From what precedes, so far as our feeble talent permitted, we have set out the operations of the niter-powder, together with the genuine causes of effects so great and so contrary — not so much in our own opinion as in that of the Peripatetics. But since the nature of niter was unfolded there only as regards a certain surface, here, lest so vast a secret of nature remain unexplained, we shall attempt to assign its genuine origin.

The elements, as we said in the second Book, are from the three chemical principles of things — which we asserted to correspond, κατὰ τὴν ἀναλογίαν [Greek: kata tēn analogian, "by analogy"], to our Salt, Mercury, and Sulfur. And Salt indeed gives consistency to all mixed bodies, Mercury the watery substance, the glue of bodies, and Sulfur the fiery activity; while air results from Mercury and Sulfur, a substance partly watery and partly fiery.

[Margin: The elements from which things are composed are not pure elements, but elemented [compounded].]

The very effect of moisture and dryness teaches us this: for we see that things are in one respect bounded, and in another respect not bounded by their proper limit. Therefore from sensation we have grasped that there is dryness and moisture in things, and that there is something composed of both. For dry flour does not glue two sheets of paper together unless it has first been subjected to moisture, nor can water without flour accomplish it in any way. Therefore moisture and dryness, just as they are the underlying subjects of all mixtures whatever, so too moisture and dryness exist as the passible qualities of those same things.

But since for the composition of a mixed body it is necessary that not only passive but also active qualities concur — for no thing lacks some active quality — it must be admitted that, besides the substance from which things have moisture and dryness, they also have a substance from which they are imbued with heat. For it is proper to cold to temper the excess of incoming heat, which is in some way the activity of cold; and that this is the doctrine of Aristotle himself is evident from *Meteorology* IV, text 13 [l. 4. *met. text.* 13].

[Margin: Moisture and dryness are passible qualities of the material; heat and cold are active.]

For since the Philosopher [Aristotle] notes that moisture and dryness, as passive and subjective qualities, properly belong to earth and water, he wisely inferred that all composites come to be from earth and water as from a subject — such as terrestrial and aquatic things, all of which have their birth either in earth or in waters, and are nourished in them. But to this material part he judged that an equal formal part must be added, which arises from heat tempered by cold — a part that is properly born from air and fire, or from the spirituous portion contained in them.

But since mixed bodies do not consist of bare qualities — namely moisture and dryness — as though from pure elements, but from bodies constituted by such moisture and dryness, the Philosopher rightly determines those bodies to which these composing qualities are attributed as the material subject.

[Margin: The opinion of Aristotle.]

Since, then, fire and earth are dry, while air and water are moist, he therefore properly attributes these passive qualities to earth and water. But why he made no mention here of fire and air — the reason is that elements of this kind, just as they are endowed with no corpulence and thickness, so they cannot, by themselves alone, concur to constitute a mixed body.

And from this doctrine of Aristotle I infer that by the name "earth" he by no means understood some physical body of the same species, individual (so to speak), nor by the name "air" some body of the same lowest similar species; but rather a certain principle, in his own manner...

[Margin: Aristotle understood "elements" abstractly, considered under a metaphysical aspect.]

to a mind accustomed to metaphysics, abstracted from all coarse and sluggish matter. Under this account — in which all coarse and solid bodies metaphysically agree — he meant Earth; then he meant by Water all those bodies that can be resolved into vapors, like watery ones; by Air the vaporous bodies endowed with a subtle fluidity; and by Fire those bodies constituted not of a vaporous but of a most subtle substance. Aristotle, I say, understood these under a certain abstract, metaphysical account. And since these accounts are found in all things, he rightly and acutely concluded that all composite bodies are made up of them.

[Margin: What he properly means by the elements.]

Yet he held that these bodies, both coarse and subtle, are a kind of aggregate and heap of utterly disparate things. That body which is called Earth, although it is

nothing other than the said heap of various things, is still called "earth" by virtue of the very fact that all mixed bodies are solid and consist of coarseness. By contrast, the element called air or fire is nothing other than a heap of vapors from the most diverse things — vapors that nevertheless all agree in this, that they are subtle, vaporous, exhalation-like bodies, and are therefore called by the common name "air" and "fire." You see, then, how Aristotle [Aristoteles] defined the accounts of the elements; and these agree beautifully with everything we have said above about the true element of Earth, Water, Air, and Fire.

For there lurks in the center of salt a certain spirituous substance which, just as it is present in all the species of mixed bodies, so it supplies to all of them their coarseness and proper consistency. This substance ought to be called the true, proper, and most immediate element of earth, of which the sensible salt is only the material substrate. In the center of the moist, by the same token, there lurks a certain mercurial and spirituous substance — the proper element of water, conferring fluidity on all bodies; and it is a kind of glue by which all things earthy and dry are bound together. Let the same judgment hold for the rest. I have thought it necessary to set down all this so that the nature of salt, niter, and saltpeter [salnitrum] might be more clearly explained.

And first of all it must be understood that artificial saltpeter, which is used today for gunpowder, is far superior to the native sort that effloresces from nitrous waters and earths. Hence people generally use the artificial kind, which (as I said above) is extracted from the stables of animals and old latrines, from the dung of hens and doves, and also from cemeteries, crypts, and the lurking-places of bats. The reason for this can escape no one who has come to know more deeply the powers that lie hidden under this excremental filth of refuse, urine, and dung.

[Margin: From what sources saltpeter is produced.]

For when this filth, by a kind of magnetic power, draws to itself whatever is nitrous that lurks within the entrails of animals, and these are then fermented for a long time within the nitrous earth, they acquire a power far greater — on account of the varied mixture of things now activated, and the bilious refuse mingled with them — than they would have in the native sort. In this way, strengthened by abundant supports, they gradually acquire that spirit and increase which they later display, joined to sulphur and charcoal, to the great consternation of mortals. For the more spirituous this saltpeter is, the greater the destructive effect it must be reckoned to produce.

[Margin: The natural composition of niter.]

Hence too, the saltpeter that is produced from the alluvial deposits of various things in subterranean burrows — partly from seawater and the influx of the other salts, partly from the native disposition of the place — once seized and kindled by inmost fires, is the cause of all the commotions and meteorological impressions, both in subterranean regions and above in the districts of the airy region; as was copiously demonstrated a little earlier, and above in Book IV [l. 4]. For the spirits of saltpeter, being most subtle, very easily transpire through the pores of the earth, and so, borne up into the air, they cause the effects of fiery impressions. Or, if they are not permitted to penetrate because of firm obstacles in the subterranean parts, then indeed they seek an exit for themselves by right and wrong alike — by the sole law of necessity — bursting the bars of the mountains.

[Margin: The wondrous power of niter.]

[Margin: Why saltpeter is more efficacious.]

Now, since saltpeter is endowed with such marvelous powers, it must now be seen how it differs from common salt, and what each is composed of. Common salt, produced from the viscous moisture of water and air, is nothing other than the earthy part of that viscous moisture, which is hardened by heat and dried into salt. But the fiery or sulphurous part that is in that viscous moisture of air and water is changed into niter, just as the earthy and watery part in it is changed into salt. Saltpeter, however, is the purer and more refined part of niter. From this it is clear that salt and niter differ chiefly in this: that niter has obtained in its composition more sulphur and mercury — that is, more fire and air — than salt, which has obtained in its composition more water and earth.

[Margin: How it differs from common salt.]

In salt, indeed, fire and air are hidden, while water and earth are manifest; in niter it is the reverse. Hence common salt by no means takes fire and flames up as niter does, because the earth and water of which salt consists impede ignition, and consequently cannot produce those violent effects of saltpeter. For what is fiery in salt — once moisture has been added, as also in niter — by this means both penetrate and dissolve all hard bodies; and provided these putrefy, they resolve them into prime matter, namely a salt similar to themselves, from which they took their origin. From this, marvels are accomplished in the Art of Chemistry, provided that pure, unalloyed moisture be perfectly and absolutely fixed — endowed with infinite virtues for routing diseases, which will be set forth more fully in the Eighth Book.

For just as niter can be called congealed water, so too it can be called congealed fire, inasmuch as in its inmost center and the bedchamber of nature it holds enclosed the treasure of all nature and the fire of life. If anyone could fix this with such skillful success of the art, and imbue it with a golden or silver tincture, then [he would possess] that supreme and inestimable secret...

[inestimable secret] which has already for whole ages been sought after by the entire school of Philosophers — I have no doubt that he would possess it. But since we have deferred these matters to another place, here we have thought only to expound its nature.

COROLLARY [CONSECTARIUM]

From these things the wonderful nature and property of saltpeter is evident. For the most part it contains three substances when not yet purified — namely alum, crackling salt, and essential niter — which are found from its distillation. The alum, indeed, is calcined with a certain heat and effervescence; the pure niter is inflamed and consumed; the salt crackles and leaps out. Taste too confirms this — aluminous, salty, nitrous. There are present in it spirits, partly cold and partly fiery; and there is also a certain wateriness mixed with fatness. From these depend the marvelous effects and properties of saltpeter. For from the diversity of elements and opposing qualities, nothing but marvels can come forth: it is born in the earth, stabled in the waters, snatches fire with a kind of Promethean cunning; into the air it spits out reeking smoke and bubbles up with wateriness; dissolved in water, it introduces intense cold; its hooflike substance, when squeezed in the hand, mostly springs apart with a crackling. It abounds in so great a supply of airy and fiery spirits that even from a small mass it breathes out an incredible quantity of exhalations, as will be seen in what follows. Imparted to natural waters, it purges, cuts, penetrates, cleanses, clears obstructions, moves and drives out the sandy substance of the kidneys and bladder. When it is distilled or sublimed, it usually feels an excess of heat and shatters the vessels; but when handled with skill, it belches out an exhalation of marvelous heat.

[Margin: The powers of niter.]

Its most potent power lies in the strong waters [aquae fortes]. From these arise solvents most apt for purging the nobler metals and for boiling down ores — a great indication of how much resolving and cleansing capacity they possess. There is no mine of mixed minerals or metallic vein that it does not (by some innate ambition of its own, I know not what) ally itself with; among the rest, it not only grows beside salt, alum, sal ammoniac, and the other salts as though most

closely akin to them, but even fills them with its own riches. Hence it is of immense use in that great masterwork of the Chemists, especially in nitrous vitriol, in which sulphur and mercury obtain equal portions of the proportion. Its fertility is evident even from this: from earths subject to its natural jurisdiction, however much you take away, you will find that after some years they have flowered again anew. Indeed, if anyone soaks and irrigates with water earths fertile with its seeds, or walls, within a short space of time you will see them sprout up again into their nitrous shoots and flowers. But let us confirm these things by experiment.

Experiment for forcing niter into flowers [Experimentum Nitrum in Flores cogendi]

[Margin: Experiment.]

Let a wooden, earthenware, or even iron tube be made, pierced with several holes, and let it be filled with tartar, quicklime, and salt — or even the urine of a wine-drinker — combined into a single mixture. When this mass has been hardened by three days' sun, let it be transferred together with the tube into a damp cellar; and not without wonder you will discover that in time the flowers of saltpeter sprout from the said mass like snowy flakes — indeed sometimes with such force that, if you allow some juices of nitrous herbs to stand for a long time in a closed glass vessel, then the niter present in them, now fermented and pregnant with spirit, burning with an immense desire to propagate and unable to be contained in a closed place, will pierce even the glass itself with its acridity, so that, with the obstacles removed, it may more freely propagate itself. See an experiment of this, truly remarkable, recorded in the preceding Books, which I remember having seen with my own eyes, confirmed by a physician of Montpellier [Montispolitanus].

CHAPTER IV [CAPUT IV]

On the manner and method of making nitrous gunpowder, and its various uses in the pyrobolic art [De Nitrosi pulveris pyrii conficiendi modo & ratione, ejusque variis in Arte pyrobolica usibus]

The manner of making gunpowder — as Chrascovitz [?] hands down in his work *On the Art of War* [*de Arte Polemia*] — is known not only to those who study pyrotechnics and to others who have made a profession of working at it, but very many also who are accustomed to handle smaller firearms and portable or hand-held guns; indeed not a few of the country folk are able to make it with their own

hands, without employing any artificial machines or instruments. "For we have seen," says the said author, "very many inhabitants of Podolia and Ukraine, whom we call Cossacks [Kozakos], preparing gunpowder in a way quite unlike the common method."

[Margin: The various preparations of gunpowder.]

That is, they put in certain portions of niter, sulphur, and charcoal, each its own (the proportions and preparations of these, namely of one material to another, they have learned from practice alone), into an earthenware pot; and after fresh water has been poured over it, they boil it thoroughly over a slow fire for the space of two or three hours, until some part evaporates and the material becomes thicker and denser. Afterward, having extracted this from the pot and dried it a little in the sun or in a warm stove-room, they pass it through a hair sieve and reduce it into the finest grains. Others, however, in a little earthenware crucible or basin, or upon a flat polished stone...

and polished [stone], grind and incorporate most finely the material intended for making gunpowder, and finally, having moistened it, work it into grains. We therefore think it superfluous to say much more on the matter and to describe the order and sequence usually observed in the preparation; it will suffice in this chapter to have set forth some mixtures, the best and most tried, for making the threefold powder.

Mixtures of powder for the larger cannon [Mixturae pulveris ad Tormenta majora]

	First Method	Second Method
Saltpeter [Salis nitri]	100 lbs	100 lbs
Sulphur [Sulphuris]	25 lbs	20 lbs
Charcoal [Carbonum]	25 lbs	24 lbs

Mixtures of powder for the larger firearms, commonly called muskets [Mixturae pulveris ad sclopeta majora, vulgò Musquetas]

	First Method	Second Method
Saltpeter	100 lbs	100 lbs
Sulphur	18 lbs	15 lbs
Charcoal	20 lbs	18 lbs

Mixtures of powder for the smaller firearms, commonly called pistols, and the like
[Mixturae pulveris ad sclopeta minora, vulgò Pistolas, & alia]

	First Method	Second Method
Saltpeter	100 lbs	100 lbs
Sulphur	12 lbs	10 lbs
Charcoal	15 lbs	8 lbs

The mixtures of powder for the larger cannon and firearms can, during the cooking, be moistened and sprinkled either with plain water alone, or with vinegar, or with urine, or with wine. But if for the smaller firearms we desire a stronger and more vigorous powder, let the two upper mixtures be sprinkled rather often with the following liquid — or with water distilled by chemical apparatus from the rinds of oranges and citrons, or of fresh lemons — and let them be cooked for 24 hours, and finally reduced into the finest grains.

[Margin: The composition of the liquid.]

The liquid is composed of: 20 measures of burnt wine [i.e. brandy]; 12 measures of spirit of vinegar distilled from white wine; 4 measures of spirit of niter; 2 measures of simple water from sal ammoniac; one measure of camphor — subdued [dissolved] in burnt wine, or pulverized with ground sulphur, or finally rendered into an oil with oil of sweet almonds. The figure of the rotary mill for forming gunpowder, among the machines and various instruments customarily kept in arsenals, we shall give in the Last Book.

[Margin: Why granulated powder is more powerful than that reduced to fine flour.]

It is a marvel in gunpowder that, granulated, it has more power and effect than when reduced to fine dust — the reason for which we gave above. For granulated powder contains more action and spirits than when reduced to fine dust, in which the dissipated spirits fly off; as indeed experience teaches in war-cannon: if, by the rammer of the cannon, it is so compressed and packed down that it loses its grains and is pulverized, the powder likewise loses the force of ejecting the ball that it would have had if it had been moderately compressed, so that it scarcely ever drives the ball out of the cannon's mouth. The same thing happens to it that happens to moistened powder, which, stripped of all its expelling power, burns up very feebly when ignited with fire; and if it has been stored in a war-machine, with fire put in through the touch-hole, it does not expel the ball, but

bursting out through the open opening of that touch-hole it does not cease to burn until the whole is consumed.

This is true in metals as well: for the more solid they are, the harder they catch fire, whereas we see that spongy or less solid ones grow hot very quickly, because they are rare and porous, and through the pores, which are full of air, they readily admit fire into their interior. The same holds in gunpowder, which, besides the reasons mentioned above, has these joined to them: that if it is condensed in such a way that the fire's rays, slipping in through the touch-hole of the war-machine, cannot penetrate its compacted body — because no empty spaces through which they might be carried have been left between the grains of powder — they certainly cannot ignite in a moment the whole powder (in which all its other force resides), and so the fire consumes the powder only by parts, since it has found material most apt for this, and is not extinguished so long as that material lasts, or is violently smothered.

Something similar to this also happens in powder which, scattered variously and not collected into one body, is ignited: there the essential force of the powder — or rather of the fire in the powder — is not indeed diluted; but the action, on account of the suffocation and packing-together of its parts, cannot obtain its effect. The practice of pyrotechnics is proof of this truth, and the reason adduced above will to some degree serve the question of why granulated powder is stronger than its flour; since in a grain of saltpeter its enclosed spirits, and the virtue united together with the sulphur and charcoal, seem more concentrated, but in the flour of compacted powder they do not. To this must also be added that if a war-cannon of a longer barrel be filled — I do not say with powder reduced to flour, but even granulated — right up to the mouth, and fire be put into the powder not through the touch-hole but through the mouth of the cannon, it will do no harm whatever to the cannon, since it acts upon the powder by parts and, being unable to ignite the whole powder in a moment, operates as it were from the upper to the lower portions, which is most discordant with its nature; or, what is more proper, it is bound by no prisons and tied by no fetters of a narrow place, nor does it have any obstacles which it must remove and break in seeking liberty, but has an open exit at the mouth of the machine.

[Margin: Experiment of granulated powder and of flour.]

[Margin: Experiment of granulated powder.]

[Margin: That gunpowder of larger grains can be more powerful than that of smaller grains.]

We think this too is not to be passed over in silence: that it is the opinion of the less experienced that gunpowder which has larger grains is more potent and vigorous, which indeed at first glance seems plausible, for the reason adduced by us above — namely, that in one larger grain more saltpeter adheres to the charcoal and sulphur. And on the other side it is false; because larger grains are resolved into fire more slowly than smaller ones, and pyrotechnical practice teaches that powder reduced into the finest grains is much more vigorous and stronger — both because smaller grains are more easily consumed, and because there (which is the crux of the matter) a greater quantity of saltpeter is mixed with the charcoal and sulphur, since powder of this sort is usually prepared only for smaller firearms and hand-held guns, whereas for the larger war-cannon it is made far slacker and less carefully worked. And since the larger cannon take a greater quantity of powder than hand-held guns, that cannon-powder also requires larger grains, so that the rays of fire may glide all the more quickly through the larger empty spaces between the larger grains of powder, and resolve all the powder into flame in one instant.

Experiments on the goodness of saltpeter [Experimenta bonitatis Salisnitri]

Let some saltpeter be placed upon a clean and polished wooden table, and let it be kindled with a burning coal, and let the following be noted.

First. If it makes a noise such as we see in common salt when it is thrown upon glowing embers, it will be a sign that it abounds greatly in salt of this kind.

[Margin: If it makes a noise on the embers, it abounds in salt.]

Second. If it makes a fat and dense foam, a sign of fatness will be obtained.

[Margin: It is reckoned fatty if it makes foam.]

If, after the burning-off of all the salt, certain unclean dregs remain, it is an infallible mark that salt of this kind contains much earthy material; and the greater the quantity of those dregs, the greater also the quantity of that material in the salt, and accordingly it will be judged much less well-purged and much less potent.

[Margin: Earthy, if it leaves dregs behind.]

But if it makes a clear, long flame, parted into many rays, while the bottom of the table remains clean, and it burns in the manner of pure charcoal without any

foam and without a horrid or unsuitable crackling, one may take it as a conjecture that the salt of niter is well purged and perfect.

Some hold that it is an infallible trace of the goodness of saltpeter if, after the second clarification performed in the customary way, no more than four pounds are wanting per hundred pounds; but if it should be clarified a second time over again, four pounds, as before, will likewise have to be lacking.

From these things it is evident that powder is the better the greater the diligence with which it has been purged, and that it has the greater force the purer the niter with which it is furnished. Hence commanders of sieges [πυροβολίας — Greek: pyrobolías, "the firing of artillery"], with 50 pounds of better powder, drive the balls of a single cannon or mortar much farther than with 50 pounds of weaker powder. As to the precise distance to which the several differences of powder hurl their balls, see the skilled masters of poliorcetics [the art of siege] and the artillerists [pyroboliftae], who exhibit differences of this sort set out in tables.

EXPERIMENTS on silent powder [EXPERIMENTA De pulvere muto]

Since that noise of cannon arises only from the spirituous substance of saltpeter, let us disclose how powder may be made without noise; and although many have written much about this powder, we shall here set down only a few of the most approved mixtures, gathered from various trustworthy authors.

First Method [Modus primus]. Of common gunpowder, 2 pounds; of Venetian borax [Boracis Venetae], one pound — ground and well incorporated, let the whole material be granulated.

Second Method [Modus secundus]. Of common powder, 6 pounds; of Venetian borax, one pound; of calamine stone [lapis calaminaris], 3 pounds; of sal ammoniac, 3 pounds — let granulated powder be made, as above.

Third Method [Modus tertius]. Of common powder, 6 pounds; of powder from a live mole calcined in a glazed earthenware pot [pulvis ex talpa viva], 3 pounds; of Venetian borax, 3 pounds.

Fourth Method [Modus quartus]. Of saltpeter, 6 pounds; of sulphur, 1½ pounds; of powder from the inner bark of elder [cortex secundus sambuci], 3 pounds; of burnt common salt, 2 pounds — let granulated powder be made in the customary way.

It must be noted, however, in this place, that powder of this sort does not have so great a force in discharging balls as nitrous powder. The reason is that the principal cause of its violence is lacking — namely the spirit present in the niter, which, unable to be contained within the narrowness of the place, so as to obtain an exit, pursues (with all obstacles driven off) that efficacy which we marvel at, with liberty. And so, in powder deprived of niter, the war-cannon is so feeble in its explosion that it scarcely hurls the ball resisting it out to a few paces.

EXPERIMENTS on imbuing gunpowder with various colors [EXPERIMENTA De pulvere pyrio variis coloribus imbuendo]

All the blackness of common gunpowder results from the black color of the charcoal. It is possible, however, to tint it with another color too, if in place of the charcoal one uses either rotten wood, or white paper first moistened and afterward dried in a hot oven and ground into powder, or some other similar thing that readily catches fire and...

and combustible, as will become clear in what follows. Let the powder be made, and let various colors be added. In this chapter, therefore, I shall set out several mixtures, wonderfully suited to imbuing powders with various colors.

WHITE POWDER

made as follows.

EXPERIMENT I.

Take 6 pounds of saltpeter, 1 pound of sulphur, 1 pound of dried elder-pith [medulla sambuci].

EXPERIMENT II.

Take 10 pounds of saltpeter, 1 pound of sulphur, 1 pound of bark or of the woody part of crushed hemp [canabis]. Proceed as prescribed above, and you will have what you seek.

EXPERIMENT III.

Take 6 pounds of saltpeter, 1 pound of sulphur, 2 ounces [℥ ij] of tartar calcined to whiteness and then boiled in common water in an unglazed pot until all the water has evaporated.

The reason for all of these is that saltpeter and the charcoal [carbones] dissolved into a white ash cannot be blackened by a single pound of sulphur, and so the powder appears to whiten.

RUDDY POWDER [PULVIS RUBICUNDUS]

EXPERIMENT I.

Take 6 pounds of saltpeter, 1 pound of sulphur, 2 pounds of amber [ambra], 1 pound of red sandalwood [sandalum rubrum].

EXPERIMENT II.

Take 8 pounds of saltpeter, 1 pound of sulphur, dried paper [papyrus] ground to powder and boiled in water of cinnabar or of brazilwood [lignum Brasilianum], and again dried, 1 pound.

The reason is that saltpeter, when imbued with things of a red color together with burnt sulphur, is easily tinged, and so both the powder and the smoke take on a ruddy hue.

YELLOW POWDER [PULVIS LUTEUS]

EXPERIMENT.

Take 8 pounds of saltpeter, 1 pound of sulphur, one pound of wild saffron [crocus sylvestris] first boiled in burnt wine [vinum adustum, i.e. distilled spirit], then thoroughly dried and pulverized. The reason is the same as above.

GREEN POWDER [PULVIS VIRIDIS]

EXPERIMENT.

Take 10 pounds of saltpeter, 1 pound of sulphur, rotten wood [lignum putridum] boiled with verdigris [aerugo aeris] and aqua vitae, then dried, 2 pounds.

BLUE POWDER [PULVIS CAERULEUS]

EXPERIMENT.

Take 8 pounds of saltpeter, 1 pound of sulphur, sawdust of lindenwood [scobis ex ligno tiliae] boiled with indigo [indacum] and burnt wine, then dried and pulverized, 1 pound. Proceed as above, and you will have what you seek.

SECTIO III

DE ALUMINE — ON ALUM

The Third Species of Salt

CAPUT I

On the Name, Definition, and Variety of Alum

After the species of common salt and of niter, we now proceed to the third species of salt: alum. It seems to have taken its name from the Greek word ἄλς [Greek: hál's, "salt"], because in taste and color it resembles salt, and is in fact nothing other than a brine [salfugo] coalesced from water, stones, and aluminous mud, which afterward, ripened by exposure to the sun, and at last by various boilings and dilutions, is condensed into alum. And just as common salt stands in relation to niter, so does alum stand in relation to vitriol — both being for the most part generated from pyrite [pyrites]. [Margin: As common salt is to niter, so alum is to vitriol.] There is scarcely a province in which alum does not either bloom forth of its own accord or get dug out of the ground.

Its species are numerous, but among the mineralogists there is great dispute and controversy over them. For my part, following Brasavola [Antonio Musa Brasavola] and other experts in mineral matters, I reduce all the species of alum to five headings. Thus one is rock alum [alumen rupeum], commonly called *alume di rocca*; another is what they call sugar-alum [alumen Zuccarium], from its conical shape, like sugar molded into cones; another is feather alum [alumen Plumae]; and another is *Scajola* alum. To these some add a fifth species, which they call dish-alum [alumen Catinum]; others divide them into still other species, which nonetheless differ not so much in substance as merely in name. For what they call *Schiston* [Greek: σχιστόν, "split, cleavable"], we call *Scajola* alum; what they call *Trichitis* [Greek: τριχίτις, "hair-like"], we call feather alum; and what, finally, they call *Strongylen* [Greek: στρογγύλην, "rounded"], we call rock alum. But lest we waste time in expounding the names, let us pass on to the matter itself and to the specific differences of each.

to be unraveled, let us now turn our attention. Most of those who suppose that rock alum is the same as what is called liquid alum [alumen liquidum] are deluded. For what they mean by "liquid" can scarcely be conceived in the mind, unless perhaps they understand alum diluted and dissolved in water — though

that is in fact said to be free, since no alum exists unless it has first been purified by water. Of the method of proceeding we shall speak later.

Authors also contend not a little with one another in settling the difference between dish-alum [alumen Catini] and alkali [alchali]. We assert that these are one and the same thing, differing only in name. For we say that alkali is nothing other than that juice which they press out of the plant the Arabs call *Hali* — so called because, when it has been put into the dish [Catinum], it trickles within it and then is thickened into alum, and so is called dish-alum; and this is very closely akin to glass.

A greater difficulty lies in determining the difference between feather alum [alumen Plumae] and amiant [amiantus], the stone they call asbestos [asbestos]. [Margin: The difference between feather alum and amiant.] Certainly these cannot be said to be one and the same thing, though it is well established that, from the great similarity of the one to the other, several authors have taken them for a single thing. For if we rightly weigh the qualities of each, we shall find a great difference between them: since feather alum catches fire and, when thrown into the fire, is easily consumed, while in water it dissolves — which by no means happens in incombustible amiant, that is, asbestos, from which it even got its name. But since we are to speak at length of asbestos and its marvels in its proper place, we have not wished to be lengthier here.

Nor do we say that *Scajola* alum is the same as *Astrofamium* or talc, as many inexperienced in these matters suppose. For burnt *Scajola* alum passes into a gypseous lime, of which only the most translucent part is genuine — which cannot be said of talc; for how difficult it is to reduce talc into lime, only those know who have hitherto sought its oil with such labors and expenses, equipped with both oil and effort. Moreover, experience teaches that *Scajola* alum, translucent with a glassy clarity, was born from gypsum; for when it is thrown into the fire or set upon glowing plates, the appearance of its former clarity is at once destroyed, and it whitens after the manner of gypsum and takes on the genuine look of it — which does not happen with talc unless it is roasted for a long time in the most intense furnace-fire. But leaving aside species of alum of this kind, let us proceed to expound that alum which is everywhere in great use among all.

CAPUT II

On the Nature, Quality, and Preparation of Alum

If all the kinds of alum are rightly weighed, no one but a person inexperienced in these matters could deny that every kind of alum gives off a dull heat — like calcanthum [calcanthum, copperas], chalcitis, and misy [misy], which, although strongly astringent, do not so much cool as warm in the highest degree. Their corrosive power, which consumes even iron itself, demonstrates this more than sufficiently — a power that they certainly do not derive from the primary qualities, but from a specific virtue implanted in them, as will be plainly shown in due course, when we treat of the strong waters [aquae fortes].

All the species of alum, therefore, by their nature warm, cleanse, and bind. Hence not inappropriately the Greeks call alum *στυπτηρία* [Greek: *styptēria*, "alum, astringent"], from *στυφω* [Greek: *stýphō*, "to be astringent, to contract"], which means to bind. But as to the view of some that all astringents are cold, they wander, as the saying goes, the whole sky away from the truth. For most astringents, being compacted by the force of heat, thereby possess the greatest burning power — as was said of calcanthum, gypsum, and the rest.

[Margin: The difference of alum from salt.] They are distinguished from the other salts by a proper and specific virtue, which alum drew from sulphur, the saline clod of earth being mingled with it. And so, according to the nature of the place, by the various combinations of the mixture of salts, in one place common salt is produced, in another niter and saltpeter from the urine of animals, and in another, finally, alum is produced — whether from dung and earths, or from stones such as pyrite, packed with sulphureous corpuscles — and they hold their virtue contained in their inmost center. From this arise the marvelous operations in chemistry, which we shall unfold in due course.

Now let us proceed to the method of extracting it from the rocks, of macerating, boiling, and congealing it. [Margin: The process of drawing out alum from calcined rocks, according to the author's own observation at Tolfa.] Certainly, when in the year 1639 I was staying at Tolfa — where, in the opinion of many, the best alum in all Europe is dug out, which they call rock alum, commonly *aluae di rocca* [recte: *alume di rocca*] — I held nothing more important than to observe, with all the diligence that can and ought to be applied, the whole sequence of the matter in its preparation there, and, having observed it, to make it public here, as in its proper place, for the common good.

The territory of Tolfa lies at a distance of ten miles from the port of Civitavecchia [Centumcellae], on the Tyrrhenian Sea, full of rocky mountains. The rocks of the mountains are seen now white, now somewhat reddish, and now bending from yellow into a sky-blue color.

[Margin: The origin of the Tolfa alum-works.] In the time of Pius II this was discovered by the following event. A nobleman of Tolfa, having bought a slave well trained over a long time in Asia in the making of alum, — one day, when this slave was examining the quality of the rocks more closely and recognized that they were full of the juice of the most excellent alum, not being unaware of how great a profit could be drawn from this, is said to have addressed his master thus: "If you will grant me my freedom, my lord, I will show you the means by which you may make yourself happy with such an abundance of riches that you may [recover?] your whole treasure." Astonished at this, when the master asked what he meant by these words, the slave replied that he had discovered an exceedingly rich vein of alum, and that this was the treasure he had promised, by which, as long as he lived, his master would be made blessed.

The master, spurred on with great eagerness, earnestly charged him to make some trial of the thing promised — which the slave did. For drawing the most noble alum from a few stones according to the rules of his art, and thereby stirred in a wonderful way to undertake something greater, he was the first of all to found alum-works, with such profit indeed that all Europe enjoys it to this very day. Today it is leased out by the Apostolic Chamber at a revenue of sixty thousand scudi.

Having premised these things, we shall now describe in detailed account the method by which this alum is prepared — a method I observed with my own eyes and with the utmost diligence.

This celebrated rock alum, commonly *alume di rocca*, is made from a certain very hard rock, of which the cliff-like mountains of this Tolfa territory are composed. [Margin: The manner of preparing the alum in the Tolfa territory.] They are of two kinds: one harder and tending toward redness; the other softer and inclining to whiteness. The latter, when duly prepared, gleams translucent like crystal; the former, though more sordid, has nonetheless a greater sharpness. The white kind is held in great esteem among the dyers of silken threads and of the finer wools and fleeces to be tinged with scarlet [coccineus] color, inasmuch as it is endowed with a milder sharpness and renders the fleeces more brilliant. Having premised these things, they proceed to the work as follows.

First. The alum quarrymen [*aluminarii rupicidae*], not in vaulted tunnels but on the rocky flanks of the mountain, open to the sky on every side, with a vast multitude of diggers continually staying there, partly with pointed mattocks tempered from the strongest steel, partly with very sharp wedges and huge mallets, split the stony wall, break the split rock, and crush it into small pieces — in exactly the manner in which they are accustomed to proceed in the quarries of stones and marbles from which great buildings are constructed. The broken and reduced rocks are carried into furnaces not unlike lime-kilns, where they are burned with the strongest fire for a space of 12 or at most 14 hours; for if they were burned longer, they would incur no small danger from the loss of the alum, which would vanish under the more prolonged fire.

Second. After the rocks have cooled, they bring the cooked material in carts onto very broad floors, and, exposing it to the sun, arrange it in conical heaps.

Third. These arranged heaps they drench with cold water four times each day, by means of buckets suitably fitted for this purpose, until the thoroughly burnt material of the stones is so softened by the long affusion of water that it is reduced into a kind of earth, damp with moisture, not unlike potter's clay [*argilla*]. ...until it is changed into something not unlike it; which first happens only when, over the space of a month and more, it has been irrigated by the repeated daily affusion of water.

Fourth. This material, now reduced to lime, they convey to huge cauldrons, into which, set within a furnace, they lead water through channels; and, having kindled the furnace-fire, they let it boil. When they find this to be so, they cast the aluminous material — now reduced to lime — into the cauldrons of boiling water. On either side stand two very robust youths, who with wooden implements not unlike oars continually mix the material thrown in with the boiling water, until the alum-material has imbibed and incorporated into itself all the water. But when they find by taste that all the water is now imbued with alum, then they let it rest, until the earthy sediment settles to the bottom.

Fifth. This done, the warm water now imbued with alum is drawn off, extracted through channels prepared for this purpose, into certain pitchers, or into certain receptacles made of oak or holm-oak wood (for vessels made of other woods are not so suitable). When in these, in the course of several days, the conveyed water has settled, the alum adheres to the oaken sides of the vessels, and, four or five fingers thick, with adamantine points and the utmost variety of polygonal figures, translucent like crystal, presents a most delightful spectacle to the beholders. The remainder of the lye [*lixivium*], being now purged of its earthy dregs, is again

poured into the cauldrons for a fresh cooking of alum, the sediment and dreggy water remaining at the bottom being let off through a tap.

Sixth. The bottom of the receptacle having been duly cleaned with brooms, they tear away with certain iron implements the alum that has accreted to the sides of the vessels; and the torn-off alum they throw into wicker baskets and wash in a nearby channel of water, the baskets being plunged into the water. The washed alum they take out, heap up, and place in a storehouse; and then, transported to Civitavecchia, they sell it to the merchants. And this is the method of preparing rock alum, which, because I saw it with my own eyes, I have thought fit to set down here as the genuine practice.

[Margin: The marvels that can occur in the condensation of alum.] Here too I observed a thing worthy of admiration: that that oaken wood possesses this virtue, that — since it is itself filled with a nitrous juice — by a kind of magnetism, as it were, it draws to itself the aluminous material akin to it. Hence, if anyone fashions out of such wood any figure or character whatever — such as crosses, stars, the name JESUS and MARY, and the like — and leaves it in such lye until the appointed day, he will find, in place of the wooden figure, a most beautiful crystalline one, distinguished by a marvelous variety of angles. And this is the method of making rock alum in the Tolfa territory — a method the most beautiful and most expeditious of all, as the excellence of the alum made there abundantly demonstrates.

I am aware that several other authors hand down many other methods of making it, and that the rationale for it is neither simple nor of a single kind. For some extract condensed alum from boiled-down aluminous water, as we taught above concerning salt and niter. Others extract it from an aluminous solution drawn from earth or rock of this kind, or from pyrite, or from some other mixed substance. Agricola [Georgius Agricola], in Book 12 of *De Re Metallica*, prescribes a somewhat more laborious method, which let the reader consult.

[Margin: How alum is extracted from pyrite.] Moreover, they extract alum from pyrite in this way. First, they expose pieces of the pyrite in an open place to the air for several months, so that they soften; then, thrown into vats, they are dissolved; and the dissolved material, poured out into rectangular leaden cauldrons, is boiled until it is condensed into alum. As for the method by which the gold, silver, and the other metals that aluminous pyrite generally holds joined to itself are separated, it will be disclosed in its proper place.

CAPUT III

On the Medicinal Powers and Other Uses of Alum

Since alum excels the rest by its notable power of binding, cleansing, drying, heating, and hardening, it can easily be gathered from this that its use is most opportune in the curing of infirmities. Hence, according to the traditions of Galen, Hippocrates, Brasavola, and other physicians:

- It removes roughness of the eyes.
- It checks itching of the body.
- It stops a complete flow of blood, applied externally.
- It stanches fluxes of blood, mixed with fat and applied.
- It restrains the putrefaction of wounds.
- It heals the eruptions of the dropsical.
- It corrects ailments of the ears, with the juice of boiled pomegranate.
- It cures phagedaenic ulcers [phagadaenae], with vinegar, or with an equal weight of burnt gall-nut.
- It draws off leprous humor, with the juice of pot-herbs.
- It removes impetigo, lichens [lerides, i.e. lichenes], and scurf.
- For burns, it helps, with whey and pitch.
- For the dysenteric, a clyster mixed with alum is beneficial.
- It restores a fallen uvula and tonsil.
- It wears away those things that overspread the clarity of the eyes.
- It eats away an excrescence of flesh.

Furthermore, it offers great use to dyers and fullers, who, for dyeing cloths and silks, cannot do without alum. Goldsmiths cleanse gold with it, and lay on its gilding-leaf [bracteae]. Tanners [coriarii] dye hides with it. Booksellers and printers, by first dipping their papers in waters in which alum has been dissolved, render them so firm and strong that they do not allow the ink to run at all.

[Margin: Water mixed with vitriol and alum tinges iron with the color of copper.] Aluminous water mixed with vitriolous water, says Agricola, gives to iron and to the other white metals the color of copper, and to copper and gold a splendid golden color. Witnesses to this experiment are the hot waters in Bohemia, at the castle named "New House," *Neuhaus*. For the silver rings of those who use that bath, through the frequent use of the vitriolous-aluminous water, in time are

eaten away piece by piece in an open spot; then they are exposed to the air for some months, so that they soften; then, cast into casks, they are dissolved; and the dissolved material, poured out into rectangular leaden cauldrons, the material is boiled until it is condensed into alum.

They take on the color of copper, while gold ones become even more illustrious and brilliant; and they also have the greatest power in hardening iron, as will be said in its proper place. But as to the method by which gold, silver, and the rest may be separated from aluminous pyrite, it will be opened up in its proper place.

Curious Experiments Discovered by Means of Alum

EXPERIMENT I.

To adorn a whole altar with crystalline furnishings.

[Margin: Experiment I.] **First.** From aluminous stones, first macerated by exposure to the sun and frequent sprinkling, as was said above, and reduced to lime, let them be boiled in a cauldron with continual agitation applied. Then let the cooked material be poured into vessels or receptacles made of oaken wood, and you will have a prepared lye [lixivium], by which you may reduce things of every kind into a crystalline substance, in this way.

First, let there be made of oaken wood a cross and candelabra, turned on a lathe from oaken or holm-oak wood, which, hung on an iron wire and submerged within the lye, you allow to stand for several days. As the water fails, in place of the wooden cross or candelabra you will find a crystalline cross and candelabra, clothed in a marvelous variety of polygons after the manner of diamonds, with no trace of the wood appearing.

Images are made by this art: let there be made of oaken wood a mold of any image whatever, closed with its own lid, in such a way that the lye may obtain access to the inner cavity through a small hole — in exactly the same manner as is usually done in the molds of fusible metals. And the aluminous lye, let into the cavity of the mold, will there fill up all the recesses of the image, condensed into alum; for which reason that copy afterward, being constrained by the narrowness of the place, cannot extend itself elsewhere than to the cavity. When the form of the mold is opened, you will find it wholly crystalline, as if carved with a chisel.

In this way the alum-workers of Tolfa are accustomed to adorn their altars, as I remember having seen with great delight of my mind. How much virtue alum

has, moreover, for inscribing letters by the art of steganography, the following experiment will teach.

[Margin: Experiment 2.]

EXPERIMENT II

Take alum purified of all dregs, grind it to a powder, place it on a small dish, and pour spring water over it. Stir the mixture until it takes on some body. This done, take a fresh pen and on white paper write whatever you wish to keep hidden; let it set until what you have written has dried. Then send the white paper to a correspondent friend, who, being already instructed in the technique, will submerge the letter in a basin full of water. After it has remained there a little while, the white writing will gradually reveal itself upon the white surface and offer itself to the friend to be read — to the astonishment of all the bystanders, who cannot tell how letters that had not appeared before are now made plainly visible.

[Margin: Experiment 3.]

EXPERIMENT III

But if you wish the letters to appear black, proceed as follows. Take vitriol, mix it with spring water to make a solution, and with this write upon paper whatever you please. None of the lettering will be visible. But when you want it to become visible, take powdered gallnut and mix it into a separate basin of water; then take the paper on which you wrote the letters and draw it gently through that water. In an instant the letters that had not appeared before will become plainly visible in the blackest color. And if you intend to display white letters on black paper, proceed thus.

[Margin: Experiment 4.]

EXPERIMENT IV

Take spring water, add to it the yolk of an egg, and blend it well, tempering it to the consistency of ink. With this liquid write whatever you wish on white paper and let it dry. This done, coat the white paper with ink and let it dry. Now, when you want the letters to appear, scrape away the earthy part of the ink, and at once white letters written upon the black will beautifully appear, not without the wonder of those who look on.

I could give countless examples of this kind here, but since I have reserved them for other places, I have judged it superfluous to describe them at greater length.

We said above that there is a great kinship between alum and vitriol, inasmuch as both have the same parent, namely pyrites. For if a hard silver-colored vein of pyrites is set in a sunny spot, crushed and left to macerate, before long you will see both vitriol and alum effloresce — with this difference, however, that the vitriol tastes of a more earthy substance, and the alum of less.

From all of this the nature of both alum and vitriol is easily gathered. And although vitriol is most commonly called shoemaker's blacking [atramentum sutorium], it must not on that account be concluded that vitriol by its own nature stains waters with a black color — by no means, since we always find vitriolic waters perfectly clear, and both alum and vitriol mixed into clear water never stain it. Yet prepared vitriol does have a certain hidden power by which, when combined with the juice of the oak gallnut, it tinges waters black in an instant. This you may verify by experiment: if you drop even a few drops of it into water in which gallnut has been boiled, they will at once blacken the water as if ink had been poured in. We will set forth the reason for this in what follows.

[Margin: On aluminous waters see what we have pursued in our own Etruria [Tuscany], and in the Fifth Book of this Work.]

Having thus examined and discussed the nature and properties of alum, let us now in the same way unfold the nature of vitriol.

SECTIO IV

DE VITRIOLO

ON VITRIOL, AND ITS MARVELOUS PROPERTIES

CAPUT I

On the Definition, Division, and Origin of Vitriol

[Margin: What vitriol is.]

Vitriol is so called from the transparent substance of glass [vitrum], which it resembles. By most it is called shoemaker's blacking [atramentum sutorium], because it serves for dyeing hides and other things black, and is so named for that

reason. By the Greeks it is also called χαλκανθον [Greek: chalkanthon, "copper-flower," i.e. vitriol], which is the same as "flower of copper" [flos aeris]; by the Arabs الكند [Arabic: al-kand, "vitriol"]; by the Spaniards *Caparosa* [copperas]. As nothing is better known than it, so nothing is more unknown, on account of its hidden powers.

[Margin: Varied opinions on its composition.]

As to the essence and composition of vitriol, I find varied opinions among the natural philosophers and chemists. Some of them assert that vitriol is a material composed chiefly of alum and sulphur. Others think it [continues on printed p. 317]

[continued from printed p. 316] is a peculiar salt, to be reckoned among the class of salts. We append our own opinion, established by various experiments.

We say, therefore, that vitriol is not materially and actually composed of alum and sulphur — especially since vitriol, when it is burned and calcined, leaves no trace or sign by which it could be referred to either of the two. For this stands as an infallible argument: that all bodies in which a material portion of sulphur is present cannot endure even the slightest touch of fire without — I will say at once — the substance of the sulphurous portion being separated from the rest, and passing off into soot or being kindled, and going up in flame after the manner of burning sulphur. So hard is it for such a body to conceal the brilliance of its nature, as is plainly evident in antimony, orpiment, marcasite, and other not dissimilar metallic bodies. Since these have some sulphur mixed in, however much more compact and solid they are than vitriol, yet once committed to fire they immediately betray their nature by their color, flame, and sulphurous odor — which never happens with vitriol.

Add to this that alum and sulphur, of which they claim vitriol is composed, both because of the wateriness of the one and because of the oiliness of the other, wage between themselves unsociable enmities, disagreements, and quarrels, so that, just like oil and water, they cannot remain joined and mixed together for long. From this it is plainly concluded that the material composition of vitriol from sulphur and alum cannot hold. Something else, then, lies hidden in the inmost chamber of vitriol, which constitutes its true, physical, and essential composition. The matter stands thus:

[Margin: The author's opinion.]

Experience perceived by the senses teaches us, and it is held for certain by all the more skilled masters of chemistry, that all mineral or subterranean bodies possess a certain sharpness, which they have had from nothing other than the acid spirit of sulphur — this being the single basis and absolute origin of all mineral acidities. And accordingly, all bodies that have the consistency of vitriol or of alum, being watery and such as are liquefied by fire, must be reckoned to have acquired their fluidity and brilliance from nowhere else than from one and the same common water. But the fact that they differ in some way and diverge from one another, whether in form, in taste, or in any other manner whatever — that, I say, must be ascribed to a third something, as we shall demonstrate clearly a little later.

[Margin: How vitriol is composed.]

Vitriol too, although it is numbered among the class of salts and concreted juices, must by no means be considered a pure and unalloyed salt, since it differs in species from salt, niter, and alum in its virtues and properties. From where, then, and from what these specific differences of salts depend, I shall now attempt to disclose.

[Margin: How it arises in the earth.]

First it must be supposed, from what we taught in the Fourth and Fifth Books, that fire lies hidden in the innermost bowels of the Earth — not eminential fire, nor that which arises from antiperistasis, but natural fire, as we have said, in quality and faculty entirely such as is the elemental fire in any other place above the earth. And just as our ordinary fire necessarily requires a subject upon which to act — such as oil, resinous materials, wood, charcoal — so too the immense Wisdom of God [D. I. = Dei Immensa], in the vessels, wombs, and receptacles of the earth in which minerals must be generated, cooked, and converted into metallic substance for the use of the human race, each according to its own species, has produced the various substances of mineral clods and earthy portions. To all and each of these it joined something fatty and oily, apt for catching fire, which we say is nothing other than sulphur.

This sulphur, therefore, once it is kindled in the said hollows of the earth by the subterranean fire through fire-bearing channels [cuniculi pyragogi], at the same time also emits from its own body a certain acid vapor, sharp and endowed with caustic power. While this vapor by its subtlety penetrates the inner fibers of the mountains, there it also imbues and tinges the subterranean waters — with which we showed, in the First Volume, the terrestrial globe to be full — with its

caustic power and sharpness, so that it becomes a true menstruum [solvent] for dissolving the aforesaid clods, of whatever kind they may finally be. With these things set forth, we now describe the constitution of vitriol as follows.

[Margin: Definition of vitriol.]

Vitriol is a mineral body composed in the deepest bowels of the earth from sulphurous spirit, water, and the ore of copper or iron, or of both mixed together. From the sulphurous spirit it has its sharpness and caustic faculty; its clarity and fluidity from the water; and its metallic color and taste from the ore of copper or iron. And from these three — the spirit of sulphur, water, and the ore of copper and iron — we know by experience that vitriol is composed. For in a similar way, and after the pattern of nature, all those who sustain their lives devoted to this profession know how to compose artificial vitriol. But everything becomes clearer by an example.

[Margin: How vitriol is composed.]

Know therefore, Reader, that the acid spirit of sulphur, with which the subterranean water is tinged, is that menstruum or solvent which, when in passing through it pervades some place beneath which there lies an ore of copper or iron, then we must be firmly convinced that at the same time some portion of that copper or iron is scraped away and eaten — as much, indeed, as the acid spirit within it can dissolve in proportion to itself. This done, you will find that a little later a liquor comes forth, green or yellowish, of a metallic and sulphurous odor, and of a sharp or rather acid and astringent taste. From this liquor, filled with vitriolic corpuscles, that vitriol of which we have been speaking is separated and condensed. But perhaps doubts [continues on printed p. 318]

[continued from printed p. 317] that occur to someone will arise; let us resolve them through the questions [posed].

[Margin: Objection.]

First. Someone might perhaps ask: since the spirit of sulphur is the principal, chief, and most active substance of both alum and vitriol — for we said above that both are born from pyrites — from where, I ask, does it come about that these two differ so greatly in their form and color? Second: since the vapor proceeding from sulphur is the cause of all acidulous mineral waters, why are they found to be of so different a nature? Third: why is that acidity not found in all baths, whether hot or cold? Fourth: since water is the subject in which the

mixture of the other bodies occurs, why, I say, is vitriol found in waters not under a solid substance, as in ores, but in a liquid one?

[Margin: Solution.]

I reply, first: that this whole specific difference of virtues displayed in salts comes not from the sulphurous spirit and water alone, but from a third body — which we say is nothing other than certain mineral clods, which possess virtues differing in species from others. Just so, the common salt of the earth joined to them is, by an innate power, changed into that disposition which the mineral clod itself bears. Hence vitriol is not born in just any ore, but has its own peculiar and most proper ore of copper or iron, which lends it solidity. So too, in turn, alum does not love every earthy clod, but a certain kind of rock, in which the salty juice of alum is actualized. Therefore, just as iron or copper differs in species from the rock that is the mother of alum, so too the salt-brine is drawn out both from copper and iron, and from the said rock, by the agency of fire.

You see, then, the common salt and water of nature, diffused through all the pathways of the Geocosm: considered in themselves, they are, as it were, universal substrates, indifferent to receiving various forms. But as soon as the water has been impregnated with the sulphurous spirit diffused through the inner bowels of the earth, then this water, where it finds a salt-brine clod, joined according to the clod's property and virtue together with the salt placed in it, will produce common salt; if it enters nitrous veins, niter; if an aluminous rock, alum; if finally it enters an iron ore, green vitriol; if a copper ore, white vitriol; if finally a silver clod, it will turn out blue vitriol. And the more these take their origin from more perfect metallic substances, the more they will also be reckoned to be of greater virtue.

[Margin: Solution of the second question.]

I reply to the second question: that water made acid by the sulphurous spirit is the cause of all the waters they call acidulous; for this water, according to the nature of the channel and of the underlying clods through which it passes, will also produce diverse properties of the waters — all of which are very fully discussed in the Fifth Book.

Then, as to the third question: namely, why for the most part sweet waters burst out from the mountains into springs and rivers, yet leave no trace, by either odor or taste, of any salt of whatever kind that may lie hidden. I reply that the cause is this: that these waters mostly take their origin from the most ample subterranean water-reservoirs [hydrophylacia], and so it cannot come about that, even if they

are imbued in some way with the sulphurous spirit, the whole mass can be penetrated by it; and consequently they do not impress a perceptible trace upon the waters — just as we also said of salt.

[Margin: Chemical experiment: salt in all [waters].]

Yet if they are reduced to the Spagyric alembic, we will find at last that, if the water has passed through saline places, there is some salt in the bottom; if through nitrous or aluminous places, some niter or alum; if finally through coppery, cupreous-rusty [aeruginous], or ferruginous places, you will find the matter of vitriol. From the constitution of the subterranean places, therefore, it depends that the waters are now of greater, now of lesser sharpness, according to the nature of the various clods. Add to this a swifter flow of the water, by which that sulphurous spirit, variously scattered and combed apart within the rocky narrows of the channels, cannot conveniently impress its power upon the waters; and so too it clings here and there to the earthy clods of the banks — which does not happen in waters collected within the crypts of the mountains, settling without agitation, which are all most easily tinged by the sulphurous spirit.

[Margin: Mineral sympathy.]

And in these matters nature plays with a certain wondrous magnetism, while each thing is drawn by its like: copper and iron, by the nature innate in them, draw to themselves that with which their vein is already filled; vitriol, scattered through the waters by the minutest vitriolic corpuscles; while alum, rejecting the coppery or ferrous vein, seeks out what is like itself, with which the rocky stone swells. In this way the salt of the saline clod desires to be joined by nature to its bridesmaid clod. The water, therefore, charged with the acid spirit of sulphur, while it eats away somewhere within the channels of the earth an aeruginous clod it has found, at the same time also mixes with itself the vitriolic corpuscles hidden in the vein of copper or iron. These, then, wherever they find an ore proportionate and sympathetic to themselves, unite and connect the offspring deposited in it by a friendly marriage.

[Margin: Fourth question solved.]

But let us come to the fourth question. I say, then, that although the matter of vitriol is not always extracted from beneath the earth out of some liquid body or prepared lye [lixivium], but is also found in the earth under a solid mass after the manner of a mine or ore — yet by this very fact I say it is in no way prevented from being reduced to some mineral body by the agency of the sulphurous spirits adhering to it. For whether the said spirits are carried through the medium of

some water into some mine, in which the collected water produces a vitriolic lake or spring; or whether, having issued from their own body, the said spirits penetrate and enter in the form of vapor into some ore, within which they produce a [vitriolic] mass; or finally in some other [continues on printed p. 319]

[continued from printed p. 318] way whatever — this must always be held as established: that all kinds of vitriol are produced from those three things: the acid spirit of sulphur, water, and the ore of copper or iron. But lest anyone be able to doubt hereafter, let us establish what has been said by experiments.

EXPERIMENT I

In a brick crucible let a clod of iron or copper be set out, pour the spirit of sulphur over it, and within a short space of time you will find the whole water imbued with vitriol — in odor, taste, and color. Since the sulphurous spirit, poured over the clod of copper, will at once dissolve it by corroding it; and once it is dissolved, the liquor of the sulphurous spirit draws to itself what lies hidden within the clod — namely the vitriol, or the minutest vitriolic corpuscles — which afterward, cooked together, are once more condensed into vitriol. What we therefore accomplish by art, we learn from the manner in which nature operates.

EXPERIMENT II

Take salt-brine earth, and again nitrous earth, then aluminous, and finally aeruginous earth. Arrange these within a certain receptacle so that separate channels run to each — MA, MB, MC, MD.

Diagram. A schematic apparatus for separating mineral substances. At the center is a round vessel labeled **M**, divided internally into compartments (marked with small cross/star symbols). From this central vessel four sinuous channels (canales) radiate outward to four small footed cups arranged at the corners.

- M (center): the central vessel, filled with common water to which the spirit of sulphur is admixed
- A (upper left cup): receptacle for the saline earth — yields salt [via channel MA]
- B (lower left cup): receptacle for the nitrous earth — yields niter [via channel MB]
- C (lower right cup): receptacle for the aluminous earth — yields alum [via channel MC]

- D (upper right cup): receptacle for the aeruginous earth — yields vitriol [via channel MD]

Let the place M be filled with common water, to which you should admix the spirit of sulphur; it will at once turn acid, yet in such a way that it expresses neither salt, nor niter, nor alum, nor vitriol by odor and taste. If you then, the stopcocks [epistomia] being opened, let it flow into the receptacles prepared with the individual earthy clods, you will find that the saline earth A passes into salt; the nitrous into niter; the aluminous into alum; the aeruginous into vitriol — the substances being dissolved. From this it is plainly gathered that the common water, imbued with the spirit of sulphur, draws to itself the salt-brine of the dissolved bodies, and in the clod converts it into the natural disposition out of which it had extracted it.

CAPUT II

Whether Iron Can Truly and Really Be Converted into Copper [Aes] by Means of the Spirit of Vitriol

Not long ago there was sent to me from Hungary by the most learned Father Andreas Schaffer [Andreas Schaffer] a vitriolic water [aqua atramentosa] together with a horseshoe, the latter's iron having been converted into copper. This matter, just as it stirred no small wonder in the minds of those who beheld it, so too raised various questions and doubts about transmutation of this kind. And since I have already long been compelled by various overseers of mines and by chemists — whom I shall cite in what follows — to set down my opinion and judgment on this matter, I will publish it here as in a fitting place.

The question, then, is asked: whether iron is converted into copper by a true and real transmutation? The alchemists, who promise themselves mountains of gold from transmutation of this kind, favor this opinion wonderfully, yet using no other argument than that in Goslar and Hungary, and in other places, iron is everywhere asserted to be converted into copper.

[Margin: The error of the chemists.]

But in very truth, since some men, drawn on by a fixed opinion — especially in the chemical business, allured by great hope of riches — are so disposed that, with no traces of truth explored, they assert and most stubbornly defend a thing wholly contrary to the principles of natural philosophy, so that, while they hunt for the greatest and subtlest secret of all, they seem to slide into the deepest abyss of ignorance (which will become especially clear in the present controversy) —

therefore, lest we stray from our purpose through fuller windings of words, we will undertake to set forth the falsity of the conceived opinion, which men are more obstinate than the Marpesian rock [Marpesia] to cling to, and, once set forth, to dissolve it by various experiments.

[Margin: The difference between transmutation and separation of one thing into another.]

It must therefore be supposed, first, that there is a great difference between the transmutation of one thing into another, and the reduction of one thing to another, or the separation of one from another. Transmutation, or substantiation, occurs when there comes about a change of two substances of one thing into another — a change as to entire and perfect form, properties, and powers — as when iron is changed into copper, silver into gold, or like metals into like. And for this transmutation it is utterly necessary that the same substances of some thing be altered through and through and wholly changed, while they must take on for themselves another form and perfection which they did not have before. Nor — as those men wrongly assert — does it suffice that we are able by the force of fire to render some liquid thing fixed, or a fixed thing fluid, or white black, or black white, or to imbue them with other colors; for these are accidental, not substantial, transmutations, as

[continued from printed p. 320 — Liber VI, Sectio IV, Caput II]

only that man knows it who weighs the truth of things not by the furnace and its fires, but by the infallible balance of irrefutable reasoning. Therefore, when iron is said to be transmuted into copper, this must be understood not of a substantial transmutation, but of a certain accidental reduction — a separating-out of parts, the disjoining of one from another. [Margin: How the conversion of iron into copper comes about.]

Now a "reduction" is the process by which certain things are gathered back up and reunited into a single mass — things that had been dispersed and scattered into the tiniest particles, or diffused and mixed together with some other substance — so that, as if lost and destroyed, they are restored by reduction to their former condition. The following experiments demonstrate this abundantly.

Experiment I

[Margin: A remarkable experiment.]

Gold dissolved in *aqua regia* is reduced to a clear, transparent liquid of saffron color, with no trace of solidity or opacity remaining. If you throw a silver rod, or

any piece of silver, into this liquid, the liquid gold will at once — by some magnetism I cannot explain — seize hold of the silver mass, and the whole of it will bind itself together with the silver. But if you then separate this gold-silver union by chemical art (a method I will disclose in what follows), the gold, brought back to its original form, will be recovered exactly as it was before, under the purest form of gold, with nothing left behind but a clear, milky-white water. [Margin: *Vide lib. 6* [?], *Sect. 4* [?], *Cap. 9, vide nos* [?] p. 214 [?].] If you then add mercury to that same *aqua regia*, you will see — not without astonishment — the mercury draw the gold to itself; and once the liquid has been drawn off, the whole of the gold will appear in the bottom of the vessel, reduced to the form of a black powder. This powder, placed together with the mercury into a small retort and committed to the fire, restores its form in the receiver as the mercury flies off, while the gold remains in the said powder form. Finally, this, placed in a crucible and committed to the fire and melted, brings the gold back to its original form of dignity. This transmutation cannot be called true, because both the gold and the mercury can be reduced once more to their proper forms — which cannot happen in a true transmutation. And another mixing of metals, of copper and silver, shows the same thing.

Experiment II

On transmutation and reduction in silver and copper.

[Margin: Another experiment with silver and copper.]

When silver is dissolved in *aqua fortis*, if you throw in a small sheet or any other particle of copper, then within the space of a few hours the silver will be seen to settle to the bottom, with the copper joined around it in the manner of a sponge. If you then commit this copper-silver union to the fire and melt it, you will find both the copper and the silver separated out, each in its original form.

