Lake — the cause is bitumen, with which it is so saturated that it can rightly be called a bituminous sea. Since, therefore, it is the heaviest of waters, as well as the densest, and most tenacious because of its glutinous and slimy matter, it will certainly hold up all the things thrown into it, provided they do not exceed the bituminous mass in their own bulk — as will be clear from what we shall shortly bring forward from the Archimedean doctrine. But in lakes that are not bituminous, yet are rich in salt, niter, or petrifying juice, the waters — loaded with saline, nitrous, and stony particles — are rendered the more powerful at holding up any heavy things thrown into them, the more they are condensed by the said particles. In some places these particles, combined with bitumen, make certain stretches of sea wholly impassable to ships, as the nautical itineraries report of the muddy sea encountered in the innermost gulf of California [Caleforniae].

The explanation, then, of lakes that hold up whatever is thrown in is easy. A greater difficulty arises in explaining those lakes in which everything — even the leaves of trees — is seized and submerged, since these marvelous effects cannot be ascribed to the levity of the water but must have other, more hidden causes, which we now set out to explain.

[Margin: Why some waters hold nothing up.]

We say, therefore, that the cause of these effects does not depend on the levity of the waters, but on the violence of the water as it discharges itself at the bottom through various subterranean channels. From this discharge, whirlpools necessarily follow; and from the whirlpools, the drawing-in of bodies thrown into them. Daily experience at Rome in the summer months teaches this: when even the most skilled swimmers happen to fall into the eddies of such a whirling river, they are dragged

[Note: the printed running header on this page reads "DE THERMIS" (On Thermal Springs), which appears to be carried over from a neighboring chapter; the body content here is the §. I of the present chapter on the gravity and levity of waters.]

down into the deepest recesses of the river by a kind of violent suction, and with no hope of escape left, they are swept away to a pitiable death.

You may learn this by experiment in a vessel pierced through its bottom with several holes made on purpose. First fill it with water while the holes are stopped; if you then throw in objects of various kinds, they will easily support themselves on the surface. But if you open the holes in the bottom, then behold —

whatever you have thrown in is driven as though into whirlpools: wood, paper, leaves, snatched up by the rushing outflow of the escaping water, soon sink. Therefore, whenever such waters are found in which all bodies are seized by a kind of suction, I would judge that the cause of this is to be assigned to the whirlpools.

§. I.

On the true and real cause of the weight — that is, the gravity and levity — of waters and of the things that float in them, from the Archimedean doctrine.

Many have supposed that bodies floating on water are caused partly by the thickness or coarseness and viscosity of the waters, and partly by the form and shape of the bodies floating in them. Thus they say that a flat dish floats on water more easily than a sphere, or a cube, or a body of some other shape. But they are mistaken, since this whole floating depends solely on the gravity and levity of the water, in proportion to the bulk of the body resting on it. And although we have demonstrated this most fully from the doctrine of Archimedes [Archimedis] in his book *On Floating Bodies* [περὶ τῶν ὀχουμένων (peri tōn ochoumenōn, "on the things that float"), i.e. *De iis quae vehuntur in aqua*] — in the Second Book of the *Art of Magnetism* [Ars Magnetica, Kircher's *Magnes*] — it nonetheless seemed worthwhile to add here a few points left out there. For nothing concerning the gravity and levity of bodies will be encountered so obscure and abstruse that you cannot assign its cause from these.

Three cases, then, can occur with things floating on water, from which their greater or lesser gravity and levity is gathered. First, if some body placed on water is, for an equal bulk, heavier than the water whose place it occupies, I say that such a body will immediately make for the bottom. Second, if a body placed on water has a gravity equal to a bulk of water equal to the place it occupies, I say that it will not go to the bottom but will rest, placed at any point within the water's depths. For it will neither rise nor project above the water's surface — otherwise it would be lighter, contrary to our supposition — nor will it descend to the bottom — otherwise it would be heavier, contrary to our supposition. Placed, therefore, at any point within the water, it will rest at rest.

But third, if a body of this kind, placed on water, floats on top, I say that it is necessarily lighter than a body of water equal to the bulk of the whole body placed on it — and precisely as much lighter as is the weight of the water that equals the magnitude of the submerged body. That is: if you place a wooden cube on the water and suppose that it sinks to its midpoint, I say that the portion of water which the half of the cube placed in it occupies will be of as much weight

as the whole cube weighs. But if the cube corresponds exactly to the surface of the water, with no part of itself projecting, I say that the water whose place the cube occupies will be of equal weight to the whole cubical body. And likewise, a body that makes for the bottom will necessarily be heavier than the body of water whose place it occupies. But I demonstrate the matter by an example.

Diagram. A large rectangular vessel (a cutaway tank of water), labeled ABCD, shown in perspective. Within and around it several small cubes are drawn at different depths to illustrate the Archimedean cases of flotation. The accompanying text below the figure reads: "Let the water be ABCD, within which a cubical body is sunk; let the surface of the water be AB, and the bottom CD." The cubes are lettered to match the proof (printed p. 278). Readable labels:

- A (upper-left corner of the tank): vertex A (the water's surface AB runs from A along the top).
- B (upper-right corner): vertex B.
- C (lower-left corner): vertex C (the bottom CD runs along the base).
- D (lower-right corner of the base): vertex D.
- E, F, G, H (small cube resting on the floor at lower left): the fully-sunken cube EFGH, sitting on the bottom CD near corner C.
- I, K, L, M (small cube at mid-height, left of center): the cube IKLM, suspended within the water; an interior point N is marked beside it (the resting point).
- N, O (cube high on the surface, upper center): the floating cube NOPQ; the letter O marks the cube projecting above the surface.
- T, X (cube at the surface, upper center-right): the cube whose label includes X, with lower vertices marked by Greek letters ρ , ς , π , θ (rho, sigma, pi, theta) and x , y , ζ , α .
- V, β , γ , ε (cube to the right, with sub-vertices): a cube with Greek-letter vertices β , γ (beta, gamma); P marks an adjacent floating cube with Greek sub-vertices δ , ε , ζ , η (delta, epsilon, zeta, eta).
- P (small cube at right, partly submerged): the cube P, two-thirds immersed.

[Below the figure:] Let the water be ABCD, within which a cubical body is sunk; let the surface of the water be AB, the bottom CD. Let some cube be immersed first within the water near A. If it descends to the bottom CD — as appears in the cube EFGH, resting on the bottom — I say that it will certainly be heavier...

than the body of water EFGH whose place it occupies. For if it were lighter than the said water, it would not make for the bottom but would stand either in the

middle or above the water's surface. But by hypothesis it makes for the bottom; therefore it will be heavier than the water whose place it occupies — which was to be shown.

But if another cube is immersed in the water so that it corresponds exactly to the water's surface AB — such as is the cube IKLM — I say that the body of water IKLM will be of equal weight to the cube, and that, placed at any point in the water (for example at N), it will rest. If not, then it will either descend to the bottom or rise above the water's surface. If the former, then it no longer is of equal weight to the water whose place it occupies, and so it will be heavier — which is contrary to the hypothesis. If the latter, then it will be lighter — which is likewise contrary to the hypothesis. Therefore it will be of equal weight to the water whose place it occupies, and consequently it will rest wherever it is placed within the water.

But if the cube taken floats on the surface of the water — as happens with the cube NOPQ — I say that the cube is lighter than the body of water which equals the cube's body, and lighter indeed in proportion as the cube stands the greater part outside the water. Let me explain. Let there be first the cube O, which is immersed in the water to one-third of its body, with two-thirds of the cube projecting. I say that the water $\rho \varsigma \pi \theta$ (which is the third part of the water equaling the whole cube), this third part, I say, of the water into which the cube is immersed, will be of equal weight to the whole mass of the wooden cube — because the watery body $\rho \varsigma \pi \theta$ is three times heavier than the portion $\rho \varsigma \pi \theta$ of the submerged cube; and therefore it is of equal weight to the whole cube; and therefore the cube will be immersed only to a third of its part.

Next, let there be the cube X, which, let into the water, is immersed to half of its part. I say that the water $x y \zeta \alpha$, at the weight of half the cube, is double the whole watery cube $T V Z \alpha$, and equal in gravity and weight to the whole wooden cube. Since, then, the half of the water is double in weight to the half of the whole cube floating above, the cube cannot be sunk to the bottom, but will be immersed to half of its part, with the other half projecting above.

The same is to be said if the cube P is immersed to two-thirds within the liquid — that is, to the whole mass $\delta \epsilon \zeta \eta$; for then only one-third of the cube will be seen to project above the water. For the watery mass of the two-thirds will be equal to the whole wooden cube, and consequently only one-third will project from the wooden cube. Similarly with the cube O: in the cube NOPQ equal to it, one-third subsiding will leave two-thirds outside the water. For just as the portions of the watery cube stand to the whole watery cube, so in the wooden cube the

submerged portions stand to the whole cube that projects. All of which is demonstrated most subtly by Archimedes, by [Christoph Clavius / "Gebold"?] [?: source has "Getholdo" — perhaps Guidobaldo del Monte (Guido Ubaldo); reading uncertain], and by Galileo [Galileo] in the cited place.

[Margin: The gravity and levity of bodies in waters is demonstrated.]

COROLLARY I.

From this it is clear that this holds true not only in solid and homogeneous bodies, but in absolutely every body floating on water — since this floating depends precisely on nothing other than the gravity of the water, with no regard had to this or that particular water. For whether the liquid is well-water, spring-water, sea-water, salt, nitrous, sulphurous, or bituminous — whatever liquid it may finally be — it makes no difference: only its gravity is to be considered. The heavier it is, the more it carries; the lighter it is, the less — as is clear from the examples adduced above. Indeed the liquid quicksilver of mercury [Mercurialis hydrargyri liquor], just as it surpasses all liquids in gravity, so too will let nothing, however heavy, that is placed on it be submerged — excepting gold, which is heavier than it.

Again, no account is to be taken of the bodies resting on the said liquids — neither of their shapes transformed into various forms (flat, round, angular), nor of any particular position of the body, as many have persuaded themselves. Whatever the body may be, and of whatever parts it is finally composed, clothed in whatever form, such a body — however heterogeneous — is always to be taken as a single, whole, solid body. If for this body you take a mass of watery body equal to it, and find that mass heavier than the weight of the immersed body, you will infer that this body must necessarily be submerged in it. But if the weight of the water is equal to the weight of the body placed on it, the body will neither rise nor descend. And if, finally, the body is lighter than the water — for the body placed on it — then it will float on top, in the proportion we prescribed just above.

For example: if someone takes a dish of bronze, and [places it] upright [?: a few words abraded; sense is "places it flat/upright on the water"], it will certainly float — not precisely by reason of its shape, as many wrongly think. For if the dish is filled with liquid and becomes heavier than the water whose place it occupies, it must certainly sink; but if the whole aggregate is still lighter than the water whose place it occupies, then only so much of it will sink as is the body of water of equal weight to that aggregate.

And from this it is clear why ships float without any danger of sinking. For if you take the whole aggregate of the ship with everything contained in it, I say that as long as the gravity of this whole aggregate is less than the magnitude of the water whose place it occupies by its immersion, the ship will float — even if it is equal in weight to the whole aggregate. From this it is clear that, whether the weight of the water is varied — as happens in certain seas filled with briny moisture — or the weight of the ship is varied, its degree of immersion is always varied accordingly. For if the water becomes heavier through some accident, then a smaller quantity of water will equal the ship's weight, and so it will sink less; whereas, when it meets with clear and pure water, the ship will sink the deeper in proportion as the water is freer of thick humors. But if the ship is weighed down with stones, casks, or other things, then

[Margin: The gravity and levity of bodies in waters is demonstrated.]

it will then doubtless require a greater quantity of water to equal the ship's weight, and consequently a greater portion of the ship will sink. But let what has been said about gravity and levity suffice — which I judged should be explained at greater length, so that whatever we have said up to now about the gravity and levity of waters, and shall afterward say about floating islands, may be referred back to it.

COROLLARY II.

On islands floating in lakes and ponds.

Floating islands are earthy portions in lakes, masses heaped up from various mixtures of lighter and viscous matter, which — driven this way and that by the wind — are nowhere firm or fixed. Seneca [Seneca] testifies that he once saw such islands in the lakes of Statonia [Stratoniensi], Tarquinii [Tarquinienesi], and Vadimon [Vadimonis]; and we ourselves have treated of them at length in our own Etruria [Etruria] — though it is found that none of them survive to the present day. Pliny [Plinius] teaches that in the Lake Cutiliae [Lacu Cutiliae] in the territory of Reate [Agri Reatini] a huge island floated in the time of the Aborigines, known to the ancient colonists of Italy by an oracle. Posidonius [Posidonius] reports that in Lydia [Lydia] there were the Saltuares Islands of the Nymphs [Nympharum Insulas Saltuares], moved at the beat of the feet of musicians keeping time. Herodotus [Herodotus] tells marvelous things about the island of Lake Chemmis [Lacus Chemnis] in Egypt, which floated while supporting groves and woods and the great temple of Apollo [Apollinis]. Today they are found in many places, both in Europe and in the other regions of the

parts of the world — Asia, Africa, America. But passing these over, let us pursue those that are both near to us and better known.

[Margin: Where floating islands come from.]

Three miles from Tivoli [Tybure] as one goes toward Rome [Romam], one must cross the river Albuneus, or Albula [Albula], so called from its milky color [a colore lacteo], which has its origin from a nearby lake — a lake notable for sixteen floating islands which they call *Barchettae*. As for their nature, properties, form, manner, and composition, I refer the reader there, since we have described them in a whole treatise in our *Latium* [*nostro Latio*, Kircher's *Latium*]. There is also, in the Gallo-Belgic province near Saint-Omer [Andomarum], a lake carrying a huge island planted with trees and rich in pastures, on which sheep and cattle, intent on the pasture, are carried along together with the island wherever the force of the winds drives them. In Gallia Narbonensis too, not far from Roussillon [Ruscinone], one is seen, bright green with fine, slender reed. But setting these aside, let us return to the argument before us.

Two things deserve to be examined here: first, why they float; second, how most of them — of which the ancients made such famous mention — eventually ceased to exist. The cause of the floating is undoubtedly the levity of the material itself, according to what we said a little earlier about things resting in water. For if they were heavier than the bulk of water whose place they occupy, they would certainly sink; but they do not sink, because — as we have often examined by curious scrutiny — just as they are compounded of bituminous earth, sulphurous clods, straws, wood, rushes, and the roots of plants, cohering by the wondrous craft of nature through the glue of viscous bitumen, mixed together with mud and slime, so too they float by the texture of their lighter material at the pleasure of the winds, and drift this way and that, stable in no place.

It remains to be examined how they are generated and how in time they decay. The matter stands thus: since nearly all floating islands in lakes are born amid bitumen, sulphur, niter, and similar fetid material, it happens that at first they are glued together by the viscosity of the bitumen, with diverse matter together with sands or mud and with sulphurous and nitrous particles, which congeal by the force of the water with which they are soaked. These, in the course of time — whether by the lake's flooding, or by storms and the force of the winds, or by rains and downpours, especially in soil that is not stony but muddy and eaten away — at last fall away; and once this has happened, they soon float by the levity of the material of which they are composed, and so turn into floating islands. It can also happen that — whether by an earthquake or some other

accident — a tufaceous portion in the bottom of the lake is cut off and, rising to the surface by its own lightness, passes into a floating island. And by these means floating islands can be generated.

[Margin: Why they sometimes disappear.]

They vanish, however — or cease to float — either by the frequent collision of many years, made both among themselves and against the shore, by which in time they are worn down and dissolved and, broken into several parts, are fixed to the shores, united to the firm earth, and grow together again; or else such islands, pressed by the excessive burden of growing herbs, stalks, and shrubs, and weighed down too by the abundance of sulphurous and nitrous matter continually accreting there, have the gravity of the island overcome the gravity of the water whose place it occupies, and at last, sunk of their own accord by their own weight, settle to the very bottom. This is the origin and corruption of floating islands. Hence it is no wonder that there were once many such islands in the lakes mentioned above which today do not appear — islands which have either coalesced with the firm earth, or, increased in weight, have at last subsided. It is no wonder, too, that today many floating islands are found which were unknown to the ancient Romans, as we reported of Lake Albuneus. In this way nature plays in the world by the perpetual alternation of generation and corruption, so that those which cease in one place rise up new in another, themselves also destined to perish in their own time. And let this suffice concerning floating islands.

CAPUT III.

On Deadly Waters and Charonian Pits, Endowed with a Lethal Power.

[De Aquis lethiferis & Scrobibus Charoneis, deleteria vi pollentibus.]

These waters differ in various ways. Some are deadly only to animals and not to humans; others, by contrast, to humans and not to animals; still others to both — and indeed even to the very plants that grow up along their banks. To the first kind belong all those Charonian pits [Charoniae fossae] which I have treated at length in my account of our own Etruria [Hetruria]. At the merest whiff of their odor, birds flying overhead drop down dead — as happens with the waters at Monte Pulciano [Mons Politianus], and near Rapolano and Volterra [Volaterra], which the locals commonly call *Puzzole*. Yet these same waters, when drunk by humans, do no harm at all: they are perfectly clear, and they provide a remedy for serious illnesses.

[Margin: Why the waters of Avernus are deadly.]

As for why they kill birds, the cause is a vapor rising from burnt sulphur. Just as this vapor is antithetical to birds — being ἀντιπαθῆ [Greek: ἀντιπαθῆ (antipathē), "antipathetic," naturally hostile] — and produces in them a suffocation of the vital spirits, so too it brings about their death. The Lake of Avernus [Lacus Avernus] has this same power, as do the waters of the Styx [Aquae Stygiae] in the territory of Caere [Ager Caeretanus], whose vapor proves deadly not only to birds but, when the *Syrophoenix* wind [Syrophoenice] blows, to cattle and other animals as well — as I heard from the very shepherds themselves while exploring these places. But since countless Charonian pits of the same property are found across the world, I pass over them and turn instead to those things which I have learned either ἀντιπαθεῖ [Greek: from direct observation] or at least by the reliable account of others — ἀντιπαθέων [Greek: ἀ. (autopsia/relation), "by autopsy or trustworthy report" — *Kircher distinguishes what he saw himself from what he heard reliably*] [?].

By contrast, there are some waters that bring death to humans and other animals but spare the fish that live in them. The only reason for this is the fish's continual exposure to the water: just as they have converted the water's poisonous power into their own nature, so too it serves them as nourishment. The same thing happens with certain humans who, by gradually taking poisonous substances, have come to use them without harm — as we read of Mithridates [Mithridates] and of Albertus Magnus [Albertus Magnus], who tells of a girl of Cologne [Colonia] that, by hunting and eating spiders, made herself immune to every kind of venom; yet she became so saturated with the poisonous spirit that she could kill others by her very breath. I say the same thing happens with fish living in poisonous waters.

By the account of the poets and historians, such was the Styx [Styx] said to be: a spring which, according to Pliny [Plinius], Seneca [Seneca], and others, falls drop by drop from a steep crag at Nonacris [Novacris] in Arcadia into a lofty rock, then flows down into the river Crathis [Crathin], and at last spreads out into a lake. It is of such great poison that, once its water is drunk, it instantly kills both humans and animals. There is also the treacherous clarity of the water, by which those tormented with thirst are deceived: the moment they have drunk, they fall down lifeless.

As for the reason, I would suppose it to be one of several things: either a certain power of the water — a petrifying force that binds and hardens the inner organs, as happens in gypseous waters; or a corrosive force, by which the stomach and the parts adjoining it are eaten away; or a suffocating and constricting force, by

which the throat and the passages of the windpipe are blocked off, leaving no power to breathe; or an arsenical spirit mixed into the waters in the most exact proportion, which, being utterly hostile to the heart, kills as quickly as possible by drying up the vital spirit and consuming the vital vessels. Any one of these is enough to kill — and with all the greater speed when they have all flowed together into a single mixture in the water.

[Margin: The property and power of a horse's hoof.]

My opinion is confirmed by the remarkable effects these waters produce. For, as the authorities just cited testify, not only do all vessels — of whatever material they are finally made: glass, crystal, *murra* [murchina], stone, earthenware — into which the water is poured shatter and burst apart, but even leaden, bronze, iron, tin, silver, gold, and electrum vessels are dissolved, just as by a certain *aqua regia*, by the true corrosive Stygian power. A horse's hoof alone sustains the water unharmed — and Pliny and Vitruvius [Vitruvius] attest that this water was offered to Alexander [Alexander], and brought death to him who drank it.

If these things are true, the reason and cause must be sought as to why a horse's hoof alone can sustain the water of the Styx without injury. Granting, then, that the matter is so, I say that this effect must be ascribed to the constitution of the horse's hoof. For since it is formed of nitrous excrements joined with a certain natural fattiness, congealing by nature's craft into a kind of horny material, it comes about that, by a certain natural condition of its own, it resists corrosive waters — just as, by a most recent experiment, *aqua regia* or Stygian water extracted from salt, niter, alum, or cinnabar (which they call the "infernal" water [*aqua infernalis*]), when poured over a horny plate or onto a hoof, leaves it unharmed, without any corrosion or eating-away.

[Margin: Antidote to arsenic.]

For there is in certain things a viscosity and stickiness so opposed to acid and corrosive substances that it seems they cannot be subdued by them at all. This is plain too from the wax which engravers [Chalcographi] spread over the plates they are to engrave: it suffers nothing from the Stygian or *aqua-regia* liquids; yet the moment it touches a bronze plate, it eats it away. From this I am quite convinced that this same effect may be obtained not only in a horse's hoof but in the hooves and horns of any other animals whatever. It is also clear from the experiment of physicians who, when they undertake to cure those who have incautiously swallowed arsenical, mercurial, or verdigris poisons, achieve their aim no more easily than by having them drink oils and similar juices imbued

with a certain stickiness and viscosity. For this poison, as it were ensnared and choked off by a kind of suffocation, can then no longer spread itself.

[These things having been set forth, let us now proceed to the rest — to setting out the properties of deadly springs.] It is not only to animals of every kind that pestiferous springs are found to be deadly, but to the very fish as well, as Agricola [Agricola] testifies. He says that in Germany, by the river Saale [Salam fluvium], there is a spring of the clearest water — yet at certain fixed seasons of the year it falls into so malignant a state of nature that it kills however many fish are in it, though the water itself departs not at all from its former condition in either color or taste. The reason for this is none other than that, at certain seasons, the subterranean *aestuaria* [steaming exhalation-chambers], stirred up, emit a virulent and most subtle vapor from the burnt putrefaction lodged there. Being most subtle, it easily mixes with the waters; the fish thus infected die at once. But soon, once the vapor has been breathed out and the subterranean exhalations cease, the water is restored to its former wholesomeness, and the lake is replenished with a fresh brood of fish — a clear sign that this affection comes on suddenly and ceases suddenly.

Experiment also teaches this. For once, when our apothecary [Pharmacopaeus] had ground arsenic into powder in a mortar, and then rinsed an ill-cleaned vessel in the basin of household water that was stocked with fish, the fish, infected on the instant by its great and virulent force, all to the last one died.

I return to the birds, which experience teaches are afflicted by pestiferous vapors of this kind beyond all other animals. Hence the Charonian pits [scrobes Charoniae] and the Plutonian caverns [Plutonia antra] not undeservedly earned among the Greeks the name ἄορνα [Greek: ἄορνα (aorna), "without birds"], to which the Latin *Avernus* corresponds.

[Margin: Why the exhalations of caverns are noxious to humans.]

That this is true I came to know for myself: when, given the opportunity, I explored such places, the sulphurous exhalations of this kind the birds shunned by a certain natural instinct, as things contrary and deadly to them. For since they are of an airy temperament, they feel a hostile force of this sort far sooner and more readily than land animals do; indeed, the moment they have inhaled it, they are seized by a kind of vertigo, swept sideways, and either suffocate in the water or perish dashed against the rocks and ground.

That the matter is no otherwise I learned by this experiment. Having placed a sparrow inside a cage, I lit, beneath the cage, sulphur mixed with a tiny portion of

bitumen — and behold, at the very first whiff of the smoke the little sparrow grew faint, and with the cage door opened it flew out, as if to take some thought for the safety of its life by flight; but with the vertigo gaining strength, it was at last, like a drunken creature, dashed to the ground, and was gradually failing. Soon, however, after cold water was sprinkled on its head and poured into its beak — the cold dissolving the vapor brought upon its head — it was restored to its former strength, though without this remedy it would surely have perished.

From this I gathered why animals brought into the grotto of Pozzuoli [spelunca Puteolana] — which they call *Cane* [Grotta del Cane] — and stupefied in a moment, are freed from their stupor and revive when they are suddenly plunged into the neighboring Lake of Agnano [lacus Agnani]. The marvelous properties of this grotto, known to the whole world and described by countless authors, I pass over; on these I do not linger. Let it suffice here to show the cause and the diversity of the effects that these exhalations produce in nearly all places where a great mass of sulphurous and other mineral waters is lodged.

And first, it is certain that the evaporations of sulphurous and mineral waters differ greatly from the pernicious vapors that the Plutonian grottoes breathe out. For the former free people, as experience teaches, from many infirmities; the latter, imbued with a certain deadly force, threaten them — I will not say with health, but with death on the spot. Why the vapors of mineral waters do not harm humans was stated in what came before; why, on the other hand, the exhalations of caverns are altogether harmful and deadly to them, we shall now explain.

I want you first to be quite convinced of this: that these fissures of the caverns, exhaling a pernicious spirit, derive their origin from the subterranean caves; and that the inner air of the caverns, deeply tinged with the dregs of many mineral juices, the moment it is stirred up by the *aestuaria* lying beneath and belched out through fissures of this kind, will produce the effects we have recounted — and indeed effects most diverse according to the diversity of the matter. For if the air has been tinged only with the exhalation of burnt sulphur, it will bring danger to none but birds; if it has belched forth exhalations mixed with the dregs of burnt bitumen, it will afflict, with a certain narcotic force, all those animals that have approached such places too incautiously. Again, if the air is tinged with calcined arsenic, antimony, or quicksilver liquid poured over it, it will, without any remedy, bring death to animals by suppression of the heart. If it is the exhalation of gypseous matter, mixed with a portion of vitriol or alum, it will strangle those who come near.

In this way it will cause differing symptoms according to the nature of the poisonous matter. These pestiferous exhalations are produced either by the inner heat of the earth, as I said, or by the force of underground fires burning the rocks and other mineral clods — such as, among other things already set forth, are pyrites, *stibium* (which they call antimony), cadmia, sublimate mercury, and countless others. These, when macerated with strong waters [aquae fortes], emit exhalations so deadly that they strike men senseless at the very first odor. All this is established by the experience of goldsmiths [Aurifabri] and of the miners themselves: the former, in handling the said minerals, unless they proceed with great caution, are afflicted with dreadful and incurable diseases; the latter, once a subterranean cavern of the mountain has been opened, are so suddenly overwhelmed by the dregs of such exhalations that often all who are working there are smothered and perish to the last man. How they are wont to meet this plague of exhalations will be told below in its place.

Finally, if a very great mass of putrefactions has flowed together into the said caverns by way of rains through the hidden channels of the earth, then — fermented by the metallic spirits and the exhalations of the *aestuaria*, dissolved by the *aestuaria* into exhalations — it infests, through the fibers of the earth, first the vegetable economy [vegetabilis Oeconomia],

then the air as well with its taint. From this, through the corrupted nourishment of living things and the contamination of the air, various and monstrous *geneses*, kinds of diseases, and the most savage plagues arise, and carry off a great part of mankind. But let the reader consult my *Scrutinium Physico-medicum* [*Scrutinium Pestis Physico-Medicum*], where I have treated these matters at length.

CAPUT IV.

On the Ebb and Flow of Certain Springs, and on the Various Changes of Waters; together with Springs that Foretell Famine and Dearth.

[De Fontium nonnullorum fluxu & refluxu, & varia Aquarum mutatione, uti & de Fontibus annonae caritatem praenunciantibus.]

It seems a marvel to some that there are springs and baths that imitate the ebb and flow of the sea, yet with remarkable irregularity. Some ebb and flow twice daily; others over cycles of twelve days or more; certain ones dry up for half the year and flow for the other half. I will not recount here what the ancients have handed down about such springs, wrapped in countless fables, but only what I

have either seen myself or learned at least from the report and writings of men entirely worthy of trust.

[Margin: A reciprocating spring.]

There is a place in Westphalia [Westphalia], about four leagues distant, beside a village which they commonly call Altenbeken [Altenbecken], in an open field; it is sown all about on every side with heaps of sand, and shows no hint of water. In this sandy plain water bursts forth twice by day with such force and roar (whence it earned the name *Bollerbrunn* [Bollerbrunn]) that it floods the whole of that surface; and then, decreasing in the same way it rose, it hides itself entirely, leaving only the sandy surface we mentioned.

The locals who dwell by the spring told me that the bishop Theodore [Theodorus] [?], an officer [?] once most eager to see this marvel, brought a party with him there for the sake of relaxation, and had a table set up in the middle of the surface, sumptuously and elegantly furnished. Being well acquainted with the nature of the place, he resolved to make sport of the curiosity of the women — who suspected nothing of nature's hidden trick, not even by a shadow. The hour of the water's eruption was now near, when, amid the conversation, while everyone was indulging pleasantly and merrily in good cheer, the water burst out with its usual force; and while they wetted themselves in the unmixed wine above, the water filling up its proper place below drenched the table-companions up to the chest, so that those who had come to the table dry-footed were now forced to seek dry ground by wading — not without the laughter and guffaws of those onlookers who, aware of nature's pranks, had withdrawn in good time. But enough of this pleasantry.

The question, then, is the cause of this ebb and flow. I say the cause is the ebb and flow of the Baltic Sea [mare Balthicum], from which it is distant a journey of ten days; and since this finds an outlet at this spot through a hidden subterranean channel, it discharges itself there at fixed hours according to the laws of the sea's tides. That this is true is shown by the varied reciprocation of the waters, which — just as in the sea, following the motion of the Moon through the Zodiac — overflow more abundantly at new and full Moon, and more sparingly when the Moon is at its half [dichotomos] state.

But you will perhaps object that these waters are fresh, and therefore cannot derive their origin from the sea. I answer that such waters can become fresh in two ways. Either by being filtered through sandy and chalky earth, as was shown in what came before. Or, second, through another subterranean river which,

when the inrush of the seawater strikes it, causes it to overflow toward the mouth of this place; while as the sea ebbs, this river too, restored to its own channel, must necessarily draw back.

[Margin: The ebb and flow of the river Timavus.]

Something similar is observed in the river which the ancients call the Timavus [Timavus], lying between Istria [Istria] and Carniola [Carnia], where there is a mountain of the same name. This mountain, packed with water-reservoirs [hydrophylacia], belches out into the river Timavus through nine mouths, as Virgil [Vergilius] attests:

Whence through nine mouths, with a great murmur of the mountain, It comes, a bursting sea, and presses the shore with its roaring flood.

For this reason it was not undeservedly called by the ancients "the spring and father of the sea." For it suffers an increase and decrease, just like the Adriatic Sea, in that last corner of the Gulf of Diomedes [Diomedeus Sinus]; and at times it swells so much that it floods the whole region with a deluge. And since it always keeps its own sweetness, many wonder why it is not tainted by the saltiness of the sea. Not far from the mouth of this river an island [Insula] was once to be seen, on which there was a most celebrated thermal spring [thermarum fons] that suffered the same reciprocation of tide as the sea; today, called the Bath of Monte Falcone [balneum montis Falconis], it is visited and frequented by crowds — although the island, joined to the mainland in the course of time by an accumulation of silt, has now lost the name of island, while the heat of the bath still endures.

The question, then, is the cause of so prodigious an increase of the river; and why it is not mingled with the marine waves, and is not deprived of its sweetness all the way to the sea itself. Before I assign this, it should be known that, fourteen miles distant from the river Timavus, there is a mountain beside a village which they call San Canzian [S. Cantiani], from whose innermost parts a great quantity of water rolls forth like a river,

which is scarcely seen unrolled into level ground when, behold, meeting a chasm in its path, it is at once swallowed up and nowhere appears again. This subterranean river, therefore, meeting the marine water that likewise enters by a subterranean channel, and being unable to overcome the violence of the maritime flood (which is of a lighter nature), and granted no power to retreat, is driven back through another channel that stretches within the cavernous Timavus mountain, and fills the whole mountain from bottom to very top. Thus

filled, overflowing with the said abundance of waters, it forms the river Timavus through its many mouths: this river suffers the said increase when the sea is flowing, but a decrease when it is ebbing.

[Margin: The ebb and flow of the river Timavus.]

It is therefore not the sea that swells the river meeting it on the outer surface by its assault, but by the hidden contrivances of the inner and subterranean constitution that it brings about the increase and decrease of the river. For while the river, swallowed up near the village of San Canzian, meets the subterranean waves of the sea, it is driven back and fills the whole mountain through its channels; whence, overflowing, it forms the Timavus, which fills everything with a flood. But as the sea ebbs, the subterranean river, having now gained looser reins, follows the ebbing subterranean waves of the sea; and the mountain being denied its usual tribute of waters, the river Timavus accordingly acquires a certain moderate level and a decrease from the springs of its native mountain, out of which it bursts — until once more, with the sea flowing, after a fresh struggle of the waters, the mountain is again filled and bestows its usual increase upon the river. This alternation of increase and decrease of the said river endures perpetually.

If anyone has rightly grasped this mystery of nature, I do not doubt that he will have a ready solution for countless cases on a similar subject. It is therefore plain that, in a fresh-water river, the cause of the increase and decrease is not the sea, but the sea's thrust into the subterranean passage, by which the subterranean river, diverted from its straight course, is violently driven into the caverns of the mountains. By this propulsion the overflowing cauldrons [lebetes] of the mountain spread the river, weighed down by a vast mass of waters, far and wide beyond the natural station of its bed.

Mountains of this kind are also found in the Pyrenees [montes Pyrenaei]. There is such a one in the territory of Poitou [Ager Pictaviensis], near the village commonly called *de la Goudenuré*; and a spring near the city of Saumur [Sammur] on the banks of the Loire [Liger], in the village commonly called *de Varins*. From these two adduced examples it is plain that, whenever springs and rivers are found that are agitated by a daily ebb and flow no differently from the sea, they must be said to draw their origin from the sea's tides through subterranean tunnels, in the way described.

Now let us see what is the cause of those rivers that flow for the space of half the year and dry up for the other half. Among these, truly memorable is the Pepper-

Bath [Balneum Piperinum], in German *Pfefferbad*, in the territory of Chur [Curiense Territorium] near the Swiss [Helvetii], which on the third day of May — namely the feast of the Finding of the Holy Cross [Inventio S. Crucis] — full of water, lasts until the 14th day of September, sacred to the Exaltation of the Holy Cross [Exaltatio S. Crucis]; but once this festival is past, as if stealing itself away by stealth, it leaves the place destitute of all water. I say the cause of this is none other than the melting of the snows on the Alpine mountains, which usually begins around the start of May. Hence it comes about that the water, the snows being dissolved by the Sun's heat, multiplied through the clefts, fissures, and channels in the inner cauldrons and basins of the mountains, drives forward the Pepper-Waters [aquae Piperinae] hidden in their path a little below the bath's location; and from this thrusting-forward the overflowing water at last fills the place set aside for the bath. But since the melting of the snows lasts almost four whole months, the bath's waters must also last that long; and once the melting of the snows ceases, the bath's waters too must necessarily cease. That this is true is plain from the fact that the bath's waters take on a notable increase from the beginning of May to the end of July, but thereafter are seen to decrease at an equal rate.