[continued at top of next column / printed p. 320, right column]

we also said that any water imbued with the acid spirit of sulphur eats away at the copper-bearing lump — or, what is the same thing, dissolves and separates the copper corpuscles by its corrosive action — and that, once dissolved, the now wholly imperceptible corpuscles are taken up into the water and to some degree mingled with it. These things granted: since a great magnetism passes between copper and iron, and since they possess a remarkable sympathy from the likeness of their origin, the moment the vitriolic corpuscles dispersed through the waters and mingled with them sense the introduced iron, then — as if to an inseparable companion, and as though destined by provident nature to a further end — they

at once flock to the iron; they surround the friendly, subjected iron and bind themselves to it in a most tenacious embrace. But because these vitriolic corpuscles possess the highest caustic power, it comes about that, penetrating the innermost pores of the iron, they convert the iron by their sharpness into manifest rust — that is, they dissolve the "glue" of the iron, the greasy part within it. [Margin: The sympathy of iron and copper.] Once this is dissolved, and the corpuscles united by sympathetic confluence, in place of the iron there comes about a heaping-together of the vitriolic corpuscles into a mass, which then, exposed to sun and air, with the iron-dross finally remaining behind, is condensed into the finest copper. This can by no means be called a transmutation, since all these things come about through a mere separation of different metals; and so each thing only restores itself in the other — that is, the copper-bearing lump restores the copper [?] gathered together out of innumerable corpuscles dispersed through the water, while the dross of the other substance, namely the iron, remains behind.

[Margin: The sympathy of iron and copper.]

It is therefore clear that vitriolic waters, having their origin from copper-bearing lumps, contain copper within themselves; and that iron put into them has no other use than to reduce and gather the inky corpuscles, by drawing off from them everything copper-like that lies hidden in them. This we establish by the following experiment.

Experiment IV

Let Hungarian copper-bearing vitriol, or vitriol of any other kind, be dissolved in water, and into the dissolved solution let a thin iron plate be lowered. When this is done, the iron will at once begin to draw to itself the dispersed copper corpuscles — indeed, all the copper that lies hidden in the vitriolated bodies. This copper, afterwards separated out by melting, is reduced to excellent copper. [Margin: Iron in copper, separated, not transmuted, properly speaking.] Indeed, if you immerse a bodkin or knife into the spirit of vitriol, it will at once, from drawing in the copper-bearing corpuscles lying hidden in the vitriol, take on a copper color. No transmutation, then, takes place here, but a pure separation of copper from iron — because the copper corpuscles substitute themselves in the place of the iron that has now been converted into dross, once the iron-dross is separated off. But if you test this same thing with iron-bearing vitriol — vitriol that has no copper in it — then that iron too will not lose its color, nor will it be found altered. And if it does draw anything to itself from that vitriol, it will be merely a certain yellow dust, nothing other than something rust-like.

Experiment V

On the reduction of iron into copper practiced in the Hungarian mines.

[Margin: How the spirit of green vitriol transmutes iron into copper.]

But how, in Hungary, iron is reduced into the most beautiful copper, I will add here as it was communicated to me by the above-praised Father Andreas Schaffer. In the Hungarian copper mines, in the deeper shafts of the pits, there is a certain stream drawn out from the vitriolated ores. By the agency of these waters they reduce iron into the most beautiful copper, in the manner that follows.

They gather together the cheapest iron implements of every kind, almost entirely consumed by rust — for the nearer the iron is to rust, the better the result obtained. [Margin: ...] These they once again work upon the anvil and hammer into thin plates. They place these plates on the bed of the stream and leave them there for nearly half a year. When this period has elapsed, they find the plates softened by the force of the inky water, like an amalgam; and when they have exposed these to air and sun, they are converted into the purest copper, ready for every use — while the iron-dross remains at the bottom of the stream. And in this way, with truly great profit, copper is prepared by art over and above what is dug from the ore. Furthermore, if anyone immerses a very thin iron plate in spirit of vitriol, he will find, in time, the iron-dross separated at the bottom of the vessel from the copper-bearing body. The reason for this is none other than — as we said above — that the vitriolated corpuscles dispersed through the water fall, by a sympathetic confluence, upon the iron plate, and once it is dissolved, substitute themselves in the place of the iron.

From all this it is plain that no substantial transmutation takes place here, since in copper-bearing vitriol no other metallic substance is found than copper itself. And when this copper has been separated from it, the vitriol loses its name, and nothing else remains but water and the acid spirit imbued in it — what is commonly called the *oil of vitriol* — and this has only as much power to transmute iron into copper as *aqua fortis* has to turn lead into gold. Hence Paracelsus [Paracelsus] the impostor is by no means to be heeded, who tries by every means to persuade the unskilled rabble of chemists that this is a true and real transmutation.

Caput III.

On the variety, powers, properties, and use of vitriol.

Among those concreted juices that are found in waters, vitriol — also called *chalcanthum* — exists together with the species connected with it, namely *sory*, *misy*, *chalcitis*, and *melanteria*. For the waters that abound in the juice of this or that species have nearly the same odor, taste, and the same nature, distinguished only in degree as more or less. Whether one looks to the authority of writers, or to the mines from which they are dug, or to the powers they possess, or to the degrees of kinship by which they are coupled — their genus being derived from pyrite, as we said above, as from the common stock of them all — you will find so great a similarity, affinity, and nearness of kinship that you may rightly call them one and the same thing, distinguished only by various accidents, since from one corrupted material another is generated. [Margin: How *misy*, *sory*, *chalcitis*, and *melanteria* are produced.] For from an astringent juice they produce not only alum but also vitriol — and indeed, out of this, *sory*, *misy*, *chalcitis*, and *melanteria*. *Misy* is the flower of vitriol, as *melanteria* is of *sory*; green vitriol grows out, in the form of a hair, from a pyrite of this kind by way of *melanteria*, and often a green growth shoots up in the shape of a hair, which it surrounds on every side. Alum is often white, vitriol rarely so, but most often green or blue is found; and of these things that are akin to it, *misy* shows the color of gold, *chalcitis* that of copper; *sory* is nearly black, as is *melanteria*, which however, when dried, usually takes on an ashen color. They differ, however, in that — besides vitriol, which is both native and artificial — all the rest are only native; yet in all of them there is an astringent power together with a sulphurous odor. Vitriol, being soft, resembles feathers; *melanteria* a kind of brine; *sory*, by the hardness of its very coarse parts, a stone, with a most pungent odor; *misy* is the finest; *chalcitis* holds the middle place. But since there is among the mineralogists a great dispute about the nature of these things, it is not to the point to pursue this at greater length. Therefore let us hasten on to set forth their powers and properties.

First: in the dyeing of wool, hides, silk, and other things, there is a great use of it among dyers and fullers.

Second: it has the greatest use in medicine, on which consult Galen [Galen], Brasavola [Antonio Musa Brasavola], Matthioli [Pietro Andrea Mattioli], and others. [Margin: The powers and properties of vitriol.]

Third: Pliny [Pliny the Elder] says that vitriol has so great a power of astringing that, if the mouths of lions are sprinkled with it, they cannot bite.

Fourth: alum is contained in vitriol; for if its mud is diluted with water, you will find alum efflorescing out of it — for they are born together and mixed from the same pyrite.

Fifth: if you burn vitriol, it becomes white, which, as the metallic tincture exhales, remains white, like salt. [Margin: Corrosive.]

Sixth: an excellent writing-ink can be made from it, which however vanishes entirely within a certain span — that is, if you mix the spirit of vitriol with a moist and tenacious material; for as the spirit evaporates, the residue with which it was imbued also turns black and vanishes.

Seventh: vitriol eats away all metals except lead; hence the boilers of vitriol boil it in none but leaden cauldrons. And when they have boiled it down to a certain point, it at once liquefies; and if they press it with a still more intense fiery torment, it is condensed into a vitriolated salt. The reason for this is that the mercurial admixture, in which it is strong, blunts and restrains the most pungent juice of vitriol and the lead. But on these matters see more in what follows, in the experiments on salts. [Margin: Astringent.]

Eighth: vitriol by its nature astringes, warms, eats away, and dries; hence it is wonderfully suited for stanching blood, for drying and incising humors, and for obstructed passages. Chemists make from it medicines of great price and usefulness for driving off desperate diseases.

Since, moreover, vitriol consists chiefly of three substances — namely water, the spirit of sulphur, and metal (whether it be copper or iron) — chemists draw seven different medicines from it, in the manner that follows.

First: they extract the water by a vaporous bath. Because this is the lightest of all, airy, and least of all sharing in the sulphurous spirit, this water is therefore called the *dew of vitriol* [ros vitrioli]. It strengthens the viscera, soothes inflammation of the blood, and restores a brain weakened by dryness and heat. [Margin: Dew of vitriol.]

[printed p. 322, right column]

Second: the water extracted from vitriol through sand, now sharing somewhat in the sulphurous spirit, is called the *second water of vitriol*. It gives off a not unpleasant odor; it is wonderfully effective for purging the kidneys, for internal corrosions, and for obstructed urinary canals, taken in the morning with meat broth.

Third: another, most subtle substance is then extracted, namely a portion of sulphur, to which the name *spirit of vitriol* is given. [Margin: Spirit of vitriol.] Its virtues are so great, and its endowments so admirable, that they can scarcely be sufficiently described: against all diseases it is a kind of admirable prophylactic. For whatever is found putrid, poisonous, and disposed toward grave diseases, it cuts, eats away, and consumes; it purifies the blood of all soot; it removes the matter of stones; it purges the kidneys and bladder, once all the viscosity of phlegm has been consumed.

Fourth: vitriol further tortured by fire yields a certain oil, swelling with burning spirits. Although to take it internally is not without danger, yet applied externally it has remarkable use in removing those abscesses that arise from cold, since it possesses a narcotic and stupefying power when brought to this degree; hence it is of the greatest and unique benefit to maniacs, frenetics, and the rest. [Margin: Oil of vitriol.]

Fifth: finally there comes out vitriol that they call *purified* — or, what is the same thing, the *Salt of Vitriol* [Sal Vitrioli]. These are the residual dregs from the acid spirit of vitriol, and it resembles a fine purplish earth. It has the same virtues as the preceding, most powerfully when applied externally. [Margin: Salt of vitriol.]

Sixth: once the spirits have been drawn off, there remains in the very fine powder of vitriol a certain airy substance, which can even be reduced into copper; it can not inaptly be called the *iron* or *copper of vitriol*. It cleanses putrid wounds, generates flesh, and does the like.

Seventh: when all the distillations are finished, there remains at last in the bottom of the vessel a kind of *caput mortuum* [dead head], which is called *Colcothar* or *earth of vitriol*. It serves for drying plasters and ointments and for closing over scars. [Margin: Colcothar.]

And from these things it is brilliantly clear how diverse the substances are — differing in form, color, taste, and weight — that are drawn even from one body of vitriol by the agency of fire; so that from this very fact you may learn how great a multitude and abundance of utterly diverse things is produced by the power of subterranean fire and of the waters in the innermost chambers of the earth.

Caput IV.

On artificial vitriol.

Vitriol is made in four different ways by those skilled in this art. [Margin: The first and second ways of making vitriol.] The first and second are from inky or vitriolated water; the rest either from a solution of *sory* and *chalcitis*, or from earthy lumps or stones, or other inky mixtures. The first method is this:

The inky or vitriolated water, collected in pools and drawn out from them by buckets, they pour — in warm regions, in the summer season — into open-air vats sunk to a certain depth, conducted through channels. There it is left until, by the heat of the sun, it concretes into vitriol.

In cold regions, and in winter, the inky water is first boiled together with fresh water in leaden cauldrons; then, after being cooled, it is poured into vats or basins which they call "wooden fish-ponds." From these are suspended, as it were, cross-beams fixed above so that they remain immovable, and from these hang little stones on extended ropes, to which the thick liquid clinging is condensed into transparent cubes or grains of vitriol, which have the appearance of grapes.

In the third method, ink — that is, vitriol — is made from *melanteria* and *sory*; but *misy* and *chalcitis* must be rejected, because they make the vitriol blotchy. [Margin: The third way of making vitriol.]

In the fourth method it is made from earthy lumps or stones imbued with vitriol, in the manner that follows. [Margin: The fourth way.]

First. The dug-out vein of vitriol they heap up into a pile drawn out lengthwise, upon a certain area set apart for carrying out this work; there, under the open sky, they leave it to be steeped for at least six months by rains, frosts, and suns, day and night. During this time, on set days, they tear the pile apart with mattocks and rakes and overturn it, and gather it again into the same heap, so that it may more easily be steeped by the rains and cooked by the heat of the sun. Then, with a cover placed over the pile, they let the material ferment for another half-year's space.

Second. Beside this they dig a covered trough, fortified partly with wooden boards, partly with bricks and lime, so that it cannot leak out anywhere. This trough they fill with the purest fresh water, into which they throw the inky earthy material — as much as the workmen judge necessary for carrying out the work — and they stir the mixed material with wooden poles prepared for this use, until the water has taken into itself everything of vitriol that is in it. Then they let the dregs settle, until the water, pregnant with vitriol, takes on clarity.

Third. When these things are done, certain holes made near the bottom of the trough in its side are opened, and the water leaping out from there is caught in a great receptacle. The water thus caught they pour into leaden cauldrons set over furnaces, and with the fire kindled beneath, they stir up the furnace for set hours. Finally they put in a piece of iron or copper (for without these the vitriol does not concrete); but the pieces of iron or copper thrown in melt away into the water in a short time.

Fourth. After they have cooked the material for the due time, the fire being withdrawn (lest the leaden vessels melt from the heat of the fire), they let the cooked liquid cool; then they leave it, poured into oaken jars, until it concretes into vitriol — which happens within the space of one natural day. There are also other methods, which see in Agricola [Georgius Agricola] and other mineralogists. We here set forth those that we have observed with our own eyes [αὐτοψία [Greek: autopsia, "eyewitness observation"]].

And these are the things I have judged should be said about the nature and property of vitriol; but the marvels that are wrought in the chemical business by the agency of vitriol will be made plain in their own time.

APPENDIX

On the fourfold kind of salts.

Questions and Properties of Salt.

1. Why does salt, when thrown into fire, crackle and leap out, and the smaller the grain, the greater, and the larger the grain, the lesser the noise it makes? I answer that the cause depends on the impatience of the enclosed air, which, attenuated by heat, while it seeks a larger space, with a sudden onrush bursts its barriers and makes the noise we perceive. The proof of this is the following: for in a small grain the spirit is more compressed than in a larger one.

Experiment.

Let little globes be made of glass, which are filled with spirit of wine worked together with saltpeter; if you place these, hermetically sealed shut, upon burning coals, then behold — the rarefied spirit, seeking an exit and finding none, with a horrendous and fearful sound like that of an exploded cannon, the glass burst into a thousand pieces, will violently open one for itself.

2. Why does salt in the same quantity crackle in a moderate fire, but in an intense fire do little or nothing? [Margin: Salt crackles in fire.] I say the cause is

that the spirit of the salt in an intense fire perishes at once, which does not happen in a moderate fire.

3. Why is salt melted more quickly by salt water than by fresh? [Margin: Salt is more easily melted in salt water.] I answer that this happens because of the thinness of the fresh water and the thickness of the salt water. For the former, as it easily penetrates, so it does not liquefy except in time; but the latter, being thicker, most easily dissolves the parts of the salt; and once the saline corpuscles are dissolved, it too must necessarily liquefy at once.

4. Why can salt water not be drunk cold, [Margin: Salt water, heated and again cooled, is more tolerably drunk than cold.] **but, heated and then again cooled, can be drunk more tolerably?** I answer that this happens because salt water, never heated, holds its corpuscles scattered through the whole substance of the water; but after it has been heated, no small part of them flies off, and once cooled, the remainder settles to the bottom; whence the water, diminished in salt, is rendered more tolerable for drinking.

5. Why is sea water — that is, salt water — unsuited for extinguishing fires? [Margin: Salt water does not extinguish flames.] I answer that this happens because sea water is imbued with the greasiness that fresh water lacks, and therefore promotes fires rather than extinguishes them. Hence lamps also burn better when salt is thrown in; hence, too, clothes cannot be washed with sea water, because the greasiness of the salt residing in them stains rather than washes.

6. Why is sea water, even though heavier than fresh water, nevertheless clearer than it? I answer that the cause is the fiery spirit with which the sea is filled, by the greasiness of the sea. Hence divers, taking oil into the mouth and blowing it out, cause a certain light in the very depths, sufficient...

7. Why are salty rains more useful than seawater, and why is salt scarcely produced unless fresh water is mixed in? I answer that the cause is this: fresh water, being lighter and finer, penetrates the salt particles present in salt water more easily and unites itself with them — which does not happen readily when thick water is mixed with thick. This is why dew, being of a finer substance, yields a more agreeable salt. As for why salt is produced more abundantly when the north wind blows, and why it then yields the greatest "flower of salt" [flos salis], the cause is the constrictive force of this intense cold wind, by which the salt particles, however minute, are easily drawn together and condensed.

[Margin: Fresh water and rain are used in making salt.]

8. Why does sal ammoniac grow in the deserts of Libya as the Moon waxes? I answer that the cause is this: as the Moon waxes, it is continually moistened with new and ever-renewed moisture; and afterward, during the day, it is condensed by the heat of the Sun, its excess humidity being either consumed or thinned into vapor. This solves the prodigious property of the salty lake near the city of Aspendus, to which (if Pliny [Pliny the Elder] is to be believed) just as much is added by night as is taken away by day — since the Moon supplies abundant moisture by night to the saline material as it grows to its full increase, while the Sun's heat consumes it once thinned.

[Margin: Sal ammoniac grows as the Moon waxes.]

9. Why is sal ammoniac extremely light while it exists within its own caverns, but very heavy once brought out into the light? I answer that the cause is this: within its caverns it mostly blooms into flakes, which, being very rare, are likewise very light. But as soon as they are brought into the light, the heat of the Sun consumes the airy and watery part that exists within them, and the remaining earthy part is condensed — by which its weight is necessarily increased.

[Margin: Sal ammoniac is lighter inside its cavern than when brought out into the light.]

10. Why do the Egyptians sprinkle their radishes with niter — as we do with salt — before eating them? I answer: because the radish itself delights in a nitrous substance so much like itself, and so is made better by a certain natural agreement. There is also this: the niter sprinkled on them yields the very cold juice of the radish, which the Egyptians delight in.

[Margin: The Egyptians eat their radishes salted.]

11. Why, when niter is thrown into vinegar, does it at once begin to fume and boil up — just as when water is poured over quicklime? I answer: because the sharpness of the vinegar excites the spirits latent in the niter; and while the mixture is roused by the gnawing action, it comes about that, once the niter is dissolved and the spirits fly off, boiling necessarily follows.

[Margin: Niter boils up in vinegar.]

12. Why, when niter is thrown into the mouths of lions and bears, does it check their bite? I answer: that they, being agitated by the discomfort of the sharpness, while they struggle to free themselves from the trouble, easily forget the injury done to them — which is common to all animals.
13. Why, when saltpeter is boiled together with sulphur, is it turned into stone? I answer: because the spirits latent both in the niter and in the sulphur, united by the boiling, are perfectly fixed; and so, with the moisture flying off from the niter, and the fatty matter gluing the two together, the earthy part must at last pass into the hardness of stone.

[Margin: Saltpeter boiled with sulphur turns into stone.]

14. Why does salt take away the numbness of the teeth, but niter does not? I answer: because salt softens and liquefies, whereas niter, on account of its harshness, constricts and does not liquefy.
15. Why do plants spring up and are nourished in salt-works, while niter neither generates nor nourishes anything? I answer that the cause is this: in niter, that fiery and earthy element by its incisive force corrodes everything — which does not happen in the moist and earthy nature of salt.

Whence comes that cleansing power in niter, by which it washes all filth from clothing, and is of such great importance for dyeing cloth among the dyers and fullers? I answer that the cause is that fiery sharpness joined together with the fatty matter present in niter; and the fiery and sharp element, pervading the stains and filth, dissolves them by its corrosive force, while that watery fattiness easily wipes them away.

Aluminis Vires.

The Properties of Alum.

16. Why is alum of the cauldron [alumen catinum] added in the melting of glass? I answer: since this alum is made from a plant which the Arabs call *Hali* [the saltwort, from which soda-ash was made], and since this kind of herb is teeming with an aluminous juice, it comes about that the added alum reinforces the aluminous substance and, by its incisive virtue, easily urges the sands into fusion. Hence the glassy substance, when the diaphanous portions of the silica and sands are joined to the aluminous parts, makes the glass clearer and more lucid — which, without the

addition of alum, would turn out much darker. But more of these matters in [the section] on the art of glassmaking [Ars vitriaria].

[Margin: The properties of alum.]

17. Why does the distilled water of any alum — most of all the rock alum [alumen rupeum] — eat away flesh, and even the metals themselves? I answer that this happens because of the deposition of the phlegm brought about by the action of the fire, which water, once freed, acquires an enormous force of sharpness suited to dissolving and eating away the metals.
18. Why does scaly alum — which they call "Donkey's Mirror" [Asini speculum], on account of its diaphanous substance — when thrown into the fire and burnt, immediately lose its native clarity and whiten like gypsum? I answer that this happens because of the dissolving of the watery parts brought about by the action of the fire; and when these have vanished, the earthy body necessarily remains, degenerating into gypsum. But how much watery content it had in itself, and how this can be explored by the device of the balance [staticum artificium], will be told elsewhere.
19. Why do printers first pass paper destined for the press through an aluminous bath? I answer that this happens because, since paper is made from beaten fragments of flax, and much alum is present in flax (for flax is one of the aluminous herbs, like woad [glastum], which is of such great use in dyeing cloth), it comes about that paper passed through aluminous water, by a certain innate force, magnetically draws to itself the aluminous particles mixed in the water. From this attraction the whole substance of the paper is wonderfully strengthened, and takes on a certain hardness, so that the ink does not flow through or run — because of the union of the aluminous parts present both in the ink and in the paper, which has been imbued with the aluminous force. For just as these parts seek union from the likeness of their nature, so too do they shrink from every dispersal of parts that comes about through running.
20. Why is wine that has turned cloudy in the cask set right with alum? I answer that the alum by its incisive force dissolves and disperses the dregs of the wine, so that the wine at once regains its former clarity. For the other properties, see the Fifth Book of this work, where we have discussed at length the vitriolated waters and hot springs.

Vitrioli vires & proprietates.

The Powers and Properties of Vitriol.

21. Why does vitriol found in mines give miners no further hope of pursuing the metallic veins any further — for, as most authors say, the discovery of vitriol in metallic veins sets the boundary of the metal? I answer that this happens because Nature, through vitriol, as the foundation of metallic generation, shows that no metal remains to be brought to its perfection; and the parts of imperfect metal in the veins neighboring the vitriol show this clearly enough. That vitriol is the proximate cause of the generation of metals is plain from this: that, as we showed above, it abounds in the spirit of sulphur together with a mercurial wateriness. From this acidity the sulphurous spirit acquires both a sharpness for eating and a fineness for penetrating the metallic clods; and so, by the innate nature of the place and by the proper force of its substance, it is readily condensed into metals — into whichever kind the mine is of, especially into copper, iron, and silver, as bodies sympathetic to it.
22. Why does vitriol confer such clarity and limpidity on the water in which it exists? I answer that this happens because the grosser parts of the water, dispersed by the incisive and subtilizing force of the vitriol [chalcantum], sink down; and so, on account of the diaphanous and glassy substance of the vitriolated corpuscles, the water is rendered more lucid, more splendid, and more limpid.
23. Why does vitriol — with the exception of lead — corrupt the other metal vessels by eating them away? I answer that this happens, as we also hinted above, because of the abundance of the mercurial humor in which lead is strong; for by this the incisive force of the vitriol is to some degree blunted.
24. Why, as Pliny reports, can the mouths of lions and bears not bite if they are smeared with vitriol? I answer that this happens because of the very great sharpness of the vitriol, which they try to remove by every means; and so they are so taken up with averting the discomfort that they readily forget the injury done to them, fearing that, if they provoke their enemies further, a greater harm may come upon them.
25. Is there alum in vitriol, and how is it present in it? I answer in the affirmative — especially in the alum which is born from pyrite. For since pyrite generates both alum and vitriol equally, I say that these substances

of different species are mixed together, and consequently are easily separated by the chemical art. For if the mud of vitriol is diluted with water, alum blooms out of it — because the aluminous corpuscles hidden in the mud, once moistened, easily effloresce, since alum is of a more airy nature, while vitriol is of a more earthy nature. And this is plain from the oil of vitriol, which gives off altogether the smell of alum, on account of the volatile nature of the alum mixed with the sulphurous spirit in which vitriol is strong.

26. Why do the diggers of vitriol easily perish in the innermost caverns? I answer that this happens because of the noxious stench of the putrefied sulphur, by whose narcotic vapor the diggers are necessarily suffocated — most of all in the "Charontic" caverns [charontici specus, deadly grottoes], which draw their poisonous and lethal exhalation from nothing but this mixture.

And these are the things we have thought fit to say about the powers of vitriol. Whoever desires more of these matters, let him turn to the following books, where, concerning the fermentation and precipitation of metallic liquors, we set forth beautiful and admirable experiments.

MUNDI SUBTERRANEI LIBER SEPTIMUS

DE MINERALIUM SEU FOSSILIIUM

THE SEVENTH BOOK OF THE SUBTERRANEAN WORLD: ON MINERALS, OR FOSSILS

which properly partake of the earthy Element — their Nature, Property, and Use; and concerning the perennial Geocosm, what comes about through their motion, their cycling-about [pericyclosis], and their revolution.

PRÆFATIO.

PREFACE.

It was altogether necessary to set the concreted juices [succī concreti] before this Book; for just as those are the base and foundation of all the rest — whether of

minerals or of metals — so too in the order of nature they deserve the first place among fossils.

That you may understand this, Reader, know that there is no body or substance in the nature of things which does not take its origin from salt, and which does not at last resolve again into the same — as was shown fully in the preceding Books. And so, by the providence of the most wise Divine Craftsman, both to furnish all things with consistency and to preserve them, and to give them the fruitfulness for propagation, salt was set in place at the first origin of things. For just as the saline substance is diffused through all the fibers of the earth and the abysses of the sea, so there is nothing which does not draw it to itself and into itself — as a good uniquely necessary to it — by a kind of natural magnetism, inasmuch as from it each thing gains firmness and strength. All these things have been shown in the preceding Books through various observations and experiments; and so nothing else remains except that we now show what salt of Nature accomplishes in the remaining mineral substances, and how it is converted into their substance. And that we may proceed methodically [εὐμεθόδως, Greek: eumethodōs, "in well-ordered fashion"] in all things: first, let us set up our reasoning concerning those Earthy substances which counterfeit either powder, or sand, gravel, grit, or ash; second, concerning the soft substances which they call earths [terrae]; third, concerning imperfect metallic bodies and stones.

SECTIO I.

DE TERRESTRIBUS PORTIONIBUS

SECTION I: ON THE EARTHY PORTIONS

and the sandy bodies which are enclosed in the womb of the Geocosm.

CAPUT I.

De Arena, Sabulo, Glarea, Cinere.

CHAPTER I: On Sand, Grit, Gravel, and Ash.

Concerning Sand — than which nothing is better known — it must be treated first, so that what it furnishes in the nature of things, and what its power, forces, and properties may be, can become known.

Sand, then, can be considered under a threefold distinction; for it is either fossil [fossilis, dug from the ground], or fluvial, or marine. Fossil sand is that which forms when a stony substance — eaten away [hu...

[Margin: Threefold sand.] — eaten away by moisture, is collected in underground pits, or is heaped up by alluvial deposit within the hollows of mountains and mines, whose whole interiors are full of it. The fluvial and marine kind is that which is rolled along the banks of rivers and seas by the agitation of the waves, and is nothing other than certain shavings of stones produced by the perpetual attrition of the water lapping against them; or it is carried down through the channels of mountains by the motion of the waters; or it is the sands heaped up after the Flood, from which arise the sandy mountains and hills — some of which, by a petrifying juice, have in the course of time been turned into stone, while others have remained under the mobile substance of sand, like Mount Janiculum [in Rome], which consists wholly of tawny-colored sands.

[Margin: Sandy desert.]

As for the sand that is found in sandy deserts, it comes from the very nature of the place — when, through the dewy moisture of stony tracts of friable nature, the rocks, gradually worn away, degenerate into a sandy material, which, agitated by the force of the winds, is heaped into mounds, and, dissolved again, is scattered over plains stretching far and wide. For the dewy moisture, infected with niter in the sands, gradually resolves the cliffs and rocky ground into sand by eating them away; and that the sand there is indeed nitrous is sufficiently demonstrated by the sal ammoniac, which is found there most abundantly. See where, in the Fourth Book, we discussed sandy tracts of land at length.

The origin of sands, therefore, comes from nowhere else than the corrosion of a certain sharp liquor, by which stones are resolved into sand; or from the drippings of grottoes, where "the drops hollow out the stones — not by force, but by often falling" [a proverbial line]; and one must reckon that just as much sand has flowed forth from there as the capacity of the cavity within the stone could contain. Or it comes from the agitation of waters running through rocky places, by which the worn rocks are resolved into sand. And this is plain, first, from the gushings of springs, which are everywhere mixed with sands of every kind — sands which indeed reflect the color of the stone, or of the metallic vein, that they wear away.

[Margin: Sign from the color of the sand from which it has flowed forth.]

If they flow through an iron vein, [the color is] black; if through a golden one, golden; if through arsenic and ochre, yellow; if through an aluminous one, white; if through a copper one, green; and so with the rest, they reflect the color. Hence from the sands a judgment can easily be made about the ore through which the sand-bearing waters flow down, as we have taught elsewhere. Marine sand is produced in exactly the same way; for since the sea is in perpetual instability of motion, and rolls its swelling waves continually toward the shores, it comes about that stones, worn by the violent agitation of the sea, are dissolved into gravel, grit, and sandy material. All of which, as daily experience teaches, makes it unnecessary to speak more fully of these matters.

[Margin: Whence marine sand?]

COROLLARIUM I.

COROLLARY I.

From these things, then, it is plain that there are as many kinds of sand as there are different kinds of the ores and rocks which are worn down by the alluvion of the waters; and each of these tastes of [savors of] the nature and property of the whole from which they have flowed down.

[Margin: How many kinds of sand?]

COROLLARIUM II.

COROLLARY II.

Hence is plain the immense yield of gold-bearing sands in some rivers. For since water — especially briny water — flowing through veins of gold, always carries off with it something from the eaten-away shavings, hence it is that springs and the neighboring streams and rivers contain so much the greater quantity of golden sands in themselves, the nearer the rivers are to the springs, or the springs to the gold-bearing channels. But the manner of gathering, washing, and separating the gold from the earthy dregs will be told elsewhere.

[Margin: Whence golden sand in springs and rivers?]

CAPUT II.

De Qualitate Usuque Arenæ.

CHAPTER II: On the Quality and Use of Sand.

Sand, if it draws its origin from a dry stony substance, will be dry; if from bituminous material and thick earth, it will be fat. In a word, sand takes on the nature and property of that from which it was cut off, as we said a little earlier. The sand found at the banks of the Nile is wholly nitrous, as is also that which covers the region of Libya; it is for the most part sterile, and so serves neither for sowing nor for planting nor for plowing — whence the proverb, "He plows the sands."

[Margin: The various qualities of sands.]

Ausonius, to Theon, Epistle 4:

"What do you do, set on the farthest shores of the earth, O Tiller of the sands, Poet, for whom the beach must be plowed?"

And that line of Ovid:

"What are you doing, O Oenone? Why do you commit seeds to the unwilling sand? You plow the shores with oxen that will yield no harvest."

Second: it is useless and unsuitable for sustaining the foundations of buildings — the cause of which is obvious. Yet because no thing in the nature of things is so small and contemptible that it does not at the same time bring great usefulness with it, we will adduce something about the usefulness of sand.

[Margin: The usefulness and harm of sand.]

And first indeed: even though sand does not serve for laying the foundations of buildings, it is nevertheless established that no structure can be raised without sand; for from lime and sand cement is made, which, being necessary for raising buildings, we cannot do without. And the drier and finer it is, the greater firmness it gives when mixed with lime, since, absorbing the moisture of the lime, it is, together with the bricks, as it were turned into stone.

Second: it is necessary for making glass...

Liber VII — Sectio I, Caput II (continued) ...it is: for which see the final volume, *On the Art of Glassmaking [de Arte vitraria]*.

[Margin: For making glass.] [Margin: For sawing marble.]

Third. Sand is useful for sawing marble; for without sand or emery [smyris] — which is likewise a kind of sand — marble cannot be sawn. The grinding action of the saw stirs up the sandy particles, and once excited, by their own hardness they gradually grind the marble together with the saw. For this work, Pliny [the Elder] tells us, Ethiopian sand was once especially valuable. Today the sand found in a certain shoal of the Adriatic Sea, brought up by the force of the tide, has an exquisite use — though nowadays marble is sawn and polished with any sand that comes to hand.

[Margin: For sandglasses.] **Fourth.** Sand serves for clocks, or hourglasses [clepsammidia], which show the hours by their flow — than which nothing is more commonplace.

[Margin: Use in chemistry.] **Fifth.** Sand has a notable use in chemistry, for digesting metallic, mineral, and vegetable liquids over a moderate fire — about which I shall speak more fully in its proper place.

Sixth. It works wonderfully on liquids imbued with bitterness or saltiness, reducing them to sweetness by filtration.

Seventh. Potters, in firing their vessels, generally use a mixture of sand. The crystalline particles of the sand, melted by the violence of the fire in the kiln, strengthen the clay mass remarkably and fortify it against cracking.

Eighth. Smiths make their fire stronger by sprinkling on sand; and in melting metals the use of sand is so necessary that without its admixture they are fused only with difficulty — especially iron and similarly stiff metals. But since the use of sand is necessary to everyone, I think it superfluous to say more about its uses.

[Margin: How sand is distinguished from coarse sand and gravel.] It remains to be said how sand [arena] is to be distinguished from coarse sand [sabulum] and gravel [glarea]. I say, then, that coarse sand is a certain species of sand, distinguished from it only in that it is coarser; it is found both hard and soft — they call the former male, the latter female. It is laid down under flints and crusts of rock and interspersed among them; it serves for paving garden walks. In a

word, coarse sand is for the most part confounded with sand by writers, so that to describe so trifling a thing further would be nothing but wasting time.

Gravel [glarea] too is scarcely distinguished from sand and coarse sand, except that gravel is coarser than both sand and coarse sand. Such are fragments of stones, marbles, flint, tufa, and not-too-large rock; they are found here and there along the banks of rivers, mostly worn smooth into a round or oval, lens-shaped form by the attrition of flowing waters.

[Margin: What is ash?] Something remains to be said about ash [cinis]. Ash is the powder left over from burning, into which a burnt thing is reduced. It stands to the things from whose combustion it results just as sand stands to the rocks and mineral clods from which it falls away. And in this sense lime [calx] is not inappropriately called a kind of ash, though of a finer essence than the ash that comes from wood. [Margin: How many kinds of ash?] All the metals too have their own ashes, which are nothing but that earthy residue which, by the violent force of fire, settles at the bottom of the furnace, either burnt or reduced to lime. And there are as many species of ash and lime as there are of combustible things. [Margin: There are as many kinds of ash as of combustible things.] Stones, as I said, yield lime in place of ash; but the burning of the rest — plants, herbs, shrubs, woods, animals, bones, horns — leaves an ash of the same virtue as the things from whose combustion they remained.

[Margin: The marvelous secret of ash.] There is in the ash of vegetables a thing truly most worthy of wonder: that it contains within itself a salt perfectly suited to the propagation of the very species of plant from which the ash remained. To make myself plain by a single example: the ash of wormwood [absinthium] contains, for instance, a salt which, when extracted from the ash and set in the earth, brings forth the species of plant from whose combustion the ash remained — namely, wormwood. But since I shall confirm these marvels of nature in the various experiments that follow, I have thought it best here not so much to explain them as merely to point them out.

[Margin: The property of ash.] If you ask about its nature, I say it is moderately warm; for all burnt things, as the Philosopher [Aristotle] attests, retain some heat, and the acrimony both of lime and ashes and of animal excrement, and salt itself, plainly teach this. Nor can it be that things burnt and roasted by excessive heat should not have some degree of heat. But let me now set out a few of the uses of ash.

I said a little earlier that not all ash is endowed with the same power, but that it varies according to the power of the burnt material. From this I conclude that ashes left from the hottest burnt things are themselves the hottest and driest. This is clear from the ashes of burnt pellitory root [pyrethrum], which are so vehement in their acrimony that the tongue can scarcely bear them at the first contact. [Margin: The various uses of the different ashes.] Fig-wood ash [cinis ficulneus] is the sharpest, and so is counted among the caustics. Ash made from sour woods is no little astringent, and checks hemorrhages. The ash of trumpet-shells [buccinae] makes a most excellent dentifrice; smeared on burns, it does not fall off until it has formed a scar — for then, as if having duly done its office, it falls off of its own accord. The ash of vine-twigs [sarmenta] has a notable burning power, and mixed with niter and vinegar is a great secret for healing sarcocele. Phrygian ash, on the Philosopher's testimony, makes a most excellent eyewash [collyrium]. Spices fumigated with ash acquire a sharper smell. Gladiators of old, when their limbs were strained, treated themselves with a draught of ash. The ash of pear-wood is an effective remedy against the poison of fungi. The use of ash so pleases the Transpadanes [people north of the Po] that they prefer it far to the dung of beasts. Some think that grapes are nourished by ash sprinkled at the roots of the vines. Ashes not only refresh the soil, but, applied to the roots of plants, they remove the diseases of crops — rust, caterpillars, and the other [diseases] of trees, plants, and crops...

[Margin: Signature: B 3]

they make a hostile [remedy against the] little creatures. The ash of the wagtail [motacilla], turned into salt and taken internally, is an admirable remedy against bladder-stone. The ashes of the ash-tree [fraxinus], on Pliny's report, put serpents to flight if their hiding-places are sprinkled with them. Little cups made from ashes have a most notable use in the chemical art.

PARADOXUM [A Paradox]

Here I cannot omit to unravel an intricate question about ash; and it is this: Whether one and the same vessel can hold equal amounts of ash and water together as it holds of the very most of either poured in separately. For if you pour water onto ash — especially hot ash — the water mixed with the ash takes up only as much space as the ash alone occupied before. This rightly seems a paradox to those unskilled in such matters. Let me explain how it comes about. I say, therefore, that ash, the dryness of its nature so requiring, is exceedingly porous, having its parts barely connected to one another; yet as soon as you pour on water — especially hot — then, behold, by the heat of the ashes the water,

partly dissolved into vapor and partly mixed with the ash, forms a muddy mass, in which the parts that were at first dispersed, now brought together, occupy the least space, on account of the condensation of the now-packed, moistened ash. And so the muddy water, partly dissolved into vapor and partly mixed with the ash, presents nearly the same space that the ash occupied before. Water poured onto cold ash does the same, though with a somewhat greater increase; for the ashy corpuscles, by their excessive dryness, just as they immediately absorb the water, so, their parts bound to one another, they make that packed mud which occupies nearly the same space. But of this experiment I shall treat more fully elsewhere.

Caput III

Pericyclosis Naturae mirabilis [The Marvelous Cycle of Nature]

It was most amply demonstrated in the Fourth Book that the Geocosm is full of subterranean fires and waters. Since this is so, the fires must necessarily act on whatever lies in their path — whether rocks [cautes] or earthy clods [glebae]. These, burnt to ashes — or, what amounts to the same thing, to lime — pass away. [Margin: From lime, or ash, the perpetual origin of minerals through fire is derived.] Lime mixed with the waters it meets makes a lye [lixivium]; the salt of that clod, which when burnt was reduced to lime, is bound up in it. [Margin: From ash, all the species of salt.] The earthy fibers, which are as it were the mesaraic veins of the minerals, draw the salt lurking in the lye, just as those veins draw the chyle, the blood, and the seed. The salt residing in the veins works up a new origin according to the condition of the clods — here of salt, there of niter, elsewhere of alum, in another place a half-mature seed of vitriol — which in the course of time are transmuted into minerals of diverse species. [Margin: Magnetically each one draws to itself what is like it.] Hence at last the water, now coppery, now iron-bearing, now salty, lays down new nurseries [seminaria] of medicinal waters, through the attraction of those earthy masses which, by sympathy, agree with this or that liquor; and from this the diverse mines [fodinae] take their origin. From these, indeed, an infinite progeny of various minerals and fossils springs up.

That this may be understood, it must first be known that fire acts on rocks and on the fossil furniture [of the earth] either immediately or mediately. [Margin: The subterranean Vulcan resolves into lime those things on which it acts immediately.] Acting immediately is the Vulcan who dissolves into lime the things on which he acts; but mediately it acts through vapors and exhalations, which,

penetrating the innermost recesses of the mountains — like the spirits in the human body entering all the veins of the Microcosm — everywhere labor according to the condition of the parts they enter. Secondly, there are generated in the bowels of the earth juices [succī] of diverse kinds, which, mixed with the waters they meet, produce marvelous effects and a marvelous generation of things, according to the nature of the earth with which they are mingled. [Margin: The diverse offspring of juices.] Thirdly, there occur various species of metals and minerals which, when mixed with juices, vapors, and exhalations of differing properties, produce an enormous abundance of fossil substances differing in their whole genus. [Margin: From these the variety of things arises.] Fourthly, there are stones, both common and precious, whose number is beyond count. Fifthly, there are earthy substances, which we call earths. And so from the intermingling of these things, and from the various combination of vapors, exhalations, juices, metals, stones, and earths, is caused that immense and inexplicable variety of things which the earth supplies to us.

These things laid down, let us now look a little more closely at the unceasing revolution of things. [Margin: A recapitulation of what has been said.] That subterranean fire, together with water, is the producer of all things has now been said over and over again. For this fire, acting immediately on rocks, masses, and clods, reduces them to lime or ash. Lime or ash, filled with the salt of the calcined things, joined with any water whatever and concocted by the power of fire, causes either a confused or a perfect mixture. Water, filled with different salts and carried hither and thither through innumerable channels and twisting little hollows, is drawn off from the earthy clods by a kind of suction, and once drawn off it congeals into one body with the clods — each earthy substance drawing to itself that which is more congenial to it in the waters. From these waters, caught in a suitable place, are also born all those juices, whether existing as concretions or as a liquid substance. Hence the rarefied substance — whether metallic or stony — which water, imbued with a sulphurous exhalation or spirit by the power of fire, gnaws, eats away, and dissolves into corpuscles mixed with the water, this same substance it [the water] deposits again in another place in a clod of the same nature...

Liber VII — Sectio I, Caput III (continued); then Sectio II begins

of [the same] nature, drawn to itself by a certain attraction; and there it lays a new storehouse [pennarium] of the metallic vein. And what is said of this one

[substance] is to be understood of all the other salts that are sympathetic to the clods. [Margin: How new mines are formed.] Thus, from the attrition and corrosion of the metallic clods, new mines emerge elsewhere by the conveyance of the water; and from the attrition of stones of every kind, stony or petrifying juices are born, whence comes a new increase of stony veins. But the material — that is, the ash from the eating-away either of the juices, or of the metallic species, or of the bituminous portions, slipping in through the hidden channels of the earth into its fire-chambers [pyrophylacia] — partly furnishes new fuel for the fire, partly confers new increase on the neighboring rocks now burnt. And so by the continuous and perpetual operation of nature [Margin: From ash, the perpetual increase of things.] — that is, by the power of fire, the perpetual ash of burnt things, out of which the lime, according to its condition, [yields] salt, niter, alum, vitriol — these in turn, by the power of exhalations and vapors, joined in the innermost parts either with metallic bodies, or with rocks of differing properties, or with the juices of the earthy clods, make various mixtures; and from the various combination of these in turn emanates that immense variety of things, propagated by a perpetual and unfailing cycle [pericyclosis]. You see, then, how all things first take their origin from the lime or ash of burnt things. But let me now describe more fully the individual species and their generations.

SECTIO II

DE HYLOCINESI GLOBI TERRESTRIS

[On the Motion of Earthy Matter of the Terrestrial Globe]

Id est [That is]:

On the great and perpetual separation of terrestrial matter, accomplished by the motion of sand, coarse sand, and gravel; or, on the resolution of clay, stones, and metallic mixtures.

Caput I

De mutationis Geocosmicae Causis [On the Cause of Geocosmic Change]

That the Geocosm turns in a kind of perpetual motion and in the alternation of changeable things was shown in the Third and Fourth Books. But how this change of terrestrial parts — which we call ὑλοκίνησις [Greek: hylokinēsin, "motion of matter"; the motion of terrestrial matter] — comes about, I have thought it best to disclose here. [Margin: The alternation of things in the terrestrial world is

necessary.] For it is certain, and confirmed by the unanimous judgment of the natural philosophers, that this Geocosm, just as it is constituted of the four elements, so likewise sustains immense and perpetual conflicts and struggles of the contrary elements, and the alternations of things — and this most of all under the ever-changing arrangement of the Sun, Moon, and stars in the celestial expanse, and the periodic revolutions that perpetually agitate it.

What is earthy in the Geocosm is brought about chiefly by water and the blowings of the winds, by a twofold motion. [Margin: Earth, water, and the stars: by whose impulse the changes of things come about.] The water that surrounds the whole globe, dissolved by the force of the stars into an immense quantity of vapors and exhalations, and condensed in the appointed regions, if it passes into drops [becomes] rain; if it freezes, hail; if it turns to snow before it passes into drops. [Margin: Rain, hail, snow, winds: how produced.] Rain, hail, and snow, drawn up from rivers, lakes, and seas, and driven by the violence of the winds onto the peaks of mountains and regions, there lay down those marvelous nurseries which I shall describe, and found the commotions and seed-beds of things.

But the approach and recession of the sea, which we call the tide [aestus], flowing and ebbing twice in the space of 24 hours, drives the water through the subterranean passages, so that it draws along with it an immense mixture of foreign matter and leads it out abroad through springs, brooks, and rivers; and so it constitutes in that ὑλοκίνησιν [hylokinēsis] the marvelous cause of the change of all things in the terrestrial globe. And so the Geocosm is perpetually beset by two, as it were, Morpheuses: the one internal, through the motion of subterranean fire and waters; the other external, through rains, showers, hailstorms, and snows, which are, as it were, the carriers and promoters of terrestrial matter. [Margin: How greatly snow can do in altering the soil.] Snow, occupying the summits of the mountains, not only ferments the earthy substance but also, by a kind of half-yearly maceration, softens the rocky substance. For chemical experience teaches us that there lurks in snow a mixture of metallic and mineral corpuscles, whence these, joined with the mineral juices of the mountains, bring about marvelous generations of things. Melted by the heat of the Sun, together with the showers, it carries off with it sand, coarse sand, and gravel of every kind of mineral species, scraping them away; and these, in turn, entrusted to the rivers, while...

Liber VII — Sectio II, Caput I (continued)

they are incapable of [bearing] so great a mass, where a way is given, spread out by inundation over plains stretched far and wide. Hence it comes about that mountains which were at first fertile, their richer clods scraped away, are left with nothing but their rocky substance; while plains which were at first squalid with sterility, or filled with marshes, are blessed by the arrival of the rich guest with the longed-for fertility. [Margin: Why mountains, at first fertile, in time become sterile.] These, however — since nothing in things is stable — in the course of time, their fertility stripped away, degenerate again into sterility, when, by the soaking of snows and the dissolving of frost, the rocky offspring of the mountains splits into crusts, and, cleft, is crumbled into lean coarse sand and gravel. [Margin: How sterile places can be made fertile again.] This gravel and coarse sand, snatched up by the rains and carried down into the fields, so covers over the fertile mud they rejoiced in that they are no longer fit for cultivation. Yet in time, and in the course of many years, it comes about that the sandy substance, filled with herbs, plants, and shoots, is clothed with trees and woody tracts. [Margin: New principles of sterility.] These, every year — namely in the autumn season — their leaves, fruits, and buds, struck down whether of their own accord or by the force of the winds, fall into the surrounding fields, whether level or mountainous; and so, by the maceration of the winter snows, rains, and showers, turned to rot together with the grasses, they cover the fields with a new skin of rich earth. And since this happens every year, no one fails to see — especially on the banks of rivers — that the earth too is thereby continually augmented and rises layer upon layer. In these banks you will plainly behold now veins of stones, or of coarse sand and gravel, now a heap of sandy or muddy earth which covers the sandy surface like a kind of crust; and so, with the arrival of a new heap of rich matter, the fields, luxuriating in a new conception of fertility, enrich the farmers with great yields. Yet these in time, with a new heap of lean coarse sand scraped from the mountains and carried down by inundation and showers, while it covers the rich matter, fill the fields with a new vicissitude of sterility; and this lasts, as long as the World shall stand, by the perennial law of alternating vicissitude.

Since in seeds, plants, shoots, grasses, leaves, flowers, and fruits there is a great deal of niter, salt, and bitumen, hence, when these falling things are committed to the earth, fermented as it were by putrefaction, they furnish a new material for generating salts and minerals; but above the rest, bituminous substance...

[Margin: Vegetable salts, before non-existent, produce new nurseries of salts.] ...

the aerial regions, raised up partly through the gushings of springs, partly through the external motion of air, water, snows, and rains, it restores to the terrestrial globe by a perennial and unfailing alternation of nature.

We have seen the admirable Cycle of Nature [Pericyclosis Naturae]; now let us set out, by way of questions, the causes of the particular effects which it produces in the terrestrial globe.

It is asked, first: How do new fields and plains arise, now sterile, now fertile? [Margin: How fields are now sterile, now fertile.] I answer: this comes about by the influx of sand, clay, coarse sand, and gravel carried down from the mountains and deposited on the plain; by which also earth, at first marshy, fills up pits and valleys and is leveled into a plain. Or else by the force of rivers running to one or the other side, which on one side they corrode and eat away, while on the other side they compensate by the addition and increase of earth — as may be seen on the banks of nearly every river. And hence it is clear that in the course of time rivers, by the eating-away of one bank and the increase of terrestrial matter on the other, change their channels over time. See what I have said most fully about these things in the Third Book.

It follows, secondly: that from the arrival of coarser coarse sand, scraped from the mountains by the violence of torrents and rains, not only are the fields filled, but the channel of the rivers too is made higher by the heap of flints and rocks. By the increase of these, and by the herbs sprouting from the mud, the water, no longer knowing how to be contained in its own channel, at length fills the more level fields with a new inundation. Yet when these are freed from the marsh-water by ditches or drains, while the sandy material is mixed with the sediment of the inundating waters, they degenerate into the best and richest [soil]. Certainly in mountainous regions, when snow has melted, it is known to all that the water flows down from on high — turbid and thick, mixed with sand, clay, mud, gravel, and other matter that it snatches along with it — through the lower places into the rivers. And not only from the neighboring mountains, but also from those lying off to either side at a distance of several days' journey, the movements of psammorrhea [ψαμμορροία, "sand-flow"] — that is, of sandy matter — convey [it]; for one may often observe the greatest mountains and forests scraped away and carried off by the force of the down-flowing water.

It is asked, secondly: Why does the same river in some places endow the fields born of alluvion with lean sand, but in others with rich mud? [Margin: How fields, in lower-lying places, are generated, and then [turned] into rich mineral-beds.] I answer: in three ways the fields and plains are made now rich, now

sterile. **First**, by coarser coarse sand and lean sand they are made sterile, but by the silting-over of clay and rich mud, fertile. **Second**, they are made sterile by the violent unloading of psammorrhea of the rivers onto the fields; fertile by a gentle flow of matter and by the sediment of rich mud on the level of the fields. **Third**, by [the deposit] of buds, herbs, and leaves falling from the trees and mixed with the earth...

[The remaining columns on p. 331 carry additional marginalia keyed to the sediment/mineral-bed discussion:] [Margin: Sands turgent with mineral juices make the earth wonderfully thick and rich; but from salts disposed by fermentation, and from mineral clods cut from the mountains and carried along by rivers, a new offspring of minerals is born, which at length is entrusted to the sea by the conveyance of the vast rivers. The sea, in turn, augmented and made teeming with all the said species of things, [returns] the entrusted increase, whether through subterranean tunnels, or by the Sun's attraction through vapors into the higher [regions]...]

by the decay of [buds/herbs — *farum?*], which, being rich in fattiness, are converted into a rich, earthy mud and so endow the fields with the fertility one desires.

The third question. How do level fields of sand arise in flat places?

[Margin: How sand-hills arise in flat places.]

I answer: the surface of the plains is leveled when, by flooding, the mud is spread in equal portion once all the hollows and ditches have been filled — just as one sees with snow, which in calm weather, settling gently as it covers the ground, makes the snow-covered surface even. In the same way the psammorrhea, when it is cast over the land without the violence of rivers, spreads the mud and sand uniformly, and from this a flat surface results. Hills, on the other hand, arise in several ways. First, if the fields are filled and heaped up with gravel and sand carried down either from the mountains or from the rivers. For in this way, when a further flood comes over them, the mud clinging to the mounds of gravel forms a kind of crust or skin, which, sprouting into shoots, is bound fast by their roots. Over time, with the muddy matter of leaves and grasses — now rotted and turned to earth — added layer upon layer, the mass of the hills is marvelously increased. To this contribute the gusts of the winds, by which the drier sandy material lying on the fields is stirred up and driven into heaps, eventually rising into lofty hills as the material is continuously added.

[Margin: How sandy hills arise near the mouth of the Tiber.]

This is just what one can see along the seacoast near the mouth of the Tiber [*Ostia Tiberina*]: packed mounds and little hillocks clothed with grasses and shrubs, which, stirred by the sea's washing and by the winds, have gradually grown together into heaped mounds of sand. And in many places along the seacoast a great many mounds of this kind are found.

The fourth question. From what source does the earthy matter of the fields come to display such a variety of colors?

[Margin: Why the earthy mass of the fields displays such variety of color.]

For in some places the earthy substance is wholly black, in others red, yellow, or whitish and ash-gray. I answer that this happens in the following ways. Either it comes from sand in which the leaves of walnut trees, the nuts and their husks, or the growths of oak-galls have rotted and turned to earth, which at once tinges the moisture of the vitriolic earth present in it into the deepest black. Tawny earth, by contrast, has its origin from mountains teeming with ochre, sulphur, or sandarach, which, carried down into the plain, propagate there a tawny or golden earth. As for rust-colored earth, we learn even from its very color that it arises from mountains abounding in copper-bearing clods. Therefore, just as the waters of rivers are variously tinged by the different juices of minerals, so too the fields are filled with sand of whatever color the clod has from which it was scraped off. From what source the different mineral-veins acquire colors of this kind will be shown elsewhere. Black earth is best suited of all for agriculture; it is produced either from grass, herbs, and fallen leaves rotted and turned to earth — by which not only earth, but also (as likewise from the dung of animals) blood, is rendered black, thick, and rich in a remarkable way. Take this as proof of it:

cumuli, which they call *pulvini* (cushions), are found? I answer: this comes from the heaping-up of the sand and mud that the rivers deposit into the sea near their mouths in a gentle and quiet flow; while from the seaward side the winds continually drive the waves toward the mouths and shores. Hence the waves resist, so that the sandy material the rivers roll out into the sea is not spread further; and so the sands, piled into mounds, form those "cushions." From this it is clear that what was once sea is in the course of time taken over by alluvia carried in by the rivers, and is thereby augmented daily by the continual influx of material.

[Margin: How land once sea afterward becomes dry land.]

so that we may safely affirm that the low-lying regions near the sea were once sea, stretched far and wide; and conversely, that where the sea now stands, there

was once dry land. But since these matters have been treated very fully in the books of the First Volume, I have judged it unnecessary to repeat them here.

Having now set out these things — perhaps at greater length than was fitting — nothing remains except to examine, one by one, the lands of the materials we have mentioned, weighing as precisely as possible from what source each one derives its origin, its property, its virtue, and its use.

CAPUT II.

What Earth properly is, from what it is generated, and concerning the various earthy substances commonly called "Earths."

In the primordial constitution of things, the Earthen globe was buried, as it were, in a kind of caul, and was covered on every side by water, as the Sacred Text witnesses (Genesis 1). In it there were as yet no mountains, no valleys, no other distinct elementary body; rather, all things lay squalid and confused, uncomposed, beneath a kind of chaotic mass — until, once light had now been created and the Earth had been struck by the voice of God and the waters had been driven down into their channels, the dry land appeared. Yet it was still under a muddy substance, which nevertheless — by the working of the inner Archeus of fire — at once took on a certain hardness, and finally was molded into a kind of stony skeleton. This was so that the earth, remaining beneath the muddy mass, should not by its own draining-away and dissolution destroy the whole order and fabric of the receptacles and chambers necessary for nature's operations. And so, with the subterranean Vulcan at once at work, that soft mass was shaped by the hand of the Pantoplastes [the All-Former, i.e. God] into various concavities and hardened by the subterranean heat. This was the first stony structure of the Geocosm, established by God to give firmer solidity to the framework of the whole globe. But since in that stony mass there remained innumerable cavities, along with great protuberances of the higher parts destined for the formation of mountains, by the singular providence of God it came about that, while that mud was still unhardened, the said empty spaces and valleys were filled in, and the surface of the whole earthen globe and of the mountains was covered, as with a hide or skin, by this same still-moist and soft mud. In this way that primeval mass became fit to produce — when struck by the voice of God — the shoots of the field, the herbs, plants, sprouts, trees, and fruits; and this took place on the third day of the World. Such was the primordial state of the earthly World.

This being established, we must now see how in the course of time this earthy substance has been augmented, and what varieties it has undergone through the varied influence of the Sun, the Moon, and the stars, and likewise of the subterranean fire and waters — and what Earth itself is according to its essence. For once these things are known, I am confident we shall easily arrive at a knowledge of the hidden workings of the Geocosm.

First, however, I want the reader to know that here we do not take "Earth" to mean that simple, uncompounded earthy body which the natural philosophers are accustomed to call an element — and which, as I denied above, we hold not to exist in the nature of things — but rather, properly, the elementated earthy substance, which we define thus:

[Margin: Definition of Earth.]

Earth is a mineral body [*corpus fossile*] which, when moistened by something wet, first softens, and then, with further moisture, becomes liquid. By this definition all those things are excluded which, though they soften when wetted, do not become liquid — such as paper, wool, and the like. Excluded too are stones and metals, which, when water is poured on them, neither soften nor melt. Therefore take it as certain that whatever is dug up, and on the addition of moisture first softens and then liquefies, is to be called Earth in the proper sense.

The first question, then, is asked: **How is this earth generated?** To resolve this difficulty, one must know that this earth can be generated on the outer surface in two ways and by two methods.

[Margin: The third generation of earth(?) [*Tertia generatio* — χθονογένεσις (chthonogenesis, "earth-generation")]]

First, this earthy substance is generated in the manner stated a little earlier — partly by the wearing-down and corrosion of stones and of clods of minerals, and partly by that of the rains, downpours, and waters, or of streams gliding through the channels of the mountains. By this action the sandy stones and the friable substance of the mineral clods are eaten away and carried off by the force of torrents and rivers: partly led down into the flatter places, partly clinging to the cavities of the mountains and to the rough slopes and crevices, and gradually turning into earth, it sprouts into herbs, plants, shoots, and trees — which is nature's one and only purpose in the lands. In this way sandy earth arises. Besides this, there is the earth which is scraped by the river's course from the walls of the banks, and which partly settles to the bottom, partly is carried out onto the fields by the river...

driven off by the force of the waters, lays down nurseries of new earthly matter.

But this method seems by no means sufficient to account for the whole process of earth-generation [χθονογένεσις]. For since this earthy matter is found over the entire surface of the earthly globe — being indeed that without which the cultivation of the earth would be useless — it must be held, by a sure and infallible argument, that there exists some other earthy substance besides the one that comes from the detritus of stones and the carrying-in of rivers. For we see, in plains stretched far and wide, in places overgrown with tamarisk and heath, where there are neither mountains nor rivers that could bring in heaps of fallen sand, that abundant and very rich earth is found. And granting that some such places are watered by rivers, I nevertheless say that these places — just as they lack the barriers of mountains — are likewise, because of their flatness, not so liable to floods, and consequently do not draw in the sands and mud by which the vast expanse of the flat fields could be filled.

[Margin: How earth is generated in flat places(?) [*Ex plani...ebus ma...*]]

Indeed, experience teaches that ditches dug in plains of this kind are, after the passage of some years, filled with new earth. From what source, then, this kind of earth — which arises neither by the carrying-in of rivers nor by the abrasion of mountains — comes to be born, must be investigated.

Again, in the plains of very high mountains — indeed on the very summits, where some are furnished with a level place, as I have very often had occasion to observe — a most abundant and very rich clod of earthy matter, most fit for pasture, is found. Yet it cannot have been gathered and heaped up either by the wearing-away of the mountain rocks or by the corrosion of rivers, which are by no means found there. Indeed, if you dig up the earth, you will always find new earth upon new earth — not caked into sandy crusts, not divided by gravelly and pebbly seams, but consisting in an even and homogeneous extension of its parts; unless, however, the earthy [matter] has been disturbed by the intrusion of clods of various minerals [χθονογένεσις/ἀλλογένεσις? — ἀλλογενῆσις? printed γρ.; "of-foreign-generation"], in which case it will generate black, yellow, or somewhat dusky earth, as will be said later. From what source, then, this kind of earth — which is produced neither by the wearing of waters nor by the corrosion of mountains whose rocks are dissolved into sandy particles — obtains its origin, we must inquire with all the keenness we can.