[Margin: The spring Esforbe.]

There is also another spring of this property in the Pyrenees, the Esforbe [Esforbe], so called from the mountain at whose roots it lies. Around the summer solstice — that is, the feast of St. John the Baptist [festum S. Ioannis Baptistae] — it rolls forth from the bowels of the mountains with a great rush and a greater roar; and this flow lasts until the day sacred to the Nativity of Christ [Natalis Christi], that is, the winter solstice [solstitium brumale], where it ceases from its flow. It differs from the preceding spring by almost a two-month postponement, the cause of which I would suppose to be this: that the waters from the melted snows in the Pyrenees spend more time filling the caverns than in the preceding case. The whole reason for the difference, then — in the anticipating or postponing of the flows — consists in the differing arrangement of the caverns and water-conducting channels [canales hydragogi]. But we will set out the matter to direct view.

Diagram. A schematic of a Pyrenean mountain illustrating an intermittent spring fed by snowmelt. The figure itself is described verbally in the text and is set up for an accompanying engraving; the labeled elements are as follows.

- A: the Pyrenean mountains, covered with snow

- B: the fissures of the mountain, through which the melted snow flows down into the submontane cavern below
- C, D, E, F, G: the submontane cavern (CDEFG) into which the meltwater collects
- C, D: the top of the cavern, which the rising water reaches
- H: the spring, accustomed to suffer the ebb [aestus]; the channel CH conveys water from the top of the cavern (CD) into the basin of the spring

The text explains the mechanism: Because at the beginning of spring the snows gradually melt by the Sun's power and efficacy, the moisture seeps through countless fissures and clefts of the mountains and collects in the cavern CDEFG. As the mass of waters within the cavern grows day by day from the ever greater quantity of melted snow, it comes about that, once the water reaches the top of the cavern (CD), it then at last discharges itself through the channel CH into the basin of the spring, and the spring begins to flow — having ceased from flowing while the cavern was unfilled. Again, the hotter the Sun, the greater the quantity of snow it melts; so through the months of July, August, and September the water increases wonderfully within the cavern, and consequently the spring H flows more abundantly. But once the melting of the snows and rains ceases for want of the Sun's heat, the supply is seen to decrease proportionally through the months of October, November, and December, until at the winter solstice it altogether fails — while the cavern, meanwhile, empties itself toward vacancy through other clefts and fissures,

[The text continues from the prior page. The water, which had been driven down toward vacancy, empties through the other clefts at the winter solstice. You see, then, from this ingenious contrivance of nature how some springs flow for half the year and stop flowing for the other half. You also see how the water of the bath described earlier [the Piperino bath] anticipates its flow by roughly a two-month interval.

Suppose that in the bath of Piperino described earlier the spring-basin is H, and that the underground cavern is CDEF, smaller than the previous one, which receives the waters from the snows melted on the Alpine mountains and from the rains. It is then perfectly clear that the smaller cavern CDEF, since it fills more quickly than the cavern CDEFG, will likewise discharge itself into the spring-basin H more quickly — and so the spring's flow is necessarily anticipated. These things are demonstrated so plainly to the eye that no one should have any further doubt about them. The whole explanation of why the flow of springs is brought forward

or held back depends on nothing but the layout of the mountains, the size and depth of the caverns, and the structure of the channels.

Here, however, someone might object that rains — which in winter are virtually continuous — can produce the same effect that the melting of the snows causes. I answer that the relationship between the two kinds of water is entirely different. For although in winter the rains are virtually continuous, it nonetheless happens that rainwater does not lodge in the mountains, but at once runs off and turns into torrents, and so has no time to work its way more deeply into the bowels of the mountains. By contrast, the snows that cling perpetually to the mountain peaks, since they dissolve only slowly and gradually — and since they are, as it were, held back by the very snow heaped up all around them, so that they do not slide down with force — clearly give the moisture sufficient time to seep little by little, through the fissures and fibres it meets, deeper into the mountains' interior. And because in winter snow is heaped upon snow with no risk of melting, for that very reason the springs' surging ceases too. The rains, as I said, run down from the mountains into the valleys with force, and even if here and there they find fissures through which they work their way into the caverns, they are still not so great that they could fill those caverns and cause them to overflow.

To these springs, however, Georgius Wernerus [Georg Wernher] reports a spring exactly the opposite, in his *Pannonia* [*De admirandis Hungariae aquis*]. He says there is a natural lake of living waters in Hungary which is nevertheless not perennial: rather, these waters spend the whole summer hidden away beneath the neighbouring mountain caverns, leaving their bed empty of water though for that period pleasant enough and very grassy; then, as autumn comes on, they flow out, and through the whole course of winter, right up to the beginning of summer, they not only flow but are filled with an abundant breeding of fish. The question, then, is why this river — which ends in a very large lake — flows only in winter and not in summer. I say the cause of this lies both in the situation of the place and in the caverns of the mountain, out of which the water rolls in autumn. As for the situation, Wernher describes it thus:

[Margin: How the waters petrify, and in what way.]

The region is quite flat and gently depressed, yet shut in on every side by mountains, and is watered by manifold channels of streams — three on the eastern side and four on the southern. As these streams flow farther from their sources, the more they run with smaller and scantier waters, which the parched soil there partly soaks up quietly as it goes, and partly

the open trenches at its lower end absorb, like the gates of huge caverns beneath those mountains.

It happens, then, in this way: when these rivers have filled those caverns with continuous waters throughout the whole course of summer, at last toward the end of autumn — the channels now being, as it were, full and overflowing — [the caverns] not only do not take in more water, but rather, by some inner motion (I know not what) and by the impulse of the air and winds (as the continuous rumblings testify), they cast back as much water as

Diagram. A cutaway view of a mountain whose interior has been opened to show the workings of the half-year spring with its smaller cavern. The mountain rises in a forested landscape; its inside is exposed as a great cavity. At the center, a fountain of water jets upward within the cavern. To the left, a watercourse runs out across the plain into a winding lake-shaped basin. The labels are:

- A (top of the inner cavity): the upper part of the cavern
- B (the central jet): the spring of water erupting upward
- C (left flank of the cavity): one side of the smaller cavern CDEF
- D (right flank of the cavity): the opposite side of the cavern
- E (lower left of the cavity, by the outflow): the channel/outlet point
- F (lower right of the cavity): the lower part of the cavern
- G (bottom of the cavity): the floor / reservoir of the cavern
- H (the basin in the plain at left): the spring-basin / lake into which the water discharges

[The full figure extends into the inner page margin; the labels A–H are read from the cutaway. No labels flagged.]

[Printed page 285.] the water that they had previously received — so that, for as many months as they had taken in water, for so many months they cast it back, as though thrown up from the jaws of Orcus [the underworld], and with such force that one can scarcely escape it, they say, even at a galloping horse's pace. And in this way, filling every low part of the place to its full capacity, the lakes fill up, occupying a space of a mile in every direction, with a depth that in places exceeds 18 cubits.

But let us explain the matter with a hydraulic diagram.

Diagram. A landscape with an exposed mountain at center showing the hydraulic mechanism of an intermittent spring; at the upper left, an inset shows the working principle of a bent siphon. The labels are:

Inset (upper left), captioned "**Syphon inflexus**" ["bent siphon"]:

- N (lower end of the bent tube, with water pouring out): the discharging mouth of the siphon
- R (the vessel beside the bent tube): the vessel within which the siphon stands

Main scene (the mountain and surrounding hills):

- A (within the mountain, upper): the bend/crest of the siphon AB
- B (within the mountain, below A): the lower limb of the siphon, joining the cavern
- C (the great mountain mass): the mountain enclosing the cavern
- D (the dark interior cavity): the great cavern within mountain C
- E (within the cavity, at the inflow): the point where the absorbed streams are gathered and pass into the cavern
- F, F (on the slopes to the right): the trenches/pits where the streams are swallowed
- G, G, G (the hills to the right): the springheads/sources of the streams
- H, H, H (the mountains rising to the right, from the east and south): the eastern and southern mountains
- I (at the mountain's foot, left of B): the outer mouth/orifice of the siphon
- K (the river flowing from I toward the lake): the river IK
- L (the lake-shaped basin at lower left): the lake formed in the hollow of the plain

[The streams run from springheads G down through pits F, are gathered at E, and discharge through the siphon's mouth I to form river K and lake L. No labels flagged.]

Let there be mountains to the east and south, HHH; springheads of streams, GGG; pits by which they are swallowed up, FFF; and from there, channeled through subterranean passages by way of E, let them flow down into the great cavern D within mountain C. Then suppose that within cavern D, running through rocky, craggy walls, there is a further passage at the bottom of the cavern, tending upward, BA, formed in the shape of a blind siphon, RN, whose mouth I opens to the outside.

These things being supposed, I assert that the river IK necessarily dries up in summer but flows in winter. For since in summer, from the channeling of the swallowed streams, the waters rise continuously over a half-year's span both

within cavern D and within the siphon BA, it follows that when the waters reach the top of the siphon AB, they are erupted out through the siphon's mouth I with the greatest force, and so form the river IK and then, within the hollow of the plain, the lake L. And since it is the nature of the reflexed siphon — which hydraulic engineers call a *diabetes* — not to stop pouring water until the whole vessel within which it stands has been drained of water, and only then, once it is drained, to cease from further pouring: from this you see that the waters rising within the cavern and siphon by equal increment, once they have reached the line LE, will then at last discharge themselves through the orifice I. And it will flow, by the property of the siphon, for just as long as water is contained within the cavern; nor can it ever cease to flow, for fear of the vacuum that might arise within the siphon AB from the discontinuation of the water.

It would, however, always flow with a perpetual course, if only as much water were poured out from the siphon as the river-waters supply to the cavern; but by the shrewd design of nature it is so arranged that the channel AB pours out more water than the rivers GF could supply. Hence the water is necessarily drained over a half-year's span down to the bottom of the cavern through the channel, and once the mouth B of the siphon is open, the waters will stop flowing — until, in the other half of the year, the caverns are once again filled by the rivers FG with water up to the line LE, and the waters begin to flow again as before. And this proceeds by a perennial law of alternation.

Whoever has rightly grasped this will find no knot of irregular surging — however intricate — showing itself in springs, rivers, and lakes, that he cannot untie by similar machines of nature. As for what the authorities relate about the Sabbatic river in Syria (namely, that it always flows except on the Sabbath, from which it also takes its name), since these accounts are entangled with various opinions, I have thought it best to touch on them only sparingly. But if they are true — as Dominicus Magrius [Domenico Magri], a most truthful man, assured me they are — I would say that the cause of this matter is not so much a miraculous effect of the Hebraizers as a physical one, since it can easily be solved from the preceding Problem. For we say that so great a quantity of water can be gathered in the subterranean basins as would suffice for six days, but falling short on the seventh would not suffice.

[Printed page 286.] Hence anyone may easily reckon how empty is the reasoning of those who attempt to ascribe such things either to the hidden influences of the stars, or to a Spirit of the World, with elaborate chains of reasoning — and so the same thing happens to them as to those who seek gold in the hollow of the Moon

while they have it hidden beneath their feet. For unless in such monsters of nature you take refuge in the proximate and nearby causes, you may be quite sure that you will labor in vain in the investigation of causes of this kind.

Some philosophers, too, torment themselves remarkably in giving the reason for the hidden properties of a certain marvelous well by the bank of the Baetis [the river Guadalquivir], which falls as the sea's tide rises and rises as the sea's tide falls. Hence many, taking refuge in some hidden power of the stars, think they can supply the cause; others, led on to I-know-not-what physical speculations, philosophize ridiculously — whereas, if they knew the proximate causes by which nature works in the interior, they would doubtless reason in a way more within the grasp of men. For there is no other cause of such a spring than that the sea's tide, entering the subterranean passages, discharges itself into some basin, which — once the sea has reached its highest swell and the basin is filled — gradually works its way into the well; and so the well seems to rise as the sea falls, in exactly the manner that appears in the preceding Figure.

CAPUT V.

De Metamorphotica vi Fontium, Fluviorum, Lacuum, quæ injecta quævis in saxa, aliasque metallicas species convertunt.

[On the metamorphic power of springs, rivers, and lakes, which convert whatever is thrown into them into stone and into other metallic kinds.]

In the Geocosm there are countless springs, lakes, and rivers which, by their petrifying power, convert whatever is thrown into them — some merely with a stony rind, others turning it to stone all the way through. Such is the Sarnus in Campania; the Silarus beyond Surrentum [Sorrento]; in Etruria the Elsa; and in the territory of Volterra a good many; the Aponitan waters [of Abano] in Lombardy; and in various places in Germany, Gaul, and Spain — for which see the preceding pages. Into these, as I said, whatever you throw, they either convert it entirely into stone or wrap it in a kind of stony rind, the body they clothe remaining wholly uncorrupted. Of the former kind there are countless examples, found here and there in the territory of Tivoli around the banks of the Anio and the Albula.

In the Museo Gualdino [the museum of Gualdo] on the Pincian Hill there may be seen, among numerous pieces of wood, the leaves of trees, fungi, crabs, a human skull, and even the very water-pipe through which the Aqua Claudia [the Claudian aqueduct] was carried, all turned into alabaster. And in my own

Museum there are several very large bones of this kind — of a certain giant — together with pieces of wood, grains of wheat, snails, and icicle-forms turned into stone; not to mention here the great number of such objects in the various museums of Rome. In the Villa Ludovisi an entire human body may be seen, transformed into stony substance. At Gallicano, a place about twenty miles distant from Rome, there is a spot where the sediment of the water has hardened into stone and, overflowing, serves in place of a bridge — the same thing that we said above occurs at the spring of the city of Clermont [Claramontana] in France. At Zepusium [Szepes], a town of Hungary, there is a spring whose water, wherever it goes, becomes stone, with such increase that the inhabitants build their houses out of it and are wont to boast that they have homes built out of water. I will say nothing here of the drippings of caverns, by which the descending water is changed into every kind of animal form. It is a marvelous thing that is reported of the grotto of Cadurci [the cave of Cahors], which playful nature, by its continuous dripping, has so aptly adorned with statues that you would swear you saw monks sitting in a semicircle. Similar ones may be seen in Hungary and Transylvania. In Picenum there is the Grotta Scura; at Anticoli in Latium; and in the other places, which are without number; in the territory of Rieti [Reatinol], where the petrifying power of the river Velino so prevails that, after certain years have rolled by, men are forced — with great effort, by cutting back the petrified masses — to make a passage for the flow of the river (which the rocks, here and there widened with a stony rind, obstruct), lest by its flooding it should swim away entirely. On the shore of the Baltic sea near Lübeck, a branch of a tree together with a bird's nest was found turned into stone, as Albertus [Albertus Magnus], and from him Agricola [Georgius Agricola], teaches. He also reports that another spring, no less worthy of admiration, exists in Gothia [Gotland/Sweden], which turns into stone whatever you immerse in it; and that, in order to get a sure experiment of this marvel, the Emperor Frederick [Friedrich] ordered a glove sealed with his own seal to be immersed halfway, and after some days the immersed part had indeed turned to stone, while the rest remained, as it was, of leather. But since almost no place seems to lack marvels of this kind, we shall not dwell on them as things commonly known. Let us instead turn our pen to the inquiry into the cause.

[Printed page 287.]

[The text continues:] [...whatever is thrown in is clothed with a stony rind.] But that these matters may be better grasped, it has seemed good to begin a little farther back.

[Margin: Why the waters petrify, and in what way.]

In two ways is that stone-making juice elaborated by nature in the waters: for either the water is mingled intimately and perfectly with certain mineral corpuscles, or only on the surface and confusedly. In the former way, the whole substance must be changed into stone, as is plain in coral-plants, which, by a certain natural appetite, draw in the petrifying juice of the sea and convert it into their own substance; and in this way various things too — herbs, leaves, wood, fruits, animals — are seen to be perfectly converted into stone, whether you regard their hardness or their weight. In the latter way, the petrific juice, which consists of an imperfect mixture of fossil corpuscles, since it neither mingles intimately and perfectly with the said things, likewise clothes wood, herbs, and reeds with a stony bark only on the surface, the inner substance remaining entirely uncorrupted — just as a wick, by frequent dipping in melted tallow, at last turns into a candle, solid and firmly set by the condensation of the cold. So all things thrown into the water do not acquire the firmness of a stony mass until they are out of the water, as is plain in coral. The reason for this is that, while the moistening lasts within the water in which they are formed — even though they are continually augmented by the addition of corpuscles through the force of the petrific juice — they still cannot, on account of the continual influx of the surrounding moisture, petrify into a hard substance, unless they have been exposed to the air for some time. For then, the superfluous moisture being either drawn off by the Sun through resolution or consumed by the dryness of the winds, they finally harden into a stony substance.

But those things that are perfectly and intimately mingled with the petrific juice must be converted into a stony substance. For since the petrific juice is nothing other than a moisture constituted and elaborated from a mixture of imperceptible corpuscles scraped from stony veins and from nitrous and saline places, and since corpuscles perfectly mingled with the moisture naturally seek to return to the state in which they once existed, therefore — by the vehicle of the saltpetrous, aluminous, or sulphureous moisture, and because of the subtlety of the spirits — they penetrate all the inner fibres and marrow of the things they meet. This done, by the force of the acrimony in which they are strong, once the softer parts of the things they meet have been consumed and eaten away, they substitute themselves in the place of what has been eaten away, and in this way transform them into a stony mass. And this juice will be the more efficacious the more it has been concocted by the subterranean heat; for the concoction, by the force of the heat, draws out from the earthy clods a certain fattiness, which, mingled with the petrific juice, supplies, as it were, a kind of glue by which the

corpuscles cling tightly together and the parts are firmly joined to the parts. And so experience teaches that things which turn to stone are first surrounded, as it were, by a kind of mucus, to which the corpuscles of the petrific juice then cling like a kind of birdlime, and ever others and others, by continual addition; until at last, clothed in a mucous bark and exposed to the air, they are converted into stone. But let us prove these things by experiment.

EXPERIMENTUM.

Take the meal of any stone whatever, reduced to an impalpable powder; knead it with water (to which a little salt, niter, and liquid bitumen has been joined) and blend it into a perfect mixture. This done, prepare a basin filled with water of any sort, in the middle of which let there be set upright herbs, dry wood, bones, and whatever else; then take the compound described a little earlier, decocted and placed in the "sleeves of Hippocrates" [Hippocratis manicae], as the chemists call them, and let it drip down. In time you will see the things placed within clothed with a kind of mucous skin, and the rudiments of a bark contriving themselves from the continual accretion of corpuscles; and these, afterward — once the water has been poured off and they have been left in the freer air — you will find, in the course of time, to have grown together into a stony hardness. And so what experiment teaches us to be done, no one but a senseless man will deny that nature performs with far greater skill.

CONSECTARIUM.

Things thrown into certain waters, then, turn to stone in the manner we have described — either because the juice (as Vitruvius holds), being stone-making, thickens like rennet the waters with which it is mixed, and the heat of the Sun then drives these thickened waters together and hardens them; or (as Agricola holds) because the stone-making juice, emanating from the veins and joints of caves, hardens before it has fallen; or, when its drops have already trickled down, then — just like the icicles of roofs that freeze into ice — the descending juice by its own power forms both icicle-shapes of stone on the vaults and stone cones on the pavement, the saltpetrous juice being gradually converted into stone; or, finally, the things themselves are converted into stones once they have drunk in the stone-making juice itself. Thus, when war had broken out and the workmen had fled into the metal-mines of Lydia near Pergamum, and the exit was blocked by the enemy, they were suffocated; but a long interval of time afterward, when the mines were reopened and cleared out, there were found amphorae and other vessels of that kind, which they had used for necessary purposes, all filled with a

certain moisture and hardened into stones — and beside them, too, human bones. I said "once the things have drunk in the juice"; because whenever the petrific juice, perfectly mixed with the water, has penetrated all the marrow, fibres, and pores of the things thrown in, then indeed the things are converted, according to their whole substance, into a stony mass — the woody or bony matter being eaten away by the petrific moisture, and stony corpuscles substituting themselves in its place, existing within the moisture by a petrific mixture perfect (as I said) — which does not happen in those things [that...].

which are clothed only with a stony rind. [Margin: How various things in springs and waters petrify.] The cause of this is a confused and external accumulation onto exposed objects of the petrific juice from the small particles — that is, the scoria and shavings scraped away from the stony veins. It works much as in the boiling of alum, within which any object's shape — fashioned, say, out of oak wood and placed inside — turns within twenty-four hours into a crystalline form. The same thing happens when boiling, suitably applied, converts sugar into a crystalline state. In short, you can see it in all the salt-making operations on the various concretions of these juices. Indeed, from the ashes of every kind of wood and herb, salt is drawn off by means of a lye appropriate to each. But since I intend in due course to deal expressly, in what follows, with the marvelous generation of every kind of stone, marble, and jasper, and with the other miraculous conversions of things into stone, I did not wish to linger over these matters any longer.

SECTIO VI.

On the Remaining Marvels of the Waters [De reliquis Aquarum Miraculis]

In the preceding pages I discussed certain prodigious effects of the waters, and I demonstrated that all of them rest upon their own natural causes. It remains for me to give some account of the water-prodigies famous among Pliny [Plinius], Aelian [Aelianus], Solinus [Solinus], the Polyhistor, and the other ancients. Since these have no foundation in nature, they are either sheer fabrications, or wrapped up in the allegorical modes of the poets, or they have taken their origin from fabulous tales which either human naïveté or the superstitions of the nations introduced. For it is innate in the human mind, at the very first encounter with some exotic effect, to attach much to it that is invented, or to mix the playful in with the serious. Indeed, those who write such things very often do not so

much seek true demonstrations of them as aim to embellish their own undertaking with charming allusions, or to amplify, with things exotic to the senses, certain matters κατὰ τὴν αὐξήσιν [Greek: kata tēn auxēsin, "by way of amplification"], rather than by proof.

So Pliny, while professing the entire History of the World and of Nature, repeatedly declares that he did not bind himself to causes — given the labors of so immense a work — and simply recounted, along with everything else he found reported, the miracles too, many of which we have brought forward and unraveled in this work, assigning genuine causes to the effects. [Margin: Fabulous spring-effects of certain authors.] We consider thoroughly fabulous what he adduces from Varro [Varro] and Theophrastus [Theophrastus] about a spring on the island of Cea [Coa Insula] and one in Cilicia: the drink of the former dulls the senses, while the latter makes them subtler and more lively. Of the same sort are the things he tells of the Sicilian springs Cleone and Gelo, the former named from the weeping [a fletu] it produces in those who drink, the latter from the laughter [a risu], because it dissolves those who drink it into laughter. Ridiculous, too, is what he recounts of the spring at Leontini, whose waters, if one drank them, made him come out a learned physician. Likewise what he tells of the springs of Cupid and Venus, of which the one would provoke love affairs, while the other would quench them — the same that Caelius [Caelius], on Pausanias's [Pausanias] authority, reports of the river Selenium [Selemnus] in Achaea, in which both men and women would lay down the love that gripped them. Empty, too, are the things Peter Martyr [Petrus Martyr] adduces, in a wide-roving hyperbole, about a spring on the island of Boriquen in Hispaniola [Bonicca Hispaniolae Insula], which wonderfully restores youth to the aged — though it neither changes gray hair nor smooths wrinkles. Out of such things that crude antiquity, and the deceitful glibness of the petty Greeks, joined many fables of this kind together with superstition. Hence all those springs dedicated to Apollo, the Muses, Neptune, Bacchus, Jupiter, Pluto, and the other gods — as one may see scattered throughout Ovid in the *Metamorphoses* [in *Metamorphosi*], throughout Virgil [Virgilius], and the other ancient poets; but since these are known even to schoolboys, I pass over them in silence.

[Margin: Whether certain springs portend sterility.] Yet, lest I seem to pass over those marvels of nature which — however fabulous they may appear — nonetheless conceal, I know not what, of nature's true sportings beneath them: this shows itself first in springs which, by some hidden power, foretell the sterility and fruitfulness of the seasons — sterility when they flow, fruitfulness when they cease to flow. Four of this kind are found in Etruria [Hetruria], as we

observed in our *Itinerarium*; among which the Lucales springs in the territory of Siena [Agro Senensi], near the village of Rosia, are especially celebrated. They flow only in certain years; and when this happens, the inhabitants take it as an omen of scarcity, whereas when they cease flowing, so that one can cross dry-shod, they promise great abundance and a plentiful harvest. Such is the spring of S. Regulus near Pienza [Pientiam] in Etruria, which, when it has dried up, portends abundance, and when it has poured forth in a great mass of water, sterility. Alberto Leandro [Albertus Leander] in his *Italy* mentions another spring of this property near Narni [Narniam]. The Lake of Vadimon [Lacus Vadimonis], as we taught in our *Etruria*, is of the same property, as its neighbors attest; concerning which Baccius [Baccius] speaks thus in his book *On Hot Springs* [de Thermis]: "The Lake of Vadimon, which is called the Lake of Bassanello, distant about thirty thousand paces from the city, we know — to give the matter greater credit — to have overflowed in this year 1569, in which there is a universal scarcity throughout Italy, already from the beginning of spring, in marvelous ways." We have received the same about the aforesaid Lucales and S. Regulus waters: namely, that having dried up for many years, this year they have overflowed, to the amazement even of the natives, who know this nature of theirs. With these things established, the cause is now sought, which I shall assign — but first let me say something about the rising of the Nile, for this will pave our way to knowledge of the true cause.

[Margin: On the Niloscope.] The Niloscope [Niloscopium], most celebrated in Egypt, was famous of old and is so still — a water-gauge [Hydrometrium]. It is a round structure on the bank of the Nile, in the manner of a well, in the middle of which a marble column is to be seen, with twenty parallel circles, their numbers cut into the column. From the rising and falling of the water at the time of the Nile's inundation, the Egyptians know in advance the coming condition of the year, whether it inclines toward sterility or toward an abundant harvest. For if the water of the Nile — which insinuates itself into the well through a hidden channel — exceeds the twentieth circle on the column, then, since excessive moisture chokes everything sown, they expect an utter dearth of things. But if it does not reach the lowest, the twelfth, circle, that same Nile, with dryness consuming everything, promises them a notable decline. The intermediate circles show now a greater, now a smaller, now a moderate fruitfulness to come, up to the eighteenth, at which the greatest yield is promised.

From this similarity to the Niloscope we shall easily arrive at the hidden causes of the signs of fertility and sterility in the other springs already recounted. In this

way, then, I should like to persuade you that nature operates in the marvelous arrangement of springs of this kind:

Diagram. A landscape cutaway showing the subterranean hydrology of a well and the fields it influences. The upper portion is an aerial view of a mountainous region with cultivated fields laid out as rectangular plots and scattered trees; the lower portion is a cross-section through the earth (rendered with dense cross-hatching), revealing a vertical well-shaft and the underground water channels feeding it. The text instructs: "Imagine to yourself, beneath the earth DE, a well ABC, into which, through hidden fissures or through some water-reservoir [hydrophylacium] — F, for example — water gradually insinuates itself, at some times more, at others less..."

- G (top, mountain peak): the highland source region from which water descends.
- F (upper right, at the cleft / reservoir mouth): the hydrophylacium (subterranean water-reservoir) feeding the well through hidden channels.
- A (top of the well-shaft): the upper terminus of the well column.
- B (middle of the well-shaft): the point of moderate water-level [punctum mediocritatis B], associated with temperate years and abundance.
- C (bottom of the well-shaft): the lowest terminus, the level below which the water does not fall in years of extreme drought.
- D (lower left field region): the surrounding region whose moisture corresponds to the well's overflow.
- E (right field region, and at the underground channel into the well): the cultivated tract and the channel by which water reaches the well.

[Resuming the body text, printed p. 289, left column.] Imagine to yourself, beneath the earth DE, a well ABC, into which, through hidden fissures or through some water-reservoir — say F — water gradually insinuates itself: at some times more, at others less; but at certain times it even overflows beyond its fixed bounds, which however does not happen except in the most humid condition of certain years. For then the water, rising gradually through the well, successively driven by the impulse of the multiplied waters, will overflow. And just as this then follows in some whole region FG — when, partly from the moisture of the rains and partly from the overflowing of the subterranean caverns, the earth within is wholly soaked, while the spring, being filled with stagnant waters, takes on a kind of dropsical and malignant constitution by which the vigor of the sprouting plants and herbs is choked and passes into rottenness — so too sterility

and a dearth of things must necessarily follow; and the sign of this is the overflowing and outflow of the spring.

Again, if at any time years have followed marked by notable aridity and prevailing dryness, then the water — drawn off partly by the heat of the Sun and the stars, and partly, in its ascent, [withdrawing] into the innermost recesses of the well ABC — will not have exceeded the terminus C; then one must judge that the same thing happens in the fields as in the well: with all the moisture consumed, the earth wasted by dryness, so that, as if assailed by a kind of consumption [phthisis], the sown crops, the herbs, and the standing corn, deprived of moisture, will fail, with sterility following; and the sign of this is the withdrawal of the water within the well. Thus both an excess and a deficiency of water, for the reasons stated, bring on sterility and a dearth of provisions, as is clear from the Niloscope. But if the year's condition has been temperate, then this well too will follow a certain middle course along with the fields; and abundance will attend this, and the standing corn, the meadows, and the sprouting plants, nourished by a kindly and proportioned nourishment, will luxuriate in a rich yield of produce — and the greater, the closer the waters have come to the point of moderation B. And this, I say, is the cause why some springs indicate sterility by their flowing and overflowing, but indicate abundance if they have ceased flowing — not, indeed, at that extreme, but at the point where their moisture attains a certain moderation.

[Margin: Whether certain springs are inserted [into] cells.] Another marvel of the waters, or rather of certain lakes, is this: that if anything be cast into them,

[Margin: Why they stir up thunderclaps and storms.] ...at once a tumult and savage tempests are stirred up. The first lake of this kind exists in the county of Foix [Comitatu Foxensi], called Tabor, sacred to St. Bartholomew [Divo Bartholomaeo]: of unexplored depth, set on the topmost summit, above the second region of the air and beyond all the air's assaults; stocked with enormous trout; its water wholesome, though always motionless, with no stream led off from it except one visible at the foot of the mountain. Of this it is commonly said that its waters, when stirred by some artificial motion — whether by the casting of stones or the agitation of staves — give and excite great rains, thunderclaps, and lightning-flashes. Such a lake is also said to be on a mountain not far distant from Trent [Tridento], which is said to stir up storms so savage that the whole neighboring district is not free of immense damage from them — so that it has been provided, under heavy penalty, that no one cast anything into it. A third is said to be in Switzerland [Helvetia], on the mountain commonly called Pilati, der

Pilatus Berg, about which they tell marvelous tales of an apparition of Pilate [Pilatus] on it on Good Friday. The cause is therefore sought of these lakes, which stir up such severe storms.

[Margin: Why thunderclaps and storms are stirred up.] I say, then, first, that not everything is true which is commonly told, nor easily to be believed, of the things reported everywhere either through the superstition of the ignorant or through some wandering illusion of the imagination — since often the cause of some unusual effect is attributed to one thing, when it derives a far different origin from that one. For it can happen that, in the summer season — when the summits of these very high mountains are usually visited for the most part — such a condition of both sky and air occurs that the said effect follows from it. There is added, besides, the illusion of the demons [Daemonum], who for the most part hold sway in desert and inaccessible places, and who, having held men's minds captive by a certain superstition, are accustomed to derange them with the persuasion that some more divine Power is working such great things. Our Fathers of Lucerne [Patres nostri Lucernenses], in whose territory Mount Pilatus lies, bear witness that they were accustomed to climb the mountain every year for the sake of relaxing the mind, and that, although a great quantity of stones was cast into the lake, they never once experienced the said stirring-up of storms. Maioli [Maiolus] reports the same of Mount Scafagioso in the Apennines, of the Momonian spring in Ireland [Hyberniae fonte Momonio], and of the Canato lake in Spain [Hispaniae].

If, however, some hidden secret of nature does lie beneath it, I should say for certain that it can be nothing other than a varied mixture of mineral juices at the bottom of the lake. For when, by the casting of a rather large stone, the pores of the innermost lake-bottom, covered over with mud, are opened, and an exit must necessarily be given to the spirits and exhalations previously shut up, these — while they penetrate the waters — carry a vapor up with them into the air; by the dryness of that vapor the kindled spirits pass off into thunderbolts and lightning, while the vapor itself, spread far and wide, is dissolved into rains by the coldness of that same air. And besides this, I find no other cause whatever, however it be brought about by combination. Yet I do not see how, from so slight a weight of stone, so great a quantity of exhalations can be drawn out to produce the said effect. Therefore I commit the matter to be tested by greater experiment, and then to be sifted by sharper minds. As for the lake which the ancients recount was wont to be stirred up at the sound of the cithara and other musical instruments, I should think it must be ascribed to fables rather than to any mystery of nature.

CAPUT VII.

On the Various Metamorphosis of Lakes, Rivers, and Springs [De varia Lacuum, Fluminum, Fontium metamorphosi], and on the changes of the terrestrial parts.

It is so arranged in the constitution of the world's natural things that nothing in them is so solid, nothing so robust and strong, that time — the devourer of things — does not in the end, if not utterly destroy it, at least so change and alter it that it can scarcely be recognized as having once been what it was. All of this is found, most of all, in the portions of the Geocosm, which, being nearer to us, are therefore more obvious. Mountains fail in one place; in another, new ones rise up. The sea, nature's marriage-broker, joining land with water, brings it about that where once there was sea, there is now land, and the reverse is seen. We read that some islands, entering into a wedlock, have adhered to the continent; others, on the contrary, having made as it were a divorce from the continent by the parting-off of their territory, we read to have come out as islands. All of which we pursued in the preceding pages with a great array of examples: [Resuming, right column] but in lakes, rivers, and springs too, similar spectacles of nature at play shine forth. Lakes are born in the very place that mountains first occupied — as happened in this year in which I write, in France [Gallia] at the Pyrenees mountains. Rivers that were once remembered now do not appear in many places, while many others have come into being, of which there is no mention among the ancients. Many springs and hot springs have today perished which of old were held most celebrated. The well of the Bullicame near Viterbo [Bullicami Viterbiensis], boiling continuously with its most fervent waters — than which I recall having seen nothing more worthy of wonder — has no mention among the ancients, yet today, by the record of many writers, it has been made famous in a marvelous way. But since we have dealt copiously with these and similar matters in our *Etruscan Itinerary* [Itinere nostro Hetrusco], we refer the reader to it. Meanwhile, let us proceed to the genuine causes of changes of this kind.

I find a twofold cause of these changes: one internal, the other external. The internal is the fury of the subterranean fires; the external is the violence of the inundations of the sea, the rivers, and the lakes — each of which let us set out in order.