[Margin: Rotted herbs, grass, and leaves turned into earth by rains and snows.]

I say, then, that this can come about, first, from the annual decay of the grasses, herbs, shoots, leaves of trees, and the like scattered by the winds, which spring up in rich growth both in the said plains and on the higher levels of the mountains. Once turned at last into earth, these augment the earthy matter, made fertile by the salt and fattiness implanted in them. And just as this happens every year, so it is likewise necessary that the plains be enriched by the increase of new earth. For that the earth is moistened by the Sun, the grasses, the plants, and the winter snows or rains — and that the leaves, grasses, and herbs softened and rotted by the winter rains or snows are turned into earth, around the beginning of November — this experience teaches; and indeed it is so commonplace that I am ashamed to say more about it. But that the earth contains within itself the implanted seeds of grasses and plants — the following experiment will show.

EXPERIMENT I.

Fill a glass flask halfway with the purest earth, contaminated by no admixtures of other seeds, and in springtime expose it to the air in a very high tower, far removed from dusts laden with various mixtures of seeds; fit it with its lid furnished with a tiny hole through which the air can penetrate. After a month's interval you will find that the earth has produced a plant of the kind that is native to your region — clear proof that something lies hidden in the earth that produces plants. This we say is nothing other than the fertile power of the salt of the earth mixed in, by whose help the earth, when watered and quickened by the Sun's heat, soon bursts forth into shoots. All of this is greatly promoted by the salt implanted in the rotted grasses and plants, which of its own nature is inclined to regenerate that which had been in the living grass.

[Margin: A plant, or its seed, can be drawn out from the salt drawn from a plant(?) [*Sal herbarum extractus seminatur... herbam herba(?)*, *ex qua extractus fuerat, sal producit(?)*]]

For if you reduce some herb (as we said earlier) to salt, and extract the salt and put it into the earth, it will produce an herb of the same species as the one from which the salt was drawn — as the following experience has taught me. Concerning these miracles of nature I shall speak more fully in their place in the following books. But since in many places where there are no trees to supply fallen leaves to the earth — indeed, within the crevices of mountains and the innermost bowels of the earth — earth of this kind is everywhere found to grow, it now remains to be explained [how].

[Margin: How earth is generated within the crevices of the mountains and the summits of the mountains.]

In the preceding books we taught at length about the inner economy of the Geocosm, agitated by the force of the subterranean fires with perpetual exhalations and vapors, which, with great impetus, perpetually breathe out from the tubular substance of the earth and the mountains, and through the innumerable fibers and crevices by which the Earth is perforated — no otherwise than the human body is full of capillary veins. Hence it comes about that the vapor mixed with exhalations, within the said crevices, fissures, and passages, always carries off with it something scraped from the stony or mineral substance; and this, afterward condensed within the said passages, or on the mountain summits as moisture is added, passes into earth of the same species as the stones or minerals it has worn away. For, as was said above, if anyone makes a ditch in the level of the said earth, he will find it filled with new earth after some years — for the moisture, with soot added, forms a mud, by which the earth is augmented by a perpetual addition. But since these things cannot be better proved than by experiments, we present the following to the reader.

EXPERIMENT II.

On the generation of earth in flat places out of the mountains.

Diagram. A pot-bellied glass vessel (an alembic-like cucurbit) with a narrow neck, set upon a grate over an open fire; flames rise from below and a small plume of vapor issues from the top of the neck. The figure is uncaptioned and illustrates Experiment II.

Take a pot-bellied vessel furnished with a narrow mouth, fill it halfway with ordinary earth, then set it over a fire and let it give off its exhalations. The earth, having taken in the heat, will at once be resolved into smokes mixed with vapor. When this has been done, you will find around the narrow part of the mouth a kind of niter-like material, which had accreted to the vessel out of the little bodies of the smoke and vapor condensed there. And this, when ground up, will at once reproduce — in odor, in taste, in color — the earth from which it had been drawn out. It is therefore clear that in the same way, on the surface of the earthly globe, earth is generated from the smokes and vapors concreted at the mouths of the earthly pores; for these, afterward diluted by rains and showers, pass into earth properly so called. And since smokes and vapors of this kind endure perpetually, it follows of necessity that the effect proceeding from them is likewise perpetual.

CAPUT III.

From what source so great a diversity of Earths arises.

In this place the true cause of so great a variety of Earths must be explained. That this may be done with greater method, we shall first set out a few species of earths.

Earth, considered simply — if you consider its primary and secondary qualities — is as follows:

It is either:	Simple(together with the means / intermediate degrees between them)	If you regard its substance:	Thin, dense.Rare, [dense].Soft, hard.Heavy, light.
		If you regard its colors , it is either:	White, black.Yellow, ash-gray.Red, purple.Green, somewhat reddish.
		If you regard its taste:	Sweet, bitter.Sharp, tasteless.γλυκόπικρος [Greek: glykopikros, "bittersweet"], harsh/austere.

These, then, are the differences of earths, which are partly simple, partly compound — either mixed with mineral juices (as their colors show) or infected with stony filings. These, mixed and combined among themselves, exhibit an almost innumerable variety of differing earths. For if you combine the 12 simple differences of earth among themselves, there will arise 479,001,600 differing mixtures of earth, as appears in the margin; and as has been amply shown in our *Ars Combinatoria* [the *Ars Magna Combinatoria*], by which, if you join the metallic earths to them, there will then be no [end to the] number of Combinations. So you need not wonder that so great a variety of things, and so great a multitude of differing earths, is found.

[Margin / table — factorials (the "Combinations"):]

n	Combinations (n!)
1	1
2	2
3	6
4	24
5	120
6	720
7	5040
8	40320
9	362880
10	3628800
11	39916800
12	479001600

Having set out these things in passing, let us now proceed to that which we promised at the outset — that is, to investigating the causes of so great a variety.

The question, then, is asked: from what source do so great differences of the species of earths derive their origin? That I may solve this question as deeply as possible, I suppose, first, from the earlier Books, that subterranean Fire is diffused through the viscera of the entire Geocosm, animating all things by its power. I suppose, second, that in the inmost bowels of the earth there are diverse substances — whether earthy, or stony, or mineral — upon which the fire acts continuously. I suppose, third, that these materials, agitated by the fire, emit abundant exhalations and smokes, that is, vapors, from themselves. I suppose, fourth, that the whole Earth is tubular, veined, and furnished with innumerable fibers running through the entire body of the Geocosm.

These things being laid down, I say that a twofold exhalation-and-vapor can here be considered: one which is excited by the subterranean fire within the bowels of the earth; the other which is drawn up by the attraction of the Sun out of the earthy portions, out of the Ocean, the seas, the lakes, the rivers, and the pools, into the higher regions of the air. It now remains for us to prove that each of the two is fit for generating earth. And so, that I may begin from the manifold concurrence of causes in the generation of earths — I say, besides the cause already stated in the preceding pages, that many more concur [in the *χθονογένεσις*, the earth-generation], and that earth can therefore be generated in diverse ways.

[Margin: The first mode of generation of earths.]

The first mode of $\chi\theta\omicron\nu\gamma\acute{\epsilon}\nu\epsilon\iota\varsigma$ (earth-generation) is caused by the diversity of the earth lurking in the womb of the Geocosm, whether pure or mixed. If, then, the subterranean Heat acts upon earth of this kind that is pure... ..pure [earth], the earth itself, thinned out, emits exhalations from itself. These are the driest little bodies. When the earth is thinned by the force of heat, these particles are dissolved and led off through the cracked fissures, clefts, and veins of the earthy mass. Wherever they encounter a moistening stone or earth, they mix with it and are converted into an earth of the same property as the earth from which they exhaled. But if a more impure earth, thinned by fire, has been dissolved into smoky particles, those particles, joined to a moist vapor within the hollows or clefts of the mountains, will generate an earth of the same property as the impure earth: if the earth was pure, a white earth; if impure, a clayey earth and the like; and if exhalations of this kind from a bituminous earth have been mixed in, then a rich and combustible earth will be generated, in proportion to a gentler or a more vehement heat.

The second mode depends on the configuration of the places, or of the underground siphons. For if the exhalation of the earthy masses passes with great force through the narrow and constricted paths of the channels, it will always strip something away by corrosion from the masses—whether stony, mineral, or earthy—as was made clear by the earlier experiment. From this the exhalation, carried up to the surface, will generate an earth filled with little stones, sands, and scaly clods. But if it passes through caverns, then, mixed with moisture, it will produce an earth of the nature of the cavern itself, filled with minerals. [Margin: The second mode.]

The third mode depends on the mingling of the exhalations and vapors. For from these, when well mixed, there is born a rich earth, well compacted and without fissures, cohering throughout; but from the same when not well mixed there is born an earth utterly contrary to the former—gaping, full of fissures, and riddled with pores. [Margin: The third mode.]

The fourth mode. If the exhalations pass through the fibers of mineral matter, then, joined to a binding vapor and proceeding along the usual fibers, they will produce—in proportion to the minerals—an earth: here coppery [aerosam] and green, there sulfurous, elsewhere ferruginous [ferrugineam], somewhere saline or nitrous or aluminous or vitriolated or mercurial, and so on with the rest. [Margin: The fourth mode.]

The fifth mode depends on the power of the Sun. For the Sun, striking with its heat the outer surface of the Geocosm, dissolves the earthy portions into exhalations and the moist portions into vapors; and just as from the exhalations a great mass of salty little bodies, so from the moist portions a great mass of vaporous little bodies is borne up into the highest regions of the air. There, condensed and driven by the force of the winds within the ridges of the loftiest mountains and over the plains of the earthly regions, it is able not only to augment the earth but, over the long course of time, to generate it. [Margin: The fifth mode.] For just as the earthy substance is dissolved by the force of fire into dry particles, of which the exhalations or soots consist, so the moist substance is dissolved into watery particles, of which the vapor consists. [Margin: How earth is generated from exhalations of vapors, both inside the earth and outside it.] And indeed the smoky soot, kindled by antiperistasis [antiperistasin] in its proper region—either beneath ignited coal or in the form of some other burnt matter, falling down—is restored to the earth and converted into it. [Margin: ...made into...] [Lacuna: a short clause set in the margin is partly cropped here.] The vapor, however, snatching up along with itself a varied mixture of earthy matter, is dissolved in the upper region and, through rains, snows, and hail, the earthy portions implanted in the vapor are likewise returned to the earth and converted into it by a perpetual cycle [pericyclosi].

Nevertheless the first mode—by which, through subterranean fires, the earthy substance is dissolved into exhalations—is the more genuine one for the generation of earths. But lest anyone should perhaps seem to contradict this reasoning of ours, I have judged it right to confirm it by the following experiments.

Diagram. An apparatus for demonstrating earth-generation, set over a fire. At the bottom, a broad cooking-pan or crucible (**A**) sits upon a grate over burning coals; flames (**V**, **S**) rise around it. Above the pan, suspended, is a bell- or dome-shaped receptacle (**B**), into which several small tubes are fitted (**C**, **D**, **E**), tapering to fine points at their ends. The whole assembly rests on a hatched base-board. The pan is filled to its middle with somewhat moistened earth; as the earth is dissolved into exhalations, these pass up into the receptacle and condense as soot in the tubes.

- A (lower vessel, in the pan over the fire): the crucible *tigillum*, filled with moistened earth
- B (upper, bell-shaped receptacle): the dome-shaped receiving vessel
- C, D, E (small tubes fitted into the dome): the fine exhalation-tubes

- V, S (flames at the base): the fire and coals

EXPERIMENT. [Margin / heading.]

Showing the cause of earth-generation [χθονογενέσεως] to the eye.

Set over a fire a broad crucible **A**, filled to the middle with any somewhat moistened earth. Above the crucible let there be suspended a receptacle **B**—made of fired clay, of iron, or of any other material whatsoever—formed in the shape of a bell, into which small tubes **C D E** are fitted, finer toward their ends. Then, with the fire **V** kindled and the coals **S** heaped around the crucible, at once the earth, dissolved into exhalations and passing into the receptacle, will there—inserted into the tubes—pass off into soot; and this soot, joined to a vapor, will pass off into an earth of the color and quality that the earth placed in the crucible possesses. [Margin: The variety of earths is tested by the experiment.] For if the earth was white—like chalk, Samian earth, and the like—it will pass off into white soot; if it was a rich and bituminous earth, into black; if sulfurous, into tawny; if coppery [aerosa], into green soot; and so the same judgment holds for the rest. These soots, then, joined together with moisture, degenerate into an earth—the very earth from which they exhaled. For exhalations of this smoky kind, driven through the pores and innermost fibers of the earth and lying hidden on the surface beneath an imperceptible dust, degenerate into earth through rains, dew, frost, and snow.

In just the same way the chemists, by means of the said instruments, are accustomed to find soots, tutties [tutias], and metallic flowers within their receptacles and bell-shaped cones; and at times they likewise find from similar soots a great abundance of mercury [hydrargyri], which is a plain sign that this lay hidden within earthy and combustible substances. For what else...

[Printed page 337 — recto. Running header: HYLOCINESIS GLOBI TERRESTRIS.]

are the soots of chimneys but the lightest little bodies, separated by the force of fire from the vapors of wood and other combustible things, packed together on the walls of the chimneys—the substance we call soot, which, kneaded with moisture and then dried out, presents a black earth. [Margin: Why so great a variety of earths in one and the same region.] [Margin: Description of Samian earth.]

COROLLARY I.

From these things it is clear whence the metalliferous earths derive their origin. For many people are amazed when, now here, they find a salty, or nitrous, or

aluminous, or vitriolated earth; now another kind elsewhere; sometimes a whole region wholly congealed with sulfur; sometimes another place filled with bitumen or naphtha, with red ochre [rubrica] or yellow ochre, and so on with the rest. Yet if these people knew the process of nature, they would cease to wonder. For since superficial earths of this kind have, in their innermost recesses, an abundance of the very materials they exhibit, and since these materials, dissolved into exhalations by the force of heat—just as like always and successively generates its like—are likewise exhaled through the pores and fibers of the earth and propagated all the way to the outermost surface by a continued heaping-up of soots: therefore, even if imperceptibly, they nevertheless augment by their accession and accretion the outermost earth, of whatever species it may finally be.

COROLLARY II.

From this it is likewise clear how it is that rocky mountains, which are worn down by the perpetual ravages of rains and snows, nevertheless do not appear to have diminished over so many thousands of years. [Margin: Why mountains, though perpetually worn down, are not diminished over so many years.] The reason is that the sooty exhalations, propagated through the innermost fibers of the mountains all the way to the outermost surface, there—by means of a petrifying juice, or of an ambient moisture mixed with the same—accrete to the rocks. But of these things a fuller occasion for discussion will be given in what follows, when we come to reason about the genesis of stones.

CAPUT IV.

On the Use of the Various Earths.

The earthy substances we touched on a little earlier have an altogether manifold use among the practitioners of the various arts; these uses we shall set out in order. And first of all there are some highly esteemed by physicians on account of the remarkable virtue they possess against poisons.

USE THE FIRST

Of certain earths in medicine.

Among the other earths, the most celebrated at all times have been: Samian earth, Lemnian earth, Armenian bole [Bulus armenus], and—in later times—Maltese earth [Melitensis], Majorican, and the like, which are to be treated of in order.

Samian earth, so called from Samos, an island of the Archipelago [the Aegean], in which it is dug, in Theophrastus's [Theophrasti] time had a vein extending lengthwise, two feet in depth and much greater in width. On either side the earth was hemmed in by rocks, from which it was separated. In the middle it had a vein of the finest quality, like marrow; then other and still other veins, marked off by a stony bedding, yet of intermediate virtue and inferior. Two species of this earth, moreover, were found in the Samian pits, according to Dioscorides [Dioscoride]: one called by the name *Collyris*, the other *Aster*. The former cured infirmities of the eyes, and was deservedly called most excellent—κατ' ἐξοχήν κολλύριον [Greek: kat' exochēn kollyrion, "an eye-salve par excellence"]. The other, *Aster* ["star"], was so named either because of a star-shaped figure impressed on it, or because of little golden grains of sand, shining like stars, that were seen inset within it. [Margin: Samian *Aster* differs from Samian earth.] Those people are mistaken who confuse this most white Samian earth with the Samian *Aster*, that is, with talc; for, as they say, the two differ "by a whole sky"—of which elsewhere. Both are astringent...

[Printed page 338 — verso. Running header: LIBER SEPTIMUS, Sect. II.]

I hear that the secret and guarded place is kept under watch; nor may anyone take anything out of it under penalty of death, except those whose office it is to dig it out and to form it into lozenges [trochiscos] stamped with the seal of the Pasha [Bassae], the Vizier [Vezirii], or even the Emperor's [Imperatoris] seal. So that many doubt whether this Sealed Earth [Sigillata terra] is the same as that ancient Lemnian one. For my part, even if it is not entirely the same, at least it is not of a wholly different nature, as is recognized from its effects—since it too shines with a red color no differently than that ancient earth; and from this they used to call it red ochre [rubricam], and "tinged with the blood of a goat," which, however, Galen [Galenus] derides as an old wives' tale of the common folk, but proves by many arguments that it consists in its native redness—the same redness of which the sealed earth of modern times also consists. [Margin: The medical virtues of Lemnian earth.] Its medical virtues are today the same as in the ancient earth. For against deadly poisons it has the virtues of an excellent antidote when drunk with wine; it expels poisons that have been swallowed by vomiting; and it heals the lethal stings and bites of serpents. But of its virtues and medical use, see Dioscorides, Pliny [Plinium], Galen, Matthiolus [Mattioli], and others.

Cardanus [Cardano] asserts that a sealed earth endowed with the very same virtues can be made by art, if one reduces common clay to a powder, [mixes it]

with water of *scordium* in which juniper seeds have been boiled, [bakes it] under fire, and shapes it into lozenges. Not long ago, Christoph Schorer [Christophorus Schorer], prefect of the territory of Lucerne, sent me from Switzerland—where it is dug—an earth similar to the Lemnian, which he holds to be the true earth described by the ancients. On account of the excellence of its virtues, he writes that a certain fellow-citizen prolonged his life to a hundred years by it. But on to other matters. [Margin: Armenian bole and its virtues.]

Armenian earth, which they also call **Armenian bole** [bolum Armenum]—that is, a clod brought from Armenia—although it presents the appearance of a stone, is nevertheless quite soft and friable; and because it dries very powerfully, therefore, according to the opinion of the physicians cited, it cures gripes [tormina], colic, dysentery, hemorrhage, rheums, and phthisis [consumption]; in pestilential diseases, ulcers of the lungs, and asthma it is wonderfully helpful. Against corrosive poisons too, such as those of cantharides, and against the putrefying poisons of the sea-hare [*lepus marinus*], it is a remedy—not so much by its dryness and fineness as by a certain specific virtue and salutary quality. But since the said earth can be debased by the manifold fraud of merchants, careful attention must be paid to how the false is to be distinguished from the true, and by what signs; on these matters consult the pharmacists.

Maltese earth [Terra Melitensis] is endowed with exactly the same faculties as the preceding, and is dug out from certain districts of the island of Malta near the sea, not far from the old city and by the grotto of St. Paul [cryptam S. Pauli], from which I myself dug out with my own hands no small quantity, together with glossopetrae [glossopetris, "tongue-stones"], of which most fully in their place. [Margin: The earth of St. Paul on the island of Malta.] This earth is most white, and is stamped with various figures of saints; it has a great power, in driving off whatever diseases are infected with a venomous quality, not so much by a natural [power] as by the privilege and benediction of St. Paul [Divi Pauli]—imparted to it, as one may piously believe—and with this virtue it is endowed.

[Margin: Various species of earths.] There are also other species of earths—for example: ochre [Ochra], red ochre [Rubrica], *Sile*, Eretrian earth [Eretria], Chian earth [Chia], *Selenusia*, Cimolian earth [Cimolia], *pnigitis*, Melian earth [Melia], *ampelitis*, Puteolan dust [pulvis puteolanus], chalk [Creta], clay [argilla], Apulian mud [Lutum Apuliae], *Myrrhi*, porcellaneous earth [Porcellana], Majorican [Majorica], Tripolitan [Tripolitana], and innumerable others, each of which has for the most part taken its name from the places in which they are dug.

[Margin: Ochre.] **Ochre**, called *Sile* by the diggers, is a tawny fossil earth, not unlike orpiment [auripigmentum], now of a yellow or somewhat-pale color—called ὄχρα [Greek: ōchra, "ochre, pale-yellow earth"] by the Greeks—and is reckoned among the pigments; and it is both native and artificial. [Margin: Red ochre.] The native kind is found not only in metallic [veins] but also in its own proper veins, especially in copper and lead mines, of which kind there are in very many places of Europe, and most of all it is dug in Germany. This ochre, then, is made in various ways. [Margin: How ochre is made.] First, lead is cast into an oblong glass flask, the flask is set upon a furnace, fire is applied beneath, and it is cooked for so long until the ochre has taken its color—the color which painters mostly use. In Germany I observed it made thus: they burn the lead and steep it, then burn and steep it again, and by this continued and repeated labor until they arrive at that color suitable for pigments which they desire. It is also made from red ochre [rubrica] in new pots smeared round with clay—everywhere of a quality so much the better the longer it is dried in the kilns.

[Margin: The transmutation of ochre into red ochre.] Now these two earths, ochre and red ochre, seem to be transmuted into each other by a kind of reciprocal conversion. For from burnt ochre is made the friable [saltilis] red ochre which workmen use in marking lines, when a cord soaked in red ochre of this sort is snapped against wooden boards and beams by vibration. But since ochre is turned into red ochre by the action of a vehement heat, I do not see how it could be turned back from red ochre into a less intense color. Therefore I judge it to be a sheer and downright illusion of the eyes, by which, when they cook ochre out of red ochre, they are deceived by the disparity of the colors. [Margin: Various species of earths.]

[Margin: Paretonian dust.] **Paretonian dust** [Pulvis paretonius]—what it truly and properly was in former times, since Pliny and Vitruvius [Vitruvius] disagree with each other, so likewise to this very day what species it was is unknown. This much is known: that it was most used by painters, and was brought from Egypt and the island of Crete.

Concerning Puteolan dust [pulvis Puteolanus], which turns to stone when immersed in water, more will be said at greater length in the following Section. For now let us proceed to describe the other species of earths.

Earths Useful or Useless to Agriculture.

Nine species of earths are found, observed by farmers, which are afterwards subdivided by a manifold variety of kinds; for the earth is either:

1. Rich or lean [Pinguis aut macra]. The former [the rich] is by nature sweet, fertile, uniquely desirable to farmers, fit for producing all crops, and moderately black.

2. Lean [Macra]...

[Printed page 339 — recto. Running header: HYLOCINESIS GLOBI TERRESTRIS.]

The following table sets out the nine species of agricultural earths with their characteristics and the crops each favors. (The first species and the opening of the second are carried over from the foot of the preceding page.)

No	Species	Character and suitable crops
1	Rich or lean [Pinguis aut macra]	(Rich:) sweet by nature, fertile, uniquely desirable to farmers, fit for producing all crops, moderately black.
2	Lean [Macra]	Lean, by contrast, since it has contrary qualities, is either beneficial or [harmful] accordingly.
3	Rich and thin [Pinguis & rara]	Rich and thin—both for its goodness, and because it is easily ploughed—is especially welcome to farmers.
4	Rich and dense [Pinguis & spissa]	This, even if on the one hand it promises a yield by its richness, on the other is difficult to cultivate and of less desire.
5	Lean and dense [Macra & spissa]	This, on account of its stony clods, promises its cultivators nothing much besides thorns and caltrops [thistles].
6	Moderately rich [Pinguis mediocriter]	Of the seed-kinds it loves spelt [filigo] and barley most; of legumes, the broad bean, flax, chickpea, hemp.
7	Moderately lean [Macra mediocriter]	It loves lupines and oats; unsuited to bearing crops of richer juice.

No

.	Species	Character and suitable crops
8	Moderately dense [Spissa mediocriter]	It loves turnips, radishes, oats.
9	Moderately rich [Pinguis mediocriter]	Most suitable for sowing all crops and legumes.

And these species of earths are either sweet or bitter, sharp or harsh; and as to colors, they are black or white, yellow or red, dusky or ash-colored. From these signs farmers chiefly infer which plant of whatever kind a given earth especially craves. But earths imbued with metallic juices and mixtures, since they eat away the roots of plants and induce corruption, are rejected by farmers. Sandy earths, too, and those filled with gravel and grit, just as they are suited to bringing forth thorns and caltrops, so likewise are for the most part rejected by farmers as useless.

[Margin: Why wheat or barley is sometimes transplanted into spelt and oats.] And from these things it is clear why wheat or barley, when sown in certain soils, is converted into spelt, and in others into oats. The reason is ready at hand: since these two grains crave the richest soil, it happens that in a meager and sterile field, filled also with metallic juices, they do not find the sufficient moisture they need; and therefore, with their nourishment failing and their roots consumed by the sharpness of the juice, they must of necessity degenerate from their natural goodness and decline, their seed degenerating. But which earth is fit for sowing each particular thing, the farmer may recognize from the herbs springing up there, by using these rules: [Margin: By what signs it is known which earth is fit for sowing what.]

First. If any field of itself produces black, bitter, and meager herbs, you may say that the earth is of the same property.

Second. If you find it abounding in rushes, reed, sedge [cyperus], and the like, they call it a marshy [uliginosam] earth, choking the seed with abundant moisture.

Third. If it produces buckthorn [rhamnus], Christ's-thorn [paliurus], and thorny offshoots, you may say it is most difficult to cultivate, inasmuch as it burdens the rakes and ploughshares with huge clods; but otherwise it is not unfit for sowing crops.

Virgil [Virgilius] indeed, in the *Georgics*, admirably describes the qualities of earths, which I have thought it would please the reader for me to set down here. And concerning the temperaments of earths he writes thus (*Georgics* 2): [Margin: *Georg.* 2.]

Nor truly can all earths bear all things: By rivers grow willows, and alders in thick marshes; Barren ash-trees [orni] are born on rocky mountains; The shores rejoice most in myrtle-groves; and finally open Hills Bacchus loves, the yew the north wind and the cold.

[*Georgics* II.109–113, here lightly compressed.]

[Margin: *Georg.* 1.]

Here crops, here vines come up more happily, Elsewhere the increase of trees, and the grasses grow green unbidden.

[*Georgics* I.54–55.]

Concerning the signs of lean and rich earth, of thin and dense, of salty and bitter, of moist, heavy, light, he sings thus: [Margin: *Georg.* 2.]

Difficult first of all are the earths, and the malign hills, Where there is thin clay and gravel in the brushy fields; [Yet] they dare to bear the Palladian woods [the olive] of the long-lived olive. A sign is, in the same tract, the wild olive [oleaster] springing up Most plentifully, and the fields strewn with wild berries.

But where the soil is rich and glad with sweet moisture, And the plain frequent with herbs and fertile in its richness— such as we often look down upon in the hollow valley of a mountain— here streams are snatched from the topmost rocks and draw down a fertile slime; and that ground which, raised toward the South wind, feeds the fern hateful to the curved ploughs.

[*Georgics* II.179–189, with minor variants in the source's text.]

Concerning the marks of a black and fertile earth he sings thus:

An earth that is generally black and rich beneath the pressing ploughshare, and whose soil is crumbling—for this is what we imitate by ploughing— is best for grain.

For indeed the hungry, sloping subsoil of a stony field scarcely furnishes the lowly bees with lavish casia and rosemary; and the rough tufa and the chalk eaten away by black water-snakes [chelydri]...

[the earth] that yet breathes out mist and flying smoke, and drinks in moisture, and—when it wills—gives it back from itself, and which always clothes itself in its own green grass, and does not harm the iron with scurf and salt rust: that earth shall weave for you broad elms with vines, that is fruitful in olive, that you will find by tilling kindly to the cattle and tolerant of the curved ploughshare. Such land does wealthy Capua plough, and the shore near Vesuvius's [Vesuvius] ridge.

[*Georgics* II.203–224, abridged; here the source telescopes several lines.]

Concerning a dense and thin earth he sings thus (*Georgics* 2): [Margin: *Georg.* 2.]

Now in what way you may distinguish each kind, I shall tell: Whether it be thin, or denser than is right, you should ask— since the one favors grain, the other Bacchus [the vine]; the denser more for Ceres [grain], the thinnest all for Lyaeus [Bacchus]. First you will choose a spot with your eyes, and order a pit to be sunk deep into the solid ground, and you will replace all the soil again, and level the surface flat with your feet. If [the soil] falls short, [it is] thin, and more apt for cattle and the kindly vines; [if it overflows...]

(continuing *Caput IV*, "*De Usu variarum Terrarum*" — the agricultural uses of earths, after the Virgilian pit-test for soil density)

For this reason such earth must also be broken open every year with the plough, combed apart with the harrow, and turned over thoroughly up and down, so that by this treatment the individual parts may be tempered to an even balance, and the whole rendered uniformly good for germination once the seed has been cast in.

The second question. Why does manure [fimus] contribute so much to making earth fertile? And why manure of one particular kind rather than another? For there are certain kinds of manure that do not so much fertilize the earth as scorch it, as the Poet rightly says (*Georgics* I [I.77–78]):

A crop of flax scorches the field, the oat-crop scorches it, and poppies steeped in Lethe's sleep scorch it too; yet the labor is light if alternated, etc.

The cause of the fertility that fields acquire from manure is the very fermentation of the excrement in the stables, which the saline and nitrous spirits, as it were, concentrate.

[Margin: How fattening matter is generated in the earth.]

For just as urine, mingled together with the excrement of animals, is utterly full of salt and niter, so — when dissolved in a damp place, as we have shown in the case of salt and niter — it acquires a certain fatness [pinguedo], which is drawn out by sympathy from earth filled with a like fatness. And so the earth, augmented by this doubled fatness, if it is already rich of itself, soon runs riot with an abundant production of seedlings; but if it is rather lean, it is imbued by the external fatness of the manure with as much richness as suffices for bearing crops. This fatness is plainly demonstrated by manure-pits, whose surface is always covered with a kind of greasy film painted in various colors — the signs of latent salt and niter. You will find this same film, in time, in the excrement of any animal soaked in water and thoroughly mixed.

The third question. From where does the earth always draw what is most suited to itself? To grasp this, it seemed best to begin a little further back. I say, then, first, that the earth possesses a certain magnetic power [vis magnetica] — not that power by which iron is drawn by the magnet, but the power by which, according to a certain analogy, like is drawn to like.

[Margin: In what this power consists, by which like draws like.]

This magnetism the admirable providence of the divine Architect of the Cosmos [Cosmotectus] handed down and implanted in the whole globe of the Earth, for the purpose of perfecting the generation of things — to this end: that things heterogeneous might be separated from things homogeneous, and these from those, and that things might be joined in friendly fellowship by their kindred nature [syngenia] for the good of nature, the heterogeneous being avoided. For just as everything dry draws by a natural force innate in it the moisture suited to it, so everything fixed draws its own volatile component. Again, just as the volatile spirits of all things reside in the air, so the fixed parts of all things reside in the earth. And just as every day they are dissolved, partly by the subterranean fires, partly by the Sun — that heavenly fire mingled with them — through attenuation, and the finer parts (which are the most subtle and lightest corpuscles, that is, the spirituous substance) are separated from the earthy and fixed parts: so, lest the earth in time be consumed by the emission of so many

spirits, a certain power was necessary to it, by which spirits thus separated might be rejoined to their own bodies from which they had flown off.

[Margin: The magnetism of Nature.]

That power is nothing other than the appetite of things, by which each thing desires to reunite itself to its own body from which it had been separated. Hence those spirits — the most subtle corpuscles with which the air is filled, separated out from the substances of all things — whether they are carried down to the earth by the blowing of winds, or by rains, snow, or hailstorms (it makes no difference), are at once linked together, each drawn by its admirable magnetism to its own like, proportioned to it.

The fourth question. How is spirituous substance of this kind separated from fixed things, and from which things, and how is it afterward reunited? To resolve this, it must be observed that the earth behaves after the manner of a fixed and material principle, from which, as from a root, all things sprout forth, and from which every birth of seedlings, shoots, and plants takes its origin, according to the variety and manifold difference of these — for not just any earth is proportioned to producing just anything.

[Margin: How the attraction of things by nature takes place.]

So when an herb germinates, or any other vegetable, two things — from the doctrine already set out — concur in making such a body grow by vegetation: first, a certain fixed, solid, corporeal, and stable part; then a subtle, spirituous, lively part, which has the character of a formal principle. Hence it comes about that the earth, pregnant with spirits of this kind, once it has wedded itself to moisture, soon — the foetus as it were conceived, and the heat acting as paranymp[h] [bridal attendant] — unfolds outward into seedlings, and, according to the manifold nature of the seed latent within the earth, now this, now that vegetable is produced.

Again, since the Sun is accustomed to attenuate things, it comes about that always some part of the seminal portions of plants is committed to the air in resolved vapor. This, condensed afterward by the nocturnal cold, is drawn down to the earth — by dew in summertime, but at other seasons by rains, snow, and hail — and is restored, drawn back by the aforesaid magnetism to the body proportioned to it from which it had been cut off. And in this way the volatile component is restored to its fixed component. There is another mode, which we hinted at in the preceding passages: when vegetables, of whatever kind they may finally be, stripped of their leaves, flowers, and fruits, are restored by the annual

law of Nature to the earth from which they had come. It happens most often that, soaked and rotted by rains and snows, they are at last turned into earth. But since the several kinds of vegetables abound in the species and spirits of all vegetables — inasmuch as these are proper to their own plants — once soaked and fermented by rains and snows, they confer new strength upon the earth, and an increase both of volatile and of fixed bodies. For if this did not happen, the earth, its spirits gradually consumed and exhausted, would necessarily perish. From what has been said, then, it is clear that this kind of recirculation [pericyclosis] has been opportunely established by nature.

The fifth question. How is the earth made fertile by the ashes of shoots and grasses burned in the fields? It might indeed seem astonishing to some that, from destructive things —

[Margin reference: Virgil, *Georgics* I — continuation of the citation begun on the previous page] If it overflows, the earth is dense; the clods will be sluggish in your hands [?], and the soil will rise above the pits once they have been refilled. Then turn over the fat clods straightaway, and the heavy ridges, and plough the earth up with strong young oxen.

Of the salty and bitter earth he sings thus (*Georgics* II [II.238–241]):

But the land that is salty, and called bitter — unlucky for crops, and not gentled by ploughing, which keeps neither the kind of the vine nor its names in the apples [?] — will give its proof in a plain taste, and will twist the mouth of those who try it with a foul bitterness.

Of the signs of rich earth (*Georgics* II [II.248–250]):

Likewise, by this test at last we learn which soil is rich: never, when tossed in the hands, does it crumble apart, but, when handled, grows sticky to the fingers like pitch.

Of the signs of moist, heavy, light, and black earth he sings thus (*Georgics* II [II.251–256]):

Moist soil feeds taller grasses, and is itself too broad — ah, may it not be over-fertile for me, nor show itself too vigorous with the first ears of grain! The heavy earth betrays itself silently by its very weight, and the light likewise; it is easy to learn the black by the eye, and any color. But to search out the accursed cold is hard: only the pitch-pines, the harmful yews, or sometimes the dark ivy, reveal its traces.

For the rest, see Pliny [the Elder], Palladius, Columella, and the other authorities on Agriculture.

CAPUT V.

Of the things required for the cultivation of fields.

Now that the qualities of earth, and their usefulness in Agriculture, have been reviewed, it remains for us to say something about the ways in which lean earth may be reduced to fatness, and by what means farmers may remedy the defects of fields. For this, seven things above all are required: namely, marl [marga], manure, the plough, the harrow, fire, fallow, and the interruption of cultivation.

[Margin: Seven things are required for Agriculture.]

And as to the first:

[Margin: What marl is.]

By the name "marl" nothing else is here understood than rich and dense earth, most apt for fertilizing fields. For it is like a certain fat of the earth, or like a gland in bodies, with the kernel of fatness condensing itself there; and it is found in many kinds. One kind is white and fluid, not unlike the marrow of bones, whence it is also commonly called by the Germans *Steinmarck* [Steinmark], that is, "stone-marrow"; and it nests above all in metallic veins and in the joints of rocks, and is of great virtue in medicine, though of little in farming. There are then other species of marl that serve agriculture better, namely the tophaceous [tufa-like] and the sandy, and that which takes on the hardness of solid stone, like the Maltese earth [terra Melitensis]. These differ greatly in color, the reason for which was indicated above. The richer the marl, the greater the fertility with which fields are blessed; but the harder it is, the more years it lasts in possession of its native fatness. And let this suffice concerning marl.

The second requisite is manure, which — being of many kinds — does not all suit every earth. Some approve the manure of thrushes, doves, and hens, rejecting the more-than-due caustic [excrement] of swimming birds, such as the droppings of geese and ducks. Others hold that goats' manure takes first place, substituting in second place sheep's, then oxen's, and afterward that of beasts of burden — so that even from this it may be plain with how many dungs and excremental refuse there is need to sustain the life of wretched man.

[Margin: Fields must be manured, and why.]

The third requisite is the plough, with which the earth is to be turned over, so that the seeds committed to it may be better received, and the lower parts may be imbued with the spirit of light and air.

[Margin: For Agriculture there is need of the plough and harrow, and why.]

The third [recte: fourth — the harrow]. The harrow covers the seed-sowing with soil, to this end: that the seeds committed between the furrows may be safe, partly against the violence of birds, partly against the dryness of sun and air, and — endowed with and steeped in the earth's fatness — may at last, once rotted, grow up into seedlings.

The fourth [recte: a continuation of the requisites — fire]. To imbue lands with fatness, shrubs, leafy boughs, brushwood, ferns, broom, chaff, and stubble must be kindled and reduced to ashes, by which fields are fertilized in a wonderful way.

[Margin: What burning into ashes contributes to fatness.]

Virgil (*Georgics* I [I.84–85]) assigns five causes of this operation, where he begins:

Often, too, it has profited to set fire to barren fields and to burn the light stubble with crackling flames.

These you should read in the cited passage. We will a little later adduce the genuine cause, besides those that the Poet adduced.

The fifth. The alternating rest of fields is required to make the earth richer, as the Poet teaches (*Georgics* I [I.71–72]):

[Margin: How fields are improved by interrupting cultivation.]

Let the fields likewise rest by turns, idle, when ploughed, and suffer the field, hardened, to grow strong [?] in idleness.

And these are the requisites necessary for procuring the goodness of the earth. But, lest I seem in this place to discharge only the office of a rustic, I shall now — about to assign the reasons for the things mentioned — perform the office of a Philosopher.

The first question, then. From where is the fatness of the earth born, and why must the earth be ploughed and turned over, filled with manure, and covered over with ashes?

[Margin: The physical reasons for what has been said.]

I say first, that there is in the earth a certain native fatness, born partly from saline, partly from bituminous spirits — with which the whole mass of the earth is filled — compounded together. This fatness, clinging to the earthy masses, makes them fertile, in that fatness, clinging on, glues part to part; and then, with moisture coming on, it makes the earth at once dense and rich, most apt for the germination of grain.

[Note on numbering: the printed running header reads "Sect. II" on this page, but the chapter content has moved into a new Caput; see anomaly note in report.]

— such fire and ash that the fields may conceive some fertility; that this nevertheless happens, the experience of every place teaches.

That this secret of Nature may be laid open, we reason thus. Since both earthy things and vegetables consist, as has been said, of two parts — the volatile and the fixed — the sterility of earth can arise from either: either from a defect of volatile spirits, or of fixed ones. And the defect [of volatile spirits] can arise from this: either that the seedlings have already drawn off nearly the greater portion of the earthy spirits, having consumed them once they were drawn in together with the nourishment; or that, drawn off by the sun, they have been committed to the air. The defect of fixed parts, on the other hand, can happen either from the very gravel of the earth, or from the leanness of earth filled with sands, in which case the spirits can neither be contained nor condensed by nature's glue. Add to these that not just any part or species of earth is found fit for germinating and vegetating. How, then, fertility may be induced in earth that is destitute of it, must be laid open.

Since, then, ash — which is born from the burning of woods, shrubs, stubble, and crops — consists of the fixed parts of vegetables (while the finer parts of the fixed are resolved into vapor by the attenuation of fire, the fixed parts remaining, which, because of the abundance of salt and the fermentation accomplished by the mixture of humid moisture, acquire a certain fatness), it comes about that that earth, reduced to leanness, is fattened and rendered fit again for cultivation, and so that is restored to it which the seedlings had carried off in their growth. But since fertility cannot attain its end without the proper spirits, now already breathed out, hence that volatile substance of spirits, drawn back by the earth's accustomed magnetism, renders the earth blessed in every part for germinating anew.

Again, since the earth is mingled with very many other forms, each one of these draws from the spirituous and volatile substance that which is nearest to itself in

likeness of nature. For if anyone should distill water from pimpernel, or borage, or a similar plant, he will find that these waters — even though it is not apparent to the eye — nevertheless differ in species; and the earthy residue remaining in the bottom of the vessel, which they call *caput mortuum* [dead head], if it is reduced to ashes — I say, both the ashes and the salt extracted from it likewise differ from one another in specific difference, though not so plainly as in the waters. For we know, taught by experience, that the ash of willow and of vine — the former inclines naturally to the willow, the latter to the vine as to a thing most kindred to it; and in the salt of each of them something remains of the whole substance, from which it can be revived, by the truly admirable counsel of Nature.

[Margin: In salt all things lie hidden by the seed of the thing, whence it comes that it is filled with the spermatic [seminal substance].]

By this counsel, in order to perpetuate the generation of things, Nature willed to preserve in the spermatic salt the faculty of each single thing. From which it is most clearly evident that the ashes of any vegetable whatsoever contribute greatly to the fertility of the earth, in that vegetables can germinate [from them]. But let us also confirm this by experiment.

EXPERIMENT I.

[Margin: Lixivium [lye] made from ashes restores the plant to fertility.]

Let a plant — of whatever species it may finally be, for example the vine, rose, wheat, and the like — be reduced to ash. This done, if you irrigate the appropriate plant with the lye [lixivium] prepared from it, you will render it wonderfully fertile and luxuriant by this connatural liquid — since this ash is more inclined to benefiting a plant of its own species than another of a different nature. Hence fields in which the remains of stubble and crops are burned to ashes, as is usually done yearly, bring much greater fertility to fields than those that are [made fertile] from the refuse of burned broom, ferns, and lotus-weeds. The reason is that the salt of the said plants, by its spermatic power, produces similar plants — that is, lotus-weed, vetch, poppy, ferns, broom, and the like — by whose admixture, just as they subtract the nourishment due to the grain, so too they cause it in a wonderful way to degenerate from its native goodness and perfection. The simpler the ashes are, therefore, the greater fertility they confer on their own species, as the following experiment teaches.

EXPERIMENT II.

[Margin: How beautiful flowers are produced.]

If anyone should desire beautiful, bright, and abundant flowers — for example, tulips, anemones, lilies of every kind, roses, and the like — let him, from those same flowers, after they have bloomed, burn the stalks and stems of the flowers into ash and make a lye, which, poured upon the roots of each of the appropriate plants, [will cause them] to sprout up with wonderful fertility and brilliance — which I would have understood of other plants as well.

COROLLARY.

[Margin: From which it is understood how one and the same earth produces so many things.]

From these things it is clear how one and the same earth produces, to the eye, such diverse things: namely because the earth holds clods of differing nature, each one of which is inclined to that which is more agreeable to it by natural affinity. From this it is also clear that not every earth is fit for producing all things. There are, therefore, earthy materials that love this earth rather than another. Hence a spirit received in the earth, imbued with the virtue for producing vines, will now be less fit for germinating wheat — and so of the rest — because in one part of the earth the fixed parts are already determined to attracting the vegetable spirits more of this kind than of that; and consequently vines germinate more happily in one place, crops in another. But these things will be shown more fully in the *Distillatory Art* [Ars distillatoria].

The sixth question. Why, from the mere cessation of sowing, is the earth — resting for one or more years — rendered richer and more fruitful?

[Margin: Why earth made to rest from cultivation is rendered better.]

I answer that this happens partly because of the rotting herb and leaves turned into the earth by the fermentation that takes place, by which the earth, already exhausted of fatness,

is again restored by a new, acquired increase of rich earth — partly through the snows, by which the enclosed spirits are confined, and the earth itself, through the subterranean vapors, acquires great increment: from within, by the vaporous soot arriving from the earth; from without, indeed, by the attraction of new volatile spirits.

CAPUT VII.

Of the earthy bodies that come into use individually for Potters and Painters.

At the first beginnings of things, God most good and great [Deus Optimus Maximus], performing the office of a potter [figulus] — the All-fashioner [Pantoplastes] — shaped the body of man from Damascene earth [terra Damascena]. This earth, being the most excellent of all earths that have ever been found, was for that reason employed by God for fashioning the most worthy body of the first-formed man [protoplastus]. Hence also the only-begotten Son of the eternal Father did not disdain to assume to himself, from that same earth — through the successive propagation of the human race made by the first-formed man — a body from the immaculate earth of the Virgin. Yet what exactly the earth of Adam may have been is disputed among the interpreters of Sacred Scripture. We, omitting that question — as one that transcends all comprehension of the human mind — will proceed to those earths which potters chiefly use.

[Margin: Which earths potters should use.]

The earths that potters use ought to be coarse, tough, dense, and soft, of the kind that marl is wont to be; and where these are lacking, the middling ones hold first place, the soft ones second. Vessels that are not broken by the force of fire are for the most part made from rich and dense earths, such as crucibles.

[Margin: The earth required for the potter's craft.]

The vessels apt for chemical operations are of this sort: those of the better kind are the lightest, which do not drink in or sweat out moisture, are not fragile, and resist fire. Of such kind are: the Saguntine [vessels] in Spain [Sagunto]; in Italy, those made at Modena [Mutina], Arezzo [Aretium], and Toscanella [?]; the cups of Sorrento [Surrentum]; the earths of the regions neighboring Naples furnish most exquisite dishes. In Germany, those made at Waldenburg [Valdenburg] are everywhere sold at a great price.

[Margin: Which earth serves for melting glass.]

But the earth that serves for liquefying glass must above all be the most fire-resistant — of the kind dug at Savona in Liguria [Savona]. But of these things at greater length in the *Art of Glassmaking* [Ars vitraria].

[Margin: Why potters mix sand into the earth of their vessels.]

But why do potters for the most part usually mix sand into the earth, so that the vessels are not broken in the fire? The cause is that sand, liquefied by a strong fire, reduces the clayey substance as it were into a kind of stony [mass], with all its pores filled up. There are therefore some vessels made from chalk, others from clay [argilla], others finally from other baked earths — which are so much the more suited to human use, the more they are formed of richer, denser, and tougher material. On these, consult the potters. The same is to be said of the earth used by modellers [plastae] and fullers. But of these things elsewhere.

Of Murrhine vessels, Porcelains, and Majolica vessels.

[Margin: What Murrhine vessels were among the Ancients.]

What the Murrhine vessels [vasa Myrrhina] of the ancients were, and from what earth they took their origin, remains to be said. If we examine Pliny's words, set forth concerning the Murrhine vessels, we shall find that they were nothing other than what we today call porcelain [porcellana], whose origin and manufacture I set out in a few words.

[Margin: How and from what porcelain is made.]

Pliny (Book 37, ch. 2), treating of precious vessels, says that the Murrhine vessels are brought from the East and shine wonderfully, and are moreover imbued with the utmost variety of colors. To these our porcelain vessels today entirely correspond; concerning the making of which various authors report various things. Best of all about these is Father Martino Martini, of the Society of Jesus [P. Martinus Martinius é Soc. Jesu], the [author?] of all others [?], who writes thus in his *Atlas Sinicus* [Sinic Atlas], folio 86, concerning the city of Jaochen [Raozhou / Jingdezhen, in Jiangnan] in the Province of Kiangnan [Jiangnan]:

But what most commends it is the elaboration and abundance of Chinese bowls, which they commonly call "porcelains" — by a name fetched, I know not where from — than which none are made more excellent in the whole realm than in the village of Feuleang [Fouliang / Fuliang] of that city. For although elsewhere they have earth from which they could perhaps be made, they by no means come up to those that are made in this village. Indeed — what is worthy of admiration — they do not draw the earth from which they form these out of the soil of this Province itself, but receive it brought in from the city of Hoeicheu [Huizhou] of the Province of Kiangnan; nor can the people there, although so great an abundance of that earth is present, in any way fashion those [vessels]. There are those who ascribe this to the temperature of the waters. From this village, then,

of this city come all those Chinese bowls and vessels, which are wrought by rustic and unskilled men by the potter's art, in the same manner as the Faentine [vessels] in Italy [Faenza majolica] are of various color — although all are made of that most subtle and somewhat translucent clay. These are tinged with a saffron color and adorned with various figures of Dragons. [Those destined] for the royal palace are commonly made red, yellow, and of a blue [caeruleus] color — for producing which a glass [glassum / cobalt-glaze] is wont to be employed by the Chinese, which is found there in great abundance, especially in the more southern Provinces, and which they also use for dyeing garments. But how rare and excellent vessels are made here it would be long to relate: no shape, no flower, no figure can you paint that the porcelain clay among them will not admit. And how great is the abundance of these vessels, anyone may gather from that which we daily see in our Europe. But I marvel from where the rumor crept abroad here that this material is prepared from eggshells or crushed sea-shells, and that it is stored up by ancestors for the grandsons of their successors over a space of a hundred years; for those truly versed in things, these tales are ridiculous and merely fabricated, since everything [is made] from the earth that [is dug] for this village...

Liber VII, Sectio II — De Hylocinesi (continued)

Caput VII — De Terrestribus corporibus, quae singulis Plastis & Pictoribus in usum veniunt (continued)

[Sub-section: De Myrrhinis, Porcellanis & Majoricis vasis — continued]

So the Chinese are reported to make the most precious and most highly approved porcelains [porcellanae] of all that are found anywhere. But as for the claims that fire can be struck from fragments of these vessels when knocked together, that they burst in the presence of poisons, and that they grow only as warm as the hot water or broth poured into them has occupied within — this, for my part, is not borne out by experiment.

In second place after porcelain vessels rank the majolica vessels [vasa Majorica], which yield little to porcelain either in luster or in price.

[The remaining medicinal and pigment earths]

It now remains to describe certain other earths possessing a medium [moderate] potency: Eretrian [Eretria], Chian [Chia], Selinusian [Selinusia], Cimolian [Cimolia], Pnigitis, Melian [Melia], and Ampelitis.

There are two kinds of Eretrian earth: one strongly whitish, the other ash-colored, which is held to be the best. For if this latter is drawn in strokes across bronze implements, it produces a violet line — the mark of the better grade. It is washed in white-lead [cerussa]; it has an astringent and cooling power, is moderately emollient, fills hollow wounds, and binds together bloody ones. So Dioscorides.

Another earth is usually found on the island of Chios [Chios], white and of the better grade, crusty and differing in molded forms, very much like Samian earth [terra Samia], whose powers it also equals; it is an excellent cosmetic both for men and for women.

Selinusian earth is especially commendable for its sheen, white and friable, and is easily and quickly dissolved by moisture.

Cimolian earth is of two kinds, one white, the other purplish; but the one that shows fattiness and feels cold to the touch is reckoned the best. Applied to burns it is wonderfully beneficial, and diluted with vinegar it disperses tumors.

Pnigitis earth resembles Eretrian in color; if someone applies a hand to it, it will cool the hand, and if the tongue, it sticks to it so firmly that it can scarcely be pulled away.

Melian earth imitates ash-colored Eretrian, rough to the touch; rubbed between the fingers it crackles like scraped pumice; it is impregnated with alum, as is plain from the taste, and from this it has a cleansing power.

Ampelitis earth is produced in Seleucia of Syria [Seleucia Syriae]; black, it is recommended above the rest; when first ground up with oil it immediately liquefies, and it dissipates, cools, and is suitable for dyeing the hair; poured over sprouting vines it kills off the little worms.

But all that we have said thus far about earths we now set out together in the following synopsis, together with the quality of each.

Diagram. A bracketed taxonomic synopsis ("brace table") classifying medicinal earths. The single left-hand category is *Terra in usum Medicum cedens* ("Earth

serving for medical use"), which a large brace divides into four sub-groups, each headed *Alia* ("another kind") with its action, and each opening onto a further brace listing the specific earths. Transcribed below as a nested table preserving the structure.

Earth serving for
medical use [Terra in
usum Medicum cedens]

Sub-group (action)	Specific earths
Another, which wards off poisons [Venena arcet]	Armenian earth, or Armenian bole [Terra Armenia, sive bolus armenus]; Lemnian earth, or Sealed earth [Terra Lemnia sive Sigillata]; Melitensian [Melitensis]
Another, which is astringent [Astringit]	Ochre [Ochra]; Sinopic red-ochre [Rubrica Siropica (<i>recte Sinopica</i>)]; workshop red-ochre [Rubrica fabrilis]; Eretrian [Eretria]; Samian [Samia]; Chian [Chia]; Selinusian [Selinusia]; every earth [Omnis terra]
Another, which disperses [Discutit]	Cimolian [Cimolia]; Ampelitis; Furnace-earth [Fornacea]
Another, which cleanses [Abstergit]	Melian earth [Melia terra]

And these are the things which, concerning the soft earthy substances, we have set out briefly, on account of the multitude of matters yet to be treated. But since we shall very often repeat mention of these earths in what follows, we shall then investigate their secrets more fully and more opportunely.

ANACEPHALEOSIS

in hoc Libro dictorum

(Recapitulation of what has been said in this Book)

So then, to reduce into a compendium what has been said up to now: I say that Salt is the common seed of the earth, the seasoning of Nature, the basis and support of all bodies, the genuine and proximate element of the earth, supplying substance to all things. Just as this salt is tinged by various minerals, so too it is converted into another salt differing in species — such as niter, alum, vitriol. Yet despite this, it always holds the cradle of its origin by an inviolable right: for once it is removed from the niter, alum, or vitriol — from the mineral by which it was tinged — that first salt will be restored to its origin. Take it away from the earthy clods and soils which we have described, and you will always find that out of which it consisted from the beginning, namely salt. I would have you understand the same of metals, and likewise of any bodies whatsoever — whether from the mineral or from the vegetable and sentient realm — when they have been burnt to ash: the same salt will nonetheless come forth from those things, out of which it had its subsistence and solidity, either through the settling of the lye [lixivium] in the vessel, or through the efflorescence of the dead head [caput mortuum]. But from where so great a variety of salts and earths, differing in powers and properties, arises — this I explain in a few words.

I say, then, that it arises from the form of the mixture [forma misti]. For just as the mixture is composed from a varied confluence of mixable things, so too, through the combination contrived by sagacious Nature, the mixed body [mixtum] acquires such a degree of essence that it is distinguished in species from all others — a degree which it always possesses by Nature's inviolable right. For example: vitriol, which had been a common salt, degenerates into a salt differing in species, out of the tincture of an airy clod and water imbued with the acid spirit of sulphur. Just as the four elements are contained in these, so too out of their combination there arises a certain saline mixed body, which differs by a specific difference from salt, niter, and alum, and is called vitriol. And this is the final degree of Nature, constituted through the combination of the four elements — that is, out of air, water, and the acid spirit of sulphur with which they are imbued — by which it is distinguished from every other thing according to the requirement of its own nature and property. In the same way, alum too is distinguished from salt, niter, and vitriol, in that it has come forth, with differing virtues, from the salt of aluminous rock, the acid spirit of sulphur supervening in

that degree in which, by Nature's wonderful combination, no other thing is constituted; and this is the final degree of Nature and essence by which alum comes to be and is said to be distinct from any other mineral.

The same must be said of all the remaining earths and mineral clods: namely, that they are all distinguished from one another on account of the differing degrees of Nature which they acquire, indivisibly [ἀτόμῳς, *atomōs*, "atomically," i.e. as indivisible units], through this or that combination of mixable things. So that Aristotle, in *Metaphysics* VII [Margin: *Aristoteles 7. Metaphys.*], not incongruously asserted that the species of things stand to one another as number to number. Add a unit to two, and it will no longer be two, but three, distinct in species from two — which is to be understood of any other numbers as well; and it is plainly evident in colors: add to white even the least bit of black, or yellow, or red, and it will at once pass over into a color differing in species. But of these things more fully in what follows.

It is therefore clear that whatever we have so far said about the various species and kinds of salts and earths differing in powers and properties must be referred to the causes set out in this recapitulation [anacephaleosis] — namely, to the mixture of things endowed with differing virtues, in which that which most predominates according to the laws of the combining Nature constitutes the mixed body in its determinate species. But all these matters will be demonstrated more plainly in what follows, with a varied apparatus of experiments. Let these things, then, be what we have said about the first fruits of the Subterranean World.

CONCLUSIO

(Conclusion)

As we struggle forth at last out of the dread and inaccessible abysses of the Subterranean World, nothing more remains for us, O God, than to turn our face to Heaven and render You the thanks we owe — You who alone do wonders, of which there is no number, in the heavens, on the earth, in the sea, and in their hidden depths. So too, that I might enter the secret sanctuaries of the Geocosm, You lent Your hand; by Your anticipating inspiration You spurred me on, unwilling though I was, to be willing; You aided the efforts of my good will to act — You who in Your own work both will, and have power, and bring to completion.

O God, O might and wisdom of our race! How wonderful through all the world is that beauty of Yours! How venerable Your form, and the glory of the holy Word, And Your name, abiding eternally from age to age!

Bless all His works, in every place of His dominion; bless the LORD, O my soul.

FINIS I. TOMI. (*End of the First Volume.*)

CATALOGUS LIBRORUM

a P. Athanasio Kircherò è Soc. Jesu hactenus editorum.

(*Catalogue of the books published thus far by Father Athanasius Kircher of the Society of Jesus.*)

- *Magnesia* — in quarto, Würzburg [Herbipolis], in the year 1630.
- *Gnomonica Catoptrica* (Catoptric Gnomonics) — in quarto, Avignon [Avenio], 1635.
- *Prodromus Coptus sive Aegyptiacus* (Coptic, or Egyptian, Forerunner) — in quarto, Rome, 1636.
- *Specula Melitensis Encyclica*, that is, a new compendium of mathematical instruments — in octavo, Naples, 1638.
- *Ars Magnetica*, or a tripartite work on the Magnet — at Rome first in quarto, 1641; then at Cologne in quarto, the same year; at Rome again in folio, in the year 1654.
- *Lingua Aegyptiaca restituta* (The Egyptian Language Restored), together with a supplement to the *Prodromus Coptus* — in quarto, Rome, 1644.
- *Ars Magna Lucis & Umbrae* (The Great Art of Light and Shadow) — in two volumes, in folio, Rome, 1646.
- *Musurgia Universalis*, or the Great Art of the Consonant and the Dissonant — in 2 volumes, in folio, Rome, 1650.
- *Obeliscus Pamphilius*, or an interpretation of the hieroglyphic obelisk restored by Innocent X, Supreme Pontiff — in folio, Rome, 1650.
- *Oedipi Aegyptiaci* (Egyptian Oedipus), Volume One — Rome, 1652, in folio.
- — Volume Two — in folio, Rome, 1653.
- — The second part of Volume Two — in folio, the same place, 1654.
- — Volume Three — in folio, Rome.
- *Scrutinium Physico-Medicum* (Physico-Medical Examination) — in quarto, the same place.

- *Iter Extaticum Coeleste* (Ecstatic Heavenly Journey) — in quarto, the same place.
- — *Terrestre* (Ecstatic Earthly Journey) — in quarto, the same place.
- *Prodromus in Mundum Subterraneum* (Forerunner to the Subterranean World) — in quarto, the same place.
- *De Crucibus Neapolitanis* (On the Neapolitan Crosses) — in octavo, the same place.
- *Polygraphia seu Artificium linguarum* (Polygraphy, or the Artifice of Languages) — in folio, the same place.

Libri ab eodem Authore, si Deus vitam concesserit, edendi, sunt:

(Books to be published by the same Author, if God grants him life:)

- *Mundus Subterraneus* (The Subterranean World), divided into two volumes, which now sweats under the press, in folio, Amsterdam.
- *Ars Combinatoria* (The Combinatory Art), by which a door is opened, by a new method, to learning all the sciences and arts in a short time — in folio, the same place.
- *Iter Hetruscum* (Etruscan Journey) — in folio.
- *Descriptio Latii novi & Veteris* (Description of New and Old Latium) — in folio.
- *Arca Noë & Turris Babel* (Noah's Ark and the Tower of Babel), delineated and described by architectonic method — in folio.

Ad Majorem Dei Gloriam cedant omnia. (May all things tend to the greater glory of God.)

INDEX RERUM ET VERBORUM LOCUPLETISSIMUS

(A Most Copious Index of Things and Words.)

The number indicates the page; the letters *a* and *b* the first and second column.