[Margin: Why rivers are dispersed and new ones arise.] The subterraneous fires, if at any time, seething from a vast supply of combustible matter, they have burst forth into conflagrations, then from these first arises a vast quantity of

exhalations mixed with most violent blasts; and from these, earthquakes, once raised, while they seek an exit and do not find one, by a certain violent shaking overturn the foundations of the mountains, and swallow up vast tracts of land together with rivers — whence wondrous metamorphoses of the earthly globe must necessarily occur. Hence subsiding mountains, pressing with their mass upon the subterranean waters, drive and force them into the station of the mountains; the swallowed rivers, while they seek an exit by the hidden working of the raging spirits within, and, insinuating themselves wherever a gate or fissure is given, make themselves an exit elsewhere; then, blocked by the collapse of the subterraneous parts, they deprive the natural channels of the rivers and springs of all their flow. So it happened in this year in the earthquake of France [Galliae terraemotu], where several rivers, their water-conducting channels [hydragogis canalibus] blocked by the collapse of a mountain, ceased from all flow, while in their place new springs and streams arose elsewhere; and hot springs, turned from the most boiling waters into cold ones, displayed the character of a different taste, smell, and color.

From a similar violence of the subterranean tyranny, at Apamea [Apameam], a city of Phrygia — as Nicolaus of Damascus [Nicolaus Damascenus] is the author — in the time of the Mithridatic War, not only did new lakes and new marshes emerge, but also new springs and rivers, and among these one salt spring, which poured out a great quantity of oysters and other sea-fish. All of which, without doubt, anyone skilled could more easily imagine to himself than I can describe in many words to have come about from the ruin either of some mountain, or of an overlying land collapsing into some underlying water-reservoir [hydrophylaceum] or channel filled with sea-water. I could adduce countless examples here, had I not discharged my pledge in recounting them in the preceding pages. See what things, in the Chapter on the earthquake, we adduced of this kind in greater number: for as the earthquake takes its origin from the violence of the subterranean fire, so too every ruin and the cause of subterraneous alterations.

[Margin: Town of S. Euphemia swallowed by an earthquake, and a lake arising.] For there is a stony substance which the fires reduce to lime; hence the most savage blasts and exhalations, excited by the power of the fire, while they are prevented from going out, battering by their violent shaking the substance now calcined and friable, at last overturn it — whence the fall and swallowing-up of mountains and lands, and from these the obstructions of springs and rivers must necessarily follow. But the waters, compressed within and time and again multiplied, boring through the earth, at last, wherever a gate is given, burst forth,

and reveal new origins of springs, rivers, and lakes, which those ignorant of nature's art behold with amazement. [Margin: The town of S. Euphemia swallowed by an earthquake.] I myself saw a spectacle of this kind in the year 1638, and was present, when the noble town of S. Euphemia in Calabria, swallowed by an earthquake, left nothing behind it but a lake — concerning which see the Preface of this work. Then, since no mention is made by Pliny and the other writers of that admirable work of nature, the Bullicame, I mean, of Viterbo [Bullicami Viterbiensis], but only of certain warm springs, it is certain that it had then not yet been born, but that a subterranean tunnel, burned and eaten away by the fires, was at last, in the course of time, brought down into the breadth of crater which we behold today. Many of this kind are found, both in Etruria and in Latium [Latio]: baths once most celebrated, which today neither steam any longer nor are in use — as also the baths of Albunea in the Tiburtine territory [Tiburtino Agro], concerning which see what was treated at length in our *Etruria* and *Latium*. The islands which Seneca [Seneca] once saw floating in the Etrurian lakes of Vadimon, Vulcine [Vulcinensi], and Stratonias [Stratonien] do not today appear: either submerged by the injuries of time, or grown onto the continental land. On the contrary, today we see islands floating in the Tiburtine lake which antiquity did not know.

Thus does Nature turn her own affairs about in the world. [Sic Natura suas versat in Orbe rotas.]

But let us now come to the external causes of changes, which are not less than the internal ones. These are the sudden inundations and swellings of the lakes and rivers. Of inundations I shall speak first.

In the year 1660, on the 4th day of November, on which I write this, an immense inundation of the Tiber [Tyberis] invaded Rome, which lasted nearly three days. The cellars and wine-vaults being filled with the river, the whole flatter part of the City was navigated by skiffs and boats, to bring relief to the needs of those who were besieged by the assaults of the waters. And it was a novel thing to see this too: boats (which otherwise carts are wont to carry) now carried by carts, distributed into the various flooded squares of the City. This inundation was preceded by continuous rains throughout all of October, most copious downpours. There followed, in the first days of November, the syzygies of almost all the planets, which seemed, as if by some appointed assembly, to be contriving the destructive inundation that the event taught a little afterward. But let us set out its causes.

[Margin: The causes that concur in the inundation of the rivers.] As in the Tiber, so in the inundations of the other rivers, several causes concur: the rains, the sea, an adverse wind, and the situation of the river — which we shall set out in order. The rains, which stand as it were as the matter of the inundation, ought not to be taken from those which rain down upon the earth in some single territory; for these, however great a quantity of water they pour down continuously,

However great a quantity of water the rains pour upon a single territory, they do not for that reason drain off into the nearby mouth of the river so quickly as they accumulate. For this reason, great inundations necessarily occur whenever the waters, multiplied little by little by constant rains across a long and remote stretch of country and swollen out of innumerable streams, are driven to an excessive degree of overflow. This is exactly what happens with the Tiber and the Po.

The Tiber rises in the Alvernian Mountain [Monte Alvernia / La Verna] on a spur of the Apennines, a full 150 miles distant from its sea-mouth. What quantity of water can it not gather from the unrelenting persistence of the rains? I myself, with deliberate effort, traveled in the year 1559 to its source in order to explore it. It stands in a forbidding place among the craggy masses of overhanging cliffs, surrounded by the inaccessible summits of the Apennines. Within a span of five miles, all the way to Plettia [Plettia / Plestia], a town of no small repute, I found it already augmented by twenty streams, even in the driest season of the year. Going on from there in both directions, I encountered on one side, from the mountains of Etruria, and on the other, from the extended ridges of the Umbrian Apennines, torrential streams and rivers in such abundance that you can scarcely advance two thousand paces without coming upon a torrent, a stream, or a river. In the winter season, when it is most rainy, the channel — unable to contain such great volumes of water — overflows both banks, and with the waters spread far and wide it so fills the fields and plains that it looks like a sea.

In this way the river is gradually swelled. Ever-new rivers, received one after another, weigh it down — most of all the Clanis [Chiana], mixed with the Palia [Paglia], which adds an enormous burden of water from the Etruscan shore; while from the other bank the Nar [Nera], joined with the Velino, and the Anio [Aniene], rivers risen from the mountains of the Abruzzi [ex Aprutiorum montibus], add to it a load that is utterly intolerable and unbearable. And so, swollen with this disastrous array of waters, the Tiber, having entered Roman territory and indeed the city itself, overturns everything in confusion — to the great and irreparable harm of the inhabitants, and with savage tyranny. For once

the underground reservoirs, the sewers, the crypts, and all the cellars have been filled, it at last renders the whole city navigable, a spectacle less wondrous than mournful.

To this the sea rightly adds the final completion: harried by the southerly blasts of the winds, it so blocks up the river's mouth with dreadful masses of water that the river — when, with this barrier as it were interposed, it is not permitted to discharge itself — is driven back, and, pressed and made to swell ever more by the new mass of descending water, it rushes wherever a level plain is offered and floods everything. And this I would judge to be the principal cause of inundation. For if the mouth is not blocked, then however much the river may be augmented by a copious abundance of rains, those waters, once received within its channel, only lash the city in passing — since the waves, following one upon another without any impediment or obstruction, in the same steady course of flow at last commit the river peacefully to the sea. This does not happen when, with the violence of the rolling southerly blasts upon the marine waves, the mouth is obstructed. Then the river, necessarily yielding to the stronger force, is compelled to retreat; and from this retreat, with the volumes of water finally multiplied, an inundation must follow.

The cause of the Tiber's inundation, therefore — and of the Po's, and of others like them — is purely contingent and accidental, having no fixed time for its flooding, unlike the Nile, the Indus, the Niger, the Zaire, and many others. [Margin: The cause of the Tiber's inundations.] These keep, in flooding the regions through which they flow, fixed laws of the seasons, which they do not transgress; nor are they, like the Tiber, pernicious because they occur only by accident. On the contrary, the inhabitants receive those floods with the greatest joy and dancing, as a gift of God and the one sure herald of the fertility to follow. As for the cause of the Nile, which floods only at a set time of the year, this was demonstrated at length in the Fourth Book.

Since, then, the space from the sources of the Tiber — counting the streams, rivers, and torrents that, partly from the mountains of Etruria and partly from the immense chain of mountains underlying Umbria, the Abruzzi, and Latium, flow together into the Tiber — embraces a great part of the rains and snows of the Apennine range, an inundation must certainly be caused by so great a deluge of rainfall, especially if the sea, driven by the Libyan [southwest] blasts as I said, repels with its untamed ferocity, by the impulse of its own waves, the waters of the swollen river pouring in. For a complete inundation, then, three things necessarily concur: an enormous excess of water, the low situation of the

channels, and the impulse of the sea against their mouths — which, not without reason, we call the formal cause of inundation.

Having now examined the causes of inundations, we must speak of the changes that result from them in the terrestrial globe.

Since springs for the most part have their place set by nature at the roots of mountains, it happens from time to time that, through continual rains, the summits of the mountains are stripped bare of their earthen sods, and these, scoured away by the torrents, are rolled down into the depths of the valleys, where they accumulate. If by chance they encounter a lower-lying spring in the countryside, they fill it up by the successive accumulation of this scoured material; and most springs would perish in this way, were it not that the inhabitants, aware of the threatening danger, forestall it with a remedy — either by building a wall around the spring, or by deliberately constructing an aqueduct, so that the water, diverted elsewhere, is kept safe from the violence of the torrents. And so springs choked by torrents in many places, when they find no outlet, fail. But since Nature can in no way be idle, she compensates for the loss of the original spring through other subterranean fibers of the earth, by the welling-up of a new and different spring. Witness to this is subterranean Rome [*Roma Subterranea*], whose streams and living springs, obstructed by the various injuries of times and ages, appear in this present day to those who labor at digging out the foundations of buildings. And in Sicily, to those digging at the roots of Etna...

[printed p. 293]

underground rivers and springs offer themselves in great numbers — springs that long ago, without doubt, flowed at the outermost surface, but which, swallowed up by the vast conflagrations of the mountain, or overwhelmed by a great mass of ashes and a shower of pumice, lie squalid within the deepest entrails of the earth. See what we have set out more fully concerning these matters in our description of Etna.

But let us now proceed to the prodigious inundations of certain lakes. The first of these, memorable from all antiquity, was the inundation of the Alban Lake [*Albanus lacus* / *Lago Albano*], which Plutarch and Livy elegantly describe as having flooded — with the Veientes defeated — under a clear sky and without rains; and they relate that the Etruscan soothsayer declared the lake would never overflow again, if, by boring through the mountain, they drew the water off elsewhere. We have treated this most fully in our *Latium*. To nearly all writers,

this overflowing of the lake has seemed to display something portentous, I know not what. We, however, say that it was an entirely natural effect, though one of the rarest occurrence; for I do not think it should be attributed to rains or snows, since it happened in clear weather and without rainfall. We suppose that it could have come about in the following way.

[Margin: Mount Alban full of waters.]

In our *Itinerarium Exstaticum Terrestris* we showed plainly that Mount Alban [Mons Albanus] is endowed with a vast water-reservoir [hydrophylacium]. The outflow of this reservoir into the lake and the springs on every side, even at the very roots of the mountain — indeed, the very basin which they call Hannibal's Camp [Hannibalis Campus], in which an enormous spring is born — clearly demonstrate it. And the inhabitants of the castle which they call Rocca di Papa affirmed with one consent, when I was exploring the place, that the whole mountain teems with waters from bottom to top. They added that, in the still silence of deep night, with their ear pressed against the rocky framework of the mountain at certain spots, they could hear some subterranean murmur of gliding waters — a plain indication of a hidden, fruitful cauldron lurking there, by which, through the said springs spread far and wide, the surrounding countryside is irrigated.

For two causes, therefore, we say this prodigy could have come about: either by the immoderate regurgitation of the sea through some fitted water-conducting channel into this reservoir; or by the violence of the subterranean winds, by which the water of the reservoir is taken up from the sea; or else the lake itself, violently pressed somewhere from outside at its bottom, raised itself up with that swelling, so that it overflowed its very rim, the mountain not yet being bored through. Swellings of this kind are to be observed, even to the point of marvel, in other lakes as well — such as the Nursine Lake [Nursinus / near Norcia], Lake Vadimon [Vadimonis lacus], and Lake Lemano [Lemano / Lake Geneva] — which we have described more fully in our *Iter Hetruscum*. The cause of this swelling can certainly be none other than the subterranean breaths and spirits [flatus et spiritus subterranei] which, struggling to find an exit and not finding one, pass beneath the floor of the lakes and force the waters into monstrous swellings, and at certain times so heighten them that they seem to be endowed with a kind of life. But of these matters, see what was treated more fully in the preceding sections.

[Margin: Epilogue.]

Here you have, reader, all that has been handed down to posterity concerning the nature and marvels of waters — whether observed by trustworthy authorities, or what I myself have brought forward here as explored by my own experience — omitting countless other fabulous things, and matters known only by uncertain report. In this one thing I have been careful: never to produce any unusual effect without joining to it its causes. With this zeal, and by the grace of the Divine Power aiding me, I have reached the point of producing no natural effect so exotic that I did not also exhibit it — aided by art and by the skill of experimental philosophy — in machines of my own invention. In this study indeed, over the course of many years, with no less expense than immense labors of the mind, I have striven so greatly for no other end than to destroy that shameful shield of occult qualities, the refuge of all ignorance, and to show that no effect of so occult a quality can be assigned whose genuine cause I could not demonstrate by experiments.

From all of which, finally, I have come to understand that it is no wonder natural philosophy has remained, down to this very day, wrapped in so much darkness and deformed by so many monsters of opinion. For the Scholastic philosophers, content with a universal knowledge of principles, just as they do not descend to the proximate causes of things, so too acquire only a remote and wholly abstract knowledge of the composition and resolution of natural things. We, in this work, consider the universal causes of things — such as the influxes of the Sun, the Moon, and the other stars into this elementary world — in such a way, however, that we by no means rest in this inquiry alone. Rather, pressing on with the investigation of the nearer causes, advancing by a varied combination of experiments according to a certain continuous Ariadne's thread of operating Nature, we have judged that we can investigate the genuine causes of things in no better way than by exhibiting those same wondrous effects and operations of Nature — which she performs by herself and by a certain implanted instinct — through the diligent industry of art, in accordance with the close analogy of Nature's prototypes. You will see that this has been done throughout this whole work.

And this I have always reckoned to be the necessary method of philosophizing about the nature of things. For to wish to penetrate the inmost nature, essence, and property of all things, the inmost compositions and mixtures of individual things, and the hidden nests of the properties implanted in each — this is indeed a mystery which, as it is granted, after God, to the angelic substances alone to know, so it has remained, down to this very day, inaccessible to the darkness of the human intellect; since we do not know the ingenious skill of Nature in

composing things or in implanting powers in them, the proportion of each thing to each, and the degree of the concurring qualities. Hence, although by the help of experiments we may, after the manner of apes of Nature...

[printed p. 294]

strive to imitate the prototype to some degree, yet by this very means we do not attain the true and legitimate operations of Nature except through a certain shadow of resemblances. [Margin: It is not the business of all philosophers to treat of those things which they demand.] She alone knows by what industry, by what proportion of the things acted upon to the things acting, by what combination and adaptation of things, she produces her wondrous effects. And if anyone should claim these things to be set within the occult and inmost chambers of things, by that very claim he will deny that he is a philosopher, since he has thereby withdrawn into the refuge of ignorance. But if anyone takes refuge in supernatural and celestial causes, he exposes himself to a like labyrinth — since our intellect stands toward the light of truth no differently than an owl toward the light of the Sun.

Whatever we know, then, we learn only by way of the senses and of the external accidents belonging to the genus, which at once present themselves abundantly to the senses; so that we must confess that this knowledge of ours dwells only about the bark, as it were, and the circumference of things. To press closer toward their center has been granted only to those few whose understanding the most kind God and Father of Lights has more deeply imbued with a ray of His eternal wisdom; those whom He has equipped with experience and with the knowledge of various things, and impelled by the investigation of the secret mysteries of nature and by the love of truth, and blessed by the guidance of a divine showing-forth [parastasis].

But as for the rest — in many of the things we have brought forward thus far in this work, we have accomplished as much as the Divine Goodness has bestowed upon us. In many other matters, I judge it more fitting merely to wonder at the works of God, encompassed by inaccessible light, than to investigate them too curiously. For He Himself is the one who spoke, and they were made; He commanded, and they were created — the Cause of causes, the Fountain of fountains, the impenetrable Abyss of Heaven, Earth, and the Seas, and the Lord and Operator of all these things.

MUNDI SUBTERRANEI LIBER SEXTUS

On the Fourth of the Natural Elements, which we call EARTH
and on the things produced from it, the first Fruits of the
Subterranean World.

[printed p. 295. Running header (page top): "MUNDI SUBTERRANEI" — book-
opening display header.]

SECTIO I.

On the wondrous variety of Earth, and whether it is truly and
properly an Element, and what and of what sort should be
understood by it.

CAPUT I.

On the Element of Earth.

[Margin: The wondrous workmanship of the Earth.]

Those who, following the common run of philosophers, persuade themselves that Earth was from the beginning of things a crude and inert thing, and a mere ἄχθος [Greek: ἐτώσιον ἄχθος (etōsion achthos, "a useless burden")], with no variety, no distinction of places and parts — reduced by God into a round form by a certain fortuitous amalgamation, like a cheese — these men deserve to be hissed and jeered off the stage by all right-thinking philosophers, as we have often shown in this work. That it was rather by a truly inexpressible artifice that the creating Mind labored in this admirable womb of Nature will be plainly understood once we have explored a little more deeply the inner recesses of this terrestrial anatomy.

By the same token, all those who have judged that the mass of this earth should be called by the name of "Element" are to be laughed at. [Margin: Earth is not an Element, but an elementate.] For how could that be called simple, in which there is nothing simple — since Nature has willed that all things be composed of innumerable elements, so that not even the smallest grain of sand can be given a body which is not fused together from various heterogeneous trifling mixtures of things? What philosopher has there ever been, down to now, who could show us a pure body of Earth, free of all composition? For if such an Element exists in the

nature of things, it will be either dust, or fine sand, or a clod of earth, or a stone, or a metal, or a metallic juice, or some similar substance compounded from the innumerable species of minerals.

[Margin: It is shown by the enumeration of the parts of the earth that the element is not simple.]

But it can be neither dust nor sand, since dust and sands are nothing other than certain leavings, or the minutest little bodies scoured away from some whole stone or rock; and as these partake of the nature of the whole, so they cannot be simple. Nor can it be stone or metal, since these — together with dryness and moisture, besides the other powers implanted in them — are mixed (as is known to those skilled in the spagyric art) with very many mineral refuse-matters; and the same must be said of the other minerals. Who, then, would assert that so many marcasites, so many salts, sulphurs, alums, arsenics, so many boles, boraxes, magnets, so many glasses, crystals, so many concreted fluors, so many unconcreted juices — so many kinds of waters, in fine — are simple bodies? No one, surely, save one utterly devoid of and unskilled in all physical matters.

I am not unaware that some hold that the virgin earth, which is found only at the center, is the true element of earth. But just as it is uncertain whether such a body is found at the center of the earth, so too this fiction is asserted without grounds. There are some who hold that either ash or earth...

[The pages in this PDF run out of printed-page order; they are presented here in their correct printed sequence: 296, 297, 298, 299.]

[Continued from the previous discussion — the candidates Kircher rejects as the "element of Earth."]

something white, of the kind that white lead [ceruse] is; and some even hold that the element of Earth is *marl* [Marnen], a kind of earth usually dug only in Gaul [France]. Against this, consider first that ash cannot be the element, since ash is itself a composite: it consists of moist and dry, of salt and of powder, as I will show in its proper place. Nor can white earth — that is, white lead, gypsum, or chalk — be the element, since their very color (as can be seen in earths dyed in all sorts of different colors) is a plain mark of composition.

[Margin: That there is no pure and simple element in the nature of things.]

Finally, the earth they call *marl* cannot be the element either. For if it is said to be found only in Gaul, I do not see how it could be called the universal principle and element for the composition of all things. For if this earth were an element, it

would have to be the element of mixed and compound bodies. Yet sand composes no mixture; and gypsum, so far from composing anything, rather destroys any mixture it is added to. As for marl, which is scattered over fields and is said to enter into the mixture of whatever is produced by the fertilizing of the soil with marl — who does not see that this cannot be so? For since marl is found only in Gaul, and consequently nowhere else, there would be neither an element of Earth nor any composition of mixed bodies elsewhere. All of which is so incongruous that I would judge it should more truly be counted among old wives' ravings than believed by sensible philosophers.

We say, therefore, that no pure and simple element exists in the nature of things — and this is as certain as the experience of things examined by the spagyric art is sure and indubitable. For if a pure, unmixed, simple, and uncompounded element could exist, it would already be either soft, or hard, or colored, or imbued with its own virtues and qualities. But this very fact — that it either resists the touch or yields to the touch, or is finally imbued with some color or other — this very fact, I say, immediately offers some evidence of composition and mixture.

But perhaps someone will object: the element of Earth is that body which is utterly dry and devoid of all moisture. Yet this too cannot be said in any way. For such a body would be either glass, or sand, or gravel, or brick, or something similar — the bodies that in our estimation seem the driest of all.

Caput II.

On the great variety of things that are contained in the womb of the earthly globe.

Earth is the center and mother of all things. Into it the elements cast their seed and sperm, which Earth cherishes, ripens, digests, and brings into actuality in its bosom, according to the first intention of Nature and the admirable disposition and providence of divine Wisdom. So that Earth might be fit to hold so great a stock of universal seeds [panspermia], divine Wisdom founded it with such art that there is nothing in it not rightly arranged, nothing not duly ordered for attaining its intended effects through a wonderful series of things. Hence — as I said in Book Two — Wisdom hollowed out countless channels within it [Margin: The arrangement of the caverns], and dug out within it countless caverns of the hydrophylacia and pyrophylacia [the subterranean water-reservoirs and fire-reservoirs]...

[Continued from p. 296: still within Caput II, the subterranean channels now compared to the veins of the human body.]

carved out the caverns, and surely with no less care and concern than that with which eternal Wisdom sported in the fabric of the human body. [Margin: The Geocosm made an admirable likeness of the Microcosm.] For just as in the fabric of the human body the branching substance of the veins is so extended into all the inmost chambers of the microcosmic economy that there is not even the smallest particle that does not draw to itself, through the capillary veins, blood as the nourishment owed to it [Margin: The comparison of Earth to the human body], so too no portion of Earth, however tiny, can be found that does not abound in the moisture owed to it. If you pierce the skin in the human body with a needle, you see blood come out at once; in the same way, if anyone digs out even the smallest portion of Earth somewhat deeply, he will find moisture present at once. If anyone could behold with his eyes the inmost constitution of these veins, he would doubtless see it arranged on exactly the same plan by which, in anatomy, we recognize the wonderful texture of the veins spread out branch by branch through the whole expanse of the body. Nothing therefore now remains except that I show what truly and properly is that element of Earth which is so greatly disputed among the authorities.

Earth, then — insofar as it is the fourth and last element — was formed and produced out of the coarser parts of the proximate principles that existed within the chaotic mass and the abyss, through the inscrutable operation of divine Wisdom, for the generation of all things. It was made, as it were, a kind of sediment, principally out of the coarser portions of salt. For salt, with its spirit working within it, alone furnishes coagulation to all the things of the world, and produces a dense and hard body. And just as salt predominates in Earth, so too we may rightly say that salt composes Earth. To make this understood:

[Margin: Out of what is Earth composed?]

A twofold earth must be distinguished here for consideration: pure earth and impure.

[Margin: What is pure earth and what impure?]

Pure earth is nothing other than coagulated salt, in whose center that spirit lies hidden which by its power fixes, condenses, and animates all things — so that salt may not incongruously be called a kind of soul of Earth. If you take away the salt from earth, and with it the powers of fixing, sprouting, germinating, and nourishing, you will find you have taken these away as well — which is as certain

as daily experience teaches us. And it appears in glass: for although glass is true earth washed by fire, as (unless I am mistaken) I showed clearly enough in the preceding chapter, in which it [Margin: Salt is incorruptible] is the dead remnant, deprived of nearly all salt, so too, deprived of all its virtues, it remains sterile and barren.

Hence it is clear that all the virtues, of which there is no counting in this earthly globe, depend on salt — as salt's own powers depend on the spirit implanted in it by Nature, as on their chief agent — so that without it the Geocosm must necessarily perish. That pure earth is coagulated salt together with its spirit, endowed with a fixative power, is clear from what has been said. But all the remaining bodies may be called impure earth, and are nothing other than an excrement, and as it were a kind of menstruum of Earth, instituted by Nature to this end: that the generations and corruptions — that is, the births and deaths of things — being driven on by a certain alteration and perpetual passage from one thing to another, might unceasingly contribute to the preservation of the world. For if all things consisted of salt alone, their birth and death would by no means proceed in this order of alternation, but rather, from the incorruptible nature of salt, they would promise themselves a certain ἀφθαρσίαν [Greek: aphtharsian, "incorruptibility"] — that is, incorruptibility, such as is seen in the quintessences, in gold, and in precious stones.

For the excrement — or, to speak with the chemists, that *recrementitious* body which girds and clothes the element of Earth with a vast compass of various dregs — just as it hinders the perfect and absolute union of the elements, so too it does not permit them to subsist for long; since things that are united by a weak and feeble bond must also undergo an easy dissolution of their parts. But in things perfectly united, just as the bond is firmer and more solid, so too it produces a more durable consistency of the parts — as is plain in the substance of gold and of lead, of which the former, on account of its intimate union and the most close-packed bond of its parts, not undeservedly wearies the wits of the chemists in dissolving it among all metals, whereas the latter melts at the very first kindling.

[Margin: The durability of bodies comes from salt.]

It is clear, then, that the more things consist of a purer substance of salt, the more perennial they are in duration — as shines forth clearer than the noonday light in the precious stones: the diamond [Adamas], beryl, topaz, emerald, ruby, and the rest, about which I shall reason at length in their own place and time.

Caput III.

On the incredible variety of things that are produced — by the power of salt, together with the auxiliary forces of the rest of the elements — in the womb of the vast Megacosm; and first of all concerning Salt and its differences.

In the preceding chapter I showed clearly enough, unless I am mistaken, wherein truly and properly the proximate element of Earth consists. Now, however, it is time to show what those things are that are produced in Earth through the agency of the salt-mediator, with the concurrence of the rest of the elements, following the enumeration of the parts; and to show from where, for all sublunary bodies, the...

[Continued from p. 297: "from where, for all sublunary bodies, that *fleshy*..." — the column-bridge word is *corpulenta*.]

that coarseness arises, let us begin, and first we must speak of the manifold difference of saline bodies, so that afterward we may go on — after the saline bodies — to the composition of the remaining concrete juices: that is, of the individual concrete mineral fluids and juices, then of stones, and of metals.

SAL. — [Salt.]

Leaving the etymology of "salt" [*sal*] to be investigated by the grammarians, I turn my pen to exploring the inmost nature of Salt.

[Margin: What is salt?]

Salt is the central body of nature, the virtue, vigor, strength, and stay of Earth; the compendium of all earthly virtues; the subject of all the principles of Nature; from whose central essence the whole science and absolute knowledge of Nature depends; the matter out of which all things are constituted, and into which, when destroyed, they are at last resolved; the first and the last, the α and ω [alpha and omega] of mixable bodies; the well of Nature, and a thing well-nigh divine. As Homer attests, [God] sprinkled it with divine salt — for no other cause, surely, than the virtue implanted in it, by which it not only keeps bodies immune from all corruption, but also propagates the same with a wonderful fecundity. For there is impressed on salt I know not what character of divinity, whereby [God] indicated that he is supremely delighted by the office of salt in sacrifices.

[Margin: That salt is something divine, and why.]

[Margin: Always used in sacrifices.]

Leviticus 2: "Whatever you offer for sacrifice, you shall season it with salt, nor shall you take away the salt of the covenant of your God from your sacrifice; in every offering you shall offer salt." And *Mark* 9: "Every victim shall be salted with salt." And countless other passages, which occur everywhere in the Sacred Scriptures of both the Old and the New Testament, indicate the nobility and excellence of salt.

That great use was made of salt in the rites of the Gentiles, Ovid shows in Book 1 of the *Fasti* [*Fasti* I]:

Inde vocor Ianus, cui cum cereale sacerdos / Imponit libum farraque mixta sale. ("Hence I am called Janus, to whom, when the priest sets cereal cake upon the altar and spelt-grain mixed with salt...")

Ante Deos homini, quod conciliare valeret, / Far erat, et puri lucida mica salis. ("Before the gods, what availed to win their favor for man was spelt, and a gleaming grain of pure salt.")

For life, to speak with Pliny [the Elder], cannot be led without salt; and it is so necessary an element that the recognition of its virtue has passed, in a way, even into the pleasures of the mind. For we say that *witticisms* are called "salts" [*sales*], so that you may know that the charm of all life, the height of cheerfulness, and the rest from labors are summed up by no other word than "salt." Hence Horace, in the *Art of Poetry*: "Our forefathers, for the most part, praised both the meters and the salts [wit] of Plautus." And the Apostle confirms it, in *Colossians* 4: "Let our speech always be seasoned with salt in grace, that you may know how you ought to answer each one." But lest I seem here to be playing the encomiast of salt, leaving aside other tributes, let me proceed to those matters that are most properly our business.

[Margin: The spirit of salt, the terrestrial element, was implanted in Earth from the beginning of things.]

The spirit of salt — the terrestrial element — was, from the beginning of things, implanted in the earthly globe by God the Best and Greatest, both for the preservation of the whole and for the generation of countless substances. Hence, by a certain reciprocal exchange, the lands and the seas cherish and nourish one another, so that the salt which the Ocean has sucked from the earthly clods and from their teeming udders, it may — once that salt has been led through subterranean conduits and channels — restore to the Earth, as a kind of pledge entrusted to it. Read, if you please, Reader, what I have set out at length in the

Third Book, with the fullest reasoning, concerning the saltiness of the sea and this reciprocal commerce of the Earth with the Ocean.

[Margin: Salt is threefold: marine, fossil, artificial.]

Common and ordinary salt can be considered under a threefold difference, so that one kind is marine salt, another fossil, and another extracted by art from terrestrial clods or briny waters by boiling. Marine salt, although it does not differ in species from fossil salt, is nevertheless distinguished by a notable diversity in this very respect: that marine salt, as sharing more in moisture, is of a softer and limper substance; whereas fossil salt, on the contrary, enjoying the predominance of earth, acquires a more compact and solid substance; and the artificial kind partakes of both.

[Margin: The hardness of fossil salt.]

Fossil salt indeed — such as is found in Doris, Calabria, Sicily, Poland, and countless other places — is of such hardness that it condenses into very hard stones, well-suited for the structures of buildings and fit for carving statues, as Solinus attests where he speaks of Sicily. "The remaining salt-mine metals," he says, "which are nearest to the Agrigentine territory, are quarried by the service of the cliffs, for from there blocks are cut out for the likenesses of men and of gods." He asserts the same of the Nasamones and the Troglodytes: "For with salt they build houses, which, cut in the manner of cliffs out of the mountains, they fit together for the use of dwellings with mortared structures."

[Margin: An experiment.]

So you have the difference between marine and fossil salt: that the former, moistened with water, easily liquefies on account of the slight close-packing of its parts; the latter, as of a more compact nature, does not easily liquefy when water is poured over it. Yet even in fossil salt there is something worthy of wonder — as long experience has taught me — namely, that a piece suspended from a thread drips down little by little, drop by drop, when the South wind [Auster] or some other wind of a moister nature is blowing, but does not do so when the North wind [Boreas] or the West wind [Zephyrus] is blowing. This for no other cause, surely, than that the moist surrounding air, gradually penetrating the substance of the salt, soaks it through with its own moistening, whence through the dripping it gradually wastes away — which I find Agricola too noted, in Book 1 *On Fossils* [Agricola, *De Natura Fossilium* I].

All salt, when roasted with fires set beneath it in a vessel, loses none or little of its substance from its bulk. It loves dryness, which — joined with heat or cold — has glued it together. Moisture, by contrast, being its enemy, melts and disperses it at once when placed in it; indeed, exposed in moist air, it suffers some loss of mass. Therefore those who wish to preserve it whole must store it in dry places. The Drepanitan salt [of Trapani, Sicily] sufficiently attests this — heaped into piles, it lasts under the open sky for a span of fifteen years; and at Utica in Africa huge heaps of salt present the appearance of hills, so condensed and stiffened by the heat of the Sun that they neither melt in the rains, but by iron...

[Continued from p. 298: "...but by iron are cut only with difficulty."]

they are cut only with difficulty. And these things, unless I am mistaken, sufficiently show that earth predominates in salt, and that it is dry in the first degree, cold in the second; and it is of such admirable virtue that it scarcely has its like among the things dug from the earth. For it cannot be numbered among the metallic bodies, because it is not dissolved by heat; nor among stones, because it liquefies when water is poured over it; nor among the remaining earthy mineral parts, because when dissolved it passes entirely into water. And yet you may not call it water, since, when dissolved by the attenuation of heat, it does not pass off into vapor, nor is it consumed by fire, but rather is burned; and once burned, then condensed again, it is restored to its own nature. So whether you torrefy it with fire, or macerate it with water, or carry it through by decoction, it always remains like itself, and reverts to the state that Nature intended — being, as it were, of an incorruptible nature, an incorruptibility conferred on it by Him who, sprung from a heavenly lineage,

Spiritus intus alit, totos diffusa per artus Mens agitat molem, et magno se corpore miscet. ("A spirit within sustains, and Mind, infused through all the limbs, stirs the whole mass and mingles itself with the great body." — Virgil, *Aeneid* VI.)

But concerning the nature and properties of this Salt, see what is treated in Book II of this work.

Caput IV.

On the Differences of Salts.

That there are as many species of salts as there are species exhibited in the nature of things, spagyric experience has taught us — since nothing offers itself in the threefold kingdom of minerals, vegetables, and animals that, when wrung

by boiling, maceration, distillation, or dilution, does not yield us salt; as will become manifest in what follows, where I will treat of the extraction of salts, through countless experiments. Therefore in this place I shall reason about common and properly so-called salt and its various division; and so that you may see the differences of common and ordinary salt at first glance, here I set down an analytical table.

Analysis of Salts.

Salt may be considered as	(sub-branch)	(sub-branch)	Kinds	Note
Natural salt	by reason of the place where it is born, and these are	—	Marine, Terrestrial, Lacustrine, Fluvial, Spring [Fontanum], Sand-derived [Arenarium].	These in turn are manifold by reason of the matrices in which they are found, and from which they draw different qualities and tinctures.
	by reason of its powers	Soft	Ammoniac, Bituminous, Urinary.	Whatever is at last extracted from fatty and oily things.
		Hard	Crystalline, Rock-salt [Sal gemmae], Stony [Saxosum].	And it embraces the whole substance of salt condensed into stone.
	by reason of its colors	Colored	White [Album], Yellow [Flavum], Red [Rubrum], Black [Nigrum].	It comprehends all those salts that are affected by the tincture of the thing from which they are

Salt may be considered as	(sub-branch)	(sub-branch)	Kinds	Note
Artificial or factitious salt is made either	by Boiling [Coctione]	—	From briny earth, From sea-water.	extracted. These in turn are of manifold difference, according to the nature and quality of the place from which they are drawn out.
	by Drying-out [Exsiccatione]	—	From marsh-water, From sand, From the urine of animals.	
	by Incineration [Incineratione]	—	From metallic bodies, From vegetables, From animals, From all natural things whatsoever.	And it embraces the universe of things.