[Editorial note: this is a two-column Latin alphabetical index, letter A. It is rendered below as a list, one entry per line, preserving the headword, its locators, and sub-entries. Page references and column letters (a/b) are transcribed exactly as printed. Several entries are partly abraded; uncertain readings are flagged [?].]

- **Byssus** [fine linen / cotton], what it is — 112.a; toward the Magellanic sea — 113.a; in the gulf Ferdinando del Poo — 146.a.

- **Aër** [air], that there is an aerial Ocean — 192.a; full of the seeds of diverse things — 217.a.
- **Aerophylacia** [air-reservoirs] — 111.b; what they are — 114.a; of Asia — *ibid.*; of Bodniae — *ibid.*b.
- **Aegyptus** [Egypt], once unsuited to approach [i.e. impassable] — 80.a.
- **Aeolipilarum** [aeolipiles, "wind-balls"], their effect in stirring up winds — 202.a; their power, various and formidable — 100.a; their power — *ibid.*; observations in Belgium — 128.b; well known to sailors — *ibid.*; in the Hebrides Islands, a wonderful variety — 143.a; observation in the open Ocean difficult — 144.a; their power in the Sicilian Strait — 152.b; their use and practice — 153; the knowledge of [tide-]fullness — 154 and following; their clock [horologium] — 157; it follows the motion of the Moon — 100.a; the inequality of the Moon's motion does not hinder it — 132.a; at London it varies — 128.a; in China anomalous [heteroclitus] — *ibid.*; the causes of the variety — 139.a [?]; the winds impede them — 139; as does the discharge of rivers and the submarine exhalation — *ibid.*; in the mouth of the Garonne [Garumna], of what sort — 142.a; immense at Panama — 145.a; as also on the Cambodian [Camboia] shore — 126.b. See the word *Fluxus & refluxus* (Ebb and Flow). [*This long composite entry conflates the headword "Aeolipila" with tidal observations; transcribed as printed.*]
- **Aetna**, the mountain — 186; its description — *ibid.*; as also of the crater of Aetna — 187; a chronicle of its conflagrations — 188.a; and the cause — 189.b; see its new increase — 189.a.
- **Africae Meridionalis flumina** [the rivers of Southern Africa] — 72.b.
- **Agri** [fields], how some are now born barren, now fruitful — 231.b; whence their earthy material is sprinkled with so great a variety of colors — 332.a.
- **Agricoltura** [agriculture], and its requisites — 340 and following.
- **Albanus lacus** [Lake Albano] — 293.a; its inundation — *ibid.*
- **Albanus Mons** [Mount Alban / Alban Mount], full of waters — 295.
- **Albula fl.** [the river Albula] — 249.a; 279.a.
- **Alkali**, a cave of alkali salt [Alkali salis specus] — 201.a.
- **Almagra**, town — 261.b.
- **Alpheus**, river of Greece — *ibid.*
- **Alvor**, town — 260.b.
- **Alumen** [alum], what it is — 312.a; its various species — 312.b; differences — 312.a; its nature and quality — *ibid.*; the difference between it and salt —

ibid.; the method of extracting it from rocks — 312.b; from pyrite — 315.b; its powers — 315 and following, 324.b.

- **Aluminis Tollensis origo** [the origin of Tolfa alum] — 313.b; the method of preparing it — 314.
- **Anas Hispaniae fl.** [the river Anas (Guadiana) of Spain] — 89.b.
- **Andes montes** [the Andes mountains] — 74.a; they collapsed — 77.b; their height — 84.a; a cavern — 120.a.
- **Aponotanium** [Aponus / Abano], an Italian bath — 265.a.
- **Aqua** [water], how it is imbued with saltiness — 164.a; how salt water freshens in drainage channels [hydragogi] — ibid.; sea-water at the roots of mountains is sweeter than in the open — 166.a; sea-water drawn up into rains, why it freshens — ibid.b; the same by distillation — ibid.; without heat it cannot be attenuated into vapor — 228.b; pressed, it ascends on high — 229.b; how sea-water is raised above mountains — 232.b; how it is condensed into salt — 300.a; how it is housed in the highest mountain peaks — 238.a; its circulation corresponds to the circulation of the blood — 340.b; which kind is more healthful — 243.b; none is free of admixture — 244; which veins of good water it favors [?] — 245.a; and mixed waters — 246.a; 247.a; the test of admixture — 246.b; improperly mixed waters, which they are — 247.a; gypseous water, where it is found — 248.a; salt water does not extinguish flames — 323.b; which is fluvial [river-water] — 244.a; its disadvantages — ibid.
- **Aqua Virginis**, an Italian bath — 265.a.
- **Aqua, aluminosae** [aluminous waters] — 249.a; herbs do not grow at them — ibid.; sulphureous — ibid.; bituminous — 249.b; petrifying [lapidescentes] — ibid.; metallic — 250.b; their effects — 252.a; their admixture — 252.b; how a manifold admixture arises in them — 259.a; they assume the color of the mineral through which they pass — 259.b; the true and real cause of their weight — 277.a; why some are heavier than others — 276; why they petrify, and how — 287.a.
- **Archipelagus Indicus** [the Indian Archipelago] — 126.a.
- **Archonautarum observatio** [the observation of the Archonautae] — 161.a.
- **Arena** [sand], threefold — 326.b; marine [sea-sand], whence it comes — 337.b; whence aerial [sand] in springs — ibid.; how it is distinguished from gravel and shingle — 228.a.
- **Arenarum variae qualitates** [the various qualities of sands] — 327.a; their uses and harms — 327 and following.

- **Arethusa**, the greater river of Armenia [Armeniae maj. fl.] — 276.b; in it nothing sinks — *ibid.*
- **Argentum** [silver], whether it is mixable with waters — 250.b.
- **Ars naturae imitatrix** [Art, the imitator of Nature] — 218.a; 236.a.
- **Arsenici antidotum** [antidote to arsenic] — 283.b.
- **Asindamus**, a lake of Africa — 276.b; in it all things float — *ibid.*
- **Asphaltites, Lacus** [the Asphalt Lake, i.e. the Dead Sea] — 242.a; in it nothing sinks — 270.b.
- **Asiae montes & flumina celebriora** [the more famous mountains and rivers of Asia] — 72.a.
- **Astrorum effectus in Terra** [the effects of the stars on the Earth] — 106.a.
- **Athon Macedoniae Mons** [Mount Athos of Macedonia] — 92.b; its height — *ibid.*
- **Atlantica Insula** [the Atlantic Island, i.e. Atlantis] — 80.b; the expedition of Osiris into it — 81.b; most ancient — 82.a; how it perished — 83.a.
- **Atmosphaera in Luna notata** [an atmosphere noted on the Moon] — 62.b.
- **Avis circa Centrum Terrae volatus** [the flight of a bird about the Center of the Earth] — 29.a.
- **Aurum** [gold], how it is generated in rivers — 247.b; in waters — *ibid.*; it cannot be mixed with waters — 248.a; 250.b.
- **Aureus pulvis** [golden powder] — 210.a.
- **Avernus, lacus** [Lake Avernus] — 280.a; what it is — 281.a.
- **Axes Coelestium corporum axi Terrae parallelum situm habent** [the axes of the celestial bodies have a position parallel to the axis of the Earth] — 104.a.
- **Aygues candes** [Aigues-Chaudes], hot springs [thermae] of Gaul — 262.b.

B.

- **Balnea** [baths], see *Thermae*.
- **Bargenaires**, baths of Gaul — 262.a.
- **Baregues** [Barèges], hot springs of Gaul — *ibid.*
- **Barchetta Ins.** [Barchetta Island] — 279.a.
- **Bed, Lacus** [Lake Bed] — 73.b; 242.b.
- **Bessa, Aquitaniae urbs** [Bessa, a city of Aquitaine] — 275.b.
- **Bollerbrun, Fons in Westphalia** [Bollerbrunn, a spring in Westphalia] — 282.a.
- **Bolus Armenus** [Armenian bole], what it is — 338.a.

- **Braccianensis lacus** [Lake Bracciano] — 242.a.

C.

- **Campus la Crau dictus** — 114.b.
- **Campania tota ignibus subjecta** [all Campania subject to fires] — 177.a.
- **Carniolia R.** [the region Carniola] — 257.a.
- **Caravana** [caravan], what it is — 111.b.

Index of Subjects and Words (Index Rerum et Verborum) — continued

[The two-column alphabetical subject index of Tomus I continues. The four leaves in this range belong to the run C–V; the PDF presents them out of sequence.

Reconstructed printed order from running headers and catchwords: the C–G page (catchword "Garumna"), then the G–M page (catchword "Maris"), then the M–P page (catchword "R. Rio"), then the R–V page. Each entry is given as headword — gloss — page locators; "a" = first (left) column of the cited page, "b" = second (right) column; "ibid." = same locator as the preceding; "& seq." = and following. Locators are transcribed as printed.]

C (continued)

Caumata [scorching heats] — what they are, and their origin: 225, b.

Caldas del Rey [Caldas do Rei], a spring of Spain: 260, b.

Cantorelli, baths: 267, b.

Canatus, a lake of Spain: 290, b.

Carpathius, a mountain: 71.

Caspius, a mountain coated with salt: 300, b.

Catadupa [cataract], a remarkable one: 115. — The cataract of the Velinus River [Velino]: *ibid.*

Catadupae [cataracts] carry off a great portion of air with them: 203, b. — How a subterranean wind is stirred up by them: 304, a. — Their violence: *ibid.*

Catiliae aquae [the Catilian waters]: 248, b.

Caucasus, a mountain: 90, a. — Where it is located: *ibid.* — It cannot be seen from the Sea of Azov [ex Maeotide]: 90, b. — Of many parts [multiplex]: *ibid.* — Its situation: *ibid.* — Its height: 90, a. — Its distance from the Sea of Azov: 91, a. — Its whole far side is lit by the Sun: *ibid.*

Ceilanum [Ceylon], an island: 202, a. — The method of navigating to it: *ibid.*

Centrum [center], what it is: 2, a. — Its nature: 1. — What the center of magnitude is: 2, b. — What the center of gravity is: 3, a. — Rules concerning each: 4, b. — How the center of gravity is to be conceived: *ibid.* — Finding the same in a trapezium: 6, a. — In a semicircle: 6, b. — In a parabola: *ibid.* — In homogeneous solid bodies: *ibid.* — In cylinders and prisms: 7, a. — In a cone and a pyramid: *ibid.* — In a frustum of a pyramid: *ibid.* b. — In regular bodies: *ibid.* — In a hemisphere: *ibid.* — Its determination by means of a thread: *ibid.* — In heterogeneous [bodies]: 8, b.

Chalcitis [chalcitis, a copper ore], what it is: 321, b.

Characteristica scientia [characteristic science], what it is: 217, a.

Charybdis: 100, b. — Its exploration: 98, b. — Description: 102, a. — When it rages most fiercely: *ibid.* — The cause of its turbulence: 102, b. — It communicates between Taormina and Mamertina [Messina]: *ibid.* — The same as Aetna: 103, a.

Chiamy, a lake: 242, a.

Choaspis [Choaspes], a river of Persia: 243, b.

Chordarum [of strings] — the harmonic motion: 52, & seq. — Their length: 49, & seq.

Chronometrum [chronometer]: 50, b. — Its construction: 51, a. — Whether the longitude of places can be found with it: 51, *ibid.* — How the motions of the stars may be measured by its thread or string: *ibid.* — How the differences of the pulses of the artery may be found: 51, b. & seq.

Chrysorrhoeas [Chrysorrhoeas], a gold-bearing river of Asia: 244, b.

Ciceronis aqua [Cicero's water], today Bagno del Prato: 267, a.

Cinis [ash], what it is: 228, a. — Its properties: 228, b.

Cineres [ashes] from burnt fields, what they contribute: 242, a.

Circulatio sanguinis [the circulation of the blood]: 240, b.

Circejus mons [Mount Circeo], once an island: 79, a.

Circulatio naturae [the circulation of nature]: 114, a.

Cleon, a spring of Sicily: 288, a.

Caelorum decor [the beauty of the heavens]: 64, b. — Their delights: 65, a.

Collimatio [sighting/alignment] in measurements is deceptive: 66, a.

Colcotar [colcothar, calcined vitriol], what it is: 321, b.

Colles arenacei [sandy hills], how they arise in level places: 322, a. — How they arose around the mouths of the Tiber: *ibid.*

Combinatio [combination], and its remarkable power: 247, a. — The mixture of salt, niter, alum, and vitriol: 322, a.

Consonantiarum genesis [the generation of consonances]: 53, b.

Corporis humani fabrica [the structure of the human body]: 111, a.

Cretacea terra [chalky earth] produces unwholesome water: 244, a.

Crypta Tartarica [the Tartarean crypt/cavern]: 113, a. — The division of caverns: 118, a. & seq. — Their varieties: 119, b.

Currentes maris [sea currents] between the Canaries and Hispaniola: 124, a. — Various ones: 126, 150, b. — Their description in the Indian Sea: 127, a. — In the Atlantic Sea: 144, a.

Cyacuybay, a lake in China: 242, a.

Cytur, a lake in Africa: *ibid.*

D

Dencausse [Dax], thermal springs of France: 262, a.

Deserta [deserts] and their vastness: 84, a. — Why they were established: *ibid.* b. — Whence the sandy ones come: 227, a.

Drepanum [Trapani], formerly Segesta: 269, a.

E

Ecnephias [ecnephias storm], what kind of wind it is: 208, b. — How it is generated: 209, a. — A sign of its approach: *ibid.* — Why it occurs at a fixed time: 209, b. — Why it stirs up the sea so much: 210, b. — In inland regions, what it is: 211, a.

Elementum Terrae [the element of Earth], whether a true and proper one exists: 110, a. 295, a. — None is given pure: *ibid.* 162, a. — One cannot subsist without another: *ibid.* — What it ought properly to be called: 308, a.

Elementi aquei natura [the nature of the watery element]: 121.

Elsa, a river of Etruria: 286, a.

Epilogismus temporis [the reckoning of time]: 37, a.

Erminius, a spring of Lusitania: 260, b.

Esforbe, a spring: 285, b.

Etesiae [Etesian winds], their cause: 196, & seq. — Why cold: 199, a.

S. Euphemiae oppidum [the town of Sant'Eufemia], swallowed by an earthquake: 291, b.

Euripus [Euripus, the Chalcidic strait]: 349, a. — The African Euripus: 150, a.

Euronoti linea [the line of the Euronotus wind], commonly called Scirocco: 152, b.

Europa [Europe], which regions it contains: 260.

Euxini aestus [the tides of the Euxine/Black Sea]: 197, b.

Exhydrius ventus [the exhydrias wind], what it is: 210, b.

F

Fallacia in refractione aëris [the deception in the refraction of the air]: 60.

Ferrum [iron], why it glows white-hot more violently than the other metals: 173, a. — Whether it can truly be turned into bronze: 319, & seq. — Its sympathy with bronze: 320, b.

Fervencas, a remarkable spring: 260, b.

Flamma ignis fluens [flame, flowing fire]: 173, b.

Flores submarini [submarine flowers]: 97, a. — How the beautiful ones are produced: 242, b.

Fluvius S. Marthae [the river of Santa Marta]: 74, b.

Flumina [rivers] change their channels: 76, b. — Subterranean ones: 119, a. 220, a. — Submarine ones: 97, b. — Of Spain: 71, a. — How they are produced from rain: 226, b. — They can be born from subterranean winds: 228, a. — How, by the attraction of moisture: 229, a. — How from the earth [?]: 240, a. — How from condensed air and from the blowing of winds: *ibid.* — Why they disappear and new ones arise: 281, a.

Fluxus et refluxus [ebb and flow / tide], why none is observed on the shores of France and Spain: 151, b. — Its equality in the Sicilian Sea: 152, b. — Where rotation [rota] is found: 56, a. — Why the Mexican marshes undergo it: 145, b. — How it happens in the harbor of Tunis: 252, a. — What it contributes to the origin of springs: 230, a. — For the rest see under the word **Aestus** [tide].

Fodinae novae [new mines], how they come to be: 330, a.

Fontes [springs], and their origin: 226, & seq. — Aristotle's opinion on it: 227, a. — Its refutation: 228, a. — The Author's opinion: 228, b. — How they are born by the attraction of moisture: 229, a. — How from an earthquake: 240, a. — How from condensed air and the blowing of winds: *ibid.* — Gold-bearing ones are found almost everywhere: 247, a. — Wine-like ones: 275, b. — Reciprocating ones: 282, a. — Whether any can foretell barrenness: 288, b. — Whether stormy ones exist: 289, b.

Fontium vena [the vein of springs], by a fourfold cause they vanish or appear: 246, a.

Fontaine Fort, a spring of France: 275, b.

Fretum Herculeum [the Strait of Hercules / Gibraltar]: 70, b. — The Sicilian Strait [of Messina]: *ibid.* — Vaigach [the Strait of Vaygach]: 142, a. — The Strait of Magellan: 206, a.

Fulgetrum subterraneum [subterranean lightning-flash]: 222, a.

Fulmen [lightning/thunderbolt], what it is: 222, a. — A subterranean one: *ibid.* — Whence its motion: 224, a. — Why it melts metals: *ibid.*

G

Galilaei sententia [Galileo's opinion] on the motion of heavy bodies upon inclined planes: 26, a. — Its refutation: *ibid.* b. — His opinion on the motion of a thrown stone: 49, a.

G (continued)

Garumna [Garonne], a river of France [Gallia]: 142, a. — Why its tide flows for 7 hours and ebbs for 5: *ibid.*

Garus [garum], what it is, and from what it is made: 302, a.

Gelon, a spring of Sicily: 288, a.

Geocosmus [the Geocosm] — the end of the entire creation, and its center: 55, a. — It is directed toward the celestial things: *ibid.* — Made for the sake of Christ: *ibid.* b. — The end for which it was created: *ibid.* — It consists of the influxes of all the celestial bodies: *ibid.* — What it is: 56, a. — Its remarkable constitution: 103, a. — By what power it is held immovable in the middle: *ibid.* — Of heterogeneous nature: 108, a. 185, b. — Similar to a Microcosm: 111, a. 296, a. — It consists of salt: 184, b.

Glacies marina [sea ice], why it is fresh: 166, a.

Globus Terraqueus [the terraqueous globe]: 65, a.

Globi Solaris situs [the position of the solar globe] corresponds to the position of the Earth: 104, a. — The adaptation of the Lunar [globe] to the Earth: *ibid.*

Golfo di Leone [the Gulf of Lion]: 102, a. — Remarkable storms in it: 205, b.

Gounapi mons [Mount Gunung Api]: 181, a.

Giellerosi, a spring of Campania: 267, a.

Grando subterranea [subterranean hail]: 220, a. — How it is generated: 223, a.

Gypsum [gypsum] naturally craves water: 239, b.

H

Halitus subterranei [subterranean exhalations] are stirred up by the Sun: 202, a. — They are drawn out from all things: 216, a. — Of noxious caverns: 281, a.

Hannibalis Campus [the Field of Hannibal]: 293, a.

Hebrides Insula [the Hebrides islands]: 143, a.

Herba [a plant/herb] does not petrify in water: 250, a. — When rotted, it is turned into earth: 234, a.

Hispaniae Flumina [the rivers of Spain]: 71, a.

Hollandia [Holland], formed from the silt of the Rhine and the Meuse [Mosa]: 80, a.

Horologium aestus marini [the clock of the sea-tide]: 157, b.

Hudson mare [Hudson Bay / the Hudson sea]: 146, b.

Humor quiescens [stagnant moisture] is subject to putrefaction: 158, a.

Humiditas [humidity], what it is: 207, b.

Hydrophylacium [hydrophylacium, a water-reservoir] of the Rhaetian Alps: 70, a. — Of Asia: 71, a.

Hydrophylacia [hydrophylacia, water-reservoirs], various: 234, & seq.

Hyoscyamus [henbane], endowed with a deleterious quality: 215, a.

Hynamnis [Hynamnis], a gold-bearing river of Carmania: 247, b.

Hydrometri descriptio [the description of the hydrometer]: 254, a. — Its various kinds: 255.

I

Iannarius [the Iannarius river], commonly Rio de la Plata: 74, b.

Ignis in Centro Terrae [fire at the center of the Earth] is spherical: 19, b. — Its true element: 170, & seq. — Three kinds: 171, a. — How charcoal lurks within it: 173, b. — Its friendship with water in subterranean places: 270, a.

Ignis Inferni [the fire of Hell] is a true fire: 113, b.

Ignis essentialis [essential fire] is neither heavy nor light, but indifferent to every situation: 172, a.

Ignis sublunaris confutatio [the refutation of the sublunary fire]: 171, a.

Ignis subterraneus [subterranean fire]: 71, a. — Its necessity: *ibid.* — Its vehemence: 83, a. — Its essence, situation, and operation: 168. — Its definition: 69,

a. — Its light is diverse: 174, a. — Its union with water within the Earth: *ibid.* — A vast apparatus of it in the belly of the earth: *ibid.* b. — Its analogy with the spirituous blood: 175, a. — Its effect is not always perpetual: *ibid.* b. — Its vents toward the malignant rock [Petra mala]: 177, b. — Father Francisco Riccardi's account of it: 182, b. — It imbues the sea with saltiness: 163, b. — It mixes saline spirits into the sea: 164, a. — It is nowhere lacking: 169, a. — The poets' allusion to it: *ibid.* — It does not arise from quicklime or ash: 69, b. — Nor from antiperistasis: *ibid.* — It is not virtual: *ibid.* — Its element is true: 170, & seq. — How it is generated by friction [attritus]: 172, a. — The active principle of all things: 183, a. — Its perpetual nourishment: 184, a. — Why it does not fly off: *ibid.* — Its fuel follows the motion of the sea: 189, b. — It does not rest [otari nescit]: 193, b. — The cause of all meteorological impressions: 219, a.

Incendium [conflagration], what it is: 175, b.

Insula S. Michaëlis [the island of São Miguel]: 82, b.

Insulae olim continentes [islands once joined to the mainland]: 76, b. — Their metamorphosis: 78, b. — Why they float in lakes: 297, b.

Ischia, an island: 267, b.

Isoquois, a lake in Canada: 242, a.

Isthmi [isthmuses]: 78, b.

Italia [Italy] teems with subterranean fires: 176, b. — Its fire-belching mountains: 185, a.

Iter ex Lusitania in Indiam [the route from Portugal to India]: 123, a. — From the Philippine Islands to Mexico: *ibid.*

L

Lacus [lakes] of a fourfold kind: 214, a. — Their origin in plains: *ibid.* — Agrigentinus [the Agrigentine lake]: 268, b. — Enneus: 269, a. — Gurgus: *ibid.* — On Mount St. Gotthard: 234, a. — In Carniola: 237, a.

Lacuum differentia [the difference of lakes]: 89, a. — Origin: 226, & seq. — Metamorphosis: 290.

Lago del Vico [Lake Vico]: 238, a.

Lapis à Luna ad centrum Terrae [a stone from the Moon to the center of the Earth], how much time it would take in falling: 26, a.

Latium scatet sulphure [Latium teems with sulphur]: 177, b.

Lemanus Lacus [Lake Geneva]: 242, b. 293, a.

Leontinus fons [the Leontine spring]: 288, a.

Liparitanus mons [the Liparitan mountain], called Vulcanellus: 77, b.

Loth [Lot]: 301, b. — His wife [turned] into a pillar of salt: *ibid.*

Luna [the Moon], by what means it moves the sea: 130, a. — Its power that stirs the sea is specific, not elemental: 129, b. — For what it was created: 64, a. — Its nature: 62, a. — Its effects: 62, a.

Lupus marinus [the sea-wolf], see **Phoca** [the seal].

Lusitanorum infelix expeditio [the unfortunate expedition of the Portuguese]: 208, b.

Lusitania Interamnensis [Portugal between the rivers], 18 leagues long, 12 wide: 260, b. — Its thermal springs: *ibid.* 25. — It counts a thousand springs [millia fontium]: *ibid.*

M

Magnetismus globorum Astralium [the magnetism of the astral globes]: 105. — Their nature: 216, b. 341, a.

Magnetica vis [the magnetic force], implanted in all the bodies of the world: 106, a. — What it is: 306, b. — Its function: 107, a.

Manca, what it is: 211, a.

Mandragora [mandrake], endowed with a deleterious quality: 215, a.

Manna [manna], what it is, and its origin: 223, b.

Maragnon [the Marañón], a river: 74, a.

Mare [the sea] increases more or less according to the differing phase of the Moon: 129, b. 139, b. — Its general motion: 122, a. — Its secondary motion: 128, a. — Its floor is uneven: 139, a. — Its motion takes on the concavities of the submarine valleys: 139, b. — Why it exerts its force chiefly at the time of new moon and full moon: 332, & seq. — Why it does not always flow or ebb for six hours: 136. — Whether it is saltier at the bottom or at the surface: 165, a. — Its remarkable alteration: 165, b. — Whether it is saltier under the torrid zone: *ibid.*

— Why in Iceland it is so salty: 166, a. — Whether its saltiness is equal throughout all the paths of the Ocean: 165. — Why it sometimes burns: 210, b. — It often overtops the highest mountains: 221, a.

Marca, what it is: 340, a.

Marium connexus [the connection of the seas]: 85, b. — Description: *ibid.* — Their communication with one another: 86, a.

Mare Mediterraneum [the Mediterranean Sea] receives very many rivers: 150, a. — Why nevertheless it does not overflow: *ibid.* — It discharges itself through subterranean passages: 150, b. — It communicates with the Red Sea: *ibid.* — The explanation of its currents: *ibid.* — Its inconstancy: 141, a.

Mare Caspium [the Caspian Sea]: 86, b. — Its passages: 87, a. — It is an abyss: 113, a. — It communicates with the Persian Gulf and the Pontus Euxinus [Black Sea]: 189, b. — It receives huge rivers: 242, a.

Mare del Zur [the Mar del Sur / the Pacific]: 144, a.

Mare Iaponicum [the Japanese Sea] is notorious for shipwrecks: 206, a.

M (continued)

Maris Rubri cum Mediterraneo nexus [the connection of the Red Sea with the Mediterranean]: 87, a. — With the Dead Sea [mari mortuo]: 87, b. — Their distance: *ibid.*

Meteoron [a meteor] is born from the Subterranean World: 219.

Melanteria [melanteria, a mineral salt], what it is: 321, b.

Memphis, today Cairo: 248, b.

Mineralia [minerals], why they are found almost everywhere: 109, b. — Their vapor harmful to the eyes: 183, a. [?] — Their conflict in [?]: 210, a. [?] — Their sympathy: 318, b.

Mineo, a town: 268, b.

Misy [misy, a copper-iron sulphate], what it is: 321, b.

Maeotis polus [the pole of the Maeotis (Sea of Azov)]: 80, a.

Mons Caesiorum [Mount Caesius/of the Caesii (Mons Casius)]: 115, a. — Its situation: 116, a. — Its marvelous effects and their cause: *ibid.* — Pierced through with cavities: 117, a.

Mons Sanctus [the Holy Mountain / Monte Nuovo] in the territory of Pozzuoli: 77, b.

Montes [mountains], necessary for the welling-up of springs: 68, a. — They existed before the Flood: 67, a. — Their utilities: 67, b. — What their chains are: 68, 69. — Their boundary: 70. — Swallowed up: 77, a. — Their rebirth: 77, b. — Why they fail: 78, a. — They cannot be seen at 100 miles: 91, a. — Their heights, whether they correspond to the depth of the sea: 96, a. — Submarine ones: 97, a. — They are not always illuminated by the Sun in the same way: 202, a. — Covered by clouds, they are forerunners of rains: 240, b. — Why those at first fertile become barren with time: 331, a. — Worn down perpetually, why they are not diminished: 227, b.

Montes Ignivomi [fire-belching mountains], see **Vulcani** [volcanoes].

Mont d'or, thermal springs of France: 262, b.

Montferran [Montferrand], baths of France: 262, a.

Motus in Centro Terrae [motion at the center of the Earth], how a perpetual one is established: 19, a. — Local definition: 21, a. — What an accelerated [motion] is: 22, a. — How heavy bodies upon inclined planes are carried toward the center: 25, a. — Where Galileo's opinion is examined and confirmed by Mersennus [Mersenne]: 38, a. — Equal as to duration: *ibid.* — Through a less-inclined plane it is faster than through a more-inclined plane: 39, a. — How its velocity toward the center is determined: 35, a.

Motus pendulorum [the motion of pendulums]: 41, & seq. — Its properties: *ibid.* — Its perpetuity in nature: 38, b. — Its use in matters pertaining to Geometry: 84, & seq.

Motus projectilium parabolicus [the parabolic motion of projectiles]: 30, a. — Its marvelous effects: 31, & seq.

Motus ponderis [the motion of a weight] is considered in two ways: 36, b.

Motus fluxus et refluxus [the motion of ebb and flow] sets the whole mass of the sea in motion: 125, a. — The sea's twofold [motion], monthly and daily: 328, b. — Not properly violent: 232.

Mundi varietatis verum amans [a true lover of the variety of the world]: 180, a.
— Its spirit: 108, b.

Mundanorum globorum natura et compositio [the nature and composition of the mundane globes]: 56, a.

Muria [brine], what it is, and from what it is made: 302, a. — Threefold: 302, b.

Myrrhina vasa [murrhine vessels], what they are: 343, a.

N

Nar, a river: 292, a.

Naphthia, a lake: 268, b.

Natura tota in continuo motu [all nature in continual motion]: 176, a.

Natura fluctuantis conditio [the condition of fluctuating nature]: 76, a. — Its remarkable cycle [pericyclosis]: 217, a.

Niger Fl. [the Niger River]: 72, a. — It bursts forth white: 89, b. — It is gold-bearing: 247, b.

Nilus Fl. [the Nile River]: 72, b. — Its origin: *ibid.* — The situation of the place of its origin: 73, a. — The places surrounding it: 72, b. — Its course: *ibid.* — Its cataracts: *ibid.* — It bursts forth white: 89, b. — Pouring itself into the sea, why it does not impede the tide: 151, b. — It is gold-bearing: 247, b. 248, a.

Nitrum [niter], where it is found: 248, b. — Its various kinds: 304, a. — The Egyptian [niter], whether it is the same as ours: 294, b. — Its admirable power in gunpowder [pulvere pyrio]: 305, b. — It boils up in vinegar: 324, a.

Nix subterranea [subterranean snow]: 220, a. — How it is generated: 223, a.

Niloscopium [the Nilometer]: 289, a.

Noviodunum, commonly Nions [Nyons]: 220, a.

Nubes descendentes [descending clouds], what force they have: 207, b. — Whence they arise: 223, a.

Nursinus lacus [the lake of Norcia / Lago di Pilato]: 293.

O

Oceanus [the Ocean], what it is: 85, a. — Its motion: 121, a. — A boreal [tide] is noted everywhere: 122, a. — Its uneven floor causes the swiftness and slowness of the tide: 125, a. — Its slope causes the rapidity of the currents: 125, b. — Various opinions concerning ebb and flow: 128, a. — The true assertion of the opinion: *ibid.* — Its ebb and flow always similar to itself: 137, a. — Unequal in different parts: 137, b. — The reason for its variation: 141, a. — Why on the shores of Norway it is imperceptible: 142, b. — Its cycle [pericyclosis]: 158. — It is absorbed under the Arctic Pole and regurgitated under the Antarctic: 159, b. — Most rapid around the Pole: 159, a. — It is vomited forth from the Southern Pole: *ibid.* — See **Mare**.

Orentaine, baths of France: 262, a.

Ormuza [Hormuz], an island, consists of salt: 300, b.

Ossamentum Terrae [the bone-structure of the Earth]: 108, b.

Oxus in Bactris Fl. [the Oxus, a river in Bactria], gold-bearing: 247, b.

P

Padrotus [Padrotus], a gold-bearing river of Asia: 247, b.

Padus, Ital. Fl. [the Po, a river of Italy], gold-bearing: 247, b.

Pampas Americae desertum [the desert pampas of America]: 84.

Panspermia [panspermia, the universal seed], what it is: 109, a. — It is carried off into various parts by the force of winds: 216, a.

Pantheon: 78, b.

Pantalarea Inf. [the island of Pantelleria]: 269, a.

Panaecura, a mountain on the island of Java: 181, a.

Parime, lacus in America [Lake Parime in America]: 241, & seq.

Pericyclosis naturae [the cycle of nature]: 217, a.

Petrarchae domus [the house of Petrarch]: 236, a.

Pharus Aegypti [the Pharos of Egypt], formerly an island: 78, b.

Phlegreus campus [the Phlegraean Field]: 277, a. — Its description: 179, a.

Phoca [the seal] — its hairs bristle at the increase of the tide: 331, a.

Picus Canariarum [the Peak of the Canaries / Teide], a mountain: 82, a. — Flame-belching: 181, b. — Its height: 82, a. — The Peak of Fayal in the Azores islands [Inf. Azoribus], of equal height with the Peak of the Canaries: 82, b.

Picus in Timor Inf. [the peak on the island of Timor], swallowed up: 181, a.

Pilatus mons [Mount Pilatus]: 290, b.

Pismam lacus [Lake Pismam]: 268, b.

Pila Aeolia [the Aeolian ball]: 203, a. — Its analogy to subterranean fire: 215, b.

Pinguedo quaedam omnibus inest [a certain fattiness is in all things]: 185, a.

Planta [a plant], why in winter it puts on a sorrowful aspect: 173, b. — Their odors, what they are: 216, a.

Planitierum divisio [the division of the plains]: 84, a.

Pluvia vermium, Serpentinum in Africa [a rain of worms and serpents in Africa]: 211, b.

Pluviae subterraneae [subterranean rains]: 219, b. — How much they can do in the alteration of the Earth: 330, b.

Polus Antarcticus [the Antarctic Pole] cannot be approached: 161, a.

Polono-Hungariae Flumina [the rivers of Poland and Hungary]: 71, a.

Pons ligneus [a wooden bridge], circular, suspended, and without support, how it may be built: 14, a.

Potisini collegii redditus [the revenues of the Potosí district [?]]: 247, b. [?]

Porcellana [porcelain], what it is, and how it is made: 244, b.

Praester ventus [the praester wind], what it is: 208, b.

Prata marina [sea-meadows]: 97, a. — Not far from Malta [Melita]: 97, b.

Principium passivum [the passive principle] produces nothing without an active one: 57, a.

Procyta Inf. [the island of Procida]: 267, b.

Promontorium Bonae Spei [the Cape of Good Hope]: 127, b. — Its description: 209, a.

Pulvis pyrius [gunpowder]: 305, b. — Its operation: 306, b. — Various preparations: 309, & seq. — Granulated, why it is more powerful than the powdered [farinaceus]: 310, a. — How a mine is made: 311, b.

Pyrenaei montes [the Pyrenees mountains]: 71, a.

Pyrophyllacia [pyrophyllacia, fire-reservoirs]: 113, & seq.

Pyrodynaste Mundi [the fire-power-keepers of the World], who they are: 224, a.

R

Rio de las Amazonas, Fl. [the River of the Amazons]: 74, b.

Rocco di Papa [Rocca di Papa], a small castle: 293, a.

S

Sabbaticus Fl. [the Sabbatic River]: 285, a.

Sal [salt] is present in all things: 162, b. 185, a. 270, b. — It is a terrestrial element: *ibid.* 110, a. — Twofold: *ibid.* — Virtually included in the Chaotic mass: *ibid.* — What it is properly: 310, b. 298, a. — Its remarkable power: *ibid.* — Its uses: 163, a. — On it depends the generation of things: 163, b. — How it was infused into the water from the beginning: *ibid.* — How into the earth: 299, a. — It is concocted by the heat of the Sun: 166, a. — The northern regions are not productive of it: 166, b. — It is called the seasoning of nature: 296, b. — Incorruptible: 297, b. — Used in sacrifices: 298, a. — Threefold: 298, b. — Marine [salt], of what kind: 300, a. — Made by art [artefactus]: *ibid.* — Terrestrial [salt], of what kind and how manifold: 300, a. — Crystalline: *ibid.* — Ammoniac: *ibid.* — As the Moon waxes it grows: 324, a. — Rock-salt [saxosus]: 300, b. — Fluviate and lacustrine: 301, a. — Extracted from wood [ex lignis]: *ibid.* — From ashes: *ibid.* — Various modes of extracting: 302, & seq. — It crackles in fire: 323, b. — Salt water freezes faster than fresh: *ibid.*

Salis ammoniaci et tartari antipathia [the antipathy of sal ammoniac and tartar]: 210, a.

Salsedo maris [the saltiness of the sea], whether equal throughout all the paths of the Ocean: 165.

Salium differentia et analysis [the difference and analysis of salts]: 299. — Salt-mines [fodinae] various throughout the world.

Salinarum cultor primus Ancus Martius [the first cultivator of salt-works was Ancus Marcius]: 300, a.

Salnitrum [saltpeter], what it is: 305, a. — How it is made: 305, b. — From what it is generated: 308, a. — Its power: 306, b. 308, b. 309, a. — Whence its goodness is recognized: 211, a. — Concocted by sulphur, it turns into stone: 324, a.

Sanna, what it is: 337, a.

Sargosso herba [the sargasso weed]: 272, b.

Sarmatia, its level lands: 197, b.

Sarnus, a river of Campania: 286, a.

Scylla — its situation and properties: 160, b. — A description of its ebb and flow: 301, a. [recte: 101, a] — Its cause: 100, b.

Semen in Centrum Terrae projectum [a seed thrown into the center of the Earth], why it would not blossom: 19, a.

Senega, Africae Fl. [the Senegal, a river of Africa]: 142, a.

Septentrionales regiones [the northern regions] less productive of salt: 166, b.

Siccitas [dryness], what it is: 307, b.

Sicilia [Sicily], once joined to Calabria: 99, a. — Wholly cavernous: 102, b.

Sierra Morena, a mountain of Spain: 261, a.

Silarus, Fl. [the Sele river]: 286, a.

Sinus Persicus [the Persian Gulf]: 127, a.

Soda, see **Alkali**.

Soras, a lake of Muscovy: 242, a.

Sory [sory, a mineral vitriol], what it is: 321, b.

Sol [the Sun] removed from the center of the Earth by 1142 semidiameters: 27, a. — In the time of the Emperor Justinian, for a whole year it shone but little: 62. — Its definition: 58. — Its powers and properties: 59, & seq. — In the year 700,

suffused as it were with a bloody color: 62. — And its instruments: 60, a. — At the time of the Moon's conjunction it is nearer: 124, b.

Solanum [nightshade], endowed with a deleterious quality: 215, a.

Solis Fons [the Spring of the Sun]: 275, a.

Spatia singulorum missilium [the spaces of individual projectiles] can be exactly defined: 46, a.

Spirituum duplex materia [the twofold matter of spirits]: 216, a.

Stellae cadentes [falling stars], what they are: 224, b.

Sterilitas [barrenness], whence: 232, a. — And its principles: *ibid.*

Stramonium [thorn-apple], endowed with a deleterious quality: 215, a.

Styx, a spring: 280, a.

Sulphuris et Nitri antipathia [the antipathy of sulphur and niter]: 210, a.

Sylva varia [various forests]: 84, a. — Submarine ones: 97, a.

Syrophoenix ventus [the Syrophoenician wind], commonly Sirocco: 152, a.

Syzygia [syzygy], what it is: 124, b.

T

Tagus, Hisp. Fl. [the Tagus, a river of Spain], gold-bearing: 247, b. 260, b.

Tamesis, Angliae Fl. [the Thames, a river of England]: 140, a.

Tartaria arenosa, olim mare [sandy Tartary, once a sea]: 86, a.

Tellus [the Earth]: 97, a. [recte: 67, a] — Its various subterranean workshops: *ibid.* — No one has measured its body: 65, a. — A remarkable discrepancy in its measurement: *ibid.* — Its solidity cannot be investigated: 67, a. — Its bone-structure is the framework of the mountains: *ibid.* — Why it ought to have been level: 68. — The cause of its changes: 77, a. — Its face today other than of old: 82, b. — Wholly cavernous: 174, a. — Its stability: 54, a. 64, a. — Its outward adornment: 56, b. — Its workmanship admirable: 295, a. — The Earth teems with salt and fattiness: 185, b. — It naturally attracts water: 229, b. — Full of veins: 239, a. — And of innumerable species of minerals: 109, a. — It is not an element, but a compound [elementatum]: 295, & seq. — From what it is composed: 297, a. —

Which part of it is pure and which impure: *ibid.* — What it is properly: 333. — Its generation: *ibid.* & seq. 335. — Whence so great a difference: *ibid.* — Its variety proved by experiment: 336, b. — Its various species: 338, b. & seq. — The healthiness of its quality: 339, & seq. — How potters use it: 343, a.

Terra Samia [Samian earth], what it is: 337, a.

Terra S. Pauli [the earth of St. Paul], what it is: 338, a.

Terra Lemnia [Lemnian earth], what it is: 337, b. — The same as the sealed [earth, *terra sigillata*]: *ibid.* — Its powers: 338, a.

Terra Armenia [Armenian earth], what it is, and its powers: *ibid.*

Terrae motus [earthquakes], the effects of subterranean conflagrations: 220. — Horrible: *ibid.* — How it happens: 221, a. — A mountain transported by its force: *ibid.* — One observed by the Author: 221, b. — Where it most often occurs: 222, b. — A terrible account: 257, b. — At the kindling of niter: 307, a.

Thermae [thermal springs] of Lusitania: 260. — Of the Algarve: *ibid.* — Of Spain: *ibid.* — Exceedingly rich: *ibid.* — In the Toledan territory: 261, b. — Of France: 262, a. — Of Germany: 262, b. — Of Hungary, Transylvania, and the adjacent regions: 264, a. — Of Italy beyond the Po [Transpadana]: 264, b. — Of St. Peter: 265, b. — Of the Domus Nova: *ibid.* — Of Mount Olbonus: 265, a. — Of St. Helena: 265, b. — Of Padua [Patavii]: *ibid.* — Of Heimnuria [?]: 266, b. — Of Campania: 267. — Of St. George in Campania: *ibid.* — Of Sicily: 268, a. — Of Syracuse: 268, b. — Liparitan: 269, a. — Of Aetna: 269, b. — Of the Megarian territory [Megaxicanii]: *ibid.* — Which saline ones are beneficial: 271, a. — What the nitrous ones afford: *ibid.* — What the aluminous ones [afford]: 271, b. — What likewise the vitriolic ones: *ibid.*

Thrasymenus, lacus [Lake Trasimene]: 241, a.

Tigris, Fl. [the Tigris river]: 89, b.

Timavus, Fl. [the Timavo river]: 282, b. — Its ebb and flow: 282, a.

Titica, lacus in Cherea [Lake Titicaca, in [?]]: 242, a.

Tonitru subterraneum [subterranean thunder]: 221, b.

Tremor [tremor], whence: 212.

Turbo, see **Typho**.

Tyburтинаe [the Tiburtine (waters/springs)]: 177, a.

Typho ventus [the typhoon wind]: 205, a. — Its effects: 205, b.

Tyberis Fl. [the Tiber river]: 291, b. — Its inundation: *ibid.*

Tyberis fons [the spring of the Tiber]: 292, a.

V

Vacui metus operatio [the operation of the fear of a vacuum]: 322, b.

Vadimonis, lacus [Lake Vadimon]: 293, a.

Vapor mineralis [mineral vapor] harmful to the eyes: 183, a. — It cannot be generated in cold places: 228, a.

Velinus Fl. [the Velino river]: 286, b. 292, a.

Venner et Vetter, lacus Siliciae [the lakes Vänern and Vättern of [Sweden]]: 47, a. — Their unfathomable depth: *ibid.*

Ventus [wind], what it is: 192, a. — Necessary to the sea: 193, b. — Sometimes arises from the motion of a void [*ex vacui motu*]: 193, b. — How manifold: 191. — Its cause: *ibid.* — Its names [denominations]: 192, b. — Its motion is likened to the motion of rivers: 192, a. — Its analogy with the human body: *ibid.* — Its diversity: 399, b. [recte: 199, b] — Observations in various places: 198, & seq. — Its cause: 200, & seq.

[No Tomus II front matter appears in this range. The Index continues beyond the V entries.]

Mundus Subterraneus — Tomus I (end) → Tomus II (front matter)

Index Rerum et Verborum (conclusion, V–Z)

[Two-column alphabetical subject index, small type. Locators are page numbers followed by a (left column) or b (right column); "*ibid.*" = the same locator as the preceding entry. Several abraded digits are flagged [?].]

Left column:

-...comes about from the rarefaction or condensation of subterranean waters, 202.b; how from exhalations and vapors, 204.b; how it breaks out through the midst of the sea, 206.b; how by the squeezing-out of clouds, 207.b. [continuation of an entry begun on the prior page — apparently *Fons* / spring]

- **Ventus Periodicus** [periodic wind], see **Etesiae**.
- **Ventus generalis** [the general wind], what it is, 192.b; its generation, 193.a; its cause, *ibid.*; whether it can be impeded by other winds, 195.b.
- **Ventus Anniversarius** [the annual wind], how it is generated, 199.b; its true origin, 202.a; how it arises from subterranean cataracts, 203.b.
- **Venti subterranei** [subterranean winds], 220.a; their cause, *ibid.*; they arise from the agitation of the sea, 176.b.
- **Ventorum** [of the winds]: their transverse motion and its cause, 211; nature and properties, 213; their quality among the Romans, 214.a; their effect depends on two factors, 214.a; their wholesomeness and unwholesomeness, 214.b; their various effects on human bodies, *ibid.*; their usefulness, 215.b; their final cause, 217.b; the analogy of pestilential winds with medicines, *ibid.*; the production of artificial [winds], 218.

TOMUS II — Engraved Title Page

Diagram. The allegorical engraved frontispiece-title page of Tomus II. At the top, two eagles (the Imperial Habsburg double eagle, split into a pair) grip the corners of a great draped cloth or banner on which the title is lettered; golden orbs (the *aureum pomum*, golden apple/orb of empire, echoing the dedication) hang at the lower corners of the banner. Beneath, an architectural interior opens at left onto a rocky landscape with miners/laborers at subterranean workings, and at right onto a colonnaded hall.

At center stands a colossal statue of the many-breasted **Diana of Ephesus** / **Artemis Ephesia** (Nature personified — *Natura*), her body sheathed in tiers of animal figures and bees, crowned with a mural/turreted crown, raised on a high pedestal. To her lower right sits a seated woman (the figure of Philosophy or the diligent inquirer / Kircher's Muse) writing in an open book on her lap. Behind her, at right, stands a youth wearing a broad-brimmed traveler's hat and holding the **caduceus** (the staff of Mercury/Hermes — Hermes Trismegistus, patron of the subterranean and hermetic arts), accompanied by a second youthful figure who reaches toward Nature.

At lower left, a winged putto holds up an oval framed **portrait medallion** of a young man (the dedicatee, the Emperor Leopold I — a long-haired figure in armor/sash). Near the putto's feet lie a sphere/globe and a conical sundial or plumb instrument.

Labels read top to bottom:

- (banner, the title): **ATHANASII KIRCHERI E SOC. IESU MUNDI SUBTERRANEI TOMUS II.us** — "Of Athanasius Kircher of the Society of Jesus, THE SUBTERRANEAN WORLD, Volume II"
- (banner, subtitle): **IN V. LIBROS DIGESTUS** — "arranged into 5 Books"
- (banner, continued): **Quibus Mundi Subterranei fructus exponuntur, et quidquid tandem rarum, insolitum, et portentosum in foecundo Naturae utero continetur, ante oculos ponitur curiosi Lectoris.** — "in which the fruits/products of the Subterranean World are set forth, and whatever finally [there is] rare, unusual, and prodigious that is contained in the fertile womb of Nature is placed before the eyes of the curious Reader."
- (above the portrait-medallion's bearer / at the figures' feet, the caption): **Orpheus**
- (the Greek epigram, two lines, beneath the central figures): **“Ὅς νάεις κατὰ πάντα μέρη κόσμοιο γενάρχα / Ὅς δαπανᾷς μὲν ἅπαντα, καὶ αὖξεις ἔμπαλιν αὖτις.** [Greek, after Orpheus — addressed to Nature as world-progenitor: "You who flow through all the parts of the cosmos, O progenitor; you who consume all things, and in turn make them grow again."]
- (the Latin rendering of the epigram, beneath the Greek): **Omnes qui partes habitas, mundique Genarcha / Absumis quae cuncta, eadem quae rursus adauges.** — "You who dwell in all the parts [of the world], and as Progenitor of the world consume all things, the very same things which you again increase."
- (lower left, engraver's signature): **C. vande Pas delineavit** — "Crispijn van de Passe drew [it]."
- (lower right, engraver's signature): **F. Sioutrema [?] sculpsit** — "F. Sioutrema [?] engraved [it]."
- (bottom imprint): **AMSTELODAMI, Typis Joannis Jansonij à Waesberge et Elizaei Weyerstraet 1665.** — "At Amsterdam, from the press of Joannes Janssonius van Waesberge and Elizaëus Weyerstraet, 1665."

TOMUS II — Dedication

[To the Emperor Leopold I. The opening leaf of Tomus II's dedicatory epistle; signature mark (*) 2 at the foot.]

TO THE MOST SACRED AND MOST UNCONQUERED LEOPOLD I,
EMPEROR OF THE ROMANS, THE JUST, THE PIOUS, THE FORTUNATE

[*SACRATISSIMO & INVICTISSIMO LEOPOLDO I. ROMANORUM IMPERATORI
JUSTO, PIO, FELICI*]

Athanasius Kircher of the Society of Jesus [sends] greeting, victory, and peace.

To the Monarch of Macedon [Alexander the Great] there was given a golden apple, cast from the golden tribute of all the parts of the world. I too am entering in, to look into the heart of the Earth — that is, the treasures of the world — so that from it I may draw out a tribute, one that I may render to you in writing, to you my Caesar: you who, first among the other princes of the House of Austria, crowned the holy, beautiful, pious, victorious, and glorious name of LEOPOLD with the most august title of Emperor, when that golden apple of empire was held out to you. You are intent on governing the world outwardly, on its surface; but I look inward, into the very Earth, to [see] what lies hidden there — and within, I sing to myself and to the Muses. For I find there no lesser, nor any less sweet, Music of God the Creator than [that] of the heavens...

Dedication (continued)

[...] that he had seen everything that goes on among the powers below. Will I not also need a lynx-eye and a lynx-pen, to see through to those mysteries and shadows that lie hidden, concealed in the bosom of the Earth, and to set them forth? I saw monsters in the heavens through my *Ecstatic Journey* [*Iter Extaticum*] — will none meet me in the caverns of the Earth? Monsters are customarily set before princely men to delight them. As for me, whatever I have found there that is rare, or memorable for its marvelousness, I set before You, O CÆSAR. Those who returned from the cave of Trophonius were ordered to sit down and, for several days, to unfold the mysteries they had seen within it. This is what my book — no, rather Your book — does here, a guest brought back not so much from the city as from the very bowels of the Globe of the Earth that gave it birth. No longer shall I strike the stars with my head held high; instead I shall descend by tireless investigation into the deep abyss of the Earth — at no less cost of labor than that with which divers plunge into the sea. The most celebrated of these was

Andreas Mergus of Genoa, who, plunging into the sea whenever anything was thrown into it, would snatch the prize from the waves. The fables also tell how Theseus once buried himself in the sea, and emerged from it crowned, bearing the gem that Minos had cast into it. I, for my part, descend into the Earth as into the depth of the sea only for the sake of that immortal crown which is with God; and whatever I bring back from there, I bring as an offering to Your Crown

— Your Imperial Crown — a gift already long owed to FERDINAND III [Ferdinand III, Holy Roman Emperor], Your august Father, by whose crown You are crowned in turn. For it is fixed with eternal adamant that a wise son is his father's crown. Great things await You, LEOPOLD; it is Yours to fill out the immense measure of this name with virtue to match — so that, of all who have borne the name of LEOPOLD, You may be the first to come to the pens of those who write; and so that, by the spotless candor of Austrian character in which You shine, no less than Your forebears and no unequal in heroic disposition to the grandeur of Imperial Majesty, and with a spirit ready for every exertion, You may labor unto eternity for the good of the Christian world, for altar and hearth.

This is what is vowed for You and for Yours by the same one who signs above, Your poor and humble servant.

[Margin / closing line:] From the Roman College [E Coll. Romano], on the Kalends of June, 1663.

PROÆMIUM AD LECTOREM — Preface to the Reader

IDEA OPERIS — The Plan of the Work

Now that, in the seven books of the First Tome of the *Mundus Subterraneus*, we have treated — by a new method of philosophizing and with a great apparatus of experiments — of the wonderful nature of the Earth's center; of the incomprehensible structure and workmanship of the Geocosm; of the hidden nature and property of the Ocean and of the watery Element; of meteors both within and beyond the Earth's surface; likewise of the generation of subterranean fires and winds; of the nature, property, diversity, and origin of the waters that encircle the terrestrial globe; and of the true and genuine element of earth — that is, of salt and of the other terrestrial clods, their nature, property, diversity, and origin — nothing remains but that we should proceed, in the remaining books of this Second Tome, to the consideration of the particular fruits and offspring of the Earth which the most fertile womb of the Geocosm brings forth at all times in richest abundance; and that we should explore the powers and properties of

each, and the proximate causes of effects so great. This we judged could fittingly be done in the five books of this Tome.

Since, then, it is by the force and efficacy of saline bodies of this kind that all the bodies found in the terrestrial globe — both interior and exterior — acquire a fixed, hard, and solid consistency, I have accordingly thought it proper to treat, in **Book VIII** [Liber VIII], of the stony substance of the Geocosm. In it Nature, with a certain admirable and unspeakable industry, has sported in the composition of stones and gems both common and precious; and these are likewise ornaments worthy of all admiration — not only as regards the incredible endowments of their inner virtues and powers, with which Nature has furnished them, but also as regards the apparatus of their manifold pictorial designs [picturæ], by which she has attempted to express whatever is contained within the bounds of the World, even to the point of rivaling the art of painting and modeling, according to the capacity of her playful genius. With what skill, moreover, has she fashioned, in her hidden workshops, bones of giant size and horns of prodigious length! With what shrewdness has she also drawn forth fossil wood beneath the earth, and coralline plants beneath the sea, by an incredible craftsmanship out of the rocks of the sea! All these things **Book VIII** lays open.

Again, just as the most wise Architect of the world has, in the threefold kingdom of nature, mixed good with evil, pure with impure, and the harmful with the wholesome, as though in some vase of Pandora, so too it seemed good to discuss most fully, in **Book IX** [Liber IX], the deadly parts of the terrestrial World — that is, the origin, nature, and powers of poisons [Venena]. There the reader will plainly recognize that nothing has [been made] by God, the true Founder of things [...]

Tomus II — Proæmium ad Lectorem / Idea Operis (conclusion) and Index Argumentorum

Conclusion of the Idea Operis

[The opening lines continue the sentence broken off at the end of the prior leaf, on poison and its remedy:] ...the Best and Greatest [God], that something so destructive and deadly should have been produced in the sublunary world without its containing within itself a remedy for life against the death that its own virulent venoms bring. And so from that one same thing it falls to God alone

to draw good out of so great an evil, harmlessness out of what is harmful — in short, from the death-bearing, to bring forth the life-giving.

Having now set out the matters that pertain to the saline, the stony, and the deleterious substance of nature, we proceed to the metallic art, which we entitle **metallurgy**. Here it is shown what art, the imitator of nature, can accomplish, as it brings forth the most abundant offspring of metallic bodies out of the womb of the Geocosm, to the great profit of human commerce. There too, in **Book X**, we treat at fullest length of the proportion, concoction, and separation of metals drawn from the matrices of the mines, and likewise of the virtues of each.

But just as the insatiable greed for gold and silver stirs the minds of mortals in a remarkable way, so too by remarkable means and cunning devices they leave nothing untried, hoping by any means to reach that final goal of natural happiness which they fix in the wealthy possession of gold and silver. For this reason we have arranged **Book XI** under the title χυμιοτεχνίας [Greek: chymioteknia, "the art of chemistry"], in which we debate whether true and natural gold can be produced through alchemy. We set forth the errors, impostures, and frauds of the alchemists, committed in every age, and we examine with the utmost rigor the art they call transmutatory, brought to the balance of natural philosophy [Phisiologia] — which Book XI accomplishes. In it the fiction of the philosophers' stone is thoroughly exploded by a varied apparatus of experiments.

There remains at last **Book XII**, the final one, which by no inappropriate name we have called the **Ape of Nature** [Naturæ simia]. In it we aim above all to show that whatever marvelous things nature exhibits in the Geocosm can — provided nature yields up her own right — be produced by the ingenuity of human skill; and this we teach and demonstrate by countless, varied, and hitherto unseen displays of experiments.

And this is the synopsis and, as it were, the ἀνακεφαλαίωσις [Greek: anakephalaiōsis, "recapitulation" or "summary"] of all that we set forth in the Second Tome of the *Mundus Subterraneus*, so far as the feebleness of our talent has permitted. If in it the reader should find anything worthy of praise or profitable to the public good, let him ascribe it not to me — the least of mortals — but to the Father of lights, from whose infinite goodness, mercy, and liberality all good things flow forth. And so too, if there be anything in me — however unworthy — that He has heaped together out of His own gifts and graces, let it flow back into the immense abyss of the divine goodness; and let honor and glory

be His alone, whose property it is to illuminate with His own light the dark recesses of minds, so that they may shine forth with something afterward.

INDEX ARGUMENTORUM — the Contents of the Second Tome of this Work

LIBER OCTAVUS — Λιθογενής [Greek: Lithogenēs, "stone-producing" / "on the generation of stones"]

On the stony substance of the Earth; on bones, horns, fossils, likewise on subterranean animals, men, and demons. — p. 1

Schematismus Lapidum resolutorius [an analytic table/schema of stones]. — 2

SECT. 1. On stones in general. — 3

Caput	Title	Page
I.	On the manifold variety of stones.	ibid.
II.	On the stony substance that is observed in the Geocosm, and the origin of mountains.	5
III.	On the stone-forming power [virtus lapidifica] diffused throughout the whole body of the Geocosm.	6
IV.	On the origin of stones and rocks, and how with the passage of time they coalesced into such great hardness.	7
V.	On the color of stones and gems, and in what manner this was implanted in them by Nature under so great a variety of colors.	8
VI.	On the colors which they call apparent.	15
VII.	In which the cause and origin of transparent stones and gems is treated — first of the crystalline gems, then of the origin of diamonds [Adamantes].	19
VIII.	On the various shapes, forms, and images with which Nature has fashioned stones and gems.	22
IX.	On the marvelous works of Nature the painter — the forms, figures, and images which she delineates upon stones and gems — and their origin and causes.	27

SECT. 2. On the transformation of juices, salts, herbs, plants, trees, animals, and men converted into stone; that is, on the petrifying faculty [facultas petrifica]. — 45

Caput	Title	Page
I.	On the origin of the petrifying juice [succus petrificus].	ibid.
II.	Various observations of things converted into stones.	48
III.	On stones accustomed to grow in the various members of animals.	50
IV.	On the generation of subterranean bones and horns.	53
V.	Fossil horns, which have great affinity with subterranean bones — where in particular the Horn of the Unicorn [Cornu Monocerotis] is treated.	62
VI.	On fossil wood and coals.	65

SECT. 3. On asbestos, amber [succinum], and the other bituminous flowings of gums, and also on those fossils which possess wondrous virtues. — 66

Caput	Title	Page
I.	On asbestos, or amianthus.	ibid.
II.	On the preparation of asbestos linen [linum asbestinum] for the weaving of cloth and the making of paper.	74
III.	On electrum, or amber [succinum]; commonly <i>Ambra</i> .	ibid.
IV.	How little animals of various kinds came to have their tomb fashioned in the middle of the amber [electrum].	75
V.	On the attractive power of amber [electrum].	76
VI.	On the medical powers of amber, or succinum.	77
VII.	On the twelve stones set in the breastplate [Rationale] of the High Priest, and in the foundations of the Apocalyptic City.	83

SECT. 4. On subterranean animals. — 86

Caput	Title	Page
I.	On certain animals which, as they cannot live outside the earth, so perpetually inhabit its hidden bowels.	ibid.

Caput	Title	Page
II.	On subterranean dragons.	89
III.	On subterranean men.	97
IV.	On subterranean demons.	101

LIBER IX — δηλοβλητο-ιατρικός [Greek: dēloblēto-iatrikos, roughly "on the poison-struck and their cure" — i.e. on poisons and their remedies][?]

On the poisonous and death-bearing fruits of the Subterranean World.

SECT. 1. On poisons, their nature, origin, and wondrous properties. — 104

Caput	Title	Page
I.	Definition of poison.	ibid.
II.	On certain terrestrial minerals, from which it is taught that all poisons primordially draw their origin from the Subterranean realms.	105
III.	On the accidental origin of poison in other vegetables, and in the bodies of animals both living and dead.	107
IV.	On the differences among poisons.	108

[The remaining chapters of Liber IX, Sect. 1 continue on the following indexed leaf.]

INDEX ARGUMENTORUM (continued) — Liber IX conclusion;
Liber X

LIBER IX (continued)

Caput	Title	Page
V.	On the difference between food, medicine, and poison; likewise on the agreement and disagreement of things, which they call Sympathy and Antipathy [Sympathia et Antipathia], with its various divisions; and whether the enmity and friendship of things is brought about through the primary or elemental qualities, or through specific virtues.	109
VI.	On the agreement and disagreement of poisons, and their	115

Caput	Title	Page
	origin and causes.	

SECT. 2. On poisons of the sensitive and vegetable nature. — 124

Caput	Title	Page
I.	How poison is generated in human bodies.	ibid.
II.	In how many ways poisons can be generated in us.	125
III.	How the poisons of animals infect and kill a man; that is, on the causes of poisons.	127
IV.	Where the viper and the rest of the species of asps recounted — the poison of the first class — have their lair, where they place their deadly seat, and [those][?] which cause their poison within the human body.	130
V.	How poisons do not harm some animals; and how poisons by the bite of a mad dog [canis rabidus] and of the tarantula [Tarantula] do not, unless at a determined time, exert themselves.	132
VI.	On the origin of diseases.	134
VII.	On the cure of poisonous infirmities.	135

SECT. 3. On imperfect metallic bodies, which as principal causes concur toward the generation of metals. In which the poisons of minerals, and also their medical powers, are more fully expounded. — 145

Caput	Title	Page
I.	On the admirable nature and property of sulphur.	ibid.
II.	On the other minerals which draw their origin from sulphur.	147
III.	The origin, nature, and property of antimony, or stibium.	149
IV.	On quicksilver, or mercury [Argentum vivum, sive Mercurius], and its nature and wondrous properties.	150
V.	On bituminous bodies.	156
VI.	On marine fruits — coral and the pearl [Corallium et Unio].	158

LIBER X — Μεταλλουργικός [Greek: Metallourgikos, "metallurgical" / "on metalworking"]

SECT. 1. On the requisites of the metallic art, and the condition of mines. — 162

Caput	Title	Page
I.	On the object of metallurgy; likewise on the material and formal cause of metals.	ibid.
II.	Whether the heaven and the stars concur toward the generation of metals [μεταλλογένεσιν][Greek: metallogenesis, "the generation of metals"], and how the heavenly bodies might concur in the production of metals.	165
III.	How that unctuous moisture, out of which metals are composed, is elaborated by Nature, and what sulphur, mercury, and salt are within it.	167
IV.	How all things are produced from the efficacy of terrestrial and humid heat; likewise what that is which renders metals fluid in fire, but not stones and plants and the rest; and how Nature proceeds in dissolving and perfecting things.	168

SECT. 2. On the mines of metals and other minerals, and the diseases and remedies of miners. — 171

Caput	Title	Page
I.	What things are required for a perfect knowledge of the metallic art; that is, on the condition of the Overseer of mines [Præfectus fodinarum].	ibid.
II.	On the diseases of miners.	172
III.	On the cure of the diseases of metalworkers.	173
IV.	On the remedies by which the malignant air in metallic tunnels is purged.	174
V.	On the manner of draining off the collection of waters which are a great hindrance to miners.	177
VI.	On the manifold ducts of the veins and fibers of minerals.	178

Caput	Title	Page
VII.	METALLOGNOMIA ; that is, on the signs of latent metal, and by what art the veins of metals may be recognized.	179

SECT. 3. On the nature, property, and various accidents of metallic mines, and various replies to the Author. — 182

RELATIO — A report on the mines of Hungary and the memorable things which occur in them.

Caput	Title	Page
I.	In which the Schemnitzian reply [Responsio Schemnitziana] to the nineteen points proposed by the Author.	183
II.	The reply to the questions proposed, by Joannes Schapellmann, prefect of the copper mines of His Sacred and Imperial Royal Majesty at Herrengrundt [Herrengrund] in Hungary.	185
III.	Of Georg Schütz, prefect in mineral affairs in the Schemnitz Chamber of His Sacred Imperial Majesty.	186
IV.	Of Father Andreas Schaffer, on the different minerals which are found in the Hungarian mines.	187
V.	And the last report, on the Tyrolean mines [Tyrolenses Mineræ], made by the most noble and distinguished gentleman, Sir Johann Gervick, Councillor of the Most Serene Archduke.	190
VI.	On metallurgical machines.	ibid.

SECT. 4. On the particular conditions of mines, and the various processes in digging, washing, concocting, and separating one metallic ore from another. — 197

Caput	Title	Page
I.	On the purification of metals.	ibid.
II.	Another method of preparing metals, from Agricola.	199
III.	The gold mine and its conditions.	200
IV.	The silver-bearing mine, and its nature and property.	203

Caput	Title	Page
V.	The mixture of metals.	205
VI.	Sympathy and antipathy [of metals].	206
VII.	On the slags and excrements of metals.	ibid.
VIII.	The wondrous fecundity of the gold and silver mines which are found in Peru, the New Kingdom [Novum Regnum, i.e. Nuevo Reino de Granada], and New Spain [Nova Hispania] in America, from the report of the Fathers of the Society of Jesus.	208
IX.	On the mines of bronze, or copper [Æs, seu Cuprum].	216
X.	On iron mines [Ferrifodinæ]. The nature and property of iron.	219
XI.	On salt mines [Salifodinæ], and the preparation of salt.	224

INDEX ARGUMENTORUM (continued) — Liber XI; Liber XII

LIBER XI — Χυμιοτεχνός [Greek: Chymioteknos, "of the art of chemistry" / "chemical-technical"]

PRÆFATIO [Preface]. — 231

SECT. 1. On the origin of alchemy. — 232

Caput	Title	Page
I.	On the name, definition, and division of alchemy.	ibid.
II.	On alchemy, which they call Chrysopœia [Chrysopœa, "gold-making"].	233
III.	On the antiquity of alchemy.	234
IV.	On pyrotechny [Pyrotechnia], or on the vessels and instruments required for chemical operations.	236
V.	On furnaces, vessels, the degrees of heats, and the other operations of the chemist.	239
VI.	Methodical and paradigmatic canons, by which the chemical operations are shown — through experiments and various examples proper to the individual operations — and are confirmed.	245

SECT. 2. On the Philosophers' Stone. — 250

Caput	Title	Page
I.	What the Philosophers' Stone is, what the Elixir or Philosophical Tincture is, and whether by its means true and natural gold can be produced by art.	ibid.
II.	Whether a true and real transmutation of one metal into another is granted.	256
III.	On the manner and method of preparing the Stone and Tincture of the Philosophers.	260
IV.	The perfect mastership [magisterium] of the Great Art [Ars Magna] is examined, after Lull [Lullus, i.e. Raymond Lull], Azoth, and the rest.	265
V.	In which it is taught that the alchemical processes of the Great Art, adduced a little before, cannot subsist.	267
VI.	It is demonstrated, from the very chiefs [Coryphæi] of the alchemists — Arnold [Arnoldus, i.e. Arnold of Villanova] and Villanovanus — that all attempts at gold-making [Chrysopœia] are in vain.	270
VII.	Objections against the said processes, and their authors, are refuted.	275
VIII.	PSEUDOCHYMICUM — On the deceits and deceptions, and the ways by which the alchemists once boasted they could make true gold, and to the present day still do not cease to boast.	280
IX.	That the Demon for the most part insinuates himself among the cultivators of alchemy.	283

SECT. 3. On Sophistical Alchemy — that is, on that alchemy which, joining gold and silver to copper, lead, and tin, thence builds up gold with great increase. — 284

Caput	Title	Page
I.	On the various sophistical operations of various practitioners, false and unlawful.	ibid.
II.	On the lawful or unlawful gold-working [Aurificium] of the chemists, which they call by "apposition" — that is, where part is [joined] to part, that is, where any metal is joined to gold and multiplies it.	288

Caput	Title	Page
III.	On the artificial gold-making [Chrysopœia] of the chemists.	298

SECT. 4.

Caput	Title	Page
I.	JURIDICUM , or LEGALE [the Juridical or Legal section]. Whether chemical gold, by whatever method it was finally made, may lawfully be sold for true [gold].	300[?]
II.	Juridico-Canonical decisions, on chemical gold, false and true.	311
III.	In which it is briefly disclosed what among the ancient alchemists the much-vaunted Philosophers' Stone properly was, and what at last the early Philosophers and their modern followers understood by it.	ibid.

` See Numerical impossibles.]

LIBER XII — πολυμήχανος [Greek: polymēchanos, "of many devices" / "resourceful"]

SECT. 1. On the Panspermia of things [Panspermia rerum, "the universal seed of things"]. — 327

Caput	Title	Page
I.	On the origin, nature, and property of seed [semen].	ibid.
II.	The manner in which Nature proceeds in the generation of minerals is expounded.	329
III.	On the seed of plants, or of vegetable Nature.	330
IV.	That this seed is nothing other than the Salt implanted in the elements of Nature, with which the three principles of Nature next [to it] are essentially combined.	331
V.	How the universal seed concurs toward the generation of animals; and on the wondrous efficacy of the plastic virtue in the seed of animals.	332

Caput	Title	Page
VI.	On the spontaneous origin of living things, or the hidden seeding of those which are said to be born from putrid matter.	336
VII.	On the various classes of spontaneously-born things.	338
VIII.	The combinative subjects, out of which spontaneous plants and animals are generated, are set forth.	340
IX.	How both zoophytes and insects of every kind are generated out of the bodies of perfect living things.	344
X.	On the spontaneous origin of insects from other perfect animals of a different species.	352

SECT. 2. On the various — both natural and artificial — production of those animals which by the Greeks are called ἔντομα [Greek: entoma, "insects"], by the Latins *Insecta*. — 353

Caput	Title	Page
I.	On the various births of insects, and their differences.	ibid.
II.	On the generation of insects which they call farinaceous [farifica][?].	357
III.	On the generation of four-winged insects [Quadripennia].	359
IV.	On the origin of those analytrous [Analytra] insects which they call two-winged [Bipennia].	361
V.	On the origin of those insects which have their wings enclosed in sheaths [vaginæ].	363
VI.	On insects which, though indeed deprived of wings, are nevertheless furnished with many feet.	366
VII.	On the worms which are generated in animals, and especially in men.	370

Index of Contents [Index Argumentorum] (continued)

(Tail of the Tomus II table of contents — the entries for Liber XII πολυμήχανος conclude, followed by the headings of Liber XIII's Sections 3–5 and Pars I–Ultima. Page numbers are the printed folio references.)

VIII. Recapitulation of the matters demonstrated experimentally [Recapitulatio dictorum Experimentalis]. 371

IX. Why Nature should have willed to produce so many and so great differences and kinds of insects. 374

Sect. 3. It examines the second kingdom of Nature — which is Botanical Philosophy — and the admirable effects that the Subterranean World produces in the generation of vegetables and plants, and what remarkable skill can be derived from it. 378

Cap. I. On the wondrous force and efficacy of the seed in growing things. *ibid.*

II. On the three principles of Nature, from which so great a variety of plants arises — the fermentative principles of all things. 379

III. On the differences of plants. What is necessary for understanding the powers of plants, and how those powers are to be investigated from their diversity. 380

IV. On the art of grafting [De Arte Emphyteutica, seu Insititia]. 382

Sect. 4. On the art of distillation [De Arte Stalactica, sive Distillatoria]. 390

Praefatio. That the art of distillation is an imitator of Nature, which accomplishes everything in her subterranean workshop or laboratory by distillation. *ibid.*

Cap. I. Definition and the manifold variety of distillation. 391

II. On the species of elements and compounds, and their use and benefit in the nature of things, arranged according to the rule of art. 398

III. On the qualities of plants — primary and manifest, hidden or specific — and of their individual parts, such as leaves, roots, flowers, fruits, seeds, woods, oils, gums, together with their powers and properties in medical use; extracted from the better-regarded monuments of the ancient and more recent physicians, and reduced into synoptic tables [in Tabulas Synopticas]. 400

IV. On the prodigious faculties of plants, which are shown to have taken their origin from things subterranean. 408

V. On various accidents of plants, to be untangled by means of questions. 409

Sect. 5. The hidden laboratories or workshops of various arts, in which marvelous operations are set up according to the prototype of the Subterranean Archeus [Archaeus]. 419

Pars I. On the chymiurgic art [De Arte Chymiurgica]. *ibid.*

Cap. I. On chymical secrets. *ibid.*

II. An iatro-chymical inquiry, by which the truth about potable gold [aurum potabile] is investigated. 423

III. Whether gold, or the preparations [magisteria] made from gold, obtain in medicine the use, virtue, and efficacy that the alchemists boast of, and whether a universal medicine [Medicina universalis] can or ought to be spoken of. 426

IV. On silver, or terrestrial Moon [De Argento, sive Luna terrestri]. 429

V. On the preparations of iron, tin, copper, and lead [De Ferri, Stanni, Cupri, Plumbi magisteriis]. 430

VI. On metallic trees, and their artificial production [De Arboribus metallicis]. 431

VII. The anacephalaeotic canons [Canones Anacephalaeotici], by which the artist is guided in chymical operations, and by which true operations may be distinguished from false — drawn both from the author and from other rightly-minded chymists. 433

Pars II. The metallostatic art [Ars Metallostatica], or on the art by which, through the science of weighing, the mixture of metals and minerals can be known with certainty — together with the weighing of moisture and dryness present in any compound, mineral as well as vegetable and animal. 439

Cap. I. In which the mixture is set forth. *ibid.*

II. On the weighings of various things. 446

Pars III. On the glassmaking art [De Arte Vitriaria], which treats not only of the admirable works of glass but also of crystals, pearls, and precious stones, made to the living exemplar of Nature. 450

Cap. I. On the nature of glass. *ibid.*

II. On the artful manufacture of precious gems and stones. 454

III. How gems can be made from molten glass or enamel [ex Smalto seu Encausto]. 455

IV. On the adulteration of gems, or on the counterfeit composition of stones and gems — confirmed partly by personal experiment, partly by the authority of the most skilled writers and the communication of friends. 458

Pars IV. The pyrobolic art, which they also call pyrotechnics [Ars Pyrabolica]. 462

Praefatio. On the invention of gunpowder [pulvis Pyrius]. *ibid.*

Cap. I. On the making of gunpowder. 468

II. On preparing incendiary fuses [funes incendiarii]. 472

III. Latro-chymical practices concerning some most-proven antidotes against burns caused by gunpowder, sulphur, red-hot iron, molten lead, and other like things. 473

IV. Practices concerning compositions for rockets of every kind — which the Italians call *Raggi* and the Germans *Raketen* — following the mind of Siemienowicz [Siemienovii] and of the other pyrotechnicians who devote their labor to making gunpowder. 474

V. On recreational aquatic globes, that is, ones that burn while floating on water. 475

VI. Other practices concerning fiery compositions for festive days. 476

VII. On luminous globes, of the kind we are accustomed to employ for recreational fires, which the Germans call *Lichtkugel*. 478

VIII. On the various exhibitions of spectacles to be set up by means of the pyrotechnic art. 479

Pars Ultima. On the secrets of certain mechanical arts, established after the exemplar of Subterranean Nature. 481

Cap. I. The art of goldsmiths and of the other craftsmen who are occupied with metals. *ibid.*

II. On miscellaneous matters. 485

Conclusion of the work [Conclusio operis]. 487

MUNDI

MUNDI SUBTERRANEI LIBER OCTAVUS

On the Stony Substance of the Earth [De Lapidosa Telluris Substantia]

On fossil bones and horns, and likewise on subterranean animals, men, and demons. [De Ossibus, Cornubusque fossilibus, item de Subterraneis animalibus, Hominibus, Daemonibus.]

PRAEFATIO [Preface]

Now that the foundations of terrestrial bodies have been set out and explained, it remains for us to pursue, with equal step, the stony substance which the Geocosm holds within the immense recesses of its womb, under the innumerable variety of stones, rocks, and gems. The Geocosm, as we taught in the third Book, consists of a stony substance; and, just like the fabric of the human body and of the other animals, it is furnished with bones for the firmer consistency of its whole mass.

[Margin: A comparison of the Geocosm with the Microcosm. — Comparatio Geocosmi cum Microcosmi.]

For just as these bones consist of their own marrow, enclosed in the hollows of the bones so that it does not flow away — much as the blood is shut in among the arteries and veins — so that in this fashion it may communicate with all the humors of the whole body; and just as the bones are clothed with nerves and cartilages, as well as with veins and arteries, through which by continuous attraction they are nourished along hidden little channels: in just the same way the terrestrial Orb, consisting of its own bony framework, would otherwise leave Nature to labor in vain in the production of things. For this bony framework consists, as it were, of a tubular substance, and was equipped by Nature with countless veins, nerves, and cartilages, fitly to connect part to part. Thus through its hidden fibers it draws into itself, as a kind of nourishment, whatever lies hidden of moisture, fatness, and glue in the terrestrial body, for the preservation of the whole fabric — drawing it by a certain powerful magnetism implanted in it by Nature.

And from this the stony body, diminished by the various erosions and abrasions of the subterranean washings, again gathers from the moisture the things that have been dispersed, and by attraction converts them to its own restoration. But whatever smells of salt, mineral, or metal — that, once attracted within the fibers

of the stony substance, passes into the seed-bed [seminarium] of metallic bodies. And these things, when mixed with the stony juice [lapidoso succo], produce that variety of stones — whether common or precious — which we shall describe in this Book. And so that this may be done as well as possible, we shall take the beginning of our reasoning from a division.

Resolutory Schema of Stones [Schematismus Lapidum resolutorius]

Diagram. A bracketed dichotomous classification tree (the standard Ramist "resolutory schema") reading left to right, with the root brace at far left labeled **Lapides ex rebus sumuntur** ("Stones are drawn from [these] things"). The tree branches successively; below, every branch is rendered as a nested list.

Stones are drawn from things [Lapides ex rebus sumuntur] that are:

- **Animate** [Animatis]:
 - **Flying** [Volatilibus]: *Chelidonium* [swallow-stone], *Palumbellarum lapis* [stone of wood-pigeons], *Alectorius* [cock-stone].
 - **Not flying** [non volatilibus]:
 - **Aquatic** [Aquatilibus]:
 - From **fishes** [Piscibus]: *Lap. Carpionum* [carp-stone], *Tuberonum* [shark-stone], *Percae* [perch-stone].
 - From **insects/lower animals** [Insectis]: *Oculi Cancræ* [crab's eyes], *Margaritæ* [pearls], *Umbilicus Veneris* [navel of Venus].
 - **Terrestrial** [Terrestribus]:
 - From **plants** [Plantis]: *Corallium* [coral], *Lapis Spongiae* [sponge-stone].
 - From **animals** [Animalibus]:
 - From **man** [Homine]: *Lap. Fellis* [gallstone], *Vesicae* [bladder-stone], *Renum* [kidney-stone].
 - From **brute** [Bruto]:
 - **Quadruped** [Quadrupede]: *Bezoar*, *Bufonius* [toad-stone], *Lap. Porcinus* [hog-stone], *Dracontias* [dragon-stone], *Asininus* [ass-stone].
 - **Insect** [Insecto]: *Limacius* [snail-stone].
 - **Inanimate** [Inanimatis]:
 - From **burning things** [Ardentibus]: *Succinum* [amber], *Gagates* [jet], *Lythantrax* [coal].
 - **Not burning, and having a shape** [non ardentibus, habentque figuram]:
 - A **definite** [Certam] shape:
 - **Mathematical** [Mathematicam]:

- **Round** [Rotundam]: *Enorchis*, *Ovum anguinum* [snake's egg], *Geodes*, *Aëtites* [eagle-stone].
- **Some other** [Aliam quamvis]:
- **Angular** [Angularem]: *Crystallus* [crystal], *Basaltes* [basalt], *Iris* [rainbow-stone].
- **Yet another** [Aliam quamvis]:
- **Hemispherical** [Hemisphaericam]: *Umbria*, *Crapandina*.
- **another** [aliam].
- **Of some thing** [Alicujus rei]:
- **Animate** [Animatae]:
- **Whole** [Totae]:
- **Of a sentient thing** [Sensitivae]: *Ostracites*.
- **Of a vegetable thing** [Vegetabilis]: *Corallina*.
- **Of a part** [Partis]:
- **Of a sentient thing** [Sensitivae]: *Hysterapetra*, *Oculus Cati* [cat's eye], *Dactilus Idaeus*, *Ammites*, *Eneostis*, *Aegophtalmus*, *Triophtalmus*, *Amianthus*, *Beli Oculus*, *Bucardia*.
- **Of a vegetable thing** [Vegetabilis]: *Pysolithus*, *Tecolythus*, *Amigdaloides*, *Cenchrates*, *Meconites*.
- **Inanimate** [Inanimatae]:
- **Natural** [Naturalis]: *Stalagmites*, *Steatites*, *Sealactites* [stalactite], *Porus*, *Pumex* [pumice], *Haematites*, *Ammochrysus*, *Cadmites*, *Capnites*.
- **Artificial** [Artificialis]: *Trochites*, *Stellaris*, *Ceraunia*, *Belemnites*.
- Stones having **no [definite shape], and they are either** [Nullam, sunt vel]:
- **Transparent** [Diaphani]:
- **Whole/entire** [Integrè]:
- **Hard** [Duri]:
- **Of some color** [Colore aliquo]:
- **Red** [Rubro]: *Rubinus* [ruby], *Spinellus* [spinel], *Balassius*, *Amandinus*, *Almandinus*, *Granatus* [garnet], *Alebandinus*, *Carbunculus*.
- **Yellow** [Flavo]: *Hyacinthus*.
- **Golden** [Aureo]: *Chrysolithus*, *Chrysophrasus*, *Chrysopasius*, *Chrysopteris*, *Chrysolampis*.
- **Green** [Viridi]: *Smaragdus* [emerald], *Prasius*.
- **Blue** [Caeruleo]: *Saphirus* [sapphire], *Berillus* [beryl].
- **Purple** [Purpureo]: *Ametisthus* [amethyst].

- Of **no [color], as** [Nullo, ut]: *Adamas* [diamond].
- **Soft** [Molles]:
- **Small** [Parvi]: *Opalus* [opal], *Fluores*.
- **Large** [Magni].
- **Not entire, according to** [Non integrè secundum]:
- **[their] parts** [Partes]: *Sarda*, *Sardonix* [sardonyx].
- **[the] whole** [Totum]: *Calcedonius* [chalcedony], *Camehuia* [cameo].
- **Opaque** [Opaci]:
- **Beautiful** [Pulchri]:
- **Small** [Parvi]: *Turchesia* [turquoise], *Lazuli* [lapis lazuli], *Camehuia*.
- **Large** [Magni]: *Jaspis* [jasper], *Achates* [agate], *Nephriticus* [jade], *Heliotropus* [bloodstone].
- **Ugly** [Turpes]: *Saxa* [rocks], *Silices* [flints], *Marmora* [marbles], *Marchasitae* [marcasites], *Lapides* [stones], *Lapis Armenus* [Armenian stone], *Calaminaris* [calamine].

SECTIO PRIMA [Section One]

ON STONES IN GENERAL [DE LAPIDIBUS IN COMMUNI]

CAPUT I [Chapter I]

On the manifold difference of stones [De multiplici Lapidum differential]

A stone, of whatever kind it may finally be, is properly nothing other than an unmeltable fossil body [corpus fossile illiquabile] — that is, one that can be dissolved into a flux neither by water nor by fire. The exceptions are those stones that take their origin from bitumen, glass, or other juices, which are easily liquefied when roasted by fire — such as glue [Gluten], amber [Succinum], and vitreous sand [arena vitrea] — and those that are compounded from metallic species, which therefore cannot properly be called stones.

Of these stones, indeed, the difference is so great that, to enumerate them all, not only the narrow limits of this Book — I will not say — but not even the volumes of many tomes could be capacious enough for so ample and copious a subject-matter. We shall nevertheless take pains to set forth, with order and method,

each and every thing worthy of consideration that concerns the difference of stones, their natures, powers, and properties — not by the reasonings commonly relied upon, but by a new array of experiments and with great industry, so that from these the reader may discern clearly what is to be concluded on this subject.

[Margin: First difference, from the place of origin. — *Prima differentia à loco natali.*]

The **first difference** of stones is taken from the place of origin in which the stone grows, and it is either inanimate or animate. The inanimate is again twofold: natural or artificial. The natural-inanimate is again either within the earth, or in water, or in air. Those that grow within the earth are for the most part the common kinds of rocks, marbles, and the other, even precious, kinds. Those that grow in water are all those stones which, from a petrifying juice in waters, congeal from a juice or slime appropriate to each, and are turned into rock. The air, for its part, supplies the *ceraunium* or thunder-stone [*lapis fulmineus*], coagulated in the clouds and cast down to the earth, and others like it, generated in the air — about which see in what follows, where the rain of stones [*pluvia saxorum*] has been treated more fully. In a fire that destroys all things, no stone can congeal. After the natural place comes the artificial, the manner and materials of which will be taught in what follows.

[Margin: From the animate place. — *A loco animato.*]

There follows, secondly, the other member of the division of the birthplace of stones: it is an **animate place**, which in turn has its fixed seat either in vegetables, or in sentient beings, or in animals. In a sentient nature a stone grows: either in man, or in quadrupeds, or in birds, or in swimming creatures, or finally in insects. In man a stone grows naturally either in the bladder, or in the kidneys, or in the gall-bladder, or even — against nature — in all the members, as will be seen in its place; where it will also be shown that there is no animal which does not engender some stony matter within itself, whether this be in quadrupeds, or in flying things, or in aquatic creatures, or in insects and zoophytes.

[Margin: Second difference, from color. — *Secunda differentia à colore.*]

The **second difference** is taken from color, which is either simple or compound. The simple stone is white, yellow, golden, green, blue, purple, ashen, or black. The compound is one constituted of one or more of the foregoing. Hence some stones are homogeneous, of one color whatever the tinting may finally be; others are heterogeneous, seen to be imbued with a great variety of colors. Some too are

transparent [diaphani], others opaque, others constituted of both; and others are devoid of color, like crystal and diamond.

[Margin: Third difference, from primary and secondary qualities. — Tertia differentia à qualitibus primis & secundis.]

The **third difference** is taken from the primary and secondary qualities — that is, the manifest ones. Since this difference varies according to the preservation of each one's form, the stones likewise yield diverse effects when applied to men. In this way one stone, being endowed with a hot quality — as is perceived in amber [succinum] and jet [gagas] — produces warmth; while a cold one, such as is found in pearls [uniones], corals, and the like, cools. Again, a cold temperateness, which becomes evident when all stones are reduced to powder, dries. There are besides the soft, the hard, the heavy, the light, the light-and-rough, the beautiful, and the ugly.

[Margin: Fourth difference, from the five senses. — Quarta differentia à quinque sensibus.]

The **fourth difference** is taken from the five sensible objects. Some stones are pleasing to the eyes — beautiful, glittering, splendid — like most precious stones; while others, on the contrary, are ugly, dark, and imbued with an unpleasant color. They differ also in sound: some have a dull sound, others a sharp one; some ring like bronze; while a few give back no sound at all, like the *Samius* and the *Armenus*, and those that congeal out of terrestrial globes. They differ likewise in smell, pleasant and unpleasant: for some — as the *Geodes Misenus* [Geodes of Misena] — give off the scent of violets; the *lapis Mariebergicus* [stone of Marienberg], on the testimony of Agricola [Georgius Agricola], smells of moss; the *Turingicus* [Thuringian stone], found near the town of Beclinga [Böhlen?], gives the scent of wild thyme [Serpillum]; the *Ophites* [serpentine] smells of must; the *Echites*, according to Solinus, smells of wine, and the *Galactites* of milk. The *Marcasitae* [marcasites] and those flints from which fire is struck give off the smell of sulphur; amber [Succinum] and jet [Gagates] the smell of resin. As for tastes, they are not detected in stones except in the softer ones, which are ground between the fingers; for just as these take their origin from various salts and metallic juices, so they also obtain their taste — ...they retain the taste of whichever they consist of, whether salt or mineral. Touch, too, distinguishes stones — the soft from the harder, the smooth from the rough.

The fifth difference is drawn partly from shape, partly from specific qualities and other remarkable properties. As to the first, some stones are angular, others

rounded, polygonal and polyhedral — that is, formed with several angles and faces, pyramidal, like all the varieties of crystalline bodies; others are found with a circular, elliptical, or oval figure, like the pebbles of rivers worn smooth at the shore; and still others are stamped with yet other forms. There are, finally, stones that reproduce the figures of all things — woodlands, cities, fields, grasses, plants, men, and animals.

Again, stones are distinguished by various specific properties. Among these, some harbor remarkable feuds of antipathy and sympathy, both among themselves and when applied to human beings; some are flammable, others not; some promote urine, others sweat; some protect against accident, others against demons, sorceries, and diseases. All of these matters will be treated in some measure, each in its order, in the course of this book. But before that is done, I now set out an analytic synopsis of everything said so far.

Diagram. A branching classification tree (bracket-and-brace dichotomy), titled *Divisio Lapidum & gemmarum* — "Division of Stones and Gems." The whole is governed at the far left by the heading **Lapis alius** ("Another kind of stone" — i.e., the stone-in-general being subdivided). The primary division is by size: **Parvus** (small) and **Magnus** (large). Each of these subdivides by frequency — **Rarus** (rare) and **Frequens** (common) — then by hardness (**Durus**, hard / **Mollis**, soft), by appearance (**Pulcher**, handsome / **Turpis**, plain), and in turn by **Color** (Colore), **Figura** (Figure/shape), or transparency (**Diaphanus**, transparent / **Opacus**, opaque; **integrè** = wholly, **non integrè** = not wholly; **Sine colore** / **absque colore** = colorless). The terminal cells list the individual stone names. The structure, fully transcribed as a nested table:

Size	Frequenc y	Hardn ess	Appearance	Sub-criterion	Stones listed
Parvus (small)	Rarus (rare)	Durus (hard)	Pulcher (handsome) — Diaphanus (transparent)	Colore (by color)	Hiacinthus, Berillus, Rubinus, Prasius, Rubicollus, Chrysophrasiu s, Spinellus, Granatus, Amandinus, Chrysolithus, Balassius,

Size	Frequenc y	Hardn ess	Appearance	Sub-criterion	Stones listed
					Carbunculus, Saphirus, Smaragdus, Gemma Solis, Almandiuus
			(transparent)	Sine colore (colorless)	Adamas
			(opaque) — Opacus, intégrè (wholly)		Turcois, Chamtus
			(opaque) — non intégrè (not wholly)		Sardonix, Astroites; Leucosaphitus, Opalus
		Durus (hard)	Turpis (plain)		Pantarbe, Brontia, Umbria, Dracontia, Aëtites, Lap. Palumbell[us], Chelidonias, Ovum anguinum
		Mollis (soft)	Pulcher (handsome)	Colore (by color)	Margarita, Bezoar, Melochites
				Figura (by shape)	Oculus cati, Glossopetra, Umbilicus Marinus, Lapis Judaicus, Trochites
		Mollis (soft)	Turpis (plain)		Morochtus, Lap.

Size	Frequency	Hardness	Appearance	Sub-criterion	Stones listed
					Caymanum, Enorchis, Lapis Ceval, Lap. Manualis, Lap. Rhenalis, Lap. Porcinus, Lap. Anguium, Enhydros, Callimus, Lapis Malacensis, Lapis Manati, Lapis Histericus, Lapis Tuberonum, Lap. Bugolda, Lapis Bufonius
	Frequens (common)	Durus (hard)			Pseudoadamantes Hungarici
		Mollis (soft)			Lapis Fellis, Oculi Cancris, Lap. Spongiæ, Lap. Limacis, Lap. Carpionum, Lap. Percæ
Magnus (large)	Rarus (rare)	Durus (hard)	Pulcher (handsome) — Diaphanus (transparent)	Opacus (opaque)	Porphyrites, Heliotropius, Smaragdites, Jaspis, Lapis Lazuli, Achates, Corallus, Ophites, Cornu

Size	Frequenc y	Hardn ess	Appearance	Sub-criterion	Stones listed
			(transparent)	Colore (by color)	Ammonis Ametistus, Topasius, Smaragdopras ius
			(transparent)	absque colore (colorless)	Crystallus; Pseudoadamas Bohemicus
		Durus (hard)	Turpis (plain)		Steatites, Eneostis, Stalagmites, Onyx, Ceraunia, Basaltes, Smiris, Dactilus Ideus, Ossifragus, Stalactites, Lydius, Lap. Nephrit[icus], Lap. Sanguinalis, Geodes, Magnes, Hæphestites, Hysterapetra
		Mollis (soft)	Pulcher (handsome)	Colore (by color)	Specularis, Alabastrum, Succinum, Armenus
				Figura (by shape)	Ammites, Stellaris
		Mollis (soft)	Turpis (plain)		Asius, Samius, Ageratus, Melitites,

Size	Frequency	Hardness	Appearance	Sub-criterion	Stones listed
					Gagates, Porus, Schistus, Thyites, Amianthus, Galactites, Magargenteus, Hæmatites, Phrygius, Calamita alba, Fungifer
Magnus (large)	Frequens (common)	Durus (hard)	Pulcher (handsome)		Marmor
		Durus (hard)	Turpis (plain)		Cos, Pyrites, Saxum, Silex
		Mollis (soft)			Gypsum, Talcum, Pumex, Scissilis, Lythantrax

CAPUT II.

On the Stony Substance Seen in the Geocosm, and the Origin of Mountains

[De Lapidosa Substantia, quæ in Geocosmo cernitur, montiumque origine.]

[Margin: The author's method in this work.]

So great is the dispute and contention among authors over the origin of stones that one can scarcely make out whose view to endorse. To avoid seeming to waste time in setting out each of their individual opinions — which can be found in countless authors — I leave to each his own view and instead put forward what I have learned by my own experience and by many years' observation. From this,

unless I am mistaken, the kind reader will easily recognize what I have contributed and what those authors have. I have no wish to imitate those writers who, while they do not even know the specific differences of stones — much less of gems — yet are not ashamed to attempt, all too presumptuously, to write about the nature of each. For my part, I held nothing more important than this: that, since I was about to write on a most subtle subject, I should first come to know the airy "species" of all the things I treat philosophically in this work; then, in my various travels, visit the quarries of rock themselves, examine everything, anxiously consult the stone-cutters and quarrymen [lapicidas & Latomos] about every difficulty that arose, and investigate with all diligence the veins, the striations, and the courses laid into the stones by nature itself.

This done, imitating nature's shrewdness, I bent to the task with all the force of my mind, so that — as far as could be done — I might come to know by some art what nature works in the stones themselves with such great industry. My hope did not deceive me. Following, as it were, nature's Ariadnean thread, I found that genuine ἀὐτοψία [Greek: autopsia, "seeing for oneself," eyewitness investigation]-based account [γνῶσις (gnōsis)] that I had so longed for. Resting on it, and setting aside the disagreements of the said authors, I resolved to bring forward only what experience and direct observation [partly ἀὐτοψία (autopsia), partly experience] had taught me, for the sake of a more solid philosophy.

[Margin: Whether the stony mountains existed from the beginning, or were born in the course of time.]

The first question, then, is this: did the stony mountains exist from the beginning of things, or did they arise in the course of time out of slime, or after the Flood out of the heaping-up of an immense mass of mud? This doubt, which presents no difficulty, I will resolve in few words. I say, then, that the stony mountains — of the kind I showed in the Third Book, those vast mountain chains stretching both from pole to pole and from east to west — were set in place by the Divine Architect at the very beginning of things, when, at God's command, after the division of the waters, the dry land appeared. This is the view of most of the interpreters of Sacred Scripture.

[Margin: The cause and reason why the chaotic slime hardened at the beginning.]

For unless that Chaotic slime had at once coalesced into a stony mass, the Earth — being too soft with excessive mud — could neither have held together nor carried out its operations, as I showed at length in the passage cited. The stony framework of the mountains was therefore wholly necessary for stabilizing and

supporting the land against the assault of the sea and the stormy tempests of rains and downpours. As for those who think that the mountains first raised their heads after the Flood out of a heaping-up of mud, their opinion — being contrary to Sacred Scripture — must be utterly rejected. For Holy Writ, in Genesis chapter 7, says expressly that the Ark came to rest upon Ararat, the mountains of Armenia [montes Armeniæ]; but it could not have rested upon what did not exist beforehand, nor could Noah [Noë] have named to posterity a mountain he knew had not existed before the Flood. Add to this that the waters of the Flood are said, in the cited passage of Genesis, to have exceeded by fifteen cubits all the mountains under heaven — an expression that implies nothing else than that the mountains already existed before the Flood.

I would not, however, deny that, through the various upheavals of the world and the spreading of inundations, the slime and mud were heaped up into vast piles and, in the course of time, hardened into a stony substance. Nor am I speaking here of those stones or marbles that serve for the everyday construction of houses, temples, and other buildings, but only of the stony substance of the mountains — by which the body of the Earth is sustained so as duly to perform its functions — which is, as it were, a kind of skeleton [offatura], or mass of substructure, intended by God for the firmer consistency of the whole Geocosm.

[Margin: What power it was that hardened the mountains.]

It remains to explain how, and by what power, that chaotic slime coalesced at the beginning of things. It is certain that there was a certain lithifying power [vim lapidificam] by which this was done — and indeed it was implanted in the earthy body at once, from the very beginning of things, by God the Best and Greatest, whose immense providence does not err in its arrangement. But what this wonderful coagulating power may be, let us now explain.

[Margin: The form of things is not constituted from the four elements.]

I do not pause here over the opinions of the heathen philosophers, who hold that everything is constituted from the confluence of the four elements; as they assert in too general a way [καθολικωτέρως (katholikōterōs), "in a too universal manner"], so they conclude nothing, since this is already known to all. Therefore something other than the mixture of the elements must have been added, by which nature might accomplish her operations amid such great variety of things. And this is what I say: that there were seminal principles [seminaria] — entrusted by the most wise Architect, God the Best and Greatest, to the earthy substance — by whose power everything that comes within our view in this

world-machine both operates and has operated, and will go on operating into the future ages of time.

[Margin: The author's pursuit.]

For seminal principles of this kind were created and established to this end: that from them, as from the first principles of things, the several species of things might obtain their essential forms. To these seminal principles He added an architectonic spirit [architectonicum spiritum], dominant in the matter, by which ...

[Fol. 6, verso — running header "LIBER OCTAVUS, Sect. I" / page 6]

it shapes and works the subject under it into this or that form, as the seminal principle requires. Many natural philosophers hold that this form emanates from a fixed and proportional mixture of the elements; but they fail to consider that a varied mixture of the elements, in the absence of seminal principles, can of itself and by its own nature produce no compound endowed with a proper and new form. For the elements remain confused and mutually opposed, retaining their own particular forms, just as before the mixture — as I have shown elsewhere through experiments. For if a thing could be generated out of the fruitful seminal principles by a form arising from matter compacted of the elements, then Divine providence would have implanted the seeds of things in the Earth in vain.

[Margin: The twofold seminal principle of things.]

Now there is a twofold seminal principle to be considered here. The first regards inanimate bodies — of which kind are all the genera and species of minerals, stones, and metals that are enclosed within the Earth's womb. The second concerns the spermatic power and the nature that is at once vegetable and sensitive, without which nothing is accomplished at these grades of nature. Of the first I will treat first; of the second, at great length, in the course of this work.

CAPUT III.

On the Lithifying Power Diffused Through the Whole Body of the Geocosm

[De virtute lapidifica per totius Geocosmi corpus diffusa.]

When I said in the preceding chapter that God established a seminal principle that regards the nature of minerals, I do not take the word "seminal principle" [Seminarium] in its proper sense — as though stones thereby acquired some

vegetative power, for I will show in what follows that this opinion is false and rash. Rather, I call it a "seminal principle" in a certain equivocal and improper sense [σπερματικῶς (spermatikōs), "seminally," in a seed-like manner], because it has the power of coagulating and hardening, and of ...

[Margin: The magnetism of Nature.]

[the column continues at the foot — see below; the chapter body resumes:]

exalting the subjacent matter, partly from the dry, partly from the moist; and these are the cause of a great change in the earthy world. For when these corpuscles find a substance similar to themselves, they at once cling to it, joined by the force of magnetism and bound in a tenacious embrace. To these is added a certain architectonic spirit, like a director and leader of the operating power, arising out of the differing seminal principles of things; by which each thing, according to the disposition of its matter, acquires the form and figure due to it. This spirit must be considered not only in the spermatic and plastic power, but also in the very inanimate nature of stones and metals.

[Margin: What constitutes inanimate bodies.]

These things being supposed, I say first — as was already said before — that in the beginning of the world there was, in the terraqueous globe, a kind of seminal principle endowed with such power that it furnished consistency and solidity to all things; and I declare this to be nothing other than the salt of Nature [salem Naturæ], implanted in the chaotic mass of the waters. After the division of the waters, joined to the mud and slime, it at once exerted its powers: penetrating the still-soft earth by its piercing force, it transformed it, by its hardening power, into that skeleton [offatura] of stony mountains which we behold with wonder. In this the architectonic spirit was by no means idle. For this spirit, naturally joined to the Salt of Nature — wherever it found matter fit for forming rock — produced rock; and wherever it found matter suitable for tilling fields and bringing forth seeds, produced soft earth. Both it brought forth under the manifold differences of stones on the one hand and of earths on the other.

[Margin: The formal cause.]

As for why the flat surfaces of the plains did not, by the power of the diffused salt, harden into stone, the cause was the excessive abundance of moisture in the plains. This moisture, flowing down from the higher mountains, by its irrigation kept the fields free from hardening; whereas the mountains themselves, stripped

of moisture by the runoff of the waters and by their own dryness, it coagulated into a solid substance.

[Margin: The material cause.]

And from this union of salt with the various clods of differing earths, three other kinds of salt gradually emerged — niter [nitri], alum [aluminis], vitriol [vitrioli] — which, with other earthy substances proportioned to themselves ...

[the column resumes mid-page after the chapter heading; the opening of CAPUT III continues here:]

these corpuscles [the vapors and exhalations], being exalted by the subterranean heat, partly from the dry, partly from the moist, are the cause of great change in the earthy world. (See the continuation above.)

[Margin: What the lithifying power and the architectonic or plastic spirit may be.]

Lest, therefore, the Earth should suffer this great loss, the lithifying, architectonic spirit of Nature was established by God to this end: that whatever had been worn away and carried off from the mountains over the span of many years should be restored to the said seminal principle of Nature, as I will show afterward. What, then, this lithifying power may be, what the architectonic spirit is, and what it does and how it operates in the economy of the stony substance — this remains to be explained. And in order to proceed more solidly in the course of this argument, certain things must first be supposed, without which the rest cannot easily be understood.

I suppose, then, first: that there exists in the nature of things a certain magnetism, by which similar bodies perpetually seek similar bodies, mutually attract one another, and draw one another by a kind of perennial circulatory motion [pericycloseos motu], while dissimilar bodies repel — which clearly shines forth in all the grades of Nature, by which the threefold realm of inanimate, vegetable, and sensitive things is constituted, as I will teach afterward.

I suppose, second: that all vapors and exhalations are nothing other than the finest, most subtle, and imperceptible corpuscles, which ...

[Margin: What this lithifying power and the architectonic spirit may be.]

[The remaining portion of this column is occupied by the marginal notes and the continuation that flows to the recto of Fol. 7 — see the following page.]

[Fol. 7, recto — running header "DE LAPIDIBUS" / page 7]

[The top of this column is the continuation of the end of CAPUT III:]

[these salts], conjoined with the [earthy] substances, gave birth to the whole variety of stones and gems.

[Margin: The efficient cause.]

This variety, then, promoted by the concurrence of the subterranean fire, the sun, the stars, and the other elements, in the course of time — through a continual combination of various things — passed into that multitude and abundance which we cannot sufficiently marvel at. And so I say that the material cause of stones is nothing other than the salt of Nature, by which all things acquire their subsistence and solidity.

[Margin: The formal and final cause of the stony substance.]

The formal cause [formalem causam], on the other hand, I say to be the power implanted in the saline genus — that is, the lithifying, hardening, and coagulating power.

[Margin: The plastic power.]

But the plastic power [Plastica vis] implanted in the seminal principle of Nature — that is, the polymorphous spirit joined to it — instructs each individual thing to take up its own form and figure, in the manner that the nature of the thing required, which I also call the efficient and formal cause. And this was the process of Nature — roused by the command of the Divine will — in the first beginnings of things. Now, descending to more particular matters, let me show, by the reasonings that follow and by a great apparatus of experiments, that these things are so.

CAPUT IV.

On the Origin of Stones and Rocks, and How in the Course of Time They Coalesced into Such Great Hardness

[De Lapidum Saxorumque origine, & quomodo successu temporis in tantam duritiem coaluerint.]

I said in the preceding chapters that stones, rocks, and gems are not made out of the pure and unmixed elements, and I added the reasons; rather, something else is required, by means of which they may grow to such great hardness and differ

among themselves in so many differences of shape and color. But what that something may be, I will explain with all the diligence that is possible.

I said above that, from the first beginnings of things, a certain seed was implanted by the inscrutable wisdom of God into the chaotic mass — not, indeed, that vegetative seed, but a thing of such a kind as would correspond, by a fixed proportion and analogy, to the inanimate bodies of stones. And I spoke above of the saline lithifying spirit [*spiritum salinum lapidificum*], which, just as it has been appointed by Nature to this end — to furnish all things with their consistency, firmness, and solidity — so too, dispersed through all the paths of the sublunary world, wherever it finds a subject (that is, mud or earthy matter suitably proportioned), at once exerts its power upon it, coagulating it [*λιθογενετικῶς* (*lithogenetikōs*), "in a stone-generating way"] and converting it into a stony substance.

[Margin: What is required to harden the slime in a given place into stone.]

For the accomplishing of this, three things especially must concur. First, a proportioned place; second, matter within it aptly disposed to receive the seed; third, urgent heat that rouses the spirituous seed. For the generation of stones requires a spirit, as it were the form, and earthy matter, as it were the subject — which, in a proportioned place, with the subterranean heat (the efficient cause) acting as the coagulating agent, at last that lithogenetic offspring [*foetus ille lithogeneticus*] is brought to completion. And a proportioned place is required for this reason: that in it the form and matter may be duly preserved, fostered, and digested, as will be most fully demonstrated in its proper place concerning the wonderful power of fermentation. The place must be enclosed, so that the spirits, as it were in a womb, may be contained lest they fly off, and so that the heat, held back as in a prison, may not breathe out or be snatched away by some external force; and so, both by the subterranean heat and by the external cold — cooperating, if not of itself toward the union, at least by accident, by repelling and constraining the spirit lest it breathe out — they may be forced to be united, and in this way the intention of Nature may be satisfied.

[Margin: How stones are said to grow in mines.]

And from this the cause appears clearly: how stones are said to grow in mines, and how earth thrown into a mine, together with the moisture joined to it, finally turns to stone over the course of many years. For the lithifying spirits, derived to that place by the Vulcanian heat, when they run into proportioned matter — such as the earth of that place or mountain — at once pervade the whole mass with

their subtlety, and gradually coagulate, condense, and turn into rock that moist mass. For, as I said above, that lithogenetic or lithifying form is nothing other than that saline spirit, or those saline corpuscles — things wholly imperceptible to the eyes — which, scraped off by the subterranean heat from the mineral bodies in which they are powerful, and exalted through the innermost fibers of the Earth, produce now this, now that rock or gem, according to the disposition of the matter in their womb.

[Margin: Whence the lithifying power has its origin.]

And although a spirit of this kind can be considered under a certain generic notion, I do not doubt that it too obtains its specific differences, according to the proportion of common salt, niter, alum, vitriol, and the other individuated salts of the differing mineral clods. For the purer and more refined these spirits are, and the more suitable and proportioned the matter and the place, the more perfect and pure the stone that results — as happens in gems, of whose origin a full account will be given in what follows.

[Margin: Why not all stones are of a purer substance, and why one is more perfect than another.]

For since three things concur in the generation of stones — matter, spirit, and bond [materia, spiritus & nexus] — and, according to the differing quality or quantity of each, different stones are made, certainly so great a difference of qualities cannot arise except from the varied commingling of such spirits with one and another differing mineral. Hence some are harder, some softer; some clear and transparent, others ...

[Margin: Three things concur in generation.]

[Continued from CAPUT IV, "On the origin of stones and rocks, and how in the course of time they coalesced into such great hardness."]

[Margin: For the different worth and value of stones.]...some attain the price of a gem, others finally hold the lowest and most worthless place, like the stones that lie about everywhere. There are, finally, still others that are not generated everywhere, because the requisite conditions are not found in every place, nor are external aids ready everywhere. For some demand a more efficacious heat, others a tepid and moderate one; there are those that, rejecting excessive heat, prefer more cold; and some require a constrictive force of heat. All of this depends on the proper proportioning both of the heat and of the matter as variously disposed.

[Margin: Example of the marcasite.] But let us explain the matter by an example. In the generation of a stone, when matter teeming with sulphurous portions and metallic spirits pervades it, it is certain that a marcasite is generated — of whatever species it may be — a stone of a nature midway between stone and metal, an androgynous nature. For that the marcasite is full of sulphur, of odor and of an inflammable nature, is abundantly attested both by its inflammable character and by the spagyric art [*ars spagyrica*], which extracts copious sulphur from it; and yet it teems with the diverse spirits of the metals. Hence arises that notable variety of marcasites, some of which counterfeit gold, others silver, others copper or lead. For according as the metallic spirits are borne — more or less purified — toward that stone-forming substance, belonging to this or that ore, and again contaminated by a varied admixture of minerals, so too are stones generated that incline toward the various natures of the metals, the lithifying matter, by an innate magnetism, drawing to itself the spirits...

[Margin: Magnetism in the generation of stones.]...the spirits which were more congruent and proportioned to accomplishing the lithogenetic effect. And if anything lurking in the underlying matter has an affinity for metal, then the metallic spirits, attracted by it, will produce a marcasite stone of the very species to which the spirits belong, like attracting like to itself. But if that metallic spirit — of whatever salt's nature it may savor — finds the underlying matter not at all congruent and proportioned for the forming of a metal, but only matter apt for producing a stone, then likewise it will produce not a metal but a stone. We see the same in seed, which, when it does not find a womb suited to it, produces no germination at all, or else degenerates into some third and different thing. So too that metallic spirit does not generate a metal, but some third thing — namely a metallic stone, of the kind that pyrites or marcasite is.

[Margin: Example in seed.] For it savors of the nature of stone, in that it has many parts incapable of liquefaction, and in this it takes on the nature of stone; but it also has other parts that easily liquefy in fire, and in this — because of the notable abundance of sulphur it possesses, and because it readily liquefies in fire together with the metallic spirits — it takes on the nature of metal. But since we shall reason most fully about the genesis of stones in what follows, we refer the reader there, where (as we hope) we shall so unravel this matter through various experiments that we trust no scruple will remain to anyone hereafter.

CAPUT V.

On the color of stones and gems, and by what reasoning so great a difference of colors has been implanted in them by Nature.

Although nothing is more commonplace than color — that common object of all visible things — and nothing more obvious, yet such is the depth of its essence that all who hitherto have toiled to explain it, even philosophers of the first rank, have at last, after fruitless labor, perplexed, honestly confessed that its essence is as clear to the senses as it is obscure to the intellect, and therefore impenetrable to the human mind. And so we may not unfittingly think along with those wisest of philosophers, Plato and Aristotle. The former does not blush to lay bare the weakness of the mind in these words:

[Margin: Plato in the *Timaeus*.] "In what measure and manner the several colors are mingled with the several, no one, even if he knew, would be wise to relate — especially since he could in no way offer either a necessary or even a probable account of these things."

Here, noticing the difficulty of the matter, he says that our intellect stands toward those things that are most manifest of all just as the eyes of bats stand toward the light of day.

[Margin: Aristotle, *Meteorology* II, ch. 1.] Yet since the world, grown more learned by the continual experience of things, has made much progress, and since today many things have come forth that in earlier ages were quite unknown, this very fact offers us some hope of gazing a little more closely upon Nature's inner sanctuaries — not that we suppose ourselves in the least comparable to the philosophers of old, but because, by the frequency of experiments and the continual investigation of hidden things, with the grace of the divine Godhead breathing upon us, we have observed certain matters that have unlocked for us a true door and the keys to penetrating the mysteries of Nature; so that if not the inmost causes and reasons of each thing (which we think granted to no one in this life), then at least, so far as the weakness of human intellect allows, we may penetrate and expound those causes that can render our mind in any way quiet and tranquil in the knowledge of the truth.

There is, then, an immense dispute and controversy among nearly all authors about colors and their origin in mixed bodies, so that you can scarcely discern

whose view to subscribe to. The opinion of most — and chiefly of the Peripatetics — is that colors are secondary qualities, sensible to the sense of sight, arising from the temperament of the primary qualities. Thus from such a temperament...

[Margin: For the different reasoning of investigating color.] [fol. 9]...is born such a color, and from another a different one. But just as this description assigns no reasons, so the words too seem mere words that do not explain the matter but wrap it up. For when the nature and essence of color has been set forth in these words, I know almost as much as when I first asked. For the question is: what is that quality? how is it produced? by what? and when? For the desire to know by no means rests here, while the human mind would always wish to know something more than that generic secondary quality which they say arises from the primaries. Once that generic quality has been posited, what does the philosopher understand that is any more or any further than what a painter, a stonecutter, or a jeweler understands?

We, then, leaving aside the generic manner of speaking of the metaphysicians, and approaching more closely the inner and lowest amulets [phylacteria] of Nature, and creeping along the soil [humus] of deliberate purpose, shall — God granting it, and not scorning the apparatus of experiments — attempt to assign the causes of colors, not the common ones but the proximate and inmost, the ones most fitting to the things themselves and most of all to Nature.

[Margin: The infinite number of colors.] So great is the multitude of colors, and so manifold their variety through the reciprocal fellowship of mixture, that in no work of hers does Nature seem to have displayed her wealth more abundantly or with greater ambition. She has demonstrated this not only in the supernal bodies of the heavens — I mean in the stars — but also in the threefold economy of the lower world: in animals, plants, flowers, herbs, metals, stones, gems, marbles, all painted, distinguished, and adorned with a wondrous and incomprehensible artistry and variety of colors. And if you ask about the diversity of these colors, I answer that their diversity is as great as the diversity of human faces, of sounds, of tastes and odors — in short, as great as the diversity of all the species shining forth in this world. And just as these involve a kind of infinitude of number, so too we hold that of what mixture each consists, and by what art it is composed, is impenetrable to human intelligence — as Plato, cited above, rightly and wisely teaches.

[Margin: To contemplate the wisdom and power [virtus] of God in the production of color.] And so the ineffable wisdom of God seems to have sported with this wondrous variety of color, and to have set it before the human intellect, not that

the intellect might inwardly comprehend these colors, but that it might marvel at the divine mind of the Maker in them, and never cease to praise and adore Him. In the contemplation of all these things it has more than once come into my mind, while I stood astonished, whether at least through art a way might be granted to penetrate the causes of those colors which Nature has fashioned with such great industry —

[Margin: Whether the same causes might be investigated by the same art by which they are produced.] — a way by which, applying the active to the passive, the cause of Nature's effect might be detected. For relying on this investigation, I hoped it would come about that what Nature does in the causes of colors, I too might do through art; and so, when the causes converged into one and the same effect was produced, I should reckon that I had detected the genuine cause. No sooner said than done. But how, I explain in a few words.

[Margin: Supposition I. Color has its foundation in salts mingled with sulphurs.] I suppose, therefore, first, from the foregoing: that in the terrestrial globe there are various juices [succil], according to the variety of the earthy clods from which they emanate. Next, various kinds of salts, or crystalline bodies, which, just as they contain (being transparent) the principle of mixture, so too are most assimilated to light. To these is added manifold sulphur, of which most metals and some stones are mixedly composed. For there is no body that does not contain a portion either of moisture or juice, or of salt of whatever species, or of sulphur — since, by a certain wondrous analogy, juice corresponds to moisture, salts to earth, spirits to air, and sulphur to fire.

[Margin: The analogy of salt, moisture, spirit, and sulphur to the four elements.]

[Margin: Supposition II. From the spirits of saline things, agitated by a Vulcanian heat...] I suppose, second: that from the varied mixture of these — especially when the spirits of similar things are stirred up by a Vulcanian fire — there arises that immense variety of colors which we admire in stones, gems, and metallic bodies.

[Margin:...is born the variety of colors in stones.]

[Margin: Supposition III. The alteration of things in the fibers of the earth.] I suppose, third: that according to the various degrees of subterranean fire, mixed bodies undergo immense alterations as regards color (as will later be taught by experiments), through the abrasion of the smallest particles or corpuscles from the mixed bodies. This abrasion, exalted together by a vapor or exhalation, causes wondrous metamorphoses in the inmost fibers and veins of the earth, according

to the condition and disposition of the underlying clods — now of opaque, now of [transparent?] bodies. [The Latin here reads "nunc opacorum, modo [transpa]rentium corporum"; the run-over is set across the column and partly obscured, but "transparentium" is the evident reading.] These suppositions being made, it now remains to say how color is born in stony minerals, stones, gems, and metals.

I do not delay here over the various definitions of color adduced by various authors; I accept this one: *Color is the extremity of the transparent [perspicuum] in a determinate body, or the extremity of a bounded transparent body*; the moving cause of it is what is according to the actuality of the transparent — that is, color moves the diaphanous medium, which is already illuminated by an actual light. Hence it is plain that, although light and color seem to have a great kinship with each other, yet they differ among themselves, and so can be considered under a twofold reasoning.

[Margin: Colors in opaque and transparent bodies, and in what way they differ.] There are some colors that are beheld only in transparent bodies, others in opaque ones, and these we call material. Those of the former kind come about thus: when a clear and perfect light, before it reaches the sight, passes through a medium less clear and not perfectly diaphanous, then by that medium — owing to the manifold thickening of surfaces in its depth — it is to some degree rendered opaque; and from that commingling of light with the opaque, different colors result, according to the diverse tincture of the light in transparent bodies (as will later be demonstrated).

[Margin: In transparent bodies the diversity of colors arises from the commingling of light with the opaque.] Hence light, in its own principle, is indeed perfect, but by the encounter of the medium the diffusion of the light is not so much impeded as altered. For while it passes through the depth of the diaphanous medium, owing to some opacity (since no body in the nature of things is given perfectly diaphanous), it meets various shadows, which we call colors distinct from light — yet not merely apparent and imaginary, but true and real. For they are not beings of reason, nor...

[Margin: Color, the second of the two of the world, exists in opaque bodies.]...nor fashioned through imagination, but they have a true and real existence of their own. The second kind of color is that which shines forth chiefly in opaque bodies, and has the ground of its essence in the composition of bodies. With this color Nature has sported with a wondrous variety, not only in the stars, but also in the elements, stones, gems, and pearls; in trees, plants, flowers, fruits, and seeds; in

animals, birds, water-creatures, insects — in short, in all the opaque bodies of the world. It remains, therefore, that we expound the origin and reasoning of both colors as they shine forth in opaque as well as in transparent bodies, beginning with the color of opaque bodies.

It must be understood, then, that color [arises] not only from light, but also has the true and real grounds of its essence from the diverse constitution of the mixed bodies — a constitution which, afterward illuminated by light, draws forth the colors innate in them, as it were from potency into act.

[Margin: Whence material color arises.] It is asked, therefore: what is that commingling, and from where, or from what composition, does a mixed body now gleam white? now grow dingy with black? now glint with green? now blaze with gold? now shine so brightly with crimson [puniceus]? I explain in a few words.

[Margin: The commingling of all colors; color is made from four principal ones — white, black, fulvous, and crimson.] It is certain that the hypostasis of colors — the four principal ones — are these: white and black, fulvous [fulvum, tawny] and crimson [puniceum], from which all the rest, the intermediate ones, result by certain steps in a wondrous combination. For if you mingle white with black, you will obtain an ash-colored [cinereus] color, which, even if it proceed to infinity, will never yield either fulvous, or crimson, or green, but always that same ash color — now blacker, now paler, according to the variety and abundance of one or the other ingredient — until the white, suffused with too much darkness, tends toward black, and the black, suffused with too much whiteness, tends toward white. Hence not without reason is white compared to light, and black to darkness; since the latter, the less light it has, the more shadowy it is, while the former, the more it is suffused with light, the more luminous it is rendered.

[Margin: White disperses the sight, black gathers the same.] Hence, just as a white suffused with too much light disperses the sight, so a black, destitute of sufficient light, gathers it. Whiteness, moreover, dissipates the sight: partly because, at the sight of it, the circuit of the pupil is most tightly constricted, so that the images of things cannot freely pass into the proper workshop of vision; and partly because exquisite whiteness, when it fills the cavity of the eye, like a certain light so overshadows the forms of other things (which are of themselves less efficacious) that it snatches them, as if wrapped up and overwhelmed, from sight. But blackness, by a certain contrary reasoning, collects and steadies the sight. For at the sight of it the eye is in a manner darkened; and so, set as it were in an opaque place, it contemplates everything else more freely. All of this is plain in the eyes

of cats, whose pupils, if you observe them in the dark, you will find very wide; but if you gaze at them in open light, you will find them all the narrower, the greater the light to which they have been exposed. And so, just as these two colors are opposite...