[Liber VI, Sectio I, Caput IV — continued: "De Differentiis Salium"]

River, Lake, and Spring Salt [Sal fluviale, lacustre & fontanum]

[Margin: River, lake, and spring salt.]

River, lake, and spring salt is the kind extracted from streams, lakes, and springs, and is usually drawn off by boiling. How salt comes to be in springs, rivers, and lakes I take to happen as follows. Wherever there are salt-bearing mountains, or beds saturated with brine, it most often happens that underground rivulets passing through such beds become charged with brine. These rivulets later break out as a spring and so produce a salt spring, which in turn feeds salt rivers. But if

such underground rivulets discharge themselves through hidden subterranean channels into some lake, then they communicate to that lake the same brackish quality that they absorbed from the salt mountains and brine-bearing beds.

[Margin: How salt arises in lakes, rivers, and springs.]

Let me confirm this by an example.

Diagram. A woodcut showing a freshwater rivulet that descends through the interior of salt mountains, emerging as a salt spring that feeds a river and a lake. The mountainous terrain is drawn in profile with a hand-like ridge at upper right; channels of water thread between the hills. The prose accompanying it reads: "Let there be some underground rivulet of fresh water, marked with the letter A, which runs in its bed through the innermost recesses of the salt mountains. It is certain that, once it has straightway drawn in the brine, it will become salt, and consequently, as soon as it breaks out at spring D, it will make spring D salt, and the river E that flows from it. The lake F, fed by the underground river ED, already charged with brine, will in the same way share in that brine."

- A (upper middle): freshwater rivulet entering the salt mountains
- B (left of center): mountain ridge (label on the slope)
- D (center, lower): the salt spring where the rivulet breaks out
- E (lower left): the river derived from the spring
- F (lower right, basin): the lake fed by the underground river

[The figure shows labels A, B, D, E, F; no point C is lettered. The prose refers to A, D, E, F.]

Salt from Burnt Wood [*Sal ex lignis combustis*]

[Margin: Salt extracted from wood.]

Authors of the highest authority have also reported that salt can be drawn from burnt wood — chiefly from oak or hazel wood, that is, from the oak and the hazel. Agricola teaches the method (*De Re Metallica* XII) [Georgius Agricola, *De Re Metallica* XII]. Those who make salt by pouring brine over burning logs must first dig pits in which to set the wood. These pits should be twelve feet long, seven wide, and 2½ deep, so that the poured-in brine does not run off; they should be built up with salt stones, so that they neither soak up the water nor let earth fall in from their front and back faces.

[Margin: Making salt from ash.]

In these pits the burnt oak or hazel leaves charcoal behind, and when salt water is poured over it, this charcoal is converted into salt — though it matches neither the color nor the purity of ordinary salt, being tinged with a black and dusky color.

The Salt Called Kali [Sal Kali]

[Margin: What the salt called Kali is, and its preparation.]

There is yet another kind of salt, called *Kali* or *Alkali*, commonly *soda*, useful for making glass. The Arab Bulcasis [Abū'l-Qāsim al-Zahrāwī (Albucasis)] wrote a whole book on this art, and I shall treat it fully in my *Treatise on the Glassmaker's Art* [*Tractatus de Arte Vitriaria*]. The salt is drawn from the herb Kali by art in this way. This herb, reduced to ash, is commonly called *soda*. They grind this soda, softened into a mass, and once it is reduced to a fine powder, they sift out the coarser admixed particles through a sieve.

To each pound of this they add an equal number of jars of water, and boil the well-diluted water for four hours, until the water is reduced to a third of its volume. Then, taking it off the fire, they let it settle for a space of twelve hours. Once the sediment is removed, you will find the water perfectly clear. They then strain it drop by drop through woolen wicks into a large vessel set beneath, and repeat this as often as needed, until they find by the test of the tongue that the water is salt. Finally, from this water they set a full pot on the fire and boil it until, the moisture having been driven off, they find the more substantial water reduced to salt.

Lake Salt [Sal lacustre]

[Margin: Lake salt. The Asphaltite Lake, the Dead Sea.]

Lake salt is what is extracted from brine-bearing lakes — such as Lake Asphaltites [Lacus Asphaltites] in Palestine, from which is drawn the salt that, from Sodom, they call "salt of Sodom." This lake is most celebrated among both sacred and secular authors, on account of the Pentapolis [Pentapolis — the five cities], whose memorable terror to mortals through every age it preserves: when, with an angry Heaven raining down sulfur, the burning fire blazed up and destroyed it. This region, as Holy Scripture attests, once rivaled Paradise in its delightfulness; but after the dreadful and unheard-of crimes of unnatural lust in which its inhabitants were entangled, it was burnt up by celestial fire, and now wears a face that, horrid and dreadful to behold, presents an infernal region

rather than any earthly one. See these matters treated more fully by the commentators on Sacred Scripture at this passage of Genesis.

Its salt is of an exceedingly bitter taste, and of so coarse a substance that it is found to be twice as heavy as sea salt. Hence bodies thrown into the lake never sink, owing to the abundant admixture of bitumen, and the lake bears up both men and animals without any aid of the swimmer's art. Yet as soon as they come out, their whole body is seen to be sprinkled with salt. The inhabitants nonetheless use salt of this kind as a necessary article of diet, just as we use ours. See Galen [Galen], *On Simples IV (De Simplicibus IV)*.

Lot's Wife Turned to Salt

[Margin: Lot's wife truly turned to salt.]

It is well known what the Sacred Page relates about the wife of Lot [Lot], turned into a statue of salt. Interpreters greatly torment themselves over why she was turned not into some other kind of stone or stump, but into a likeness of salt. I judge it to have been done for a twofold cause, partly physical, partly moral. For if we consider the nature of the place, we shall find it — by the records of all historians — utterly full of salt. It is therefore far more likely that she was transformed into a mixture of that sort, with which the Sodomite plain abounded, than into some other kind of stone or substance, of which the place had none.

[Margin: The marvels reported of this statue.]

A moral cause is added: just as the foolish woman, despite the prior divine warning, would not be wise, so, to her own ruin turned into a statue of salt, she might by her fearful example warn those who look upon her — and the tasteless minds of mortals — among later generations, that it is not to be made light of, what the offended mind of the Divine Power avenges with such rigor and severity by its just judgment. Let them therefore be wise and foresee the last things. Tertullian [Tertullian] relates that in his own day the statue was still to be seen. Brocardus [Burchard of Mount Sion], who lived about 300 years ago, likewise reports that in his own time it stood between Engedi and the Dead Sea. Adrichomius [Christian van Adrichem], a writer of this century, that it still exists. And the Jerusalem Targum [Targum Hierosolymitanum] reports that it will endure until the consummation of the age and the common resurrection of mankind.

It is remarkable what Tertullian reports of it: that this statue, as if it were alive, gives off a moisture not unlike the flux of women's menses; and again, that if this

same statue be mutilated by anyone, it as it were repairs its mutilated wound and seems to fill up what has been cut away. But since Tertullian describes these things not inelegantly in a certain poem on Sodom, I thought it should be added here:

The very image, keeping its body's form bodiless, Endures still, never washed away by rains, nor leveled by winds; Indeed, if any stranger mutilates the form, Straightway of itself it fills its own wounds anew; And it is said, though living now with another body's sex, To shed, marvelous, its accustomed monthly courses of blood.

And concerning it the following riddle is also offered:

The corpse has no tomb of its own, The tomb has no corpse of its own,
Yet the tomb and the corpse are within.

But this is by the way [Greek: παρέργως (parergōs, "incidentally," "by way of digression")]. Now let us return to the matter we set ourselves.

Salt from Muria and Garum

[Margin: What muria and garum are, and how they are made.]

That salt is extracted from *muria* and *garum* too is better known than need be said. But what is properly meant by *muria* and *garum* must first be stated. *Muria*, then, which they once used as a seasoning for food, was nothing other than that liquor pressed from the *garum* fish — also called the mackerel [scomber] — and secondly from the fish that they boiled down from the tunny [thynnus], which they seasoned with wine, saffron, chopped herbs, and in other ways.

[Margin: The three kinds of garum.]

And the *muria* that they prepared from mackerel under the name of *garum* — being the most exquisite — was for that reason set only on the tables of princes. The second, prepared from the tunny fish, was likewise a noble seasoning, much used by the rich and the nobility. The third, made from anchovy [apua] and the cheapest little fish and called *halec*, being of meaner quality, fell only to the use of common people. Afterward, however, the usage prevailed that any salt water — whether by itself alone, or with other seasonings added — was called *muria*. See Horace [Horace], *Satires* II.4 (*Sermones* II, Satire 4), where he sets out two kinds of sauce: one made of oil alone, the other compounded of muria, oil, wine, pounded herbs, and other things — which is indeed best if tempered with muria from a Byzantine jar.

But anyone who desires more about muria and garum and the manner of making them should consult Columella [Columella], Dioscorides [Dioscorides], Galen, and others. Many today call *muria* that liquor compounded of salt and fresh water mixed together: if an egg thrown into it does not sink but floats upon it, they say the muria is complete. But this liquor obtained the name *muria* only by a kind of metaphorical manner of speaking.

[Margin: An experiment.]

Although the use of muria from garum and tunny has ceased in Europe in our day, it still flourishes at Constantinople among the Turks, as I have learned from various people; and that only the word now remains is shown by the Greek terms: ὀξύγαρον [Greek: ὀξύγαρον (oxygaron, "a broth made of anything compounded of sour and sweet")], everything made from a sour-and-sweet mixture; ἐλαιόγαρον [Greek: ἐλαιόγαρον (elaiogaron, "made of salt and oil")], what is made of salt and oil; ὑδρόγαρον [Greek: ὑδρόγαρον (hydrogaron, "made of brine")], the liquor made of salt water — not unlike those sauces the Italians call *salsa*, *intingoli*, *guazzetti*. But let this suffice concerning muria and garum.

Caput V. — De modo Salium extrahendorum

Chapter V. — On the Method of Extracting Salts

Whatever can be reduced by the force of fire into ash and lime — whether it comes from the animal, the vegetable, or the mineral kingdom — there should be no room for anyone to doubt that salt can be extracted from it. And in these mixed bodies the power lies latent; in others — as in sea water, muria, brine-bearing earths, and the rest of the places rich in niter, halinitrum, alum, and vitriol; likewise in the acidic excrements of animals, chiefly of birds such as doves and hens — the salt is present in actuality, either coagulated or dissolved. Hence the method of extracting their salts is not so very difficult. Let us now see how salts are to be extracted from all the things mentioned. The chemists assign several methods, which we reduce to a threefold distinction: so that one is easy, the second subtle, the third subtle and arcane.

The First Method: Extracting Salts from Vegetables [Primus modus ex vegetabilibus extrahendi sales]

[Margin: The first method, of extracting salt from vegetables.]

From the class of vegetables, choose whatever plants you please. Dry them first in the sun or shade, then resolve them into ash within a pit built either of stones or

of fired bricks. The ash thus left behind is heaped in a pot, water is poured on, and it is boiled; the dilute liquid is then poured off into a vat. Once the sediment has formed, the salt liquor — which we call *lixivium* (lye) — is strained off through a filter and coagulated by evaporating it down to the consistency of a sauce or thicker broth [embamma]. It is not boiled down to dryness, lest it be scorched. The remaining moisture is dissipated, the salt staying behind, either by the gentle heat of a furnace or by the sun's warmth. Still, I think it more advisable to pass this liquor through various wicks, following Bulcasis's [Albucasis] instructions, or through various filters.

[The following corresponds to printed p. 303, the conclusion of Caput V's methods of extraction.]

The Second Method [Modus secundus]

[Margin: The second method.]

The second method is this: Burn the dry herb, enclosed in an earthen vessel, into a most white ash in a furnace built up with a very fierce fire. To this ash, placed in a glass cucurbit, add rain or fresh water previously purified by distillation, and cook it in a bath of ashes until a fourth part is consumed. Then let it rest until the dregs settle to the bottom. This done, the separated liquor, strained through a filter, is transferred into another vessel, in which it will coagulate into the salt sought.

The Third Method [Modus tertius]

[Margin: The third method.]

The third method: Let a freshly gathered herb, still swollen with its own juice, be distilled. The water being separated, let the remainder be reduced to ash by fire in a closed vessel. To this purified ash let its own water, set aside a little before, be restored; and let the combined liquor be digested in dung or in a bath for some days. Once digested in this way and carefully removed, let it be distilled down to the consistency of honey; then let the juice be poured into a glass dish, where it gradually coagulates. I have seen most of the better chemists work in this way.

These methods I have set out as the easier ones, which do not differ much from those by which salt is drawn from the ashes of burnt reeds, rushes, hazels, and oaks. Such salts lack the signs and tokens of the essence that lies hidden in the inmost center; they ooze with an oily fattiness, are tinged with a foul color and a urine-like smell, and are not pleasing in odor. And so corrective arts have been invented by those skilled in chemistry, by which these salts may be amended and

at last attain their perfection. What these methods of proceeding are, I shall now disclose.

The Fourth Method: A Subtler Extraction [Modus quartus, subtilior]

[Margin: The fourth method, of extracting the aforesaid salt more subtly.]

Those who seek the more subtle mastery of salt go about it in various ways. Some, in order to remove all the aforesaid effects and the smell of urine entirely, do not coagulate the extracted salts to dryness, but reduce them to the form of a syrup, so that the surviving moisture is either tinted by the sun or dried by the heat of a furnace. Others dilute them with rose water, filter, and coagulate by an oft-repeated operation. Some reverberate them to dryness; nor are there lacking those who melt them and liquefy them with fire.

But we recognize that not even in this way will the salt attain its perfection, since such a thing is only a material body. Therefore, in order that it may achieve perfection, spirit of wine or radical vinegar is needed to complete the work. So, after some preliminary washing, let the ashes be mixed with spirit of wine or vinegar; let the mixture be distilled, the distillate drawn off, filtered, and coagulated. This is repeated until, after percolation through the filter by a threefold operation, nothing remains, and the salt comes out entirely etherial. This is the first true method of extracting salts from plants and animals — and from those things analogous to plants.

From lime [calx], salts are separated much more easily still, by the same procedure, save that the water used must not be drawn from rain, river, or spring, but properly distilled fresh water. Some, leaving aside the first dregs, take up the extracted juice, and from this draw out the first tincture, or fifth essence [quintessence], two or three times, until the most subtle part is separated. Then they evaporate the feculent juice to dryness and reduce it to ashes; and from these, with singular ingenuity and industry, they bring the salt to its highest perfection, using its own phlegm, or that very menstruum by which its proper and essential juice was secreted.

The Fifth Method [Modus quintus]

[Margin: The fifth method.]

Let the remains of the pressed-out herbs, together with the magma or thick residue of the juice, after drying, be put into a pot and allowed to settle. Let the empty pot be filled to the brim with new material — which may also be done by adding whole herbs, so that in this way a threefold substance of the same herb

comes together. Let the pot, closed but with a small breathing-hole left, be reverberated by degrees, so that the topmost layer, buried by the first, glows white-hot. The ash being removed, let warm distilled water be directed onto it; the clear water poured off, let it be strained, coagulated, dissolved, filtered; and this done, let it be coagulated once more, until its purity, color, and taste are pleasing.

In some, once the sulphureous and mercurial essences have been rendered up, the dead heads [capita mortua] still retain salt, so that there is no need of fresh burnings or calcinations; but to the ground residue is added either its own phlegm or distilled fresh water, which is at once impregnated with the salt drawn to itself. And this is fixed salt, for the volatile had already flown off in the first distillation; yet this fixed salt too will become volatile if it is tormented by a further distillation.

In this same way, salt is extracted from all the species of saline bodies — as from the residues of distilled vitriol, tartar, salt, alum, halinitrum; likewise from the dead heads of sublimated quicksilver and the sediments of strong waters [aquae fortes] — which is also accomplished by the coagulation of spirits. For the spirits of the said salts, drawn out from a retort by the force of fire or through an alembic, when the spirituous moisture has gradually separated and withdrawn itself, are at last condensed into salt. In this way salt is extracted from tartar — on which see Oswald Croll [Oswald Croll] in his *Basilica* (*Basilica Chymica*). But of all these matters more abundant material for discussion will be given in the following books; so let us turn to other things.

Liber VI, Sectio II — De Nitro

SECTIO II.

CAPUT I.

DE NITRO

And its varieties: rock-niter [Salnitrum], aphronitre [Aphronitrum], and halinitre [Halinitrum].

[Margin: Niter, the second variety of salt.]

The second variety of salt is niter [nitrum]. It is called by various names, which, though they agree entirely in essence, differ only in their accidental qualities —

names that sound different but mean the same thing. Like common salt, niter is either native or manufactured.

[Margin: Native and manufactured.]

Native niter is found either within the earth or outside it. When it lies hidden within the earth, it is quarried like other fossils [minerals], for it is hard and dense, like stone — and from this the Venetians are said to make borax, or what amounts to the same thing, chrysocolla [Veneti conflare dicuntur]. Or else it is gathered in caves, on whose walls and vaulted ceilings it forms like icicles. Or, while still liquid and dripping down into the ground, it passes into a kind of efflorescence which the Latins call *spuma* [foam] and the Greeks ἀφρόνιτρον [Greek: aphronitron, "niter-foam," aphronitre].