[so the eye, on account of the harm and injury they do to vision, takes no delight in them]. Therefore, to constitute the variety of colors, Nature established three others — yellow [flavum], red [rubrum], and blue [caeruleum] — from whose mixture, above all, all the rest, the intermediate ones (which are without number, as we shall later show), are constituted. These mixtures, since they are not unknown to anyone and are found in nearly all authors, and since we have treated of them at length in our *Ars Magna Lucis et Umbrae* [*The Great Art of Light and Shadow*] and in our *Musurgia*, I have not thought fit to repeat. Since in this place only the aim of our undertaking is fixed — namely, whence colors are born in so great a diversity of stones, and first of all in opaque bodies (since regarding the color of transparent bodies no such great difficulty arises, as we shall later show) —

[Margin: Colors are born from the various salts mingled with sulphurs.] I say, therefore, first: that these colors are born, according to the first supposition, from the various salts, with which all bodies are imbued, mingled together with sulphur. For the more perfect, more purified, and purer the pus [pus — the impure earthy matter] from which a stone is generated, the nearer its color will be to light, and consequently it will display a nobler species; the more impure it is, and the more filled with an abundance of dregs, the more it will exhibit a color tending toward blackness. Yet because in this mixture salts are never lacking, they indeed — notwithstanding the muddy and befouled sulphur — induce the highest smoothness [levor] in such mixtures: partly on account of the hardness which they acquire from the abundance of salt, and partly on account of the splendor which saline bodies possess as though implanted in them by nature.

[Margin: The spagyric art teaches that colors are born from sulphur.] I say, second: from the spagyric art it has long since become known, by countless experiments, that from sulphur, variously tormented by fire, innumerable species of colors result. Hence the alchemists tell such tales of the peacock's tail and of the phoenix, as a brilliant sign of approach to the harbor of the great work [magnum opus]. Although I, for my part, judge that this diversity of colors must be ascribed not so much to the substance of the sulphur as to the saline bodies — vitriol, alum, and especially sal ammoniac — with which it teems; for the moisture of this sulphur, even at the least heat, is turned into innumerable colors,

just as sulphur too, agitated by various torments of fire, does not obtain such great differences of colors except from the sal ammoniac and vitriol with which it is saturated.

[Margin: All colors of sulphur are produced by sal ammoniac, vitriol, and the sulphurous salts mixed in.] These colors, however, it does not acquire except from the said salts, which, just as they follow the nature of transparent bodies, so too possess implanted in them the seminary of all colors. And those who attribute these colors to it from the mercury mixed in, they too assert that this comes about only from the salts of which it wholly consists — especially of vitriol; which, just as it possesses the same powers as sulphur, so too they [sulphur and vitriol] are cognate, and as to essence as it were the same, as the oil of sulphur and of mercury openly show, concerning which elsewhere. Hence, at the various degrees of fire, the saline-metallic spirits, sublimated, now...

now show black, now saffron-yellow [croceum], a little later intense red, and at last blue. The same happens in the sublimation of mercury together with sulphur, from which they elicit cinnabar's [cinabrium] intense red color; and in mercury, according as different salts and minerals [are added]. [The line is compressed in the column; "tum salia, tum minerarum" — "both salts and minerals."] Since we have elucidated all these things in the treatise on salts, and shall reason about sulphur as fully as possible in what follows, I refer the reader there. These things being thus laid down beforehand, let us now see whence comes so great a variety of colors in stones.

[Margin: The origin of color in stones.] It is certain that all stones are constituted chiefly of four things: of salt, of a sulphurous clod, of water, and of a lithifying [lapidifico] and dyeing mineral spirit. Whenever, therefore, a body consists of a predominance of salt and the least part of sulphur, a stone of white color will be born, like the white marbles. But if it grow up out of a predominance of burnt and impure sulphur, contaminated with earthy refuse, a black, porous, rough, and dark stone will be born. In marbles, however, from the abundance of salt (as I said a little before), the unrefined sulphur conceives that notable splendor and brightness in which we so greatly delight. If a greater part of vitriol be added to the sulphur, a coppery, somewhat reddish stone will be born, which, if it be mixed with verdigris [aerugo], becomes a stone imbued with a green color; and so of the rest, according to the variety of the intervening combination of the said four things.

And since there exists a great diversity of sulphur — for there is one sulphur that is black, another ashen, another fulvous, another ruddy, all of which depend on

the greater or lesser concoction of the sulphur — for through concoction the sulphur is purified, and the saline bodies are exalted, which, just as they are of themselves and by their own nature bright and diaphanous, so too, with the addition of a tinging mineral spirit (which we not unfittingly call sal ammoniac), most of all partaking of light, the stone — according to the quality and quantity of the admixed salt and the disposition of the matter — degenerates now into this, now into that color.

[Margin: How a stone is colored from the various salts.] In jaspers, however, which are of diverse colors, it is necessary that one color and another result, the spirit of sal ammoniac tinging the stone into those colors which the proportion of the diverse parts, by the magnetism innate in it, demands. The chromatism, then, or coloration of stones, is nothing else than the diverse reduction of vitriol-laden sulphur to a diverse temper, or to purity or impurity, according as the sulphur — which is mixed with all minerals — is in diverse ways purged and disposed by heat. For whether by its own proper fire, in which it is strong, or by an external or Vulcanian one, or even by light in its own way, those sulphurous parts are kindled; and, the refuse being surely consumed, the saline bodies will exert their power there, by a certain magnetic confluence, while like seeks like — or in some other way it must now needs become manifest through fire. And these,

[Margin: The reason for the purging of sulphur.] when, according to their diverse disposition, they are variously tinged with the aforesaid spirit, will likewise give off various colors.

[Margin: Chromatism consists in an igneous and spirituous part.] For although sulphur is not the fixed part of the stone, but the igneous and spirituous one, yet if it be pure and most thoroughly purified, it degenerates (as the spagyric experiments teach) into a crystalline body; and so it rises up no longer as an opaque, but as a luminous body. For coloration requires opacity, to which it may superadd light.

[Margin: From the various concoction of sulphur all colors arise.] Hence it is also plain why the saline corpuscles, which most of all concur in the generation of stones, since they are diaphanous, do not admit the same colors as the transparent things they surround: namely, because they are mixed with sulphur, and diffused through the whole substance of the stone; whence, from the thickening of the opaque part, they cannot exhibit themselves as luminous except on the surface only, according to the reckoning of the tincture they have undergone. If that tincture be red, [the surface will be] red; if white, white; if black, black; if fulvous, fulvous — and so of the rest. Yet if these saline bodies had

been freed and had gained liberty from every portion of earthy sulphur, they would assuredly gleam no longer with that material color, but with the one proper to transparent bodies.

[Margin: From the various concoction of salts and sulphurs all colors arise.] But how that may be done by the chemical art will be told in its own place. Such colors are nothing else than light and fire — the former representing the salts, the latter the sulphur — variously disposing itself, when mixed with the native gluing moisture and concocted, as daily experience teaches.

[Margin: Example from chemical operations.] For all things, while they come into being and are produced in their first beginnings, are adorned with colors far other and more distinct than in the middle and the end of their origin — as will be amply demonstrated in Book XI — for no other cause than that their hot and moist, mingled with the salt and sulphur with which they are imbued, are altered and cooked in various and distinct ways, both at the beginning of generation, and in the middle, and at the end. By the alteration of these, while the rock is dyed with its own volatile [part], it must needs (to speak after the manner of the chemists) result in diverse colors.

[Margin: Example from herbs.] Hence most minerals, roasted in furnaces and alembics, give off from themselves smokes of such differing colors; and in the great magistry [magisterium magnum] the colors — first dark, then bright, up to the most intense redness, which for that reason they call the *Red Lion* [Leo ruber] — by which they imagine they have attained the end of the work, emerge in a certain wondrous order. The same may be seen in plants too, whose parts near the root first flower with white, then with pale green, finally with intense green, until — the juice being consumed in autumn — they at last degenerate into yellowness. All of this happens from the subtlety or condensation of the moist and the hot, and from the various concoction of the radical moisture and of the sulphur appropriated to them. But of these things in their own time and place. Yet that these things stand no otherwise than as we have said, let us demonstrate all and each by irrefragable experiments.

EXPERIMENT I.

Pour the sharpest vinegar into a goblet or a lead dish. It will at once act upon the leaden substance, so that within a few days the lead, dissolved by the great acrimony of the vinegar, is converted into the purest white-cream lead [ceruffa, white lead/ceruse] — the very kind painters and apothecaries use to make countless preparations. [Margin: Lead is converted into white lead by vinegar.]

Now take this white lead out, place it in a crucible, and roast it over a very strong fire. Within a short time you will find that it has degenerated first into the most intense red color (which they call red lead [minium]), and finally into a black slag [scoria]. You will therefore ask: how does this color — first the whitest, then the reddest, and at last a black slag — come about?

[Margin: The cause and explanation of the experiment.] I answer that this happens through the increase of the heat of the fire. For first the vinegar, possessing a certain fiery acrimony, dissolves the lead into the tiniest particles. Since these particles are charged with salt, it follows that each one, separated from its earthy dregs, presents its own most luminous corpuscle. If you examine them under a microscope, you will see them in the form of crystalline grains — though, because of the calx mixed with them, they retain a little opacity; otherwise they are transparent. It is no different from when you crush glass into the smallest pieces: what was previously transparent now appears as a white powder, because the breaking-up of the compound, while it gives each particle its own particular mode of existence, also makes them appear no longer transparent but, through the mutual communication of reflected whiteness, bright and white. This is plainly seen in the dashing of water down from cliffs, where the water, broken into the smallest particles by the fall of the stream, appears white and snow-like for the same reason we have given.

It remains to explain how the white lead, when roasted, at last degenerates into the reddest color, and finally into a black slag. [Margin: How white lead is made red.] I say this happens through the various degrees of heat. For if you fix your eyes on a crucible set on the fire, you will see the white lead, at first white, gradually — at the very first whiff of fire — pass into a bright yellowish hue; a little later into a grass-green of first downy growth; then again into a tawny color; and at last bend toward the longed-for, most intense red of red lead. I said this happens through the various degrees of heat, but that reason does not suffice, since no one could deny it: something else therefore lies hidden, which constitutes this metamorphosis. How it happens, then, I will disclose.

[Margin: Lead is converted into white lead by vinegar.] We said above that all color is owed to the saline bodies mixed in metals. Now then, when the lead is eaten away by the acrimony of the vinegar, behold, there occurs a dissolution of the saline particles mixed with the calx; and since these have not yet undergone fire, they glow under the natural form of salt and calx. But once they have undergone Vulcan's fire, the sulphur — at first imperceptible, mixed with the lead and charged with salts — being roasted, passes from whiteness into a yellow salt;

[Margin: Roasted by fire, the leaden calx is turned into red lead, through diverse degrees of salt.] because the roasting transmutes the particles of the calx into a color near to white; and the saline spirit imparts brightness to it. But if the white lead is roasted more strongly, then — its bodies darkened by the increase — it will be seen tinged with a color compounded of white and yellow, somewhat greenish, which the reflection of light displays in such a disposed combination of matter. Again, if this is roasted still more violently, it gradually [passes] into a yellow color, because the matter, stirred up by the strong heat, degenerates — following the natural progression of colors — into that color which is nearer to green; for saline bodies exhibit, under the illumination of light, the color that the increase of roasting carries with it. And in this way the most intense degree of redness — that is, red lead — is at last produced by the most intense force of heat. From that degree, if the degree of fire is intensified more and more violently, you will see that, just as it grew up through the degrees of luminous colors into red, so now it bends gradually, through the degrees of shadowy and dark colors — that is, scarlet [puniceum], blue, ash-gray — in order, until, with all the spirits now dissolved, it degenerates into a black-colored slag, opposite to white, like coals. And from these things it is plainly clear how, by the force of heat, colors in minerals are gradually transmuted from one to another, step by step, according to the order of natural mixture.

[Margin: Why the same does not happen in the burning of wood.] But you will ask: why does not the same thing happen in the burning of wood, where the whitest wood at once bends into a charcoal color? I answer that this happens because of the abundance of moisture lurking in the wood. [Margin:...] This moisture, raised by heat into soot, tinges the wood with the color it is itself imbued with; and as the color increases and spreads through the whole substance, it is resolved into charcoal. The greasy soot still remaining in the charcoal a more violent fire at last strips of all its greasy moisture, as it were of a glue by which the parts in the charcoal were still held together; and that material, afterward mixed with another mineral matter and roasted by fire, undergoes the same gradual color-metamorphoses we have described. From this single experiment it is more than sufficiently clear how colors arise in minerals. But let us add another experiment.

EXPERIMENT II.

[Margin: Gall-liquor turns vitriol into ink, and why.] How saline corpuscles mutually destroy and restore one another we shall teach by this experiment. If you mix vitriol into an infusion of galls dissolved in clear water, it will at once

degenerate into ink. The reason for this is asked. I say it happens because the gall consists in greatest part of burnt sulphur, which it possesses impure and rough, as is most evident from its porous substance — a property which the water in which it is steeped communicates to it. Hence if you precipitate vitriol or vitriolated water into it, it comes about that the porous sulphur-particles lurking in the gall, and communicated to the water, at once [attract] the vitriol to themselves by their innate force, as to a body

[Fol. 13 recto, left column] congenial to themselves. And since the parts of the gall, as I said, contain a great deal of porous and burnt sulphur, pregnant with a black tincture, the particles of vitriolated water, joined to the particles of the gall, tinge the black color implanted in the gall — whence ink results. [Margin: A wonderful effect.] But if you pour Stygian water [aqua stygia, a strong acid] over this ink-tincture, then — marvelous to say — the inky water is at once restored to its former clarity. The cause of this effect is asked.

I say that the Stygian water, by its Stygian acrimony, immediately consumes utterly the eaten-away corpuscles of the galls mixed into the waters by the act of pouring; and since the tinging corpuscles are thus consumed, the clarity of the vitriolated water must necessarily return. But if you now pour oil of tartar onto this water restored to its former clarity, it will at once be turned back into ink. If you ask the cause of this, know it to be this: that oil of tartar contains in itself the same, or a not dissimilar, tincture as the gall. And so, poured upon the water now imbued with Stygian water, it comes about that the saline corpuscles — that is, the particles both of vitriol and of Stygian water, sublimed by the natural fattiness of the oil and imbued together with the black-colored tincture implanted in the oil of tartar — once more [yield] ink.

[Margin: A steganographic secret.] Hence a beautiful secret in steganography is revealed. For if you write whatever you wish on white paper with vitriolated water, the written letters soon vanish so completely, as though they had never been written, leaving no trace of them. But the moment you immerse the paper in an infusion of galls, the letters at once, imbued with the blackest color, [appear] — not without the [Margin: A wonderful blackness amid whiteness, and conversely, and the transformation.] [admiration] of onlookers. If you wish to make the whiteness complete again, do it with spirit of vitriol or Stygian water taken up with a pen and drawn over the letters; the liquor of tartar then poured upon this will restore it to its former state of clarity — the cause of which has already been made clear from what was said above. In the same way, [Margin: The blue tincture of violets turns purple, which turns into green.] the blue

tincture of violets, when oil of vitriol is poured over it, turns purple; and if you add to this a few drops of spirit of hartshorn [spiritus cornu cervi], that purple color is straightway turned into green. All these things depend on the varied constitution of the different bodies, which abound in various and different salts that tinge variously; and so too, from the natural quarrels by which they are at odds among themselves, or agree, they admit various transmutations of colors. But these matters will be set out more fully in the treatise on the fermentation and precipitation of metallic liquors, with a very rich heap of experiments.

EXPERIMENT III.

Take iron or steel, skillfully polished and most shining. If you press it with a moderate heat of fire, it will put on a saffron color; with a more vehement heat, blue or violet; but with the most vehement heat, before it glows red-hot, it will be turned into a black color — by which ignition alone it almost loses its luster. The experiment is commonly known, most familiar and everyday to blacksmiths; yet they cannot give the reason for this coloration [chromatismus], nor — I think — is it so obvious even to those who imagine themselves to be great Doctors in Philosophy. We persist, therefore, in this: that coloration and tincture arise from sulphur mixed with salts, and that, according to the diversity of pure or impure sulphur, it produces different colors, as we have already said above.

[Margin: The fiery process of the iron's coloration and tincture.] For while the iron is shining, polished, and wiped clean, if it is placed on a fire, or [exposed] to some other fiery heat — as when it is quenched while glowing — the sulphureous parts of it, at once kindled, exhale their subtlest parts at the outermost surface; and those that remain on that external surface, being deprived of [the finer parts] and being more impure, are accordingly turned, under the form of rust, into that saffron or wheaten color. For since a lesser opacity is required for a color of that kind, as soon as some of the purer substance has flown off, what remains of the fixed salt mixed with the volatile sulphur must necessarily incline to a saffron color. But if, from a more intense fire, the withdrawal of the subtler and brighter parts increases, it comes about that the parts which remain thicken still more in the said surface and become opaque, and so degenerate into a kind of shadowy color, such as blue is; until at last, with the increase of the fire and the light poured over it, the surface is converted into a black color, the more impure parts being packed together on the surface.

[Margin: Why the color of iron does not come about in the same way in boiling water as in fire.] But you will perhaps ask whether this metamorphosis of colors could come about through some other agent — for instance, if iron were thrown

into the most boiling water. I answer: no. For this effect requires a true fire and a burning heat; otherwise the sulphureous parts diffused through the whole substance of the iron would not be kindled. But they are kindled even at the moderate heat of the applied fire; to a single one, all of them — and the whole substance of the iron — are altered by it, because the subtler parts, flying off, carry with them out of the inmost recesses of the iron the more impure parts, which — being more impure and deprived of spirits — likewise, unaccustomed to flight, settle as if fixed on the external surface.

Now that the truth of colors in stones and metals has been demonstrated through the preceding experiments, nothing more remains except to demonstrate by what reasoning stones are colored in the inmost bowels of the earth. I say, then, that since most rocks and stones consist of their own sulphur and salts, it comes about that if mineral spirits of salts, raised by the subterranean fire into vapor or exhalation, penetrate — by reason of their utmost subtlety — the inmost crevices and veins of the mountains, then, where they have fallen upon suitable matter, joined to the volatile or fixed sulphur that is in that matter, that matter is turned, according to the variety of the tinging spirit, now into this, now into another color; which a lapidifying spirit or juice, coming afterward, at last hardens into a stony substance. But since in what follows

[Fol. 14 verso]

various occasion for discussion of these and similar matters will be given, I have thought it superfluous to elucidate the matter here at greater length. It remains, then, that we now show the genesis of the mixture of colors, and of their degrees, according to nature. We here lay down five principal kinds of colors as a foundation: White, Yellow, Red, Blue, Black — from whose mixture all the others, the intermediates, of which there is no number, are born; and they are comprised in the following scheme.

Diagram. A nested-arch (pyramidal) scheme of color mixtures spanning the top of the page, set between the two text columns of Fol. 14 verso. Five base colors are labeled in *italic* along the bottom baseline; above them, a tier of intervening arches each carries the name of an intermediate color produced by mixing its two neighbors below, building up in successive tiers to a single apex color. All labels are legible.

Baseline (left to right):

- *Albus* — White
- *Flavus* — Yellow

- *Ruber* — Red
- *Caeruleus* — Blue
- *Niger* — Black

First tier of intermediates (each between the two base colors beneath it, left to right):

- *Subalbus* — off-white (White + Yellow)
- *Aureus* — golden (Yellow + Red)
- *Purpureus* — purple (Red + Blue)
- *Subcaeruleus* — bluish (Blue + Black)

Second tier:

- *Incarnatus* — flesh-color (above Subalbus/Aureus region)
- *Aureus* — golden
- *Purpureus* — purple
- *Subruber* — reddish

Third tier:

- *Cinereus* — ashen
- *Viridis* — green
- *Fuscus* — dusky/brown

Apex:

- *Cineritius* — ash-gray

White mixed with black in equal proportions of parts gives birth to nothing other than an ash-gray [cineritium], whatever some Peripatetics may say. For black mixed with white always produces something whitish, and white with black always something blackish and dark — until either the whole white color is changed into manifest blackness (by repeatedly throwing in more white), or the whole black into whiteness; and conversely, the whole white into blackness (by ever and repeatedly throwing in more black). Nor is it possible for any other intermediate among the bright colors to be produced from these, since they are opposite colors, which admit no mean. But let us now pass on to others.

1. White with yellow will produce an off-yellow near to white; yellow with red, a golden, tawny, or saffron color; red with blue, purple; and blue with black, an off-blue nearest to black.

2. White with red will produce the color called flesh-color [incarnatum], and red with black an off-red verging toward blackness, as is seen in red tulips.
3. White with blue, a color not unlike ash-gray; and yellow with black, a dusky color which they call lion-color [leoninum], the color of dusky clay.
4. Finally, yellow with blue produces the noblest green of all, made up of nearly all the intermediates — the one color which Nature seems to have intended for the recreation of men and animals; whence it deservedly occupies the middle place among all colors.

And from this fourfold combination of colors all the rest derive their origin. For from white to true yellow, by the continual addition of yellow, are recalled all those colors which they now call yellow, more intense or more remiss. From red to yellow, by continual addition, result all those colors which are recalled to red, now more remiss, now more intense,

up to true red. By the addition of red to blue are recalled all those colors which have red either more intensely or more remissly. Finally, by the addition of blue to black, are recalled all those blue colors which decline toward black. The same is to be said of the addition of red to white, of red to black, of white to blue, of yellow to black, and lastly of yellow to blue. For white, yellow, red, blue, and black are not the same in all things, established at an immutable and fixed degree; nor is green the same in all things, nor golden the same, nor purple the same; but according to the varied mixture of the five principal colors named, countless species of each emerge. So that here you may have [a means] to reckon into which class of colors you should number each one — each of which draws its name from the things in which they reside: namely from the elements, the clouds, from light, from minerals, metals, herbs, flowers, from animals, birds, fishes, reptiles and insects, and others. On which see our *Ars Magna Lucis et Umbrae*, where this is treated more fully at fol. 66.

COROLLARY.

[Margin: Sulphur by its power has all colors.] From this it is likewise clear how, from the varied concoction of sulphur mixed with various salts, various and most diverse colors arise according to the degrees here set forth — as has been made more than sufficiently clear by the experiments adduced. These things being shown, let us now proceed to expound the genesis of those colors which they call apparent.

EXPERIMENT.

[Margin: Experiment of the mixture of color.] To more forcibly confirm what we have said about the combination of the aforesaid colors, you will perform the following experiment. Take crystalline glasses tinged with the five aforesaid kinds of colors — white (that is, glass devoid of color), yellow, red, blue, black. You will find that, from the superimposition of

[Fol. 15 recto, left column] one glass upon another, all those species of colors which we described in the preceding scheme are produced. So if you superimpose yellow glass upon red, you will see all objects seen through it at once shine with a certain golden color; the same will happen by the reflected ray, if you catch the sun's rays passing through the glasses on white paper. For while [the light] passes through the transparent medium, it imbues the paper with the color of the transparent medium — here, golden. Again, if you superimpose yellow upon blue, you will find everything grows green with a most brilliant species of color; but if you try the matter with the conjunction of red and blue glass, you will find everything turns purple. In this way, blue with green will display the color they call peacock [pavonaceum]. But if you superimpose a blackish glass upon white, no other color will come forth than ash-gray. In this way, with glasses tinged with only the five named colors, you will display the mixtures of all colors — an experiment no less full of delight than most worthy of admiration, demonstrating the causes of colors to the eye. Let no one, therefore, call these colors fantastical, since the glasses are tinged with a true color, drawn not from vegetables but from various minerals. [Margin: Apparent colors are not imaginary, but true and real.] Nor can the diverse color be said to be merely apparent,

since they proceed from a true and real mixture, and from light tinged according to the nature of the medium. In exactly the same way I say it stands with transparent gems: [Margin: How transparent gems are generated.] crystal, which [is generated] from white; chrysoprase, from yellow; carbuncle, from red; sapphire, from blue. But black, being shadowy, generates no gem imbued with this color. Crystalline [stone], as it emulates pure light, cannot properly be called a color. But the sapphire is tinged with the color belonging to the saline-sulphureous tinging spirits by which it was coagulated. The carbuncle, tinged with sulphur most thoroughly purified and concocted by sal ammoniac, glitters with the reddest color. The sapphire, with a tincture of vitriol [tinctura vitrioli aërosa], is dyed into a most beautiful blue of heavenly color. The emerald, resulting from a mixture of yellow and blue color, shines with a most brilliant

green. So whatever the saline tinging agents joined to the sulphur shall have been, such will be the gem that thereby turns to stone — concerning which, later. It is therefore clear that in gems the colors are not merely apparent, but true and real, arising from a true and real tincture. From these, let us now proceed to the colors most apparent in polygonal glasses, caused by the various reflection of refraction.

CAPUT VI.

On the Colors which they call Apparent.

[Margin: Apparent colors are not imaginary, but true and real.] Those are called apparent colors, for the most part, which do not flow from the surfaces of opaque and mixed bodies, but which present themselves to the sight in diverse ways through the diverse media of transparent bodies. These have, in the view of most people, been given this etymology because, of themselves and by their own nature, they are unstable, and are seen now in this, now in another color, according to the differing flux of fluid and the differing constitution of the eye; and therefore are thought not true and real, but imaginary. But we — whatever the Peripatetics may say — hold that no color is purely apparent; rather, all are true colors, which contain within themselves the true causes and reasons of their mixture and appearance. They are observed, for the most part, in the rainbow [iris], in the feathers of certain birds such as ducks, doves, and peacocks; in the differing color of the sea and the clouds; in triangular glasses [prisms] and the other crystalline polyhedral bodies, resulting from the various reflection of light. And first we shall reason — by a parallel course — about the colors in polygonal glasses, and then also about those that appear in the feathers of birds.

How Color comes about in transparent angular bodies, that is, in triangular and polyhedral glasses.

How the diversity of colors is produced in transparent angular bodies — that is, in triangular and polyhedral crystalline ones — is a matter of great controversy among the philosophers. Most of them, while they too contentiously assert that there is no real entity of colors there, but a purely fantastical and imaginary one, demonstrate that they are equipped with but slight experience of natural things, being about to dispute over those most hidden matters of nature, which they have not so much as greeted at the threshold. But those who have come nearer to her most secret recesses are compelled, by Nature herself as mistress and teacher, to say otherwise. But, to bring forth at last from the darkness into the light the manifold offspring of light: I would have you know, Reader, that

crystalline and glassy bodies, no differently than all other mixed mineral bodies, consist of their own salino-mercurial bodies — [Margin: All transparent bodies consist of their own sulphur and salts.] since glass is made from ashes turbid with salt, and from crystalline bodies, namely salts, of which there is none that is not transparent, as is clear from the microscope. These corpuscles, although they appear colorless in a glass devoid of angles, the cause is the continuity of the same, spread out and united into one flat and polished surface, through which the sight, passing straight, just as it finds no shadows, so too is not altered by differing kinds of shadows. But as soon as it falls upon angular transparent [bodies], then behold, the saline corpuscles, now affected in diverse ways — now by the defilement of shadows, now varied by the various refraction of light in a denser medium — will display colors in the order we described above; for the more

[The reading order of these four s non-linear; they are presented here in folio order: fol. 16 (verso), fol. 17 (recto), fol. 18 (verso), fol. 19 (recto).]

the smaller shadows, the closer they are to the light, will yield colors nearer the light, while the greater shadows, the more they prevail, will yield colors nearer to darkness. As for why these colors do not appear in non-angular bodies, the reason is the one I gave: straight, unimpeded light passes through to the visual faculty, and since all the corpuscles are as perfectly united as possible, they likewise absorb the pure light in the same uniform way. Consequently no colors at all appear in a medium of this kind, because of the uniformity of the light.

[Margin: Why the salt corpuscles set within a transparent body are not displayed in a non-angular transparent body, but are displayed only in an angular one.]

But the moment the opacity of an angle intervenes, the light, now darkened by the variety of the shadows, returns exactly the series of colors that the greater or lesser shadows require. With the salt corpuscles dispersed throughout the whole transparent body, the light—refracted, and mixed with shadows of varying opacity—brings into the open the very color that each corpuscle of a different tincture demands, together with the differing degrees of opacity. All this we demonstrate in the following figure. [Margin: Which colors are seen in the prism, with the explanation set forth.]

Diagram. A geometric figure illustrating refraction through a triangular crystalline prism. At upper right the Sun is drawn as a radiant face, with three rays (labeled near the Sun) descending obliquely onto the upper-right face of the prism. The prism is an elongated crystal: its apex region is the triangle **S** at top, with the upper short edge running **R–T**, and the body of the crystal extending

downward to a pointed base at **V–X–Y**. The refracted rays exit toward the upper left, where the eye is at **H**, with ray-terminations labeled **K, I, D**. Along the upper refracting surface, near the apex **S**, small italic letters mark the points where rays strike and bend (**a, b, c, e, g, n, o, r**).

- Sun (upper right): radiant face, source of the incident rays
- C, E, I, N (rays from Sun, upper right): the Sun's rays striking the prism's right face
- S (apex, top center): top vertex of the triangular prism
- R (upper left edge): left end of the prism's upper edge
- T (upper right edge): right end of the prism's upper edge
- V (lower left): left shoulder of the pointed base
- X (lower right): right shoulder of the pointed base
- Y (bottom point): the base apex of the crystal
- H (upper left): the eye [oculus]
- K, I, D (upper left, near H): terminations of the refracted rays reaching the eye
- a, b, c, e, g, n, o, r (small italics along the upper face): the points of incidence and refraction of the individual rays

Let the prism, or crystalline triangle, be **R T S V X Y**; the Sun's rays, **C E I N**; the eye, **D I K H**. Here a twofold appearance of objects is seen. The first is by the reflected ray, which alters the object neither in shape nor in color—though it shows it reversed—and this happens when the object passes through the glass perpendicularly. The second is by the refracted ray, and here the object is shown neither in its natural position nor in the same color; instead it appears now curved, now oval, and finally decked out in every kind of color. For when a ray of the Sun, **F**, or of any light, strikes the side **S T** of the triangle obliquely, it is twice refracted and returns to the eye **D I K H**. And since by this refraction it loses much of its original vigor on account of the greater or lesser depth of the medium, the light—thus diversely darkened and stained—renders colors that tend now more toward white, now more toward dark.

Now in the triangle there appear three principal colors, mentioned above—chiefly yellow, red, and blue—and from these are mixed green and purple, white and black being excluded as unsuited for producing the intermediate colors. [Margin: How yellow, red, blue, green, and purple arise in the triangle.] They arise in the triangle as follows. Let there first be the ray **C**, which strikes the glass at the point **b**, and since it must pass through a denser medium, it is refracted

from **b** to **a**, and from there reaches the eye placed at **Z**. Now since **a–b** is a short passage, at this place it would indeed produce a color most like the light, that is, like white; but because the solid angle **S V** of the glass darkens the neighboring ray considerably by its shadow, it generates not white—nor yellow, as it should if the angle did not obstruct it—but the most intense redness.

By contrast, if the ray of light **N** strikes at **O**, then in the deepest part of all, **O r**, which it traverses, it is refracted and runs to the eye placed at **H** under a blue color bordering on black. Both by the double refraction, and by the depth of the medium, and by the opacity of the angle, it has degenerated far from its native purity and ends in a dark color, such as blue is. But the ray of light **E**, falling on the point **e** of the triangle, is twice refracted—from **e** to **g**, and then finally reaches the eye at the point **I**. This ray, since it proceeds by a kind of middle path, neither much darkened by the shadow of the more remote solid angle nor immersed to so great a depth, will display a color of the middle kind, nearer to white, gleaming in a saffron robe. The remaining two colors, green and peacock-blue [pavonaceus], are composed—the former from a mixture of yellow and blue, the latter from a mixture of red and blue—and likewise show themselves at the boundaries of the said colors. In this figure, **a**, **b** mark the smallest breadth of the glass; **g e** and **n l** the middle breadth; and **o r** the greatest breadth or depth.

From all this the cause of the colors in the glass triangle, and in other angular crystalline bodies, is evident. It is none other than this: first, the solid angles cast shadows; the light, refracted in various ways as it passes through a medium of varying density, and variously modified by the shadows, and tinted by the salt corpuscles more or less dispersed, shows itself clothed in so many and so great distinctions of color. If you have rightly grasped this, you will also have the causes of the colors that shine forth in the rainbow, the sea, and the rest of things laid bare. See, reader, what we treated with fuller reasoning in our cited book *On Light and Shadow* [*Ars Magna Lucis et Umbrae*].

You have perceived, reader—unless I am mistaken—from the foregoing, that the internal light, or innate heat, which is called the sulphur of Nature and exists within each thing, is by its concoction the source of all the various colors. You have also heard how innumerable colors that mercurial liquid displays when mixed with salt bodies—colors which whoever has not seen will surely not believe me when I write of them; but those who have seen them, astonished at the novelty of the thing, cannot sufficiently marvel at that "tail of the chemical peacock," glittering with such unwonted kinds of color. But how this comes about, I shall teach right after the experiment proposed below.

A WONDERFUL EXPERIMENT, exhibiting colors of every kind.

If you place quicksilver, coagulated by the vapor of lead, on a copper spoon and heat it over burning coals, behold: presently there will emerge in the liquefied material such a variety of colors as no greater can be seen in the world—so brilliant that the so-called apparent colors can scarcely be compared with them. [Margin: The cause of so many colors.] The cause of this is sought. I say it is the exaltation of the salt corpuscles—which before lay hidden in the moist liquid mercury—brought about through the coagulation produced by the vapor of lead. For when the corpuscles are separated by the force of the heat, then behold: once the earthy dross has been either consumed or settled out, the tinging spirits of the salts alone, raised to the surface, first grow insolent with the ambition of dominating, and—tinged by their varied confluence—demonstrate their power by exerting it across nearly all the differences of color. Therefore no one of sound mind should be reckoned to dare to call these colors purely imaginary. For they are the various spirits of the tinging salts, present within the mercury by the force of the lead, which, exalted to the surface by the force of the heat, by the aid of the incident light display so many and so varied differences of the said colors. For inasmuch as they are transparent, so the corpuscles, set one upon another, express through whatever opacity now this color, now that—just as was said above concerning tinted glasses set one upon another.

The cause of the colors that shine in the feathers of birds—that is, of peacocks, doves, ducks, and other birds.

That birds swell with sulphur and salts is clear from this: that out of stables and dovecotes an immense quantity of niter and other salts is extracted. Since, therefore, they cast out by their excrement the oily portion (to speak with the chemists) of the sulphur and salts, but cannot discharge the finer parts of the salts through urine, which they lack, Nature seems by all means to have assigned these, with a higher design, to the clothing of the feathers. For since these most subtle salino-sulphureous spirits continually exhale, they, working their way into the hollow little channels of the feathers, are there condensed by the surrounding air and pass over into feathers, others and others continually succeeding. And just as the feathers are constituted of salt material variously tinging, so too they are imbued with various colors according to the incidence of the light and according to the differing structure of the feathers. [Margin: How black, white,

mixed, and the various other colors arise in birds.] For if the feathers are imbued with the soot of burnt sulphur, the birds will turn out black; if with abundant niter salt, white; if they grow from a vapor at once white and black, the birds will be born black-and-white, like magpies and swallows. But if various tinctures of salts come in, birds of diverse colors will emerge. And about these there is indeed no dispute; but how in peacocks

and doves so varied, inconstant, and changeable a variety of colors is produced according to the varying incidence of the light—of that no one, so far as I know, has yet given the true and genuine explanation. I will set out in a few words what I have observed. From frequently inspecting feathers of this kind under the microscope, it became known to me that all those feathers, radiant with so great a variety of colors and conspicuously born in peacocks and other birds, arise from the natural structure of the feathers. [Margin: The many-colored feathers of the peacock arranged in transparent, triangular-glass shapes.] Nature has so disposed their filaments that they are both transparent and fashioned into an angular form not unlike the glass triangles—all of which the microscope plainly demonstrates. Therefore, when feathers of this kind have coalesced into such an angular form out of a mixture of various tinging salts, the same thing happens in them as we taught just above happens in the triangle: that infinite variety of colors arises from the innumerable multitude of such angular feathers, by the varied refraction of one into another. And so I reckon this to be the demonstrated cause of the colors in the feathers of birds. But since we have set out all of this more fully in the *Ecstatic Journey through the Terrestrial World* [*Iter Exstaticum*], we refer the reader there, where he will also find the colors of the clouds, the sea, and the minerals treated most abundantly.

Various experiments on the colors emanating from metals and mineral bodies.

EXPERIMENT I.

The first experiment, by which it is shown that in any glass ball, watery bubble, dewdrops, and the drops of the rainbow and of leaping fountains, the same colors are generated as we showed above are produced in the triangle and the other polygons; from this too you may gather the genuine cause of the colors.

Take a glass sphere filled with the clearest water, and set it out in such a way that the incident light of the Sun may be reflected from it into your eye. Let the sphere be **B C D**, the eye **E**, **A–F** the bounding rays of the Sun, and you will see at the point **D** the most intense

Diagram. A geometric figure illustrating refraction and reflection of sunlight within a water-filled glass sphere. At upper left the Sun is drawn as a radiant face, marked **A** above and **F** below. Two dashed rays run from the Sun rightward to a circle (the glass sphere) at the right; within and around the circle are an inner small circle and inscribed lines forming the ray paths, with the inner region labeled **B C D**. The eye, **E**, is at lower left, drawn as a small eye, with rays running up to the sphere.

- **A** (above the Sun, upper left): label of the Sun / upper bound
- **F** (below the Sun, upper left): lower bound of the Sun
- **V, I** (top of the sphere): points where the bounding rays meet the sphere
- **K** (upper left of inner circle): refraction point
- **C** (right of sphere): point on the sphere
- **B C D** (center, inner region): the inner refracting/reflecting points within the sphere
- **G** (lower left of inner circle): refraction point
- **H** (right of sphere): point on the sphere
- **D** (bottom of sphere): the point of most intense color
- **E** (lower left): the eye [oculus]

redness, but when the angle is changed you will see that color manifestly varied from red into blue mixed with yellow. [Margin: Refraction of the light the cause of the different colors.] At **K** likewise the same image of red color will appear, though much fainter than at **D**. The reason for this is none other than the varied refraction in the denser medium, by which the light, variously darkened in the deeper parts of the sphere, produces the colors I have named. And from the figure here appended it is sufficiently apparent: at the point **V** of the sphere the light of the Sun strikes; refracted in the denser medium, it falls upon **C**, and from there, reflected, is driven back to **D**, and then from **D**, refracted again, reaches the eye at **E**. Since, therefore, the light is here twice refracted—once reflected in a homogeneous medium—it finally arrives at **H**; necessarily, stained by the shadows of the medium, it at last reaches the eye, having degenerated from its native brightness into a kind of shadowy light, as if in a shadow. That this manifold refraction is the cause of the colors is therefore clear from this: that at **K** the red is much varied, and the redness at **D** (inasmuch as it verges on crimson at **D**) is more remote from the white that is like the light, and so it must necessarily undergo more refractions. Moreover, the ray of the Sun **E**, striking at **G**, is refracted to **H**, thence to **I**, and from **I** to **K**, and from there at last into the eye **E**. You see, then, that a color becomes the more shadowy the more refractions it has

undergone in some transparent circular or polygonal body. Hence from this experiment the whole account of the rainbow and of the watery drops and bubbles of leaping fountains depends.

EXPERIMENT II.

There follows the color of an inflammable material, or of an oil dyed with any color whatever. [Margin: Green flame.] For if you mix verdigris [aerugineum] color thoroughly into a dish of *aqua vitae* or spirit of wine, and kindle the prepared liquid and a wick imbued with a similar color, you will see, not without wonder, a flame burning with an intense green. If you put this into a glass flask painted with grapes and plants in a bright color, on a nearby wall or white panel it will display the fruits and plants in the most intense green. For the tincture of the copper vitriol present in the verdigris, exalted by the heat, will imbue the flame with a color like itself; and the dyed light, passing through the glass flask, will tint it with a similar color, and will dye the green picture with a still more intense green. [Margin: Purple flame.] But if you mix cinnabar thoroughly with oil, the kindled liquid will make in the flame the redness of the most intense color; and if sulphur is mixed into this, it will be changed from red into a blue color. [Margin: Blue flame.] It is the same flame, but it acquires a different color according to the difference of the dyed liquid; and all this depends on the difference of the salt spirits variously dyed. [Margin: Black flame.] Finally, if you imbue the wick and the oil with soot mixed with the liquor of the cuttlefish, behold: presently a flame will rise up imbued with a black color, which will also tint the faces of the bystanders with the same color, not without the wonder and horror of the spectators. From this, in natural magic, various astounding effects can be produced, which we have shown elsewhere.

EXPERIMENT III.

On the colors of metals.

To change the color of copper [aes] into white, proceed thus: throw a powder made from calx of tartar, and likewise from alum and white arsenic dissolved in lye of lime and dried again, into melted copper, and it will gleam with a silver color. [Margin: The variety of colors in minerals through the various degrees of fire.] The same will happen if you make a water from sublimated mercury and dilute it with sal ammoniac by deliquescence; for in this, copper and iron quenched will be imbued with a silver color. But if you wish to transmute black lead into a white color, proceed thus: from white arsenic, calx of tartar, rock salt [sal gemma], and sal ammoniac let a powder be made, which you will macerate,

drenched with vinegar, for the space of seven days; and the macerated mixture you will boil down to dryness. Its fine flour, cast upon melted lead, will give great help in the casting of vessels that look like silver. By the power of fire, gradually, from ochre is made red lead [rubrica], burnt in new pots smeared round with clay; and the same, made red-hot and quenched with vinegar, will display a purple color. Copper burnt with sulphur degenerates into cinnabar; spirit of vitriol dyes iron into copper; sal ammoniac dyes lead into tin. The colors of potters, if they are smeared over with other kinds of color, will acquire another form of a different color, as will the kinds of vitriol [calcanthum]. For the heat dissolves the material into spirits, and salt bodies fixed and exalted by heat render dark colors much more brilliant.

As for the philosophical tincture, you should know that its colors are as unstable as can be, and ever and again returning. For when from dark blackness it has proceeded through innumerable colors all the way to snowy white, suddenly everything is again wrapped in black night; and then out of that blackness new colors springing up ever and again terminate first in the peacock's tail, then in the redness vainly sought by the chemists; and finally new colors, which by a false error produce colors like those already experienced and changes wholly resembling the true ones, do so not without a sure hope of perfecting the magistry. If you ask the reason for this marvelous metamorphosis, I say that these changes take their origin from the refraction of the internal light, from which all colors are generated. For since in the aforesaid material there exist together the dense and the subtle, from their mixture various refractions must necessarily arise. And first, indeed, what is subtle is absorbed by the dense; and by that putrefaction, the parts being wonderfully confused, a blackness is born, the light as it were eclipsed.

it is born; and then, out of the ebullition, the spirits bursting forth all together cover that whole vessel with clouds; thence the gross parts of the sublimation, their force now attenuated, are so mixed with the subtle parts that from this there arises a very unequal, color-generating refraction of the light. Finally, the spirits being used up, the earth remains dry and thirsty, and so, greedily reabsorbing its own spirit, by a new fermentation it begets a new blackness—while, the earthy parts now fermented and attenuated being mixed with the subtle parts, it makes new colors arise; and at last, out of the perfect mixture, a whiteness that ripens by its own fire into redness.

EXPERIMENT IV.

On the dyeing of colors in vegetable matter.

The white borax of goldsmiths will be made blue if, ground and worked up with urine, it is dyed with woad [glastum]; or it will be made purple if it is dyed more intensely. [Margin: The way and method of the juices that dye.] Now among the dyeing substances in vegetable matter are the juices of black grapes, of amaranth, of bloodroot [sanguineus], of mulberries [babustiae], of dyer's knotgrass [polygonum cocciger], the seeds of the three-seeded heliotrope [heliotropium tricoccum]—which at its first rubbing yields a green color, then a blue and purple most apt for dyeing papers—and likewise the leaves of *cyperus* or alkanet [Alcanna], with whose juice the Arabs are accustomed to dye the manes and tails of horses and the feathers of ostriches red and yellow. A whole book would have to be woven here if I wished to set out the manner and method by which metals, bones, woods, feathers, horses, and dogs can be dyed in colors of every kind. But since these things lie outside the limits of our undertaking, leaving them aside, let us proceed to those that are proper to our argument.

CHAPTER VII.

In which the cause and origin of transparent stones and gems is treated; and first indeed the generation of crystalline gems, then the origin of diamonds, will be discussed.

From the foregoing it has already become known that the earthy body is full of metallic and salt spirits—of salt, niter, alum, vitriol—which, scraped off by the subterranean fire from the clods appropriate to each, and turned into exhalation or vapor, are exalted through the innermost and almost imperceptible fibers of the earth. [Margin: The vapor of the salt spirits the cause of the crystals.] Wherever they find earthy portions proportioned to themselves, there they exert their power upon them, partly by dyeing, partly by hardening. For if within the recesses of the mountains they happen anywhere upon clods swelling with salt, then suddenly—as if a kind of magnetism were stirred up—the finer parts flow together to like parts; and since these are most subtle and all transparent, once united in a fitting place, with the lapidific spirit set within them cooperating, they coalesce into that crystalline substance which we marvel at. And this is the origin and rise of all those gems which Nature willed to be pellucid and transparent—which indeed differ from the baser kinds in nobility and excellence only by hardness and tincture. For the harder they are and dyed with a nobler color, the more they are valued. [Margin: What hardness and tincture confer on gems.] The

hardness, however, comes from no other source than the most exquisite union and almost inseparable bond of the parts, as happens in diamonds, of which later. And the tincture—yellow or golden, red, blue, purple, green—comes from nothing else than the various species of the tinging salts (which a little earlier we showed by various experiments), exalted by the force of heat now into this, now into that color. This tincture, as it argues a varied mixture of salts, so likewise the same varied virtues and properties accompany it—like the sun by its shadow—so that, indeed, the exquisite union of the most minute corpuscles confers on them hardness, while the tincture, differing one from another, confers the various powers and properties that we find by experience in gems.

But to scrutinize the origin of the transparent gems a little more closely: it is asked, first, how and by what means crystal is born. There are those who hold that crystal is born only from the purest waters of melted snows, by the force of a coagulating spirit, and is produced only in the coldest regions. [Margin: Crystal not born only in cold regions, but also in the hottest.] That both of these are false, manifold experience has long since shown. For not only in various places of Europe, but also in the Indies, in Africa, in America, in the regions situated under the very torrid zone, a great abundance of crystal is produced—so all who have explored those regions report. [Margin: A temple in Chile carved out of crystal.] The History of the Kingdom of Chile relates that in those tracts, in a certain deep valley which the ridges of the Andes [Andium juga] bound, on an island in the middle of a very large river, there is an immense rock entirely of crystal, in which a whole temple has been carved out by the pagan inhabitants with marvelous art, transparent on every side. Likewise, that from the Mountains of the Moon [montes Lunae] of Africa, lying under the torrid zone, an immense quantity of crystal is extracted; which the writers of Eastern history report also of the islands of the East Indies, Ceylon [Zeilanum] and Sumatra [Sumatra]. But since there can and ought to be no doubt about these things, leaving them aside, let us proceed to investigate the cause of its origin. [Margin: The origin of crystal.]

In the mountains, therefore, where there lies hidden the greatest quantity of the purest salt within the hollows of the mountains, it comes about that, with the subterranean heat acting, other salt bodies through a salt vapor ...and purged of all coarser bodies, these are drawn upward. Once elevated through the inner fissures of the earth (as I said) and finding a subject in sympathy with them, there too — by a kind of magnetism that Nature interposes — an attraction of like parts to like parts arises. These parts, joined by the coagulative spirit that acts as their attendant, are coupled in a marvelous union, and from the joining of transparent corpuscles that transparent crystal is at last born.

That this is in fact how the matter stands, and that crystal is made from the purest salt, we confirm by experiment. You will test that crystal consists of fully refined salt as follows.

EXPERIMENT

[Margin: Crystal consists of salt.]

Pound the crystal into the finest powder, add twice its weight of sulphur, and grind them into a thorough mixture. Place this in a crucible and subject it to a reverberatory fire for the space of six hours; then digest what has been reverberated in horse-dung for fourteen days. Next take it out and distil it. When the distillation is complete, you will find the salt-bodies separated out and, condensed again by cold, settled at the bottom of the receiver in the form of the whitest salt. The crystal is therefore resolved by the force of heat back into that from which it was originally constituted.

[Margin: When crystal is distilled, the salt remains at the bottom.]

As for why crystal is softer than the other gems, the softness of salt is the cause. Salt by its own nature is moist and of a fluid character, so its parts do not unite with one another into the same hardness into which certain others of a drier nature settle. But this crystal-genesis also requires a proportioned place, so that the vapor carried there does not evaporate away, but, collected and with no avenue of escape, may — by the moisture acting as a kind of proportioned glue — produce the effect we have described.

[Margin: Where the colors — yellow, blue, red, green — come from. They are tinged in the topaz, chrysolite, sapphire, carbuncle, and emerald.]

Now if the vapor is yellow and saline, tinged with the saffron of iron, and has met with material suited to it, it will tint that material yellow, making it glow as a topaz or chrysolite shining with a yellow color, distinct in both hardness and in the properties of its tincture. But if it has been mixed with the vapor of vitriol abraded from a copper clod, the minute saline corpuscles, united by an innate appetite, will produce a sapphire glowing with a sky-blue color; and it will acquire a hardness even greater than crystal's, since it takes its tincture from vitriol, which is of a more strongly uniting property of parts.

[Margin: Different tincture gives gems their different powers.]

In this way all the transparent gems, of whatever sort they finally are, consist of saline corpuscles from their very beginnings. Afterwards, mixed with various

species of salts, they acquire — as they are concocted through the different degrees of heat — both their different tinctures and their hardness, along with their other distinct powers. For just as salt set in a moist place dissolves and moistens, while the same salt, roasted by fire and with its moisture evaporated, takes on another, dry and corrosive property —

[Margin: An example from salt, an egg, and urine.]

— and just as an egg lightly cooked to a liquid state has one virtue, and one cooked hard another, so that according to the intensity of the fire it takes on both a different state and different powers — and this is plain too in urine, which by the moderate heat of a healthy man becomes citrine-yellow, in the excessive heat of the feverish turns to a red, and in a man abounding in undigested humors, through a mild heat, presents a watery fluid. (See, reader, what I taught most amply about the colors of urine in Book Two of the *Ars Magna Lucis et Umbrae*; there too you will find by what method water can be prepared from urine and from other salts, water which, set over a fire and evaporated onto images placed above, displays to the eye in those paper images countless colors according to the varying incidence of light — a generation of colors from salts demonstrated entirely παρ' ὀφθαλμοῖς [Greek: *par' ophthalmois*, "before one's very eyes"].)

[Fol. 21]

[Margin: The ridiculous opinion of certain people about the origin of the diamond.]

There remains at this point a single difficulty to untangle, one that has astonishingly vexed the wits of many men — and that is the untamed nature of the diamond.

[Margin: The true and genuine cause of the origin of diamonds is set out.]

The question, then, is this: from where does the diamond derive the seed-bed of such great powers, and how does it coalesce into such hardness and such smoothness? The diamond is the King of all gems, a stone the most noble among all the crystalline or transparent gems, whether you regard its hardness or its powers.

[Margin: The diamond, King of gems. By its hardness and powers it has always been held in great esteem by monarchs.]

For its hardness or its powers it is the most noble and the most precious of all; and so by emperors and kings it was of old called the very symbol of royal

splendor. In ancient times Pliny [Pliny the Elder] believed it could, by reason of its hardness, evade all the blows of the hammer.

[Margin: It is false that the diamond cannot be shattered by a hammer.]

But everyday experience has long since taught the contrary: not only can it be broken, but it can even be reduced to the finest powder. Many supposed too that, on account of its corrosive power, it was lethal to a man, yet experience has shown this to be false.

[Margin: Things falsely believed about the diamond, harmful to man.]

For in India the diggers of these stones, generally to avoid being accused of theft, swallow them in great quantity without harm, and afterwards, once they have passed them out again, lay them aside in a safe place for profit. Since, then, these stones — fitted by Nature with the sharpest points — when swallowed do no injury to the entrails, how much less shall we judge that the finest dust, wrapped in the humors of the stomach and the excrement of the intestines, will do harm? The diamond therefore contains in itself nothing, whether of internal or external quality, that is pernicious — not to say lethal. Indeed Anselmus Boodt [Anselmus de Boodt] has asserted that in long-lasting dysenteric complaints it has been given by him to a boy with great benefit. As for the prodigious powers that writers recount, most have been found utterly false:

[Margin: The superstitious use of the diamond.]

as, for instance, that it is said to restore quarreling spouses to harmony, to dispel sorceries and incantations, and to repress the assaults of demons. But these faculties, being above nature, and depending on the human will and free choice — being thus supernatural — cannot produce such far-removed effects; nor can the diamond impress any power upon incorporeal demons for driving them away, especially if superstitions are added to it, as Marbodeus [Marbodus of Rennes] teaches, who thinks —

[Margin: Marbodeus's astrological superstition concerning a figure carved on the diamond.]

— that it acquires inestimable powers if, under such-and-such a sign or such-and-such an ascendant, this or that figure is carved upon it. But since I have already refuted such delusions of idle-minded men, with arguments, in many of my works, I did not wish to linger over them in this place.

[Margin: The diamond is not consumed by the blood of a he-goat.]

That the diamond steals away the powers of the magnet, or grows soft in the blood of a he-goat, long experience of things has likewise taught to be equally false. See what we have discussed most fully about these matters in our *Ars Magnetica*. Setting such things aside, then, let us now return to our undertaking, which was to show from where the diamond draws so great a hardness, and how Nature produces it.

I say, then, that it is produced not only in the East Indies, but in many other parts of the world as well — indeed it is found even in Bohemia and Hungary, though it does not attain the hardness of the Indian stone.

[Margin: Where true diamonds properly grow.]

Only the East Indies have been found to produce true and genuine diamonds, especially in the province called Bisnaga [Vijayanagara], where three diamond-bearing crags are kept under perpetual guard by soldiers. In the kingdom of Decan [the Deccan] there is another crag, as also in the domain of a certain petty king, in which are found the most outstanding stones, in hardness, in smoothness, and in virtues — those that the natives commonly call *Naïfes*, "of the old crag." Around the islands near New Batavia [the Dutch East Indies], too, fragments of rocky crags packed with diamonds are found within the sea, at the foot of very high cliffs. These fragments, battered by the assaults of the sea in frequent storms, are over time worn away and gathered up from the gathered rubble by a multitude of slaves, who, having collected them knee-deep in the shallowest waters, toss them into a bag tied to their backs. Afterwards, dissolved with iron hammers in nearby workshops, they are sold to merchants. And Nature produces them there already so polished that, without any other smoothing instrument, they are worn just as they are drawn from the crag. There is also another mountain, not far from Malacca, that bears diamonds. The rest, wherever they may finally be found, are inferior to those here mentioned.

The question, then, is about their genesis.

[Margin: The ridiculous opinion of certain people about the origin of the diamond.]

Many think it happens because they are nearer to the rising Sun — a quite stupid argument, as if a circumstance of this kind were the cause of this admirable genesis. Do not these ill-conditioned men know that every place in the world is, by a different relation, now eastern, now western? On this argument it could be neatly proved that the kingdom of Decan, where Nature produces diamonds in greater abundance and of better quality, must — since with respect to Malacca it lies many hours to the west — against all custom and experience be incapable of

producing diamonds, for no other reason than that Malacca, where we have said diamonds are also produced, lies further east, while Decan inclines more to the west. With such trifles do those stupid philosophasters entangle themselves, when, unfit for philosophizing, they attempt to approach the causes of hidden things, and the mysteries of Nature, too rashly and (so to speak) with unwashed hands.

[Margin: The true and genuine cause of the origin of diamonds is set out.]

Wherever, then, in the regions of India the saline spirits, exalted by the force of the subterranean fire through the innermost fibers of the mountains — drawn from the purest and most thoroughly refined salt — have found a suitable and porous crag, that is, a proportioned place within the crag's hollows, and wherever in those places there is found within the crags an abundance of much fixed, purest salt, stripped of all moisture by the heat of the Sun (most burning in those parts) shining from without; and provided too that the natural moisture of the place, or some dewy substance evaporated through the pores of the rocks by the innermost veins of the mountains, or insinuated from elsewhere and resolved as it were into certain droplets, is added — then it comes about that the volatile spirits of the purest salt, joined to the fixed corpuscles of the most thoroughly concocted salt within the pores there, with the coagulative spirit acting strongly as their attendant (which unites and connects the minute fixed parts of the purest salt with the volatile ones into one continuous body as compactly as can be), and with there concurring also in that same place some species of the subtlest fatness, transparent and much like the gum of cherry trees, by which the parts are also bound together most compactly, glue-fashion, with the gift of splendor communicated to them — these salts at last grow into this most noble of all gems.

[Margin: What is required for the genesis of the diamond.]

You see, then, that for the genesis of this gem there is required, first, the purest spirits of salt, not at all defiled by tinctures of any other juices or minerals, nor contaminated by coarser particles; and these must be volatile, for without that volatility the pure parts cannot be separated from the impure. Second, I have said, there is required a proportioned place within the hollows of some porous crag — a place which, as for the other gems, so also for this most noble of all, had to be destined by Nature as supremely pure, so that in it, as in a kind of womb, the volatile spirits of salts may be concocted, and within it, just as through certain umbilical veins, received and there enclosed, and then aptly joined to the fixed parts of the purest salt with which the said crag is pregnant. But because without some glue, which is moist, and without the coagulative spirit, the intended effect

cannot at all be produced, hence the lapidific spirit — which is nearly always joined to the saline spirits in an indivisible partnership — once it has found that dewy moisture, then, behold, by that happy marriage of Nature between the volatile spirits and the fixed, with moisture as the means, in the course of time grows together into the gem of the diamond. And this gem is the more compact and hard, the more minute, subtle, and well-purified the saline parts have been. And this I judge to be the true genesis of the diamond.

There is added the testimony of Father Hyacinthus de Magistris, Procurator of the East Indies, who, having himself inspected crags of this kind, affirmed that what we have said is so. For he observed that the diamonds were born there in proportion to the size of the openings or pores, scarcely ever exceeding the size of a pea —

[Fol. 22]

— and, with the cavities from which they had been hollowed out still visibly remaining, those in the lower part of the crag were larger, and those in the upper part smaller. He adds, moreover, that by an occult property of the crag there is born a certain very subtle species of transparent gum, which, mixed with the coagulating agent, confers on the diamond that supreme splendor we admire in it. He notes too that it has become known by the frequent experience of the Indians that diamonds already removed from the crag are born anew after the passage of about two years — which agrees perfectly with what we have said about the genesis of the diamond. For by the nature of the place there is a perpetual exhalation of the said volatile spirits, exalted from the innermost bowels of the earth by heat; and these, enclosed within the little chambers of the porous rock and there joined to the rock by means of moisture, at last accomplish their work in the birth of a new offspring.

And from this reasoning it is plainly evident that diamantine hardness results from saline corpuscles of the utmost refinement, bound by the lapidific spirit into the tightest union; that its transparency is conferred on it by the saline corpuscles themselves (which, the more they are purged of earthy dregs, the greater the transparency they acquire); and that its smoothness and that extraordinary splendor are acquired from the aforesaid subtlest vapor of gum, with the external heat of the burning Sun cooperating very greatly — by which the crags, struck through, conceive a heat suited to accomplishing the work. And these are the conditions that constitute the diamond as the most excellent gem of all — conditions which, since the remaining crystalline gems, as well as the Bohemian and Hungarian diamonds, lack them, are likewise, as regards perfection, not to be

compared with the Indian stones. Whoever desires more about the diamond, let him consult the chapter on diamonds in the following Section, where the imitation and counterfeit diamonds, their correction, and their many medical virtues will be treated more fully.

CAPUT VIII

On the various figures, forms, and images with which Nature has furnished stones and gems.

I judge that there is no one of so dull a mind that, having entered somewhat deeply into the stony economy of the Earth, is not seized with the greatest admiration when he sees with what ingenuity and industry Nature has played in the various stones and gems — so much so that what she accomplished in the realm of vegetables and animals, she must be reckoned to have accomplished likewise in stones and gems. For whether you regard the variety of colors in plants, herbs, and flowers, or in birds, animals, and insects, or the variety of figures and forms in all of these, the stony kingdom seems to yield to them in nothing.

[Margin: Nature's marvelous industry in painting upon rocks.]

And it plainly appears that Lithogenetic Nature aimed at the very same thing, in producing effects according to the grades of Nature, that the vegetative and sensitive nature aimed at in its own realm. For she has always, so far as she could and was permitted, taken pains that, upon those creatures into which she could not — that lowest grade of Nature resisting — instill life and motion, she might at least not fail to impress a figure on her stony and gem-bearing offspring.

[Margin: Nature the Geometer.]

And first of all, in the stones she fulfilled all the parts of a good Geometer, when she marked their surfaces not only with points, lines, and every kind of figure, but also displayed solid bodies adorned with every kind of polygon. Nor did her industry stop here, but, rising higher —

[Margin: Nature the Astronomer.]

— she pitched her tents of heaven in the gem-bearing realm, and clothed them with Sun, Moon, and Stars in marvelous order. Then, progressing to optics —

[Margin: Optics.]

— she painted rivers, woods, meadows, mountains, and seas on many stones to the exact rule of perspective, so that she seems to have wished to leave nothing for the hand of any optician to desire beyond her own industry.

[*Margin: The Painter.*]

Then, embracing the art of painting and sculpture, she delineated whatever in the nature of things is perceptible to the senses, and in some she even played at a variety of figures with a certain artful sculpture of exquisite workmanship.

[*Margin: The Victor.*]

Lest we should seem to have described all these sports of Nature merely for the sake of their charm and elegance, we have undertaken to explain each and every one of her works by a detailed account — as they are observed in the kingdom of stony substance — especially since no one among the natural philosophers has hitherto been found who has set out the true and genuine causes of such great effects. We shall begin with the geometrical figures.

[*Margin: Stones and gems with points.*]

1. There are found, then, certain kinds of stones marked with countless points: among which may not undeservedly be numbered the stone called *Jasponyx* by Pliny, and the *Sandaster*, which, radiant within like the likeness of stars in a translucent medium, shine with golden droplets. The *Ophites* is varied with colors and points, and so is called by Dioscorides χαμαιπιτυώδης [Greek: *chamaipityōdēs*, "ground-pine-like"]. The *Ammochrysus*, which I take to be the same stone that today they call *Venturino*, radiates with countless little stars. Sky-blue blisters here and there encircle the *Ostracites*; a great variety of warts roughens the *Myrtilus*. Bloody patches at the bottom mark the *Haematites* here and there; golden droplets adorn the *Lazuli* stone. Egyptian marble, from which the obelisks were carved, consists of a fourfold mixture of points — black, red, blue, and white — which men used to signify the four Elements mystically, as we showed in our *Oedipus*. So indeed all these stones, dotted with points of different colors, can be referred to this class of pointed stones, of which, since the number is infinite —

[Fol. 23]

— let it suffice that I have indicated it here in these few words.

[*Margin: Lined stones and gems.*]

2. There are found some stones which, with figures growing variously into gems — with spots and warts of lines, in a manifold tracing — affect the gem with that color, and in those gems always appear as though implanted by nature; and no less than in plants, they keep the number and the proportion of leaves and fruits. Cleavable stones, which they call σχιστούς [Greek: *schistous*, "split/cleavable"], may not inappropriately be called πολύγραμμοι [Greek: *polygrammoi*, "many-lined"], because their whole body appears as if composed of contiguous lines. Of this kind are the various sorts of *Haematites*; the *Meseleucus*, which divides the middle of the gem with a white line; the *Mesomelas*, which follows with the tracing of a black line. Add to these the *Ophicardalus*, which two white lines enclose with a black. The species of *Prasius* is distinguished by three lines. Another is adorned with many lines as with zones, and is therefore called πολύζωνος [Greek: *polyzōnos*, "many-zoned"]. Others, marked with countless lines, are therefore called πολύγραμμοι [many-lined]. To these are referred all the stones painted by nature in a manifold order of furrows after the fashion of striae.

When some years ago I was surveying the Tolfa district together with its alum-works, I came upon a certain hill in which a certain kind of stone was found, sky-blue, much like schist, in which, in white and most subtle lines, whatever of shapes could be devised was found designed by Nature. Therefore, with marvelous things presenting themselves to move my admiration, as I considered more attentively the tracings of the individual lines, I found not only all the letters of the Greek alphabet, but of the Latin one as well; and besides, nearly all the simple geometrical schemes which Euclid demonstrates in his *Elements* of Geometry. And since the matter seemed worthy, I have judged it right to set it forth here separately, taken out just in the manner in which Nature had formed it.

Diagram. A small woodcut at upper left shows an oval banded stone (a cleavable schist specimen marked with parallel lines). Below it, a framed plate is captioned "A specimen of lined stones, of the kind found in a certain stone of the schist family, in the Tolfa and Bassano districts." The plate is divided into two labeled panels:

- Upper panel, captioned *Litterae Alphabeti in Saxi à natura formatae* ("Letters of the alphabet naturally formed in rocks"): three rows of small framed squares, each containing a letter outlined by natural veining —

reading across, the Latin alphabet: **A B C D E F G H I / L M N O P Q R S T / V X Y Z Æ.**

- Lower panel, captioned *Figurae Geometricae à natura in Saxis formatae* ("Geometric figures naturally formed in rocks"): four rows of framed squares each containing a simple geometric figure drawn in natural lines — triangles, crossed lines (X), nested/divided rectangles, diagonals, a square with inscribed diagonals, a circle within a square, a plus/cross, and a star/asterisk among them. (The figures correspond to Euclidean elementary schemes: triangles, squares, parallels, a cross, and a radiating star.)

The whole plate is captioned beneath: *Figurae Geometricae à Natura impressae lapidibus* ("Geometric figures impressed by Nature upon stones").

These figures of letters and of geometric schemes I have collected on purpose, in order to adorn marvels with these marvels produced by Nature's industry. If haste toward other matters had allowed me to collect more, surely whatever Geometry could gather in angles, triangles, quadrangles, trapezia, and parallels could have been found with little trouble. But so that the curious reader may, from the claw, infer the lion, we have thought it right to add here these few out of countless examples.

[Margin: The cause of the lines in growing stones.]

The question, then, is how Nature produces so great a variety of lines. I say, then, that the cause is the earthy substance from which the stone grew: this substance, first indeed a soft clay, then, through the intervening dryness, opened into various cracks — just as happens in muddy pools after rains, which, dried little by little by the heat of the Sun, are split into countless cracks of every kind. So too in these stones, before they were hardened by the lapidific spirit, we judge it to have happened: cracks which afterward a gypseous vapor, with which the place naturally abounds —

vapor enters and, condensing, passed along the courses of the cracks, producing that variety of bluish-white lines in the blue ground which we have described.

The truth of this a subsequent experiment taught me.

EXPERIMENT

Take a small cake of soft clay and lay it over a grill fitted with fine iron wires and supported on a tripod. Underneath, place glowing coals: at once, as the moisture is driven off, the heat will crack the mass into many fissures.

[Margin: How lined stones are produced artificially.]

Once this is done, set white lead [ceruffa] in a crucible and stir it vigorously over a strong fire. You will see the white lead rise as a vapor, penetrate the cracks of the clay cake, and lodge there, somewhat condensed by the surrounding cold. After this, take away the clay, and along the courses of the cracks it will display countless white lines. The operation, however, must be carried out skillfully: the grill should be set not directly above the crucible but somewhat higher, so that the vapor does not become too rarefied and vanish within the cracks, but condenses at the first touch of cold. If instead you try the experiment with red lead [minium], it will produce red lines; with ochre, golden ones; with verdigris [erugo], green ones. From this experiment it became certain to me that lined stones of this kind are produced in no other way than the one described: for these clay masses, lined and then baked in a furnace, will display lines running through the whole depth of the stone, exactly like the natural ones that Nature generates in the mines.

Dotted stones [lapides punctati] differ from lined ones only in this: that their soft material is still highly porous and, once dried out, leaves various empty hollows in its midst. These are afterward filled by the vapor of whatever mineral it may be and, hardened there, exhibit on that outermost surface the multitude of dots we have spoken of. I would have you note here, reader, that in translucent gems this variety, whether of dots or of lines, is not produced in the same way: rather, such spots and tracts of lines arise for the most part from the spirits of various salts diffused in a certain order — about which more in another place. So here it is enough to have merely pointed out the cause.

On the genesis of polygonal gems [De Polygonarum gemmarum genesi]

This wonderful property of stones is observed above all in translucent gems, all of which Nature has willed to be born either round or polygonal. To what end, I will set forth as far as the weakness of my talent allows — though I am well aware that nothing has so vexed the minds of natural philosophers up to now as this prodigious offspring of angular progeny. Various writers bring forward various explanations, but nothing that satisfies a mind hungry for the truth. I will set out what I have observed by long experience in such matters.

From what has been said above it is established that all transparent gems have one and the same origin, that is, from a saline liquor. Yet, just as they have been endowed by Nature with —

Diagram. A woodcut of a crystal-bearing mineral specimen, captioned "*Minera Crytalli ex Museo Anifori*" ["Crystal ore, from the Museum of Anisori"]. The specimen is a rounded, cushion-shaped mass densely covered over its whole upper surface with sharp pyramidal quartz crystals radiating outward, resting on a rough nodular base.

Diagram. A woodcut captioned "*Pseudocrytallus*" ["False crystal" / pseudo-crystal], placed below the first specimen. It shows an irregular nodular stone whose surface bears a dense field of small star-like and rosette-like crystalline growths, with a few larger pointed crystals projecting at the edges.

Diagram. An uncaptioned woodcut of a rounded mineral specimen whose surface is covered with large flower-like (chrysanthemum-shaped) radiating crystalline rosettes.

Diagram. A woodcut plate captioned "*Formæ Topaziorum, Amethistorum, Beryllorum*" ["The forms of topazes, amethysts, and beryls"], showing nine faceted crystal shapes arranged in three rows of three. They depict the characteristic polygonal (prismatic and pyramidal) habits of these gems — tabular, elongated-prismatic, and bipyramidal forms with hexagonal and tetragonal cross-sections. No individual labels.

with a blue tincture, it should unite the parts, a sapphire will be born; if with a red tincture it should unite the parts still more strongly, a pyrope or carbuncle will be born; if with a green tincture it unites them equally, an emerald will be born; and if, finally, it unites the parts most strongly of all, then is born the hardest of all, the diamond [adamas], free of every tincture, glorying in light and splendor alone. And from these, according to one tincture or another, greater or lesser, countless other species of gems emerge — which, however, are referred back to some one of the principal kinds just named. Hence the gem-dealers carefully observe the constitution of the most diverse topazes, beryls, emeralds, carbuncles, opals, diamonds, and the rest of the gems; and as these are tintured to a greater or lesser degree, or even with different colors, so they receive countless names.

In all of them, nevertheless, Nature has fashioned something I-know-not-what of the angular: for some are tuberous, some triangular [triquedrae], some tetrahedral, very many — chiefly the crystals — hexahedral; in topazes one occasionally finds even dodecahedral forms, as is apparent from these figures. The cause, therefore, of these angles, and the purpose Nature intends in them, is not unreasonably asked.

[Margin: Why crystalline gems are everywhere polygonal.]

For since this unusual form is to be observed above all in transparent gems, it has — to the point that the matter became a byword — dragged many into despair in their inquiry into the cause; and to those struck with wonder at such exotic effects it has, so as to penetrate to the cause that produces such great things, applied sharp goads, but to no avail. It is now time for us to disclose what we think.

That there is in saline bodies a certain radiating power [virtutem actinobolicam], which we call radiative [radiativam], the experience of many years has taught us. This power consists in the following: the spirit hidden within the body of the salt, going out from the center to the circumference by its own nature and by a kind of natural appetite, gradually, by its own thrusting, distributes the corpuscles into certain rays. If it splits the diameter into four parts, this will be the base — and, as it were, a kind of ground-plan [ichnographia] — on which the gem is figured, the gem that Nature wills to be of square form; if into five, it will lay the rudiment of a pentagonal form; if into six, of a hexagonal one (proper to crystals and amethysts); and so on for the rest up to twelve. It will constitute the figure with just as many sides as the rays into which the saline spirit has thrust its corpuscles.

First, then, that all transparent gems consist of various species of salts was confirmed above by various experiments, and is accepted by the unanimous consensus of the chemists. Second, that there is in each individual saline corpuscle something implanted by nature, of that figure which the gem formed from them displays. For if, with crystal reduced to powder, you examine the individual corpuscles under a microscope, you will find each of them displaying something I-know-not-what of the radiate; and the same is plainly clear in the other saline corpuscles — of niter, alum, vitriol, sugar, and the like. We have demonstrated this at length in the *Diatribē on the prodigious crucibles* [*Diatribē de Crucibus prodigiosis*], regarding the figures seen at Naples in the linen garments of men. Not inappropriately can we call this the plastic faculty of gems, entirely analogous to that which the sensitive grade of Nature uses in fashioning the organs of living things — though we more fittingly call it ἀκτινοβολικὴν [Greek: aktinobolikēn, "ray-emitting," the radiative power], that is, the radiative force. For the spirit in each corpuscle, by itself and its own nature seeking radiation, lying hidden as if in a center, solicits each corpuscle through the rays already implanted in it, and so also unfolds each from its own center: beginning first from the root, in crystals it lays down roots in place of a six-fold ground-plan; then upward, radiating κατὰ ὀρθάς [Greek: kata orthas, "at right angles"], with new

accession of corpuscles it at last grows out into this form we admire — namely, the hexagonal. But since in the intervening space a most pure humor is mixed with these saline corpuscles, it comes about — by a kind of wondrous magnetism, by which similar bodies are drawn to one another — that saline parts adhere to corpuscles of their own kind, now arranged into the form due to it through this radiation [actinobolismum], while dissimilar watery corpuscles are driven outside and separated off. And lest any void be left in the intervening space, a new liquor of most pure water is substituted in the place of those departing; and finally, the lapidific spirit, supervening upon this enclosed water, hardens that whole crystalline mass under the form of angles which is owed to it by nature. But since many things here may occur that could raise a doubt in the reader, I will explain them in few words.

It is asked, then, first: how does it come about that that radiation degenerates not into a circle but into polygonal figures? I answer that this happens through a proportional diminution of the radiative power, by which the rays always decrease more and more from the first. Thus indeed: just as the radiative power of the salt extends into three, four, or six rays equally distant from one another, so the remaining rays interposed among these — being weaker — fall short of that distance proportionally, so that the farther a ray is from the strongest, the shorter it is and consequently extended to a lesser space. But let us show these things by geometrical reasoning. Let there be, in the triangle of a hexagon, A G F.

Diagram. A geometric figure: a regular hexagon inscribed in a circle, demonstrating the proportional diminution of the radiative rays. The center is labeled **A**. The six vertices of the hexagon are labeled clockwise from upper-left: **C** (top-left), **D** (top-right), **E** (right), **F** (bottom-right), **G** (bottom-left), **B** (left). Numerous rays are drawn from the center A to the perimeter; a fan of closely-spaced rays runs from A down toward the lower edge between G and F. Along that lower edge (the base G–F) are marked the points **H**, **I**, **K** (between G and F), at the feet of the principal and intermediate rays.

- A (center): center of radiation
- B (left vertex): hexagon vertex
- C (upper-left vertex): hexagon vertex
- D (upper-right vertex): hexagon vertex
- E (right vertex): hexagon vertex
- F (lower-right vertex): hexagon vertex
- G (lower-left vertex): hexagon vertex
- H, I, K (along base G–F): feet of the intermediate rays on the base

The center of radiation is A; the principal rays are A G, A F, and so on for the rest. I say that the rays D A H, —

A H, A I, A K gradually fall short and descend to the side A K of the triangle, and from there increase in the same proportion up to the side A F; and the ray A K will be at right angles and, in this radiation, the smallest. And since in one triangle of the hexagon several lines are drawn from the vertex A to the base G F, the triangle A K G will be greater than the triangle H A K, and this triangle greater than the triangle A I K — because the base G K is greater than H K, and this than I K, while the base A K is common; therefore the hypotenuse A G will be greater than A H, and this than A I. Now the point I is farther from G, the terminus of greatest power, than is H — because, the part I K being taken away, the remainder I G is greater. And so onto the individual points of the base K G fall unequal rays of power; and the more they are removed, the shorter they are, and accordingly falling short gradually and proportionally. What therefore has been shown in one triangle of the hexagon, let the same judgment hold of all the rest.

The rays, then, flying out from the point A — gradually and proportionally falling short of the principal rays, or increasing from the middle line — will at last produce in crystalline bodies that equality of sides which we admire. Once this saline power has thus been laid down as a kind of ground-plan delineation, immediately the remaining corpuscles, as if impelled and attracted by a kind of magnetism, arrange themselves around these; and these, afterward augmented by the accession of others and others again, at last rise to the due quantity of the crystal through the continuous influx of individual particles radiating each in like manner. But because in this way the smallest particles, most tightly united, acquire an exact continuity, it comes about that saline corpuscles of this kind, thus made continuous, emerge at last into a transparent body, with all separation of parts repudiated. And if any separation does occur — behold, at once, as though transparency were obliterated, some traces of shadows come to light. So that this separation of parts may be hindered, and the beauty of form better preserved in the clearest crystal, surely Nature could give it no more fitting figure than the hexagonal — which it also uniquely aims at by the radiation of its implanted power. For this figure, being most perfect on account of the exact connection and continuity of its parts, easily removes all those things that might bring harm or unsightliness to the gem, and preserves it in the splendor due to it by nature.

These things being laid down, let us now more fully confirm, through various experiments, what we have deduced κατὰ τὴν θεωρίαν [Greek: kata tēn theōrian,

"according to theory"]. It was said above that these polygonal figures belong to gems chiefly by reason of the salt; and that salt is present in gems is manifest from their incineration. The same can also be established from their artificial composition: for either metallic juices [succi metallici] are taken as the material — as we shall say in its proper place — or ashes rich in abundant salt, and flints, are roasted together into the same. And who would doubt that metals are of the nature of salt, since they are wholly resolved into vitriol, a species of salt? Therefore the figure of that salt whose nature it shares will be present in the gem.

EXPERIMENTS

First. That in saline bodies Nature aims at an I-know-not-what πολυγωνισμόν [Greek: polygōnismōn, "polygon-making," a tendency to many angles], that is, the multiangular, you will find by experiment thus. Take a pound of vitriol, first dissolve it in clear water, then digest the dissolved liquid — strained through a Hippocrates' sleeve [manica Hippocratis, a conical filter-bag] — over the fire, until it draws a skin [cuticula]. This done, pour the decoction now into a basin and let the moisture evaporate; and you will find, plainly visible, the corpuscles of vitriol dispersed and scattered in the liquid, drawn to the sides of the basin by a kind of magnetic force and united, then soon working out — by their radiate unfolding — the polygonal form due to them by nature. And if anyone considers it with a somewhat keener eye through optical lenses, he will see a certain motion which I say is nothing other than the spirit animating the corpuscles into mutual co-radiation. This shows itself in the fact that little droplets, as it were, always cling at the extremity of the filaments, which droplets, however, are soon converted by the force of the spirit into a solid; and — what is remarkable — the filaments themselves likewise, some into prisms, some into pyramids (the shape they aim at), co-radiate to a point, now with three, now with four, five, or six lines, which exhibit the genesis of crystalline bodies by a kind of ocular demonstration. The same will happen if you try the matter with a solution of niter or alum. But since we have already presented experiments of this kind above in the *Section on salts* [*Sectione de salibus*], we refer the reader there.

It only remains to give the experiment on extracting salts from the lyes of herbs, from which it will appear plainly and clearly that all saline bodies — even those drawn from plants and animals — have been imbued by Nature with this implanted crystallogenic faculty.

EXPERIMENT II

Take whatever herb you like, chiefly one that abounds in a manifold tract of fibers — we usually use the nettle [*urtica*] — reduce it to ashes in a very well glazed pot, and after the incineration is done, pour water over the ashes, and a lye will form. Pour this into a basin, expose it to a winter's night, and leave it until it draws a thin layer of ice on the surface; and you will see, with admiration, the ice exhibit the leaves of the nettle so exactly as if they had been imprinted on it. And if you examine this icy effigy more closely with the aid of a microscope tube, [you will see] all the dots and certain rays — now more, now fewer — unfolding by a kind of rough ground-plan to build polygonal bodies; while those parts that cling to the sides of the vessel for the most part express square tesserae. But how this genesis is brought to completion must now be told.

We said a little before that whenever the saline —

[Margin: Crystallogenesis.]

spirit enters, with a great accompanying abundance of salt, into a certain matrix duly disposed for generating a crystal, the saline bodies gradually consume, by their drying virtue, the moisture that occupies the matrix. Once the moisture has been gradually consumed, then for the first time that marvelous confluence of the saline corpuscles — which were at first dispersed in the moisture — and the co-radiation of the individual particles together come to bear upon building the polygonal form due to them. And by the force of the spirit, with ever new and renewed accession of corpuscles, the crystalline bodies at last acquire the form owed to them. But let us confirm these things by experiment.

EXPERIMENT

Take water thoroughly worked up with niter or any other salt you please — such as vitriol or alum — in such a way, however, that the water remains as transparent as possible. This done, take silk threads or horsehairs stretched into the figure of a tetragonal or hexagonal prism, immerse them in the prepared liquor, and leave them there three or four days, more or less. You will find that all the corpuscles of salt, dispersed here and there in the liquid, at last adhere to the threads, and in the course of time, by the continuous influx of particles, finally acquire a crystalline form — not solid throughout, but like a kind of structure supported on saline columns: truly a beautiful spectacle of Nature, demonstrating to the eye how the saline corpuscles, drawn and united by a magnetic force, at last degenerate into a solid mass. That, therefore, which we here show by artificial contrivance, no one ought to doubt that Nature herself performs by the

radiation [actinobolismum] implanted in her. Let there be a vessel filled with saline water, A B; threads...

Diagram. A schematic of the crystallization apparatus described in the experiment: a tall cylindrical glass vessel, full of saline water (shown by the wavy hatching of the liquid). The vessel is labeled **A** at the top (a small loop/handle at the mouth) and **B** at the bottom (foot of the vessel). Inside hang two horizontal rings/disks, labeled **C** (upper, near the mouth) and **D** (lower, near the base), to which the threads are fastened. The threads (silk or horsehair) hang vertically between the two rings, labeled **E, F, G, H** — the fourth thread-label reads as printed like "14" but corresponds to **H** [recte: H]. The crystalline growth forms along these submerged threads.

- A (top of vessel): mouth / suspension point
- B (bottom of vessel): foot of the vessel
- C (upper ring): upper ring holding the threads
- D (lower ring): lower ring holding the threads
- E, F, G, H (vertical threads): the suspended silk threads / horsehairs on which crystals form ["H" printed as "14"]

fastened to opposing rings C D; let the threads or hairs be E F G H. These, stretched on the rings and let down into the liquor, will exhibit what we have signified by this experiment. The remaining experiments concerning crystalline bodies will be presented in what follows, in their proper place, with fuller apparatus.

CAPUT IX.

On the marvelous painterly works of Nature — the forms, figures, and images she delineates in stones and gems — and their origin and causes [De admirandis Naturae pictricis operibus, formis, figuris, imaginibus, quas in lapidibus & gemmis delineat, eorumque origine & causis]

[Margin: Nature the painter.]

We saw in the preceding pages how Nature, in the genesis of crystals, exercises all the parts of a good geometer. Now let us contemplate, with equal step, the specimens of her skill in the painter's art. These are so marvelous that there is no philosopher who, in scrutinizing them more attentively, has not been left as if

thunderstruck. Nor ought this to seem strange to anyone: for the farther they advanced in the inquiry into the cause of such exotic effects, the more and more their understanding was darkened by a fog, until at last — the matter being, as it were, given up for lost — they frankly confessed that there is something in them τὸ θεῖον [Greek: to theion, "the divine"], a divine element, I say, which, being inexplorable to the human mind, has set here a boundary beyond which the labor of human subtlety wearies itself in vain. Yet since nothing in the nature of things is so abstruse and unusual that we cannot assign at least its probable causes, if not its inmost ones, I have — having long and much speculated upon Nature's images [ectypa] of this kind — judged it worth setting out here for the curious reader what I have observed and discovered.

Nature, in her play, since she could not attain the vegetative and sensitive faculty in the mineral kingdom, did what she could: that is, since she could not give them life and sense, she judged it enough to have at least bestowed figure upon them. Imitating the painters, she has been seen to delineate, with the ambitious mastery of her brush, the figures of all things contained in the world. For whoever considers a little more attentively the constitution of stones, marbles, and gems — especially those endowed with a manifold variety of streaks and tracts — will surely see plainly that, by a certain wondrous industry, Nature has depicted in them:

First, instruments of every kind, made by art — knives, saws, grapnels, anvils, lances, banners, crosses, circles, baskets, compasses, and geometric figures without number: triangles, squares, parallelograms, cubes, rhombs, and prisms of every kind.

[Margin: She paints instruments of every kind in stones.]

Second, Nature, as if contemplating the heavens, has in them depicted stars arranged into certain constellations [asterisms] — as appears in the *Astroites* [star-stone] — or has painted them to the envy of painters. In some gems... —

has depicted the Sun, with its radiant projection, in a stunning way in certain gems—as in a particular cameo [camaea] which the most inquisitive Francesco Qualdi, a knight, once showed me as a great miracle of Nature, and which he keeps in his museum, very richly furnished with similar things.

Diagram. A round gem engraved with a human-faced Sun at its center, surrounded by a dense, even halo of straight rays radiating outward to the gem's edge.

- Caption (below): *Gemma heliaca Franc. Qualdi* [the heliac (Sun) gem of Francesco Qualdi]

[Margin: Nature paints the sky, the stars, the Sun, the Moon.]

In the same way, the figure of the Moon—not only full, but also crescent-shaped [cornuta] and in its half phase [dichotoma]—is not infrequently found in stones and gems. The *Selenites* [selenite, "moon-stone"] attests to this, the stone that takes its very name from the figure of the Moon.

Diagram. An irregular, lobed agate stone whose surface shows a central disc resembling a crescent Moon, ringed and scattered about with several engraved stars.

- Caption (below): *Achates* [Greek: ἀστερίτης (asteritēs, "star-bearing" — the star-agate)]

Ambrosini relates in his book *On Stones* that he saw an agate in which the celestial circles were drawn together with the stars, and another in which the asterism of the Great Bear [Ursa Maior] appeared. I recall having observed something similar in a piece of lapis lazuli filled with the brightest stars. But these things are too well known to need stating.

The most noble Magninus, a knight and Roman patrician, also possesses a heliotrope stone [lapis heliotropius] in which the four elements, each with its own proper colors, are depicted so vividly that they seem drawn not by Nature but by some outstanding painter.

Diagram. An oblong banded stone divided into four horizontal layers, each labeled with an element and its color.

- Top band: *Ignis Aureo* [Fire — golden]
- Second band: *Aer Puniceo* [Air — crimson]
- Third band: *Aqua Caeruleo* [Water — blue]
- Bottom band: *Terra Atro Colore* [Earth — black in color]

Third. Delighting in the sea, in cities, woods, and rivers, Nature has not only painted all these things beautifully, but has also shaded them in with fitting colors, so that they seem scarcely to yield to artificial paintings.

Diagram. A row of leafy, full-crowned trees of varying heights standing along a ground line, the natural tree-figures formed within the stone.

- Caption (below): *Dendrites Hetruriae* [the dendrite (tree-stone) of Tuscany]

[Margin: She paints woods, fields, rivers, cities.]

Such, for example, are the ones from Tuscany [Hetruria], where Nature produces them, of which I have brought a considerable quantity into my museum. Among others, some agates and jaspers display rivers and streams, and cities together with woods and fields, so perfectly and according to all the laws of perspective, that it seems nothing could be added to them.

Fourth. Nature does not seem to stop here, but, entering the very workshop of the vegetable economy, she draws flowers of every kind—roses in the *Entrochus*, lilies in the *Encrinus*. In many varieties of jasper you may see narcissi, hyacinths, tulips, peonies, jasmines, and the flowers of other plants, all marvelously fashioned together with the plants themselves.

[Margin: She paints herbs and flowers of every kind.]

Fifth. Not content with these, advancing further and gazing into the workshop of sensitive nature, she paints animals of every kind—birds, quadrupeds, swimming things, insects—as will afterward be clear from the figures themselves.

[Margin: Animals of every kind.]

Sixth. Lest she should seem to have neglected the human form, the noblest of all, in stones—by an equal play of fortune—she has tried to depict the human figure with its various postures and gestures, not only as to the whole symmetry of the body, but also as to each of its individual members. In one place you will find them imbued with figures of the head, the heart, the liver; in another, of the eyes, ears, and nostrils; here, of the chest, arms, and feet—expressed not on the surface only, but within solid stones. Indeed, as in the *enorchis*, she has expressed both sexes of the human being. On these matters see Agricola [Georgius Agricola] and Gesner [Conrad Gesner] treating them more fully in their books *On Stones*.

[Margin: Human figures and gestures in various ways.]

Seventh. Advancing still further—and to what exceeds the bounds of Nature—she has even attempted to draw, in certain stones, the very Angels and the Blessed [Coelites], as well as the Virgin Mother of God [Deipara Virgo], the other Saints, and even Christ the Lord crucified, as will appear in the following figures of them.

[Margin: Angels and the Blessed.]

Having thus set forth the ingenious diligence of Nature in depicting things, nothing else remains but that, now—after the model of these same things has

been displayed—we adduce the reasons and causes of the individual figures. For I have not yet found any author who has done this, and it is a most worthy subject, in the investigation of which the talent of a true philosopher may exert itself. And so that we may proceed in good order, we shall first set forth examples of those figures which we considered in the preceding seven points, so that from them, as from Nature's prototypes, we may search out the hidden causes of natural craft [Greek: φυσιοτεχνίας (physiotechnias, "natural artistry" — the workmanship of Nature)].

[The First Figure: Mathematical and instruments of every kind, depicted by Nature in stones.]

[Margin: First Figure: Mathematical instruments and instruments of every kind, depicted by Nature in stones.]

In the preceding pages enough has been said of plane geometric figures; now let us also consider the pictures of solid figures. We discussed the crystalline polygons a little earlier—...

that is, in the form of cubes and prisms of every kind, such as those which the following plate displays.

Diagram. A drawing of a dodecahedron seen in perspective, its twelve faces outlined, with several of the visible faces containing inscribed circles. Four corner-points are lettered.

- Caption (above): *Fig. Dodecaedri* [Figure of the Dodecahedron]
- A (upper): vertex
- B (right): vertex
- C (lower): vertex
- D (left): vertex

Diagram. Two rounded, concentrically banded stones lying side by side, each engraved on its upper face with curved lines forming an astrolabe-like network of arcs.

Here you see how Nature has labored a dodecahedron, A B C D—that is, a figure of twelve sides—in marble. And although (if I may make light of it) for want of a compass she drew it only with a rough pen, with lines and circles somewhat distorted, and not in due proportion to the pentagonal sides, she nonetheless did what she could; and by what art and skill, will be explained afterward.

[Margin: An astrolabe drawn by Nature.]

Ambrosini says that he himself saw a little cup [scaphium] made out of a snail-shell, in the hollow of which Nature had drawn and painted an astrolabe with those tracings of lines which the second figure shows. In Calabria there is a mine in which all the stones that are found—even the smallest—are seen under the figure of a cube; and Father Matheus Taberna, an inquisitive explorer of natural things, gave to my museum no small quantity of these, which he had brought with him. Of the spherical figures of stones we shall speak afterward.

[Margin: Cubic rocks formed by Nature.]

Diagram. Three small cubic stones drawn in perspective, each rendered as a die-like cube with hatched shading.

- Caption (above): *Lapides Cubici* [Cubic stones]

[Margin: Nature alters rocks into the prismatic form.]

In Tuscany, near Volsinium [Bolsena], as you go about a thousand paces toward Mount Flascon [Montefiascone], on the left side of the Lake of Volsinium [Lake Bolsena], a cliff is seen which is wholly composed of stony parallelepipeds, in the figures that follow, A B C D E F.

Diagram. A cluster of tall, straight rectangular stone columns of varying heights rising side by side like a bundle of prisms, drawn in perspective and lettered at several columns.

- Caption (above): *Juxta Volsinium in Italia, Rueus in Misnia Germaniae* [Near Volsinium in Italy; Rueus reports the same in Meissen, Germany]
- A (left)
- B (upper center)
- C (center)
- D (upper right)
- E (right)
- F (far right, lowest)

[The same kind] is constituted [in Germany]. Rueus [Jean de Rueus / Johannes Ruæus] relates something similar about the citadel of Stolp in Meissen [Misnia].

These little stones were sent to me from Germany not long ago, all of a round, disc-like figure, in the middle of each of which Nature has expressed—with a truly elegant brush—the figure of an eye diffusing its rays.

Spherical stones are also found in many places—large, small, and very large—so that, on the testimony of Rueus, some have been found of such a size that they would serve, in place of iron ones, for loading military engines. Such, on the testimony of Agricola, are found in the territory of Hildesheim [Ager Hildesiensis]; similar ones in the Kingdom of Naples, near the city called Potentia [Potenza]; and in many other places in Italy, Germany, France, and Spain. Concerning these, see Agricola, Rueus, and others; but how Nature forms them, we shall explain afterward.

Second. As for the Elements, Nature expresses these too, so exactly that they seem expressed by a painter. Of this kind is a certain gem of hematite which Carolus Magnus [Carlo Magnini] possesses, in which the four elements are so skillfully exhibited by the natural drawing of the colors, that they could not be painted better or more exactly by any painter. Again, mountains, fields, rivers, which are seen above all to astonishment in certain marbles and in agate—indeed, even the air with clouds and with birds flying in it: a thing of which I was first taught by the Altar in the church of St. Peter at Rome [Divi Petri Romae], where, as you enter, on the right hand the chapel of the Holy Cross has been built. The altar is made of yellow marble variously mottled, in which you will find mountains and rivers, lakes, woods, and air skillfully painted by Nature. The same thing may be seen in the magnificent [chapel] of the Blessed Virgin at S. Maria Major [Santa Maria Maggiore]...

[S. Maria] Major, in the chapel built by Pope Paul V [Paulus V], in which the same wonders of Nature the painter that I have mentioned are exhibited.

Third. That Nature has also displayed the starry sky in stones, we have already said above.

[Margin: Trees and woods are expressed by Nature in stones.]

Fourth. Meadows and woods set thick with trees are seen above all in those stones which they call *dendrites* [Greek: δένδριτες (dendrites, "tree-stones")] after the trees they express, and which are brought in great quantity from Tuscany to Rome for the adornment of tables, cabinets, and other things...

Diagram. A landscape engraving of a walled, towered town—an array of buildings with windows, pointed conical roofs and spires, a few trees rising among them, set beneath a banded sky of clouds; the natural image as formed within a stone.

- Caption (above): *Urbs Turrata* [The Towered City]

[Margin: An expression of cities and ruins in stones.]

are transported. In these you may see not only the branching outgrowth of trees, but also, all around, leaves, flowers, and the like sports of Nature; so that in another marble stone you may likewise see cities, mountains, and clouds depicted—of which kind there is one in my museum: a towered city with houses fitted with windows, just as the figure here set down shows. In the high altar of the church of St. Sebastian outside Rome [S. Sebastiani extra Romam], the marble into which the crucifix is inserted, exhibits clouds and bright portions of the sky marvelously shaded in.

[Margin: Lapidific exhalation.]

Fifth. Nor are the four-footed classes of animals lacking in stones. You may see in them, first, insects of every kind—such as serpents, flies, butterflies, worms, and the like, down to fleas and bedbugs themselves: of which kind are certain species of *asteria*. See the serpent-shaped figure [Greek: ὀφιδόμορφον (ophiomorphon, "snake-shaped")] marked with the letter Z in what follows. Then follow the stones which exhibit, with marvelous art, fishes, whales, dolphins, sea-bream, trout, sea-fish, and the like—which I recall having seen here and there in various museums, both here at Rome and elsewhere. Hence I have thought to add the figures for the gratification of the curious reader. See Plate III.

[Margin: Serpents, fleas, flies, butterflies, lice in stones.] [Margin: An expression of whales and the other fishes in stones.]

Sixth. Next come the winged creatures, which Nature has exhibited in various ways in stones. In the sacristy of the Roman College there is a marble column of mixed black and white, in which Nature has painted a pelican with twisted neck opening its breast to itself—though with the claws of its feet mutilated. There are those that also exhibit cocks, and hens with chicks, just as may be seen in the following figures.

[Margin: An expression of birds in stones.]

The figures of four-footed animals, moreover, are found everywhere in stones—either in the whole symmetry of the body, or with the head only, or shown from the chest, feet, and shoulders—of which Ambrosini too [speaks] in his book *On Metallic Things*, which is called the *Supplement to Aldrovandi*. See Plate II, which depicts the animals.

[Margin: An expression of quadruped animals in stones.]

Seventh. Stones are so filled with human figures of every kind, that there is hardly any in which they do not...

Diagram. A large engraved plate of an irregular flat stone (a dendrite slab) whose surface is covered with fine, branching, fern- or tree-like growths spreading across the upper portion—the natural foliage-figures formed within the marble.

[Margin: Wondrous images of things.]

[in the mu]seum of Aldrovandi at Bologna. Agricola too mentions these apparitions in these words: *"A kind of schistous stone was not long ago discovered near the Hercynian forest [nemus Hercynium], which expressed various species of animals—as among fishes, the largest pike and perch; among birds, cocks, and now and then salamanders; indeed, the effigy of the Roman Pontiff, bearded and bearing on his head the triple crown, was found, which many saw, and besides this an image of the Blessed Virgin holding the Child in her arms."* I will add a work of Nature most worthy of all admiration, which Nature—by the undoubted disposition of God—expressed in the Kingdom of Chile in forming an image of the Mother of God [Deipara]; of which Father Alphonsus Dovalius [Alonso de Ovalle] [writes] fully in his *History of Chile*, whose whole account we shall recite in what follows.

[Margin: Crucifix impressed in stones.]

These things, then, having been set forth, it remains that we behold in stones what is the greatest of all—the image of Christ crucified—lest it should seem to be wanting in the busy work of Nature. There is, on the testimony of Ambrosini, an inquisitive explorer of these matters, at Ticinum [Pavia]—commonly Pavia—in the Carthusian monastery situated at the fifth milestone outside the city, a certain marble in which Nature has elegantly depicted the image of Christ our Savior hanging on the cross, and crowned with a crown of thorns. At Venice too a figure of Christ crucified appears in marble, on the same testimony, in the church of St. George the Greater [S. Giorgio Maggiore], in the same...

one and the same form. Ambrosini reports that a similar image is to be seen at Pisa and at Bologna. A like figure of the Blessed Virgin is said to be impressed in a flint in the Aldrovandi Museum at Bologna [Museo Aldrovandino]. Agricola too mentions these phenomena [phasmata] in these words: [Margin: Remarkable images.] *"A kind of schist-stone was found in the Hercynian forest [nemus Hercynium] not long ago, which expressed various species of animals — so that among the kinds of fish you might marvel at sea-sparrows, pikes, perch; among birds at cocks and hens; sometimes salamanders; indeed the very effigy of a bearded*

Roman Pontiff bearing the triple crown upon his head was found there, which many have seen, and besides this an effigy of the Blessed Virgin carrying the boy [Child] in her arms."

We shall add a work of Nature most worthy of all admiration, which Nature — by God's unquestionable disposition — expressed in forming the image of the Mother of God [Deipara] in the Kingdom of Chile [Regnum Chilense]. Father Alonso de Ovalle [P. Alphonsus Dovalius] gives a full account of it in his *History of Chile*, whose entire narrative we shall recite in what follows.

Diagram. [Tab. IV — referenced in the text as "Tabula IV."] An engraved plate titled "*The Expression of Images of the Human Figure in Stones*" [Humanae figurae imaginum in lapidibus expressio], showing seven picture-stones with naturally-formed human and bird images. From top to bottom:

- Top left: a female bust with curling hair, marked N; captioned *Heroína* ("Heroine").
- Top center: a draped half-figure in profile facing left, beneath an arch; captioned *Figura palliata* ("Cloaked figure").
- Top right: a swan- or stork-like bird; captioned *Avium in lapidibus expressio* ("The expression of birds in stones").
- Middle left: an irregular stone showing a robed half-figure in profile; captioned *Homo. Sacerdos* ("A man. A priest").
- Middle right: an oval stone with a woman's bust, hair drawn up; captioned *In silice Foeminae effigies* ("The effigy of a woman in a flint").
- Bottom left: a large flint with a Madonna-and-Child figure in an arched recess, marked A; captioned *Silex apud Ambrosinum Beatae Virginis cum filio in brachiis* ("A flint, in Ambrosini, of the Blessed Virgin with the Child in her arms").
- Bottom right: an oval stone showing a crowned female bust below, with a dragon-like winged creature above, marked B; captioned *B. Virginis cum filio et draconis effigies* ("The effigy of the Blessed Virgin with the Child, and of a dragon").

[Margin: The crucified Christ impressed in stones.] Now that these have been set forth, it remains that we contemplate in stones the greatest image of all — the image of Christ crucified — so that nothing of all things may seem to be lacking in the busy work of Nature. On the testimony of Ambrosini, that careful investigator of these matters, there is at Ticinum [Ticini] — commonly Pavia — in the monastery of the Carthusians [Coenobium Carthusianorum] five miles outside

the city, a marble in which Nature has elegantly painted the image of Christ our Saviour hanging upon the cross and crowned with the crown of thorns. At Venice [Venetiis] too a figure of Christ crucified appears in marble, on the same authority, in the church of St. George the Greater [templum S. Georgii majoris], in the same...

way represented, as appears in the figure of Tab. IV.

[Margin: All the members of the human body.] Furthermore, there is no member of the human body that Nature has not expressed in stones: the head, ears, eyes, arms, chest, belly, feet — and finally the figures of the sexual organs, which from this even obtained the name of *enorchides* [stones bearing the likeness of testicles].

Know finally, careful Reader, that for one who inspects diligently and curiously such marble stones when they have been cut and polished, the images not only of the things mentioned but also of others will be ready to hand — such as instruments of every kind, household furnishings, and countless similar things — which I leave to be considered by curious investigators of these matters.

Sectio I — TAB. I.

FIGURES OF BIRDS [FIGURAE VOLUCRIUM]

Which Nature has painted in stones, culled from various Museums and transmitted from elsewhere.

Diagram. [Tab. I] An engraved plate titled "*Figures of birds, which Nature has painted in stones, culled from various Museums and transmitted from elsewhere.*" Seven numbered picture-stones:

- **Fig. 1** (top left): an irregular stone showing a long-necked wading bird (stork) with a small quadruped above it; captioned *Ciconiae et Noctuae figurae* ("Figures of a stork and an owl").
- **2** (top right): a stone of tangled, confused forms; captioned *Confusae rerum variarum forma* ("A confused form of various things").
- **3** (left, two birds): two birds, one with raised wings; captioned *Venetiis in Templo S. Georgii* ("At Venice, in the church of St. George").
- **4** (center): an owl's face within a stone; captioned *Caput Noctuae* ("The head of an owl").
- **5** (right): a stone with a small bird in relief; captioned *Figura Motacillae* ("Figure of a wagtail").

- 6 (lower center): a stone showing a crested bird's head; captioned *Animalis iubati* ("Of a crested animal").
- **Fig. 7** (lower right): an oval stone with a long-tailed bird; uncaptioned.

Plate legend (printed beneath):

1. The first figure marks a stork's head, with — annexed to it — some quadruped animal I cannot identify. At the top, something resembling a human face, taken from the Aldrovandi collection [ex Aldrovandino].
2. It displays various forms of things and parts of animals, both birds and quadrupeds, though very imperfect, the explanation of which we have given in the Physical disquisition.
3. It shows the images of two birds, which Ambrosini reports were expressed by Nature in marble in the church of St. George at Venice.
4. It shows the head of an owl [noctua], surrounded by other rudimentary forms of birds.
5. It expresses the figure of a wagtail [motacilla] — or, as others would have it, of a peacock.
6. It exhibits the figure of a monstrous bird.
7. It expresses the figure of a blackbird [merula].

[Margin: Trees and woods are expressed in stones by nature.]

[Margin: The expression in stones of serpents, fleas, bedbugs, flies, and butterflies.]

[Margin: The expression in stones of whales and the other fishes.]

[Margin: The expression of birds in stones.]

in various ways in stones is to be seen — and the crest [crista] which the column of the Roman College [Collegium Romanum] gathered: a marble column of mixed black and white, on which Nature painted a pelican with twisted neck opening its own breast, though with the claws of its feet mutilated. There are also some stones that exhibit cocks and hens with their chicks, as one may behold in the following figures.

[Margin: The figures of four-footed animals expressed in stones.] Moreover the figures of four-footed animals are everywhere found here and there in stones — either in the full symmetry of the body, or shown by the head alone, by the feet and shoulders — concerning which Ambrosini also writes in his book *On Metals*

[De metallicis], which is called a supplement to Aldrovandi. See Tab. II, which expresses animals.

[Margin: Human figures.] **Seventh.** With human figures of every kind the stones are so crammed that in scarcely any are there not various... But Nature expresses in marble not only human figures of every sort, but also the figures of the *Coelites* — that is, of the Saintly Men — by I know not what disposition; of these speaks the often-cited Ambrosini. Let us begin the narration from the figures of the most Blessed Virgin Mother and of the Angels; and as regards the Blessed Virgin, she is first seen impressed by nature in marble in various places and regions. See Figure A, impressed in flint. Here at Rome, in the chapel of the Holy Virgin — on the right as you enter the church of St. Peter, beside the organ — there is a notable image in which the most Blessed Virgin of Loreto [Virgo Lauretana] is so skillfully painted by Nature that she seems delineated by an artist's hand. She is clothed in a garment marked with a threefold band, and holds the little Son in her arms...

Diagram. [Tab. II] An engraved plate titled "*Of the Figures of Four-footed Animals*" [Figurarum Animalium Quadrupedum]. Nine numbered picture-stones, the first two arch-topped:

- 1 & 2 (top, two arched panels): scenes of confused animal forms — in 1, dog-heads and a man's capped figure with shapes resembling swimmers in water; in 2, a reclining dog-like figure with the rudiment of a ship.
- 3 (right oval): a four-footed animal (deer- or goat-like) standing in profile.
- 4 (left): an irregular stone with a dog's figure and a small fox-like form below.
- 5 (small, pear-shaped): a seated fox-like animal.
- 6 (small): an animal's head in a stone.
- 7 (large square): a complete cat (or feline) in profile with curling tail.
- 8 (right): a rough stone showing a capped human head in profile amid scattered forms.
- 9 (lower right): a shaggy animal's head in a stone.

Plate legend (printed beneath):

1 & 2. The figures show dogs' heads, together with the figure of a capped man: in fig. 1 they appear as if swimming in water; in fig. 2 the rudiment of a ship is seen. Besides this, the head of a cock — and signs of the moon too — which Ambrosini says he preserves as an *ectypon* [cast/impression] in his Museum. 3. It exhibits I know not what monstrous animal, not unlike a pig if you except the head; others

will have it the figure of an elephant. 4. It expresses the head of a mastiff dog [canis molossus]. 5. The head of a horse. 6. The figure of a dog's head. 7. It exhibits the perfect figure of a cat or feline, the explanation of which we give in the second mode of the disquisition; Ambrosini reports that he saw it expressed by nature in a certain marble. 8. It represents the form of a capped peasant, with a miscellany of various things. 9. It expresses the head of a capped peasant.

LIBER VIII ("Λιθογενής"), Sectio I — De Lapidibus in communi

Caput IX. De admirandis Naturae pictricis operibus (continued)

TAB. III. — Displaying the form of fish [Piscium figuram exhibens]

Diagram. Plate III, a picture-stone plate showing fish-forms impressed in stone. The engraving carries three numbered figures. At the upper right is an inscribed plate-title cartouche: "Tab. 3 / Piscium figuras exhibens" [Plate 3, displaying the forms of fish]. The three figures:

- **Fig. 1** (top): a stone split open into two matching halves, each half showing one fish-form, so that the single fish appears mirrored on both fractured faces of the rock.
- **Fig. 2** (middle): an elongated fish in profile, head to the right, shown lying within the stone.
- **Fig. 3** (bottom): a broad-bodied fish with a heavy head, lying flat within the stone slab.

Printed legend beneath the plate:

Fig. 1. Shows two fish, which are nevertheless one fish enclosed within the stone after the manner of a mold, so that it impresses half of itself on each face of the stone. From the Gualdo Museum [Musaeum Gualdinum] at Rome. 2. It reproduces the form of a parrotfish [scarus], within the stone. 3. It reproduces the form of a tench [tinca], within petrified stone.

TAB. Altera. — Displaying the forms of fish [Piscium figuras exprimens]

Diagram. A second fish plate ("the other plate" / Tab. Altera), displaying the forms of fish impressed in stone, with three numbered figures continuing the numbering of the previous plate:

- **Fig. 4** (top): a broad, deep-bodied fish (the gilthead/sea-bream type) shown in left profile, head to the left, impressed in a slab of rock.
- **Fig. 5** (middle): an arched, scaled fish, head to the lower right, curved as if swimming, within the stone.
- **Fig. 6** (bottom): two slender fish, one above the other, shown as if swimming through water, lying in the stone.

Printed legend beneath the plate:

4. It reproduces the form of a gilthead [aurata], likewise, just as the others, turned within the rock into stone.
5. It shows two fish as if swimming in water, which are seen in the Aldrovandi Museum [Musaeum Aldovrandinum].

TAB. IV. — Displaying human figures [Figuras humanas exhibens]

Diagram. Plate IV, displaying human figures impressed in stone, arranged in two rows of three numbered figures (six in all). Each figure carries a small inscribed label within the engraving.

Top row:

- **Fig. 1** (label: "Idol. Aegypti" [Egyptian idol]): an old, bearded, seated man wearing a tall conical cap, set in a cave, holding in his hands a child swaddled in bands; the swaddled child is likewise shown in a similar old-man's garb.
- **Fig. 2** (label: "Ex Musaeo Ambrosini" [From the Ambrosini Museum]): a cloaked standing figure with a large head, holding a small figure at its breast, with smaller hooded heads to either side.
- **Fig. 3** (label: "Fig. 3. Fi. S. Joh. Bapt." [Figure of St. John the Baptist]): a standing, shaggy/hairy man.

Bottom row:

- **Fig. 4** (label: "In Specie Bethlemico. Figura S. Hieronymi" [In the Bethlehem grotto. Figure of St. Jerome]): a tall robed and hooded figure.

- **Fig. 5** (label: "Ticini in Monasterio Carthusianorum" [At Pavia (Ticinum), in the Carthusian monastery]): a frontal figure of the crucified Christ with arms outstretched.
- **Fig. 6** (label: "In Templo S. Petri Romae" [In St. Peter's Church at Rome]): a tall conical robed figure (a veiled standing Virgin) with small angels at either side.

Printed legend beneath the plate:

Fig. 1. It shows a fillet-wearing old man seated, holding in his hands a child wrapped in swaddling-bands, dressed in a habit like the old man's — not unlike the Aurruncus idol of the Egyptians, concerning which see Vol. 3 of the *Oedipus Aegyptiacus*, the *Syntagma de Idolis Aurruncis* [Treatise on the Aurruncan Idols]; and as to how it was impressed in the stone, see Mode 3 of the preceding Disquisition. 2. It presents a cloaked figure carrying a child in its bosom, around which I-know-not-what traces of angels are to be seen, so that I think it is nothing other than an image of the Mother of God [Deipara] carrying her blessed little son in her bosom, with angels standing about on either side. 3. It shows the image of a hairy man, whom some take to represent a hermit, others St. John the Baptist. 4. They suppose it to display the figure of St. Jerome [S. Hieronymus], because, on the testimony of Brocardus in his Jerusalem itinerary, it appears to have been impressed in stone by Nature in the Bethlehem grotto. 5. It displays the figure of Christ crucified, impressed by Nature — on the testimony of Cardano [Cardanus] — at Pavia [Ticinum], in the monastery of the Carthusians. They assert that a similar one is seen by the Venetians in the Church of St. George. 6. At Rome, in the Church of St. Peter, in the chapel of the Blessed Virgin, there is seen impressed in marble [an image] not unlike the Loreto Virgin [Virgin of Loreto].

DISQUISITIO PHYSICA — A Physical Inquiry into the Images Impressed in Stones [Imaginum lapidibus impressarum]

In this inquiry the ectypes [ectypa] of all the objects just set out, formed within stones, are examined; the causes and reasons of each are assigned in various ways; and at last it is shown by what art and ingenuity, and to what end, Nature has expressed so many forms and images in stones.

Figures in stones may be considered in two ways: either as they appear set upon the flat, polished surface of stones, or as they appear constituted in the shapes of

solid stones variously transformed. I shall speak first of the former, afterwards of the latter. Now these figures are seen chiefly on the smoothest surfaces of variegated marbles that have been cut and polished — of which there are countless kinds — but very rarely, and scarcely in any precious gems, especially those endowed with a transparent substance, agates excepted.

[Margin: The forms are impressed in stones in four ways.]

I say, then, that they could have been expressed in stones in four ways. The first is fortuitous. The second is from the disposition of the earthy substance: within this, as within a mold, a tinted fluid is received, and at length, by the stone-making spirit [*spiritus lapidificus*], it hardens into whatever shape the matrix of the earthy substance presents. Third, they arise into this or that figure from some singular accident. Fourth, in certain images — and especially in the figures of the heavenly saints [*coelites*] — they are produced by Nature from a singular divine disposition, with the help of the Angels. Each of these is to be treated in order.

Here it must be noted that the figures in some stones are quite imperfect and mutilated in their members; in some, only the faintest traces of the figures appear; in others, a perfect and complete form is seen, in whatever genus of things. All of which afford us great indications of the hidden causes. But now to the matter.

Modus Primus [The First Mode]

[Margin: The fortuitous and chance impression of figures.]

By the first mode I assert that most of the forms that have arisen in stones were produced fortuitously and by chance. That this may be understood, let the Reader know the following. Just as the imagination of men, when it sees the sky overcast with a variety of clouds, pictures to itself various things — now flying dragons, now ships, now mountains, cities, and castles, now crosses, now human figures and similar apparitions — out of the unordered presentation of the clouds: so too, even in spittle cast upon the ground, we notice that something is sometimes figured which is now like this thing, now like that. Indeed, on our travels, seeing the spread of mountains under a certain shape, we now conceive a table — as with the Cape of Good Hope [*promontorium bonae spei*] and the promontory of Sicily; now a man stretched out on his back — as in the Apennine mountain of the people of Camerino [*Apenninus Camertensium*], whose summit expresses the head, whose sloping extension and slight further protuberance the chest and belly,

[Margin: The figures are impressed in stones in various ways.]

a rock jutting out into the valley the arm, and two thighs subsiding into a forked valley the various outlying parts of the mountain. On the island of Malta [Insula Melitensis] a seaside rock, hanging apart from the mountain, expresses a hanging monk — commonly called *frate impiccato* [the hanged friar]. Sometimes rocks and shrubs and the fragments of cliffs display a human likeness under the figure of a coin, as at Palermo [Panormus] a mountain which from its figure is commonly called the *testa della medaglia* [the head on the coin]. I could adduce countless apparitions of this kind in this place, but because such things are nowhere lacking, I have wished only to hint at them here. You may also see, on the rough surfaces of fired bricks, various traces of insects, birds, and other things — which nevertheless are intended by Nature to no end, but, because of a certain similarity of things, a man imagines to himself that they are such. With these matters thus set forth, one might now justly ask whence so great a host of apparitions of images in stones has taken its origin.

[Margin: The cause of figures of this kind.]

I reply that all these are born from the flowing of a saline fluid [fluor salini liquoris]. When this fluid has insinuated itself into the earthy and suitable substance — still soft, and gaping with dryness into many cracks and winding channels, as may be seen in marbles — then, just as there, by the stone-making spirit, in the course of time, the whole coalesces together into a hard and stony mass, so, according to the configuration of the cracks and fissures, the insinuated fluid delineates — in whatever way it can, and according to the disposition of the matter now gaping with dryness into various rifts and hollow cavities — now the loveliest patterns, now branching trees, now the form of a bird, or an insect, or a quadruped, or even a human likeness, or at least some member of the human body. That these are in fact constituted by a kind of flowing is clearly taught by the winding courses of the patterns, painted in diverse ways according to the diversity of the tinting spirit, which are seen now elegantly mixed from black into white, now from white into yellow, or into green and blue channels. That the earth was at first soft is established from this: that after many cycles of years the nature of the place is observed to produce the same stones imbued with the same diversity of figures and colors.

[Margin: The cause of the channels of these forms, like a watercourse.]

This would not happen if the subterranean economy did not tint the earthy matter — macerated and fermented over a span of many years — with its own

variable flowing, the spirits being sent through it into various colors as it gapes with varying heat. As to the experiment of this matter, consult what was delivered above.

[Margin: No likeness made by chance is perfect.]

There is also another not slight argument that these similar apparitions are constituted by a fortuitous and chance flux: namely, that scarcely any of those which counterfeit the figure of an animal turn out perfect in form. Rather, there is always found to be lacking something required for the constituting of the whole figure — as in heads, either an eye, or a nose, or a mouth; in arms, the hand and fingers; in legs, the feet — a deficiency which the industry of painters for the most part makes good. So that they are not so much what they really are, ...than what the imaginative faculty fancies them to be. Let us judge them just as we did a little earlier in the case of clouds, mountains, spittle, and the other such things.

One may ask by what process Nature formed this fish. I answer that it happened in this way. We know that in many places great river floods occur in winter, and that as a result a vast quantity of mud is heaped up over the fields and hills. By these floods, then, many fishes were cast out together and wrapped in the mud; and the mud, in the course of time, was converted into stone by the stone-making spirit. As happened to this fish, so many other fishes were enveloped, and in the mud — serving as a kind of mold and matrix — they impressed their own native shape. That this is so can be demonstrated by the fact that the spines are still present along with the scales, and that the fleshy parts are seen as though violently torn away and mangled, while the bone-structure, together with its spiny substance, is so perfectly reproduced that not even a painter, however skilled his hand, could match Nature's original. This is clear evidence that there was a real fish's substance there, which impressed its shape, as it were, in the muddy matrix.

[Margin: How fishes and serpents impress their shape into mud as into a mold.]

For if you examine the stone I mentioned a moment ago more deeply, as to its inner substance, you will find a hollow inside, corresponding to the size of the fish. As for the fact that no pulp or entrails appear inside, that is no wonder, since the whole of that soft, flaccid substance — most liable to corruption — was either consumed, or dried out by heat and turned to powder, and could leave nothing behind but the harder substance of the bones. This is evident from the tombs of the ancients, in which, apart from the skeleton, you will find not even a trace of

any other portion or limb of the human body. And this is the origin of those fishes that the natural philosophers call *fossil* [*pisces fossiles*], which are found in many places — as has been shown above — and which everywhere turn up in the cabinets of curious men.

In the same way, serpents wrapped in mud seem to have impressed their shape in a similar manner, as is evident from the figure set here, from the Aldobrandini Museum [Mufzo Aldobrandino]; and the same judgment is to be made about all animals.

[Margin: How the shapes of flat animals are impressed.]

In other cases, moreover, what appears is not the bone-structure but a true and genuine likeness of the animal; how this came to be impressed upon the rock I shall now explain. It was said above that saline bodies, by a certain wondrous appetite which we call the magnetism of Nature, mutually attract one another. Since, therefore, the matter of stone is full of saline particles, just as the bodies of animals are, it comes about that when some animal, wrapped in muddy clay,

[Printed page 39 — the page bearing the engraved stone with serpents and fishes] ...has impressed its own shape there — at that same spot, as soon as it has expressed its figure: a confluence of the saline parts in the animal toward the saline parts in the argillaceous matter will take place. And since all things flow together by a certain marvelous radiation [*actinobolismus*] or beaming-out,

Diagram. A large, irregularly shaped stone (woodcut) occupying the upper portion of the page, depicting in low relief a tangle of serpents and fishes whose forms wind across the surface of the rock. The engraved caption runs vertically up the right-hand edge of the stone.

- Caption (right edge, vertical): "Saxum Serpantium Piscium figuram referens" — "A stone reproducing the figure of serpents and fishes."
- The relief shows several elongated serpentine bodies interwoven with broader-bodied fishes, rendered as natural markings in the stone's surface.

[Resuming the text of the central column:] ...it comes about that the radiating particles imbue the matter of the stone with the very tincture in which they themselves are rich. Hence at last either the whole figure of the living creature, or its parts, emerge in the stone with a certain marvelous symmetry — the plastic faculty [*facultas plastica*] contributing greatly to this work, a faculty which we shall demonstrate in what follows still to remain in the cadavers of plants and animals.

I would not, however, have it understood in this place that things of this kind are generated as it were from some seed cut off from a plant or animal, but rather through something that corresponds to seed by a certain proportion. In this way, the stone immediately impresses upon the earth it touches — once that earth has been disposed nearly to the nature of stone — a form like its own. So too a pre-existing portion of gold, once the matter near it has been disposed to take on the substance of gold, converts that matter into the substance of gold. In the same way silver draws toward itself all matter disposed for the production of silver, so as to make a substance like itself; and the same judgment is to be made of all the other metals, each attracting to itself what resembles it — not, as many wrongly suppose, through any true vegetation [vera vegetatio], but through a confluence of similar corpuscles coming together by a certain magnetic attraction, or, what amounts to the same thing, through juxtaposition, after the manner of inanimate things.

[Margin: Magnetism of Nature.]

And this is done by Nature's great wisdom: lest the species of corruptible substances should in time be utterly abolished, sagacious Nature has implanted in all things a means of generating things like themselves, so that those things which can never persist as individuals may at least attain perpetuity in their species, and so, according to the measure and capacity of their nature, may enjoy the perennial gift of incorruptibility — which is the end for the sake of which all things act that act according to nature.