[Margin: What is ἀφρόνιτρον?]

This foam-niter differs from the solid form in nothing but its hardness or softness. In ancient times a kind of niter was highly prized which was gathered in Egypt — in fields after the flooding of the Nile, once the moisture had already evaporated and it had solidified. Another, much-prized kind was dug up near Philadelphia in Lydia and Magnesia, a city of Caria.

[Margin: Where the best niter is produced.]

Outside the mines, however — in valleys, plains, and lakes, from whose edges it bloomed out like salt — it was scraped off; and this they called ἅλμυραγία [Greek: halmyragia, "salt-efflorescence" — a salt deposit]. By art it is prepared in this way: just as in Egypt the niter-bearing substance is found sweating out of the earth and clods in nearly all places — no differently than sea-salt — and is boiled into salt by the power of the Sun in little beds [areolis] hollowed out by the technique mentioned above, or in a pool; so too the water of the Nile alone, either channeled into niter-beds (which they call *Nitrariae*) or left standing in the hollows of the fields by the Nile's flooding, solidifies into niter through the Sun's action, as the fresh waters are thinned away into vapor.

[Margin: How it was prepared by art in ancient times.]

And this is to be understood of all those places where niter-bearing earth abounds. For, as was said above, fresh water flowing through such places takes on the nature of the soil according to the natural disposition of the terrain beneath it: if it has sucked up salt and drawn it to itself, it will grow into salt; if it has passed through niter-bearing places, it will be imbued with niter and at last

bloom out into niter; if through aluminous places, into alum; if through vitriol-bearing places, into vitriol — all of which was set out at length in Book V.

[Margin: Fresh water acquires the quality of the terrain beneath it as it flows, taking its nature from the underlying ground.]

In Egypt niter is produced in such abundance that, heaped into mounds, it grows in time into rock, from which elegant vessels are formed. And if it is sometimes found tinged with various colors, this proves nothing different about the niter, since it draws every color from the color of the earth out of which it was extracted: from red earth, red; from white, white; and so on.

Whether Egyptian niter is the same as ours is a matter of dispute among natural philosophers and physicians. We for our part judge that our niter does not differ in species from the Egyptian, but only in accidental qualities — in much the same way that salt is produced of a more excellent nature in some places than in others.

[Margin: Whether Egyptian niter is the same as ours.]

For the terrain's disposition by place, its situation, the aspect of the heavens, and a differing climate — just as in some places they generate nobler products than in others (since places differ in their disposition) — so too do they generate nobler mineral compounds. The same happens with all the other varieties of salts, as spagyric experience clearly teaches. For if you take salt or niter, whether pure or imperfect, impure, base, and contaminated with various adulterations, and reduce it to perfection by the torture of fire through repeated distillation, you will at last obtain the purest niter, one that yields to no other niter however pure in excellence. So the excellence of niter does not differ from a less excellent niter, except that the latter is found less pure and refined than the former. Once these impediments are removed, the nature is utterly the same wherever in the world it may be produced — so that it seems pointless that it was named by the ancients under so many different names, as though distinct in species.

[Margin: Pure niter differs from impure only accidentally.]

For just as salt is made by a threefold technique — from brine, from a dilution, or from a lye [lixivium] — so too is niter, drawn from the same sources.

[Margin: Salt and niter are made by a threefold method.]

For niter-bearing water, like brine, is converted into niter; niter-bearing earth, drenched and mixed with fresh rain water, is likewise transmuted into niter by

the heat of the Sun; while from oak and similar woods burned and reduced to ash, a lye is prepared that is wonderfully suited to extracting niter, by the technique we hinted at above.

As for niter-bearing waters, they too take on various differences according to the proportion of the substances mixed in with them. The Nile water of Egypt, although niter-bearing, nevertheless when strained yields a drink that is not only most healthful but also wonderfully suited to making women fertile, as we showed in our *Oedipus* [*Oedipus Aegyptiacus*]. Other niter-bearing waters are extremely sharp, others very bitter, others finally mild and possessed of scarcely any corrosive power. See what we wrote at length on the power of niter-bearing waters in Book V of this work.

[Margin: The nature of niter sprung from the sea.]

Niter sprung from the sea in Egypt is beautifully explained by St. Jerome [D. Hieronymus] on that passage of Proverbs 25 [Prov. 25.20], where he aptly transfers the teaching "*Vinegar upon niter, he who sings songs to a wicked heart.*" "Niter," he says, "and the province of Nitria, where..."

[Margin: St. Jerome.]

where it is most accustomed to form, took its name; and it does not differ much from the variety called sal ammoniac [sal Ammoniacum]. For just as on the seashore the Sun's heat makes salt, hardening into rock the sea waters that a greater force of winds — or the seething of the sea itself — has cast onto the further parts of the shore: so in Nitria, where in summer the more prolonged rains soak the ground, and where the star's heat is so great that it concocts the very rainwaters, across the breadth of the sands, into a stone of salt — one most similar in appearance to salt or even ice, yet having nothing of icy cold nor of salty taste. Nevertheless, by the nature of salt, it is accustomed to endure in burning heat [in caumate] and to flow and liquefy in a misty atmosphere. The natives use it, where need arises, as a soap [pro lomento].

Hence sinful Judaea is told in Jeremiah [Jerem. 2.22]: "*Though you wash yourself with niter, and multiply for yourself the herb borith, you are stained in your iniquity, says the Lord.*" But quicklime crackles in water and indeed perishes, yet it renders the water fit for washing. Solomon, seeing this nature suited to his figure, says: "*Vinegar in niter, like one who sings songs to a most wicked heart*" [Proverbs 25.20]. For if vinegar is poured onto niter, it of course at once seethes and boils up; so too a perverse mind, when it is rebuked through reproof, or when good things are urged upon it through the sweetness of preaching, becomes

worse for the correction, and is thereby kindled into the iniquity of murmuring — when it ought to have been restrained from iniquity. So far St. Jerome, indeed wittily and elegantly.

CAPUT II.

On rock-niter [Salnitrum], the third variety of salt.

[Margin: The remarkable power of rock-niter.]

Niter — called by the Greeks λίτρον [Greek: litron] or ἀλίνιτρον [Greek: halinitron] — is distinguished from ordinary niter [Nitro ordinario] by this mark: that it is wonderfully full of wind [flatuosum], abounds in an enormous efficacy of spirits, and holds a middle nature between salt and niter. This they also call "the foam of niter" [nitri spumam], on the testimony of Albertus [Albertus Magnus], being of a more subtle substance and power than niter itself. Hence most meteorologists call this kind of niter the sole cause of the enormous commotions beneath the earth. Gunpowder [pulvis pyrius], with which rock-niter is mixed, proves this more than sufficiently by the great slaughter of mortals. And although we treated these matters at length in Book IV [*Quarto Libro*], here nevertheless we shall examine more exactly certain things omitted there, so that the marvelous power of this salt may become more and more evident.

For in it shines forth the distinguished dignity of Nature, and also some necessity for our use. For art is the attendant of Nature herself, and as it were her handmaid in her works. First, then, just like salt and niter, rock-niter too occurs native. As Baccius and Agricola [Georgius Agricola] write, a certain kind of earthy niter has recently been found among the Saxons, which whitens on the surface of the ground, sprinkled like flour, and which also runs riot in veins below; from this they make rock-niter.

[Margin: How rock-niter is made.]

Yet I myself do not believe this to be the genuine matter of saltpeter, but rather some rotted offshoot of bitumen — with which all Saxony especially abounds — or rather a kind of dung, such as Baccius writes he saw near the town of Fabriano, in the innermost cavern (which they call "the dark one"), beneath the Apennines, where, from myriads of owls roosting overnight, from their dung heaped up and aged there over many centuries, they gathered an inestimable treasure of saltpeter.

[Margin: From the excrement of bats and owls in a certain cavern near Fabriano, a great quantity of niter is extracted.]

I hear that there teems with such a kind of dung and fertility an immense cavern productive of saltpeter, one indeed extending very far, but rendered inaccessible by the multitude of bats — so much so that in flight they extinguish even lamps. And perhaps of this kind is that whitish and rotten matter among the Saxons, near the borders of Vulturena [?], where one crosses over to the Rhaeti [Rhaetians].

Moreover, it is worth the effort, because of the novelty of this product of saltpeter, and because its qualities have not yet been so thoroughly explored or written down, to investigate its nature — truly marvelous and paradoxical in some respects. Saltpeter is made today from a very sharp lye, which is strained off from such dung or aged excrement, or even from the rotted rubble of cemeteries and from earths deliberately rotted together — water being poured on repeatedly in wooden vessels. This same lye is then boiled in great cauldrons, and saltpeter forms with long fibers (like a kind of salt) congealing at the bottom of the vessel.

This is sharp to the taste at the first sensation, then extremely sharp, overturning the stomach and eroding the intestines. Its use is now all too well known in engines of war and in cannon [bombardis], by which the superstition of "thundering Jove" has now been made empty, and the warlike instruments of the ancients rendered ridiculous. For with the incomparable force and crash of this powder — flashing more than Jove, with more than giant-like daring — the savagery of this age dares not only to overcome the unconquered ramparts of cities, but even

[Margin: The astonishing power and efficacy of niter in gunpowder.]

to shatter the very metal-bearing mountains, to undermine them, and to open a road by sea and land. This is a marvelous effect of saltpeter; but more worthy of wonder still, and more difficult to scrutinize, is the fact that saltpeter produces such contrary effects with both water and fire. For in gunpowder, which is made from saltpeter with sulfur and added charcoal, at even the slightest approach of a spark it is ignited; and it does not so much burn of itself as it is suddenly diffused into a windy and violent spirit — these being the properties of the fire-bearing powder-mixture.

Yet it is remarkable that saltpeter shows a wholly contrary effect when cast into water. For as daily experience here at Rome teaches in summertime: when water

is poured into a glass flask, or saltpeter is placed within a basin filled with water, the water within a brief space of time takes on so great an increase of cold that the whole of it passes into ice, beyond every degree of coldness. Of this diversity...

the artful effect produced from lead furnishes us some path toward investigating the causes — the effect that Galen records in *On Simple Medicines* IX [Galenus, *de Simpl. med.* 9].

[Margin: Water agitated in a leaden vessel grows cold.]

For he asserts that cold water, agitated in a leaden vessel, becomes much colder in it; and likewise oil, wine, and any liquid whatever — which is of course to be attributed to the nature of lead, of a watery and earthy substance, cold and moist in the second degree. But since this miracle of saltpeter is greater than that by as much as its effect is more prodigious, I have thought it worthwhile to investigate diligently — with the care it deserves — just how it performs actions so contrary both with fire and with water, and to the extreme degree: so that with fire it becomes fire, but with water the coldest water.

Whoever has searched into Nature more deeply will discover that almost all things are endowed with contrary qualities. Thus the same thing can doubtless operate in diverse ways — as is clearly evident in the operations of simple medicines, with Galen too as authority. Moreover, one and the same thing does not have the same relation in acting and being acted upon toward one thing as it has toward another. For the action and reaction of each will occur, but differently — as with niter's action toward fire, and niter's action toward water. And in these three suppositions consists the whole reason for the diversity of saltpeter's effects, as Baccius rightly notes.

[Margin: The power and explanation of saltpeter.]

To explore this difficulty, let us bring forward some experiments with various substances, where the manifest cause is plain in oil [Experimenta].

[Margin: Experiments.]

In oil we observe a threefold diversity relevant to our purpose. Oil never mixes with water; better with wine; with lye it becomes one body — and that of a sharp and warm faculty — because of the conformity (or the disagreement) of substance that it has with the one and not with the other. But concerning lime [calx], the examples are more in tune with our subject, for lime is actually cold yet potentially wholly fire. Lime dissolves when water is poured on it, and boils up with the greatest fervor; but when oil is brought near or poured on, it does not

mix — indeed, if it is finally dissolved, it keeps its powers and is used by physicians together with oil as a caustic. But if lime is applied together with egg-white, you will see a sudden mutual gluing-together take place; for the lime so absorbs the whole egg-white into itself that it at once dries it.

[Margin: Why quicklime, mixed with egg-white, becomes so strong that it joins broken glass.]

And so it comes about that, if it is applied in the same instant of time, the glue applied to a shattered glass or earthenware vessel is found to be most tenacious. The cause of all these things must be referred both to the contrary qualities of the same thing, and to the dissimilarity and differing relation that the same thing has with one thing and with another in acting and being acted upon.

But to return to lime mixed with cold water: lime, poured on or placed under water, dissolves and grows so hot, because of the dissimilarity of substance, as Fracastorius [Girolamo Fracastoro] would have it.

[Margin: Why lime mixed with water grows hot.]

Add the manifest cause: because of the struggle that is stirred up between these two contraries, water and lime; or better, between the fiery parts of the lime and the cold parts of the water. For the water, growing hot from the fiery part of the lime, at once evaporates; the vapors, multiplied, expand, and by the impulse of the water following after, drive out the air they nearest touch. Thus part drives part, the air flies out most easily, the water succeeds into the pores, and everywhere through the smallest passages, lest a vacuum be given. Hence the water grows hot, and the lime grows hot too, its heat-producing quality being drawn from potency into act. The lime is dissolved, its particles being separated, as the water and the water's vapor penetrate the whole of it.

But lime is not stirred to any action and struggle with oil, because they have some communion with each other. Hence oil, since it is not vaporizable, easily unites with lime, keeps its qualities for it, and retains its viscosity in its own sharpness. But egg-white is itself viscous and not vaporizable; yet because of its cold and moist qualities, opposite to those of lime, when applied it makes the lime exhale. And since the egg-white does not succeed into the lime's pores — because egg-white does not evaporate — the lime suddenly immerses the whole of itself and incorporates the egg-white into itself, lest a vacuum be given; and in that very instant of time it also draws with it and glues together, in that strong union, the parts of the broken vessel.

By these examples the difficulty concerning the contrary faculties of saltpeter may now appear smaller.

[Margin: The power and operation of niter.]

First, indeed, saltpeter seems to belong to the class of salty things, whence it is easily dissolved in water — and of this there is no doubt. Further, from its effects so diverse with water and with fire, it is plainly evident that saltpeter passes over and dissolves into water simply; but it does not catch fire simply, rather by means of a kindling agent it carries with it — namely sulfur, which is a substance and power that is fiery — and by means of charcoal, which dries out the excessive moisture of the saltpeter and tempers the powder itself, so that it catches fire easily.

Therefore it must be granted that the substance of saltpeter consists of contrary parts: of very many watery and cold parts in act, whence the whole of it melts in water; and of parts that are by turns fiery, sharp, and oily — which it has drawn to itself from dung and its sharpness, and through which it is in potency to fire. According to this constitution of the nature of saltpeter, the explanation of those difficulties must be given.

[Margin: The explanation of so great a power, with the sulfur, and why in the cold it becomes coldest.]

First: how is it that saltpeter, when burning, produces so great a violence and vast onset? Then: why, when poured into water, does it chill it so suddenly — indeed, render it at once colder than if ice were poured in — which seems contradictory, since ice is the highest of cold things, and saltpeter consists of fiery parts?

To these difficulties, beyond saltpeter's natural disposition toward fire and toward water, in each case a certain violence intervenes, and in each case a maximum is understood. As to the first: the violence is incomparable, and first shines forth in lightning. It arises from the part of saltpeter's watery and cold substance, which is not naturally apt to burn, but, forced by the power of the overcoming fire, is suddenly turned and leaps out into a nature midway between water and fire — that is, into a blast [flatum]. Therefore in saltpeter violence occurs, but the effect is that of the whole powder together: for the sulfur seizes the fire, the fire in the saltpeter violently excites a blast, the blast urges and dilates the conflagration; the conflagration, because...

[Margin: The operation of gunpowder.]

because it is stirred up with force and suddenly makes its onset and crash; and at last too its ruin and destruction. To this, a threefold violence concurs: the first is the fire itself, the second the urgency of the blast, and the third the narrowness of the place. Whence the vehemence of the fire, finding no exit nor place where by its nature it might most widely dilate itself, turns its whole force against the obstacle, which it expels with so great an impulse of nature that it would shatter even metal-bearing mountains.

As to the second [difficulty]: saltpeter dissolves into water, for it is of a watery nature; it chills the water itself, because it is actually cold; and finally it chills more quickly and more strongly than ice, because of the violent *antiperistasis* [Greek: antiperistasis, the mutual reaction/concentration of opposed qualities] and the extinction of the warm parts by the surrounding water and the moisture predominant in it. This is the nature of saltpeter and of saltpeter-charged water.

COROLLARY [Consectarium].

[Margin: Earthquakes arise from the kindling of niter.]

Hence is made clear the reason and cause of earthquakes: namely, that the spirituous substance of niter, kindled in the subterranean passages, unable to bear the narrowness of the place, while it seeks a wider one, throws everything into confusion. Just as in mines [cuniculis], saltpeter-powder overturns the places laid above it with such violence that the very mountains seem to be hurled into the air — which could not happen without niter — and is clearly evident in the subterranean fires, which, never deprived of their fuel, always burn, and yet do not cause that earthquake. But as soon as the fire has entered some passage filled with niter, then indeed that, once kindled, with its untamed violence produces those great ruins which we read have occurred at various times and in diverse places, to the great terror of the mind. Whence it also follows that not cavernous places, but places lying above niter-bearing passages, are subject to earthquakes.

The true and physical cause of an earthquake, therefore, is the sudden kindling of saltpeter-bearing matter in the subterranean passages; which, all at once thinned out, seeking a roomier place for itself, when it cannot be contained by the narrowness of the place, bursts all obstacles and opens a way of escape for itself.

CAPUT III.

On the generation, nature, and powers of saltpeter.