MODUS TERTIUS

[Margin: How the shapes of trees are impressed in stones.]

It arises from some particular accident, by which figures in stones emerge now into this, now into that form.

These are wondrous and altogether paradoxical things which Nature works in fashioning figures in stones; their explanation is not easy to assign. I shall nonetheless attempt — being rather well practiced from frequent investigation of these matters — to set forth in this place the cause of each of these apparitions [phasmata], making my beginning from those stones which, from their abundance of trees, are called *dendritae* [tree-stones]. Of these no small quantity is to be seen here at Rome, both in my own Museum and in others; some of them contain separate trees, others entire apparitions of trees and groves drawn out according to all the laws of perspective. Stones of this kind are found above all on

Mount Sinai — whence the stone is also named *petra Sinai* [the Sinai stone] — and in Etruria [Hetruria] near the town of Bargam [Barga], even though these are not really plants, nor have they any life, but are pure and simple simulacra of painted plants, by Nature's marvelous craftsmanship. Before I explain their generation, the following must be noted.

Four kinds of stone are to be found in which the likenesses of plants and trees, and the images of crops, are seen marvelously depicted by Nature. The first of these, called *Botrycitis* by Pliny [Pliny the Elder], represents a plant flowering with white or blood-red fronds on a black ground.

[Margin: Tree-stones.]

The second, named *Nemorosa petra* [the wooded stone] by Imperato [Ferrante Imperato], the celebrated antiquary — which is the same as the Sinai stone — is called *Dendrachates* by Agricola [Georgius Agricola]; on the interior walls of the split stone it displays countless images of plants and crops, and is properly called *dendritis*. The third is the kind that reproduces the serrated leaves of the willow, whence it is also called *folium salicis* [the willow-leaf stone].

[Margin: Willow-leaf stone.]

The fourth kind of stone is called by Imperato *frumentatum* [the grain-stone], because it expresses the species of wheat and other crops, which

[Printed page 40]

all I remember having seen, and curiously examined, long ago in the celebrated Museum of Imperato.

One asks, then, the cause of such great marvels. I say, therefore, that these figures could have been impressed in the following way. It is known to all that herbs and plants of various kinds are seen growing on many inaccessible heights of ancient buildings — yet how they grew up there is rightly thought paradoxical by those unskilled in such matters. Pliny relates that twice a palm sprang up on the topmost summit of the Capitol [Capitolium], and that after the palm had been beaten down by storms, a fig tree sprang up in the same place, in the consulship of M. Messala and C. Cassius [in the consulship of Marcus Messala and Gaius Cassius]. And not only in that age, but down to the present day, we see all the ruins of the Baths, the Aqueducts, and the Amphitheaters flowering not only with palms, wild figs, and mastic-trees, but also with countless other herbs — of which Panarola, in his book on this subject, records up to 200 in his "Amphitheater of Plants" [*Amphitheatrum de plantis*]. The matter is so trite and nearly

commonplace that its cause should not on that account be reckoned hidden from anyone. For since the crannies of the said ruins are continually filled with dust, and with that dust seeds of every kind are carried thither — whether by the force of the winds or by the agency of birds, or even deposited there in the droppings of birds (in which the kernels of dates, cherries, plums, figs, and other hard seeds remain intact) — then, once the dusts are softened by rain or dew, nothing is easier than that, with the addition of the sun's heat, each should gradually blossom into the germ proper to its own species. There is also the fact that the powders of lime [calx] have some innate property — I know not what — for producing various herbs. But of these things more fully elsewhere. With this premised, then,

I say that the very same thing can happen in stones. For since in petrifying earth there are present the powders of various shrubs and plants, in which — together with a slight heat — there still resides some seminal something [nescio quid spermaticum], this, having found in the stone (while its matter is still soft) a material somehow suited to it, and being unable to constitute the substance of plants out of that matter, does what it can: that is, by the plastic faculty (which still in some way resides in the seminal virtue), it depicts in the matter the mere images of trees and herbs. So everywhere Nature strives to produce something like herself; she would indeed wish to beget an essence similar to herself, but being hindered — both by the weakness of the agent and by the unfitness of the patient — when she cannot effect what she would, she at least generates the accidents and images of plants, as plants equivocally (to speak with the Schools). And this Aristotle proves by the example of the generation of man, who always intends to generate a male, but, failing utterly of his wish, generates a female — the male, as it is said, being defective; and the same must be said of the generation of the other animals indiscriminately.

[Margin: L. 3, *de Spon[taneo] vivorum [motu].*]

To the point, then: since in the earth from which the stone is born there are pre-existing powders of various

[Margin: How figures are impressed in crystal and in amber.]

Now let us propose another mode by which we may suppose the images of plants could have been made in stones. Before the rock came to be, there were somewhere shrubs and plants — especially of a smaller and finer substance, such as the mossy kind — which were contained there; afterward, when soil-borne moisture was poured over them on every side and converted into stone, the rock

grew up together with the little herbs and crops, so that it reproduced their images, they being petrified within it. And clear evidence of this is that stones of this kind, when opened by a parallel section, do not in all respects display likenesses similar to those grown on the first surface, but, owing to the differing courses of the branches, show now a trunk, now branches as if cut off, now formed in one way and another. This clearly indicates that the little plant, diffused through that stony mass while it was still muddy and afterward hardened, exhibited — according to the different sections — different parts of the trees.

I illustrate the matter most aptly by an example. In crystalline bodies, little mossy shrubs of this kind are not infrequently seen, which I remember having beheld with no small pleasure; and the distinguished philosophers Liceti and Lorenzo Pignoria [Laurentius Pignorius] attest to having seen a green little herb in the middle of crystal — the former in his work *On the spontaneous motion of living things*, the latter in his exposition of the hieroglyphic Tablet [the *Mensa Isiaca*].

[Margin: How [things grow] in crystal and amber — moss, flies, and the like enclosed.]

How that herb came to grow within the crystal is not difficult to investigate. For it is certain that this little herb, having first been present as a true plant in the matter suited to generating the crystal, was afterward hardened by the stone-making faculty together with the crystal — just as in amber [succinum] little animals of many kinds, enclosed by an eternal barrier, have presented themselves to view. For if anyone were to cut the crystal, he would doubtless find no longer a living, vegetating plant, but a stony one — and that not diffused through the whole crystalline mass, but cut up into its own branches. So what happens to the little herb enclosed in crystal, on account of its transparency, to the sensible sight, no one ought to doubt could have happened in opaque bodies while they were still consisting under soft matter.

It now remains for us to explain by what brush of Nature [penicillum Naturae] the form of certain animals has been so skillfully expressed in stone. Certainly the paths of Nature are so hidden, and her manner of proceeding in the production of diverse things so occult, that unless one has been instructed by the experience of many years, and has devoted all his effort to the perfect investigation and exploration of the composition of things, it cannot be that, by the reasoning of the intellect alone, anyone should attain to the proximate, true, and genuine causes of such great

[Printed page 41]

marvels. For experience illuminates the intellect: here, by aptly combining particular things with particular things, it leads at last to the desired knowledge of hidden causes.

[Margin: How figures are impressed in subterranean rocks.]

In the perfect expression, then, of the images which are everywhere found in stones, several partial causes concur. The first is a certain disposition of the matter, fit to receive the form. The second requires something else as well, which may impress upon the matter the form — now this, now that — like a kind of seal; and to this there always belongs a certain action endowed with vehement magnetism, by which like are drawn to like.

As for the matter: it had first to be soft and steeped in a certain moist mud; otherwise, by its hardness, it would repel all the penetrative faculty of the tinctorial spirit. This is evident from the fact that almost all stones are softer in their own mine, and only then pass into adamantine hardness when they have received the dry breath of the air. But the form or seal, which impresses the figure upon the matter, can likewise be twofold: purely natural, and composed of natural and artificial together. Of the former I say that it could have been the cadaver of some animal, whose skin, glued to the still-soft matter, impressed upon it a figure like itself, by the working of the plastic faculty which (as we said above) still remains in the cadavers of animals.

[Margin: How the figures of animals are impressed.]

Indeed, Albertus Magnus [Albert the Great], in Book I *de rebus metallicis*, treatise 2, chapter 9, says this expressly in these words: "It seems wonderful to all," he says, "that stones are sometimes found which have the images of animals both within and without — for on the outside they have the lineaments, and when they are broken, there is found in them the figure of the entrails; which could not have come about by any other means than from an animal there converted into stone." For when [Nature], on account of the unfitness of the underlying matter, cannot animate it into life, she at least impresses upon it a figure like herself; and this through the agency of the saline bodies lying hidden in the cadaver, which — while they flow together from the disposed matter by the magnetic attraction of salt (as we said), drawn one to another — carry with them the plastic power naturally implanted in them. At length, when the more flaccid parts of the cadaver have been consumed, the stone-making power converts what remains, together with its figure, into rock. And a clear indication of this is that perfect

images of things of this kind do not penetrate the whole substance of the rock, but cling only to the surface — as all those who devote themselves to cutting stones of this kind, the stone-cutters [λιθοτόμοι (lithotomoi, "stone-cutters")] whom we have rigorously consulted about this, testify. As for the fact that sometimes only the feet, the head, or one foot and another appear in stones, this could have come about either because of the broken-up parts of the cadaver, or because of an interruption in the flowing earthen matter, by which the parts were torn from the parts, and cannot show forth any but the isolated parts of the animal. Hence it also comes about that some parts are seen as twisted and as it were wrinkled, which could happen because of the motion of the skin, wrinkled in some part by the flow of the matter. Having set forth the natural account of the figures of animals in stones, let us now explain how this can come about from a composition of the natural and the artificial.

MODUS QUARTUS

[Margin: The marvelous quarry-mines of Tivoli [Tibur].]

It is certain — and daily experience teaches it — that in the mines of Tivoli [Tyburtinis fodinis], within the very heart of the rocks, various iron instruments are found: nails, spades, the diggers' mallets which the masons [*Piccozze?*] [?] call *Piccone* [pickaxes], and the like; tools once left there and buried, covered over by the earth and by the chippings of the rocks, which at last, after much time, coalesced anew with the stone. For it is so well known that the Tivoli mines are, over a certain course of years, replenished with new rocks by the coagulative force of the sulphurous water flowing out of Lake Albula [Lacus Albula] and running through subterranean channels under that whole plain, that no one can any longer doubt of it; and we shall demonstrate this (God granting) in our *Latium*. Moreover, the stone-cutters or quarrymen, who labor there in great numbers, almost always have their own huts built on the spot, in which there are also sacred images, crucifixes, and the like, pertaining to divine worship — each according to his own devotion, as we ourselves observed, not without a singular feeling of the mind.

[Margin: Sacred figures impressed in subterranean images.]

This whole furniture, abandoned after the workmen departed and variously scattered among so many ditches, could easily be lost. For once they have emptied one place of its rocks, they are accustomed at once to cover the caverns and ditches with dust, chippings, and clods of earth — so that, in this way (as I

said), over the course of many years, that whole heap of things may be converted into new rock.

These things being established, then, I now say that it can happen that one of these images, wrapped in mud, may in the same way (as we said above concerning the cadavers of animals) impress its own figure. For since colors consist of various minerals, and one mineral (as we said above) draws another by natural magnetism, it can come about that the mineral particles inhering in the images, having acquired some other mineral matter that symbolizes with them, impress in it a figure like themselves.

While I was pondering these things within myself with great mental excitement, it happened this very year, in which we are writing these things, that, while I was in the Tivoli countryside for the sake of exploring it, I fell into familiar conversation with the overseer of the ditches; and conferring with him about many matters concerning the properties of the place and the nature of the mines, I brought up whatever I have just adduced about the various instruments found in the heart of the rocks — and on his testimony I found it to be true. Indeed, he added that there had been found, among other things, in a certain rock, these four letters, I N R I,

[Margin: A wonderful observation about the title of the crucified Christ, impressed in a Tivoli stone.]

which refer to the title of the crucified Christ, depicted there by Nature, and sold to a certain foreigner for a great sum of money: no small

[The opening sentences below continue from the previous page, mid-account of the petrified Crucifix-title experiment in the Tivoli quarries.]

I thought about how this could happen, and I saw it — which I will explain in a few words. I say, then, that once a certain sacred image of the Crucified was left and buried there amid the scraps of stones and earthy debris, it could easily happen that the title [of the cross], being detached from the cross, clung to material suitably disposed to receive its form. With the passage of time, this material together with [the title] was converted into a stony mass, and there left behind its own cast [ectypon] in the stone. A great part of those images found in marbles, therefore, may be ascribed to this cause — especially when they are so perfect that an effect of this kind cannot be ascribed to a merely natural cause.

So that I might make some trial of this matter, I painted various little images, which I placed between two slabs of marble and left buried for the space of a

whole month. When, after that time had nearly elapsed, I opened the slabs — wonderful to say — I found each of the figures (among which was the most sacred Name of JESUS) not only impressed and expressed at the surface, but penetrated to some depth toward the bottom, so that even when I smoothed the slab down with pumice the same figures kept reappearing. You should set up the experiment as follows.

[Margin: An experiment demonstrating it nicely.]

EXPERIMENT

[Greek: εικονογένεσιν (eikonogenesin, "image-generation")] demonstrating it to the eye in stones.

Paint whatever image you like on paper with this preparation of colors: let the colors — which must be mineral — be mixed with vitriol, with salt dissolved in water, and with distilled petroleum, first with some portion of alum. Place the paper so painted between two marble tablets planed down to an exact smoothness, and with the joints smeared over with wax and pitch so that no moisture can get in. Store these in a damp place; and when the term of a month — or even of two or three months — has passed, take the tablets apart, and you will find on one or the other tablet the images depicted to the life, distorted in no part; and you will find that they have penetrated even into the very body of the tablet to some depth with their colors. You will have the same success if you trace the picture with ink alone, with vitriol well diluted.

COROLLARY [I]

From this experiment it is abundantly clear that many of the more perfect images within stones — especially the better ones — were formed in no other way than by the method just described. Of this kind are those we display in the following diagram: two birds marked with the number 5, which appear to have undergone the figure of a cat or...

[The text here jumps across the column to continue at folio 43, left column.
Resuming:]

[the figure marked number] 2; the image of the Crucified marked number 3; and the figure marked number 4, which perfectly imitates an Egyptian idol — these are explained by the considerations I brought forward, of the sort of which I displayed various schemes in my *Oedipus*, Tome III. The one marked number 5 seems to have been an image of the Blessed Virgin with the Child in her bosom,

whom two angels above seem to be crowning. As for the fact that these two are seen somewhat distorted and imperfect, it could have happened because the painting, crumpling in the damp, disrupted somewhat the intended symmetry of the lineaments; and it is likely that the same happened with the rest of these similar cases.

[Margin: Reasons for the images.]

But you will perhaps object that it cannot be grasped how such images crept into the stones of the deep. I answer as I indicated a little above: that quarries [were] once dug out and emptied of old [and] over time [silted up and refilled?]. It could therefore have happened that men devoted to painting, long ago in those quarries, painted images of this kind to pass the idle time — or that the images were brought there from elsewhere; that afterward, through some chance or other intervening, they were abandoned and scattered, buried under sand and debris; and that at length, moistened by subterranean evaporation and by rains and showers, they adhered aptly to material destined to generate marble, and in this way, together with the images, were converted into marble, leaving their likenesses expressed there. So that what Pliny [Plinius] relates of the ring of King Pyrrhus [Pyrrhi regis] — in which the nine Muses together with Apollo were seen depicted — I am persuaded had its origin from nothing other than a similar figure, without any painting, lost in some mine.

[Margin: An objection from the bones of animals.]

You will object, secondly: why do there not appear bones of animals, or paper or cloth or wood, in which the impressed images are discerned? I answer: that all these, moistened over the long lapse of time, underwent a vast alteration, until everything was resolved into corruption [tabum], eaten away by the sharpness of the metallic juices, reduced to powder, and dispersed into the tiniest particles, with no trace left behind — and then at last coalesced together with the matter into stone, the image alone remaining. The image remains because the cloth or paper on which it had been painted, since it had clung — glued to the apt material from the very beginning — likewise impressed upon it a permanent and stable form.

COROLLARY II

From these things it is clear how some images are found depicted in stones with a certain incredible perfection, in which not only grace and luster, but also a marvelous variety of colors and shadows nestling [within them] wonderfully

solicits the eyes and minds of the beholders. Of this kind is one which the most excellent prince of Bassano [Bassanensis] showed me not long ago.

[Margin: The image of the Guardian Angel committed to him expressed in stone, at S. Angelo.]

It was a picture of the Guardian Angel with the soul, under the form of a boy, committed to his care, as appears in the figure — produced, as he himself thought, by nature in this way. I, examining it with the greatest...

[Resuming at folio 43, left column top:]

diligence the image and the brightness, elegance, and liveliness of the countenance — the face with which [the Angel] gazed upon the boy, and this boy's most devout affections [of devotion] toward the Angel — I judged it could not be that Nature, being [Greek: ἄλογον (alogon, "irrational," "without reason")], that is, irrational, could intend any such thing, which would not be granted even to a painter unless of the greatest genius. But that this was a pure work of Nature, the said prince was moved [to believe] by no other argument than that the said image permeated the whole substance of the stone, so that however many sections were made, just so many new copies of the said images would result.

While, then, I was pondering this deeply, and the manner in which it could have come about, I happened upon a painter — of whom I had already long ago heard that he could paint similar images. When I had discussed with him the rationale of this said painting, and asked whether anything similar to this could be done by art, he at once added that it was true: that he had offered images of this kind to Urban VIII, Supreme Pontiff [Urbano VIII, Pont. Max.], as an unheard-of specimen of the art, expressed in marble — in which, since the colors penetrate the whole substance of the stone, when a section was made parallel [to the surface], just so many new images would result as sections were made. And when I asked him for the rationale, he denied that it could be done; but I, sniffing out the rationale, at last, after making the experiment, found it to be true.

[Margin: A new and rare experiment.]

There is still to this very day here at Rome a painter, the Knight Vannius [Eques Vannius], who has sold this art at a great price, and cannot be induced to communicate his art to anyone. When I had heard this, I pondered seriously with myself how it could be done, [and] by what means colors suited to this could be prepared. So, by consultation with the distinguished German chemist Alberto Guntero [Albert Günther] the Saxon, we accomplished so much by combination

and by experiments with substances that we not only dug out the secret but also enriched it with a manifold variety of colors, which the aforesaid Knight lacked. And since the matter is most worthy, and we have already made the experiment in our Museum, I will here gladly and willingly communicate to the curious Reader the whole rationale of the secret, since these things contribute much to confirming the aims of our undertaking.

[Margin: An experiment by which any figure whatever is dissolved into the marble, penetrating the whole solidity of the stone.]

The colors are prepared as follows. I take two ounces of aqua fortis [aquam fortem]; likewise 2 ounces of aqua fortis or aqua regia [aqua fortis sive aqua regia]; one ounce of sal ammoniac [salis ammoniaci]; 3 drachms of the best spirit of wine [spiritus vini]; as much gold as is bought for 3 julii [giulii]; 2 drachms of purified silver [argenti depurati]. With these prepared, now put calcined silver into a flask, and with 2 drachms of aqua fortis poured over it, leave it to evaporate, and you will have a water that will give you first a blue color, and afterward a black. Next put calcined gold into the flask, and with aqua fortis poured over it, until it has evaporated, I set it aside; then I leave the sal ammoniac, together with the poured-on spirit of wine, until the spirit has evaporated, and you will have a water of golden color, which will give you various colors. And by this art you will be able to extract from the remaining minerals various tinctures of colors.

These things being done, then, with these two waters you will paint whatever image you wish on white marble of a somewhat soft substance; and renew the figure daily by the fresh addition of the waters; and in time you will find that the painting has penetrated the solidity of the whole stone, so that, when cut into however many parts you wish, it always exhibits to you the same figure on either side. This thing, being as rare as it is unusual, also gives rise to the greatest admiration in the beholders.

[Margin: Another from the heads of angels [seen] in full.]

A similar image was shown by the most excellent Paolo Giordano Orsini [Paulus Iordanus Ursinus], Duke of Bracciano [Dux Braccianensis], in a many-sided stone, in which as many sides as there were, just so many angelic heads stood out — of a different figure, however, now upright, now twisted back, according to the manner of the oblique section made. But with these things set forth, [let us come] now to the rhombus.

[Margin: The rationale of the [colored] juices.]

We say, then, that whenever images are found penetrating the whole substance [of the stone], this could not have happened except by the agency of mineral juices, and through the intervention of salts of every most corrosive kind. But those that penetrate the inner substance less, we must judge to be endowed with a smaller quantity of the said juices. The truth of this I have found in the agate which represented a Heroine, as I related above: which, cut through the middle, showed nothing of those things that appeared expressed on the outermost surface — except for certain lines diffused in an irregular course. But let these things suffice concerning the fifth mode; let us come to the sixth mode.

MODUS SEXTUS [SIXTH MODE]

On images of stones in which something divine is believed to inhere.

In what precedes we have narrated several images of Christ crucified, of the most blessed Virgin Mother with her divine little Son taken up in her arms, and of the likenesses of the other saints — concerning which it is rightly asked how Nature expressed them. I say that the execution of Divine providence comes about for the most part through second causes; that is, whenever prodigious effects in the nature of things appear — in the heavens, indeed, new births of stars; in the lower world, monstrous births; and in stones, prodigious images — those [effects], I say, are always directed, by that admirable connection by which Divine [matters?] are joined, toward signifying something.

[Margin: How the Nature of things would cooperate in producing prodigious images.]

For providence presupposes two things, namely ordination and the execution of the order, of which the former regards the cognitive power, the latter the operation. Since, then, in GOD there resides for ordaining an infinite wisdom...

[Resuming at folio 44, left column top:]

and for operating a power and potency boundless and free of every limit, it necessarily follows that He arranges all the orders even of the least things, while the least things, indeed, or even the lowest, [He arranges] through inferior powers — as it were, through natural executrices of Divine providence; that is, through the concurrence of natural causes, through which He Himself, as the universal cause of things, operates. Hence we read that signs of this kind have always appeared in great events; and we have pursued this most fully in our *Diatriba* on the prodigious Neapolitan crosses [seen] in the linen garments of men at Naples [Neapoli].

[Margin: Threatening signs of evils impressed on a stone.]

A stone was found in a mine of Switzerland [Helvetia], as Ambrosinus [Ambrosinus] reports, with this scheme of figures; which, although it is a pure work of nature, GOD nevertheless, out of His eternal providence — by which He holds all the orders of the World and the connected rationale of their effects — willed to signify by means of those wars that followed a little afterward. So, where He wishes the cult of the Mother of God or of some other Saint to be instituted, He generally signifies it, as it were, through signs of this kind, indices of the divine will. In this way, in the Kingdom of the Chinese [Regnum Sinarum], a little before the Gospel...

[Resuming at folio 44, right column:]

the Gospel was brought in there, river crabs marked on their backs with images of all the crosses were seen, in an unusual order of things, in an unusual way, as appears in figures L [and] M.

[Margin: In China and Japan crosses appeared on the backs of crabs and in the trunks of trees.]

Diagram. Two small woodcut figures of river crabs seen from above, each bearing a cross-marking on its carapace, illustrating the "crosses on the backs of crabs" reported in China before the preaching of the Gospel.

- L (left figure): an elongated crab/crustacean with a long-snouted body, a cross-shaped marking running down the center of its shell.
- M (right figure): a broader, rounder crab with claws spread, bearing a cross-shaped marking on its carapace.

In Japan [Japonia] likewise, at the very beginning of the preaching of the Gospel, the figure of a cross appeared in cut [i.e. felled] trees. Admirable is what happened at the same time in the Kingdom of Chile [Regnum Chilense]: a new image of the Mother of God, never before seen, appeared among the inaccessible hiding-places of the cliffs as a spectacle to be admired by all — not by the help of a mortal painter, but by the brush of Nature, from the intention of GOD, delineated in various differently-colored kinds of jasper according to all the laws of Optics.

[Margin: A wonderful account of the image of the Blessed Virgin seen in the Kingdom of Chile.]

[Margin: True [images] on the backs of crabs and in the trunks of trees.]

But because the matter is most worthy of consideration, I will append the description of this image from the history compiled by Father Alfonso de Valle [P. Alfonso de Valle], together with the image.

Diagram. A large full-width engraved plate (uncaptioned) occupying the lower two-thirds of the page. It depicts a rugged rock cavern or grotto, within whose dark, excavated hollow stands the figure of the Blessed Virgin Mary holding the Christ Child on her left arm. The Virgin is shown full-length, with long hair flowing down over her shoulders and a long robe and mantle; the folds of the drapery merge into the striated rock of the cave. The Child is held against her body. The whole figure appears as though naturally formed in the variegated stone of the cliff face — the engraving rendering the "image of the Virgin seen in the rocks of Chile" described in the text. No labels or lettering appear on the plate.

[Resuming at folio 45, left column top — printed in italic, the description translated from Spanish:]

The true effigy of the Blessed Virgin in Arauco [Arauco], which is seen in a cavity of the rock in the manner of an arched shrine, not delineated by any craftsman, but constructed by the Author of nature out of jasper of various colors, with a white face beneath black hair, with a mantle inwardly sky-blue, outwardly red in color, woven with a rose-colored garment. I will here set forth in a few words its history, translated by me from Spanish into Latin.

On the shore of the Pacific Sea, which faces Arauco, [at a place] called Inbulia [Imbulia?], there is a mountainous spot, almost inaccessible because of the cliffs and rugged rocks, until you come to a plain and a pleasant little hill, where — looking toward the hollowed-out cliff — you will behold the wonderful and prodigious image of the Blessed Virgin, expressed there by nature, with her precious Son in her arms. The black stone forms the hair, fanned out and spread over the back and shoulders; while white [stone] forms the face, turned to one side and, as they say, in profile, so that only one eye, of great proportion and elegance, appears delineated.

The garment [is] of rose color up to the girdle; the mantle, of citron color below, appearing of sky-blue color [above] — the image, in a word, fashioned in such a way as wonderfully to affect the eyes of all who behold it.

It was first noticed, some 8 or 10 years ago, by a boy staying with his mother in the said plain, who addressed his mother with these words: "Do you see — do you see, mother, that beautiful Lady with her lovely [Son], whom she holds in her arms?" The mother, with her eyes thereupon cast toward the place where the boy had

pointed, found the thing to be most true, which she at once published by public report throughout the whole territory. When the rumor reached the ears of the Reverend Fathers, they soon went to the place, and found it to be true, just as the woman had related. Whereupon the still-heathen peoples, moved by the miraculous effigy — having first been instructed about the meaning of the image — with unanimous consent took up the Christian faith, to the great solace and joy of all. Nor did God fail the devotion of the Neophytes toward Himself and His mother: when, after a year, the way to this place had now been leveled flat, He confirmed their devotion with the customary processions, frequented by great miracles.

[End of the italic translated account.]

And from all these things it is at last concluded that, even if the said images — whatever sort they may finally be — are properly made by Nature, according to the second, third, fourth, or fifth modes set out a little before: yet because the operation of Nature always depends on the concurrence of the providence that [governs] all things, so too, if notable events follow such phantasms of Nature, these were already foreseen in their causes, according to the immutable rationale of the divine archetype, connected by the laws of nature — although things of this kind ought by no means to be called miracles, but marvels, as St. Thomas [D. Thomas] rightly teaches, *Contra Gentes* III.3 [Book 3]. But let these things suffice concerning the [Greek: εικονογένεσιν (eikonogenesin, "image-generation")] in stones.

SECTIO II [SECTION II]

ON THE TRANSFORMATION

of Juices, Salts, Herbs, Plants, Trees, Animals, and Men
converted into stone; or, On the petrifying faculty.

CAPUT I [CHAPTER I]

On the origin of the petrifying juice.

That there is in the innermost bowels of the Earth a certain faculty which, having got hold of suitable material, presently converts all things into stone, we said above; now, however, we will treat of it expressly. It is asked, then, what this force and faculty is, and from where it derives its origin. I answer: this petrifying faculty resides in the various species of minerals which are found, elaborated by manifold and marvelous art, in the subterranean workshops; and, as we have

said, it is produced in manifold ways, according to the differing nature and property of the subterranean juices.

First, we see water dripping in subterranean caves for the most part converted into stony icicles [stalactites]. The reason for this is that rainwater, penetrating the inmost passages and fissures of the mountains, carries down with it a vast quantity of fragments stuffed with niter and salt and scraped off from the stony structure of the mountain. These [fragments], mingled with the water — whether perfectly or confusedly — dripping within the cave, suddenly, when the moisture is consumed by the dryness of the surrounding [air], are converted into stone of that kind of which the fragments were; and of this sort of juices are all those stones which take their origin from the vaults of caverns and cliffs. Whatever, moreover, you place within the orifices of such dripping waters — whether it be wood, or fronds, or herbs, or anything similar — within a short time is either wholly converted into stone (if the fragments of the stone have been well united and mixed), or, if they have been confusedly and not well mixed, at least whatever they touch they will clothe with a stony crust. Of this...

if they have been perfectly mixed together with the [stony] sediments and the water; or, if they have come together in an imperfect and confused mixture, then — since the juice is not free to penetrate into the inmost part of the substance — it will likewise clothe plants, herbs, straws, and twigs with a crust only, as is shown in figure A B C. You can see something of this kind at the Albula near Tivoli [Aqua Albula], where you will find herbs, straws, stalks, wood, broom, and similar shoots clothed only with a stony, niter-bearing crust; and you will also observe that the assemblage of sugar-like grains is very imperfectly united, indeed easily dissolved by the touch of the fingers into a white lime.

Diagram. A small woodcut in the left column showing three encrusted plant-shapes set side by side, lettered A, B, C, illustrating objects clothed with a stony, niter-bearing crust.

- A (left): an upright stem or reed-like stalk encased in a thick, ringed stony sheath.
- B (center): a more open, branching plant — herbage or broom — coated with a crust along each frond.
- C (right): a slighter, feathery shoot with a thinner incrustation.

Canon III.

[Margin: The petrifying juice from niter and sulphur makes the very hardest stone.]

Whenever water of any kind whatever — especially within the hollows of mountains — comes together with niter and sulphur and the shavings of stony, salt-laden rock, then a stone-making juice is mixed, which will convert whatever it envelops into the dense substance of stone. For the salt opens the pores of the substance, the niter fills them, and the sulphur — once all moisture has been driven off by its own heat — will transmute the whole into a substance of iron-like hardness. A sign of this is that when such stones are struck with iron, they give off a ringing that rivals and resembles that of metal. [Margin: Sulphur cooked together with niter is converted into stone.] There is also this experiment of it: if you cook sulphur together with niter, you will find the whole pass over into a stony substance.

Canon IV.

[Margin: The petrifying juice from pyrite and vitriol-bearing clods, what it produces.]

But whenever, in the underground reservoirs of water, the concreted juices — such as pyrite, misy, sorry, melanteria, or chalcitis — have blossomed forth, or have crossed through rocks impregnated with vitriol, and then are perfectly and most minutely mixed together out of the shavings of the rock or clod (which serve as a kind of vessel in which the said juices are contained), then a certain petrifying juice will be born. When this juice is mingled with rocks and clods of another species, it converts them into precious stone, varied according to the proportion of the tincture. And if a petrifying juice of this kind is raised up by the heat of subterranean fire, it is driven through the inmost crevices of the mountains and rocks; and wherever it finds a properly disposed matrix — or if it is a most limpid liquor — it will at once, according to the tincture and the proportion of a more exact mixture, harden into a transparent precious stone: into crystal, beryl, amethyst, topaz, diamond, and the like, now harder, now less hard according to the quantity of salt and alum joined to it, with the cold of the place contributing. [Margin: Where gems come from.] Together with these, great endowments arising from the nature of the salt-juices are imparted and conferred upon them. So here you have the genuine origin of gems, which we also treated above, comprehended in this canon.

Canon V.

[Margin: The petrifying juice variously gives rise to marbles, how it does so.]

But whenever the petrifying juice has been mixed out of the various species of niter, alum, vitriol, and the other salts, and out of the diverse shavings of mineral

clods — the said salts having been eaten away by their own pungency — in the inmost bowels of the earth, then by the heat of subterranean fire the juice is resolved into a vapor; and wandering through the fissures and channels of the rocky substructures, wherever it finds a fitting matrix, there it will form either variegated marble (from the manifold tincture in which it is rich) or the various kinds of jasper. And whatever it envelops — the little plants of mossy material nearby — it will likewise coagulate together with the rock; whence so many little herbs and shreds of moss are everywhere to be seen within the stones.

And from these five canons, once well understood, the curious reader will easily grasp the whole rationale of λιθογένεσις [Greek: lithogénesis, "stone-generation," the formation of stone], and will have set out clearly the manner and the rationale of λιθομεταμόρφωσις [Greek: lithometamórhōsis, "stone-transformation"] — that is, of those things which are converted into stone — so that, given any case whatever of stone-formation [casus lithomorphoticus], he may at once be able to assign its cause. Now nothing further remains except that we append a kind of historical account of all those things which, to such great wonder of men, are seen to have been converted into stone.

with the shavings of the rock having been rubbed off, it will generate the very hardest and altogether adamantine stone. Of this kind are certain pieces of wood converted into stone, which — on account of their extreme hardness, as Agricola [Georgius Agricola] testifies — people use in place of a whetstone, and which, at any more vigorous rubbing, send out fiery sparks from themselves and are therefore most suitable for tinder-boxes. Indeed, in Germany such stones are found that smiths, as Agricola testifies, use in place of an anvil.

[Margin: How wood is converted into the very hardest stone.]

Now since, from the mixture of such waters with concreted juices and the various species of salts, they make different stone-making juices, so too it is necessary that, according to the variety of the juices, various species of stone arise, differing in nature and property in the things converted into stone. By means of several canons we shall set out each case individually.

Canon I.

[Margin: Waters not petrifiable produce nothing in stone.]

Whenever water — whether by rain, or by a river, or through sandy materials — passes through rocks not at all stocked with any supply of concreted juices and salts, that water too will convert nothing into stone, because of the deficiency of

the petrifying faculty. So it happens in the most limpid springheads, which, since they lack every heterogeneous admixture, likewise leave no trace of any stony concretion, neither on their shores nor in the crevices of the caves.

Canon II.

Whenever rainwater, or water dissolved from snow, passing through the crevices and fissures of the mountains, insinuates itself into rocks stocked with niter — or some river whose banks have been filled with niter-bearing material — then the water will mix the niter-bearing material, either with its smallest particles only, or perfectly, or but confusedly, by way of the shavings. If the former, then a smooth, polished, and slick stone will be born, and the waters will also convert into the same stony material whatever they envelop with their flow. But if the latter, then from the dripping of waters within the caverns of the mountains there will be born a rough, jagged, and unpolished stone, which rises up now into the shapes of hanging icicles [stalactites], now into pyramids and columns by successive increase; and this too likewise transmutes whatever it envelops into a stone like itself, the stone from which it flowed. And such are all those monstrous shapes of things which we behold with wonder, converted into stone in caves of this kind. [Margin: How the juice and the stone-making liquid are converted in the rocks.] But if the water of a river or lake has been imbued with this niter-bearing power, then herbs and plants, having drawn in the stone-forming juice, will remain soft so long as they stand within the water, with the moisture impeding [the process]; but once they have been pulled up and cast onto the shore, then the petrifying juice drawn into them — by the heat and dryness of the surrounding [air] resolving the moisture — within a short time turns them either wholly into stone, if the niter-bearing particles cling to the stony shavings...

Cap. II.

Observations of various things converted into stones.

I shall not speak in this place of the innumerable oysters, shells, clams, conchs, mushrooms [sea-fungi], seaweeds, and the rest of the sea's furniture converted into stone, since these are so commonly met with everywhere that they hardly deserve to be mentioned. For since these — on account of their innate saltiness — have a nearness to stone, so likewise, easily exposed to the air and the shore, they turn to stone once their moisture has been consumed. But, lest I dwell on these, I shall bring forward here only those which have some remarkable feature attached, or those which I have either seen myself in the various museums of learned men or read of in trustworthy authors.

Diagram. An engraving in the left column showing a large irregular mass of rock densely packed and encrusted with shells of every kind — bivalves, snails, and conch-like forms heaped together.

Caption (verbatim): *Saxa moles omni conchiliorum genere referta*. [A mass of rock stocked with every kind of shell.]

[Margin: A nest together with its chicks, entwined in the branch of a tree, converted into stone.]

[Margin: The petrified glove of the Emperor Frederick.]

Albertus Magnus [Albertus Magnus], in Book I of his *Mineralia*, tractate 2, chapter 7, relates that something marvelous happened in his own time: namely, that near the city of Lübeck a great branch of a tree was found, in which there was a nest of birds, and in the nest the chicks — all converted into stone. This, however, could not have happened otherwise than that, after the tree, together with the nest and chicks, fell by the force of the winds into petrifying water, it was in time — as is wont to happen with all other things — converted into stone by the stone-engendering spirit [spiritus lithogeneticus]. The same Albertus relates that there is also in Gothia a spring which converts whatever is immersed in it into stone. To prove the truth of this, the Emperor Frederick [Friedrich] sent a sealed glove to that spring; and when, after some days, half of the leather and the seals had been submerged in the spring, that whole half was turned into stone, the remaining half — the leather — staying as it was.

[Margin: Why drops of water of this kind, poured onto the ground, turn to stone, but the ever-flowing stream does not.]

But why do drops of a spring of this kind, poured out upon the earth, soon turn into stone, while the perpetually flowing stream does so least of all? I answer that this happens because drops diffused upon the ground, not being easily dried up by the air — by which the moisture is consumed — coalesce, just as do all things converted into stone; whereas, since the stream exists in perpetual motion, its particles, just as they cannot easily be united, so too can least of all be coagulated.

[Margin: Petrified plants.]

Theophrastus [Theophrastus] reports, in his book *On Stones* [recte: *On Plants*; the text reads *l. de stirp.*], that by the Red Sea, in the Gulf of Heroopolis [in finu Heroo], laurels, olives, and other shoots are everywhere found converted into stone together with their leaves and flowers. [Margin: A petrified human figure.] A stone was also found in the river Sapena which beautifully rendered a human

shape; and such things are to be referred to those which are generated under a like form by petrifying drippings. As for how the idols of the gentiles are sometimes found converted into stone — the cause of this is not hard to track down. Since they had been overflowed by the petrifying juice and clothed as it were with a crust, they exhibited the very form which they had clothed, just as we taught above concerning the artificial fashioning of images by means of drippings. And as for the fact that, as Agricola testifies, other simulacra of this same stamp have been found — such as in human form, or a human head armed with a helmet, and the like — these were produced only by the petrifying juice imbued with a shape similar to the stone or to a clod of earth. [Margin: An image of the Mother of God converted into stone.] To this belongs what Eusebius Nieremberg [Eusebius Nieremberg] relates of an image of the Mother of God turned into stone by nature, shown at Madrid fixed upon a certain stone made by nature; [Margin:...together with a crucifix.] it is likewise displayed in Spain among the nuns of Saint Augustine. He relates the same of a certain crucifix made of stone by nature. [Margin: A marvel in the field of Clavijo in Spain.] Indeed, in the field of Clavijo [Clavijo], not far from Compostela [Santiago de Compostela], cut rocks display the image of Saint James [Divus Iacobus] sculpted and painted by nature. [Margin: The reason.] The reason for this is easily clear from what was said above. For since all those who go to Compostela to venerate the holy places of Saint James provide themselves with images, whether sculpted or painted — which are sold there in great abundance for the devotion of the pilgrims — it could easily come about that, for those dwelling in the neighboring field, with various images dispersed among the rocks, in the course of time, by the petrifying juice together with the neighboring material being arranged, they coalesced into a solid stone (if they were little statues) or into the surface of a rock (if they were images), in the manner we described above.

[Margin: A spiral stone, in whose center is depicted an image of the Mother of God.]

This too is worthy of wonder: that in the year 1659, in Switzerland [Helvetia], within a mountain commonly called *Gottes Wald*, a stone was found coiled into spirals, in whose center the figure of the Mother of God appeared — not without the astonishment of the onlookers — which the most illustrious and noble Lord von Sonnenberg [de Sonnenberg] also published in print, together with a historical account. We set down the figure that follows, and meanwhile those things which exhale something divine. Indeed, there is scarcely anything — whether of plants, or of fruits, fish, shells...

Diagram. A large engraving filling the upper half of the page: an oval, almond-shaped (mandorla) frame radiating long pointed sun-rays outward in two concentric rings, with, at its center, a crowned figure of the Virgin Mary holding the crowned Christ Child (both with haloes), standing upon a base. Above, clouds. This depicts the spiral/figured stone discovered in 1659.

Caption (verbatim): *Anno 1659. Typus in medio saxi inventus, in Helvetia, quae etiamnum hodie in Ecclesia vulgo Gottes Vald, prope Lucernam spectatur.* [In the year 1659. A figure found in the middle of a stone, in Switzerland, which even today is to be seen in the church commonly called Gottes Wald, near Lucerne.]

Diagram. An engraving showing an open rectangular stone box or slab, viewed in perspective, within which lies a human skeleton turned to stone — skull, ribcage, limbs, and bones embedded in and emerging from the rock matrix.

Caption (verbatim): *Skeleton humani corporis in saxum conversum, ex Palatio Pinciano Principis Ludovisi.* [The skeleton of a human body converted into stone, from the Pincian Palace of Prince Ludovisi.]

[Margin: Into stone are converted almost all things.]

of other things, or of living creatures, that we do not observe converted into stone in various museums: dates, nuts, plums, olives, apples, pears, mushrooms, fruits of every kind — indeed, cheese and bread. Here too at Rome, in the palace of the Ludovisi Garden [Horti Ludovisiani], is seen a human body wholly...

so that, accordingly, it is established that stones are found in all animals and in their parts. Schenck [Johann Schenck von Grafenberg], indeed, in his *Observations* reported that they occur not only in a single part of the human body but in every member of it. One of our own Society, Father Bartholomaeus Conventinus, master of philosophy, gave proof of this: after his sudden death his internal organs were opened in my presence, and Joannes Trulla, a most celebrated surgeon, found in the artery near the *vena cava* various small stones, or tartareous matter, which, since they obstructed the artery, impeded the motion of the blood; and so, the vital channels being thus shut off, the soul was necessarily driven out by force. But to demonstrate the matter methodically, let me begin from the head.

[Margin: Stone in the human brain.] Rueus and Gesner [Conrad Gessner] affirm, with a remarkable account, that stones are generated in the human brain. When a young man died from eating, after being afflicted by long and dreadful headaches and at last carried off, the body was opened, and in the brain a stone

exactly resembling a mulberry was found — the cause of such great pains and of his death. Schenck, Cornelius Gemma, Mercurialis [Girolamo Mercuriale], and countless others confirm this history.

[Margin: In the mouth.] Langius affirms that small stones are generated in the mouth. While treating a canon of Regensburg [Ratisbon] who was suffering from an abscess of the tonsils, once the abscess had been softened and a violent cough had supervened, the canon, he relates, at last coughed up a gypseous stone; and he says that in a certain other case entrusted to his care he found a stone under the tongue.

[Margin: In the kidneys and bladder.] I will not speak here of the stones of the kidneys and of the bladder in both sexes, since these are the genuine microcosmic stone-mines, than which nothing is more common. I will bring forward only one, which I am accustomed to display in my Museum, of unusual size and weighing eleven ounces. It was extracted from the bladder of Father Leo Santius, a man most celebrated for his writings and for the publishing of books, and prefect of higher studies at the Roman College. Although burdened by so great a weight, he passed urine with no impediment whatever, so that in the judgment of the physicians he did not appear to suffer from the stone at all — until after his death it was found hanging within the sides of the bladder, which was the reason why it had not been able to obstruct the bladder's orifice.

But to return to where we digressed: not in the principal members alone — the bladder and kidneys — but also in the heart, liver, lungs, spleen, stomach, intestines, and gallbladder, stones small, middling, and large have been found in vast number, as Gessner and Ambroise Paré [Ambrosius Paraeus] testify. Indeed, that within the female womb the foetus itself has been turned to stone is established by the assertion of most physicians; and Hippocrates (*Epidemics* V) says that a certain woman, long vexed by pain about the womb, at last gave birth to a stone of remarkable roughness, issuing from the mouth of the womb.

[Margin: Foetus in the female womb turned to stone.] [Margin: Another paradox.] Of a stony foetus produced not within the womb but among the ribs, in the preceding year, in Germany, the matter is established in a pamphlet already published. In the knees, feet, hands, ulcers, and the other subcutaneous parts, and indeed in the very veins, small stones are engendered.

[Margin: In the outer members.] Laurentius [André du Laurens] reports, in his *Anatomy*, that stones have been engendered in these outer parts. But having recited those stones which cited authors attest to be born in the members of the

human body, let us now show that, by like reasoning, these are also found in the remaining parts of living creatures.

Lapides in partibus animalium reperiri soliti — [Margin: Stones in animals.] Stones commonly found in the parts of animals are reported to be, for the most part, of great virtue, such as: the *alectorius* of barnyard cocks; the *chelidonium* of swallows, from which they earned their name; the Indian *mergus* [diver-bird] produces a stone highly esteemed by the barbarians; Albertus [Magnus], in his book *On Stones*, says that in the brain of the vulture a stone named *Quandrium* is found, infamous under the name of superstition. I do not speak here of the small stones found in the stomach of hens and ducks (for I say that these are not born there but swallowed), but rather of those that are born in the brain and in the other impervious parts.

In four-footed animals — horses, oxen, sheep, goats, stags — stones of great virtue are found, as Albertus, Cardano [Cardanus], and Agricola report. In my Museum there is a ball, not indeed stony, but concreted from countless fibers of herbs, found in the stomach of an ox; and Anselmus Boetius [Anselm Boece de Boodt] teaches that one is found in its gall as well. The same authors cited above record that pigs too are troubled by stones of the kidneys and bladder.

[Margin: Stone from the porcupine.] From the Indies are brought stones of great value extracted from the bristle-bearing pig, that is, the porcupine — a fine remedy for driving off fevers. Lodovico Dolce [Ludovicus Dulcis] relates that a stone is extracted from the wild ass, or onager, and accordingly marked with the name "asinine." The animals called *zybethi* [civets] also produce a stone, or rather a fluid, which, hardened into a tear-drop, yields a precious scent that they call *zibethum* [civet]. The stone extracted from the goat-stags of Persia and India, which is commonly called *bezoar*, can be counted among these — but of that elsewhere.

Nothing is almost more common than that stones are extracted from serpents. The river-snake [*coluber fluviatilis*], on the testimony of Hollerius [Jacques Houllier], is said to belch up a stone that cures epilepsy [a stone marked with roughness, [?]] from the mouth of the womb [?]. The Indians and the Ethiopians seem to hold nothing dearer than the stones extracted from the heads of great serpents, which they call dragons.

[Margin: Serpentine stones.] Most well known is the stone which they call, from the toad [*bufo*], the *bufonites*, and from the Greek βάτραχος [Greek: batrachos, "frog"] the *batrachites*, found in its brain. It also has this feature, worthy of

admiration: that it usually marks itself with its own figure and likeness, of the kind that the figure here appended shows. The reason for this we have explained above.

Diagram. A small uncaptioned woodcut showing the *bufonites* (toad-stone): an irregular oval stone with an uneven, lobed border, within which is impressed the figure of a toad or frog shown in profile, oriented to the left. No labels.

[Margin: Toad-stone.]

we showed that it arises from the spermatic faculty of the animal; and Albertus testifies that in his own day he saw a similar stone marked with the figure of a toad. Cesalpino [Andrea Cesalpinus] also says that toad-stones are sometimes found on which the figure of the red toad [*rubeta*] is impressed; the reason for which we will assign elsewhere in what follows.

Moreover, fishermen have found by experience that among the other living creatures — especially the aquatic ones, and those that frequent damp and marshy places — stones abound, as in the heads of the *aselli* [hakes], carp, pike, *cinaedi* [?], perch, and *tiburones* [sharks], and indeed in river-lobsters [crayfish]. All of these have been found, by some hidden consent of nature, to help in driving off the stone.

[Margin: In the heads of fish.] I will not speak here of the stones born within the various kinds of crustaceans, mollusks, and bloodless creatures, nor of the pearl-bearing shells, which, since they have a greater disposition toward stony matter, accordingly are found in them in greater number; nor of the tortoises and snails, from which they are called *cochlites* (from the snails) and *chelonites* (from the tortoises). But let this suffice to demonstrate that stones are born in every kind of living creature. How nature forms them, it now remains to be said.

DISQUISITIO

λιθογενεσίας in Lapidibus

[Greek: λιθογενεσίας (lithogenesis, "of stone-generation" — the genesis of stones)] — An Inquiry into Stones.

We said above that nature proceeds everywhere by an equal step in converting any objects whatever into stone; but by what virtue it accomplishes this is the thing to be investigated. We say, therefore, that the matter from which the stone is produced in animals is a superfluous humor separated from the nourishment, which consists of simple water and earthy matter. This matter varies according to

the nature of the nourishment: for it is either thick and hard to liquefy, or thin and easily liquefied. The thick kind, like mud, is resolved by nature out of the earthy portions of the nourishment into the smallest particles; the liquefiable kind is, like common salt, transparent and dissolves in water, which afterward, according to the various differences of salts, turns out manifold again.

Such a humor, therefore, gradually degenerating from earth, water, and salt into a tartareous or nitrous substance — while it is not expelled through the channels appointed for that purpose, and while it lingers in the viscera — produces obstructions, from which various diseases result. And when the watery moisture withdraws from it, either wholly or in part, then it is converted into stone. For that earth is resolved into the smallest particles on account of the salt remaining in it, which is coagulated to it because of its innate property — unless it is diluted by a great quantity of humor. Hence, in order for a stone to be generated, it is not necessary that all the humor withdraw; it suffices that the greater part of it evaporate.

This salt, however, together with the earthy matter, is not generated *in* a man, nor in any other animal, but flows in from the nourishment. For it first resides in the nourishment, since salt is by nature a balsam; afterward it clings to the humor that arises from the nourishment; then it is mixed with the blood, bile, and phlegm. When it has become superfluous, separated by the strong excretory faculty, the juice becomes stone-producing, and at last, according to the variety of the members in which it has been received, it is coagulated into stone. Hence those who generate much salt, niter, or tartar, from a like quality of their foods, are more exposed than others to the generating of stones; for the spirit of salt, when it finds tartareous matter in the human body, soon fixes it into stone. Hence many who have been freed of their stones by surgery at last conceive them again — in much the same way that emptied stone-quarries in time conceive new broods of stones.

For the generation of stones in living creatures there concur, first, the weakness of the expelling faculty, and also an abundance of earthy and saline matter diluted in the moist. For these two, joined by the benefit of the moist, are easily glued together and generate a matter not unlike tartar, which, joined to the salt, consolidates the stone more and more — in proportion to the quantity of the nitrous salt — making it more or less hard or soft.

COROLLARIUM

From these things it is plain that in all stone-producing animals there is a certain definite disposition and proportion of the humors — now lodging in this member, now in that — from which, by the saline quality (as we said above concerning precious stones), a stone is born, of this or that quality and virtue, according to the virtue of the coagulating agent that produces the stone.

EXPERIMENTUM

[Margin: Generation of a stone in the bladder — an experiment.] In a vessel of the kind in which urine is usually collected, let a horsehair, or something similar, be placed, so that it rises from the bottom up to the surface; and leave it thus exposed to the urine. You will see that the saline-nitrous corpuscles present in the urine immediately adhere to this hair, and gradually grow into a large crust — not indeed a stony one, but a friable matter like lime — which, however, you will find soon hardens once removed into the air. And by this experiment I learned how stone or calculus grows in the bladder. For if viscous matter, strained through the ureters, settles in the bladder, it is glued either to its sides or, remaining in the middle, gradually attracts to itself the saline-nitrous corpuscles, which, by the perpetual influx of matter, will at last so increase it that from it grows a certain soft and sandy mass. For if the matter fluctuates back and forth within the bladder, it, by obstructing the bladder's channels, will cause those pains that the stone-afflicted feel. Hence, unless it is removed by a syringe, it will take away all faculty of urinating; but if it has been glued to the sides by its viscosity...

[The text here continues onto Fol. 53, which resumes:]...the matter grows for the most part into an enormous mass, and these indeed have the faculty of urinating, but from the weight of the hanging stone, which continually plucks at the nerves of the bladder, they afflict the sick man with intolerable pain. Again, either the stone is smooth, formed from the purer parts of the salt, and in this way does not cause those torments; or, if it has been compacted from particles concreted with nitrous salts particle by particle, then by its roughness and harshness — besides wounding the bladder — it will also bring forth great pains from its prickings, together with a discharge of blood with the urine. Here you have the genuine genesis of the stone in the bladder.

In the kidneys, however, since these are microcosmic strainers, by which the pure parts of the serum are separated from the impure, it comes about that, the moisture being gradually consumed by heat, the saline-nitrous parts flow

together and at last concrete either into a stone or into a sandy mass, according to the greater or lesser quantity of dryness. The same is to be understood of the other excrescent members; since nature, in each and every member, generates from the nourishment a stone-producing juice suited to stone in whatever member it may be, in exactly the manner we described in the generation of natural stones. But let these things be said in passing [Greek: παρέργως (parergōs, "by the way, incidentally")].

[Resuming the lower portion of Fol. 50, where the corpus-humanum petrification narrative and Caput III opening appear:]

turned to stone, with the bones still intact, but overlaid with a stony rind. All these things, as I said, happen in this way in watery places abounding in petrifying juice, or in those places where a vapor of petrifying power, full of nitrous corpuscles, exhales copiously from the subterranean passages. When these have entered the pores of any body whatever, then, packed close together there, and the moisture lodging in them being expelled, at last they are converted into stone according to the Canons set forth above. So great is the force of this that not only the roots of trees and plants, but also the parts of animals — such as the callused hooves of horses in the Reatine country [Rieti], on Pliny's testimony — are hardened into a stony rigidity.

[Margin: A human body turned to stone.] [Margin: Horses' hooves hardened into stone.]...so that, accordingly, the hoof is packed into a stony hardness and therefore has no need of iron shoes. But since we have treated of these things at length elsewhere, in the first Volume, I shall delay no longer. I will add only this, by way of a finishing flourish: a dreadful history which happened in our own times in a village called Cucu in interior Africa, which in our own times was wholly turned to stone by a certain astonishing metamorphosis — together with its men, animals, trees, household furniture, grain, and food.

[Margin: A remarkable history of an African town turned to stone together with its inhabitants and animals.] Since the matter was found to be true on the testimony of most weighty and trustworthy men — and all the Arabs of those regions whom I consulted on the matter confessed that it was so — I have thought it right to set down here the whole series of the affair, exactly as Habelus, Vice-Chancellor of the Order of the Knights of Jerusalem, described it to me from Malta:

Victoria, formerly called Calsurakie, of swarthy complexion, captured together with six hundred other Ethiopians distributed among five cargo-ships sent from Tripoli

of Barbary to Constantinople and destined for the slave-block, fell as a captive to our triremes under a happy auspice. Through our Lord General Baglivi [?], she was today cleansed at the sacred font of Carlo Valdina, and now serves the Archdeacon Lord Eugenio Testaferrata on the island of Malta, where she landed in the year 1634, being about ten years of age. She says she was born in the city of Cucu in the province of Tongil, and that at the age of five she learned from her maternal aunt, who lived in the village of Biegioda — to which her parents had taken her — that the village of Biedoblo, an equal distance from the aforesaid places, in the summer season, in the dead of night, together with its inhabitants, animals, trees, and all its grain — amid crashing

- thunderclaps from the upper air, not without frequent shaking of the soil, in a moment stiffened into the hardest stone. Her parents and elder brother, roused by the messengers of this extraordinary event, mounted on two horses and a camel, and taking their daughter with them, made straight for Biedoblo on a journey of three hours from Biegioda, and saw with their own eyes by what manner of fate men and beasts had retained the same posture and bearing in which the divine justice had caught the guilty for punishment. For that kind of men was not free of unspeakable crimes — they were not Ethiopians, but Arabs, who, accustomed to roaming those vast regions, had chosen Biedoblo for their seat, with huts and shacks hastily built of mud, wood, and wicker, the richness of the soil inviting them; and there grew, not as elsewhere single ears from one stalk, but on every side equally from the lowest part up to the top very many, and of the length of a single man, and quite full of grains, vying with a pomegranate in fertility.*

When an innumerable multitude of men flocked there day by day, the Regulus [petty king] of the city of Cucu, after he had come as an eyewitness inspector, forbade by edict that anyone should presume to approach further without the prior leave of the King. All things narrated up to this point she both saw with her own eyes and heard with her own ears from the gentiles — the above-praised Victoria — over the whole year during which she afterward stayed in Cucu, until she was captured, while at play with her companions on the shore, by other Ethiopians, and sold in the city of Borna, a journey of four months distant. From Borna she was led with a great band of slaves into the royal city, and finally sold off to Tripoli, and from there sent on to Constantinople, where she fell happily into the hands of merchants among the faithful of Christ.

In Tartary, indeed, in the desert of Great Horda, geographers report that an entire horde of men and animals turned to stone is still to be seen; and if these things are true, I would certainly judge them to be the effect not so much of Nature as of a higher Cause — as the relation about the African village teaches, and as Holy Scripture clearly shows concerning the statue of Lot's wife.

[Margin: A horde turned to stone in Tartary.] Whoever desires more of this kind, let him consult Gessner, Agricola, Rueus, and Fallopius [Gabriele Falloppio]. But let what has now been said about the marvels of petrified things suffice. So, on to other matters.

CAPUT III.

De Lapidibus in diversis animalium membris enasci solitis

On the stones that commonly arise in the various members of animals.

Nature, always and everywhere, the matter being already disposed, does the same thing. For just as in the subterranean realm, or on the outer surface of the earth, it produces stones of every kind — partly homogeneous, partly heterogeneous — so too in the grade of vegetative nature (as is plain in the *lithospermum* [gromwell], in corals, and in countless others) it produces the same, as was clear in the preceding chapters. And in the kingdom of sensitive nature, there is neither an animal nor a part of an animal in which the power [Greek: λιθογενετική (lithogenetikē, "stone-generating" — the stone-generating faculty)] does not exercise its office; for wherever it has found a juice proportioned to generating a stone, there it must exercise its virtue.

[Margin: Stones are generated in all things.] This power indeed lies hidden in all those things on which either an animal or a man feeds; and these, afterward taken in as nourishment, when they find a viscid, undigested, and aptly disposed humor, strive to coagulate it into stone by the faculty innate within them...

CAPUT IV.

De ossium & cornuum subterraneorum genesi

On the genesis of subterranean bones and horns.

There are found here and there in the subterranean realm — whether in caves, or in pits — bones of every kind: teeth, shin-bones, ribs of enormous size, which many say are the bones of Giants; horns too of incredible length, which they say

belong to unicorns [*monocerotes*]. Let us set forth in few words what is to be thought of these fossils, and first concerning the bones of Giants.

§. I.

De ossibus Gigantum subterraneis

On the subterranean bones of Giants.

Bones of manifold kind are sometimes found in the subterranean passages, as also in the ancient crypts of tombs; and of these, indeed, the shin-bones of enormous size, and the bones of certain members resembling the human, they call the bones of Giants. And as for what concerns the Giants — since the sacred text contradicts us, just as we cannot deny them, so too something must be granted to common report, which the various accounts of authors concerning Giants extort, as if by their own right, from those who read them and believe.

And first I grant that in some monuments skeletons of unusual size are found — just as Fazellus [Tommaso Fazello] and Qualquarnera [?] write were found in Sicily; and the most excellent and most learned Carlo Calà [Carolus Kalà], Duke of Diano and prefect of the Royal Chamber in the Kingdom of Naples, describes in his book *On the Life of Blessed Giovanni Calà*, folio 202, that they were found in the caves of Calabria near the city of Cosenza [Confentinam]. The truth of this matter, inasmuch as it is confirmed by the testimony of the Viceroy, and is established by the most ample testimony of Father Luca Mandelli [Lucas Mandellus] of the Order of Saint Augustine in the following letter sent to me, I gladly acknowledge. The letter follows.

[Margin: Giants' bones found in the Cosenza district.] *The opening of a Giant's tomb in this city in these years manifestly demonstrates that they were here. For I received [word] that this tomb was found in a certain garden adjacent to the Church of Saint Peter, and near the walls of this city, from which*

- a great many bones of unusual size were dug up, and stored away in the same place. We were hearing these things in wonder, when by chance a man of honorable condition, advanced in age, a surgeon by profession, passed by us. Then Rugius [?] said: "Here, opportunely, is an eyewitness, to whom credit is not to be denied." We asked the man, therefore, to inform us of the sequence of this affair; and he, nodding to us out of his innate candor, began thus:*

"It happened a few years ago that, returning rather late one day from the countryside, I found the city gates shut, and so I was compelled to pass the night

with a gardener known to me. This man, being most devoted to me, told me that whenever he tilled the earth in a certain part of the garden, he perceived a subterranean sound — an unmistakable sign of hollowness beneath. To him I said (for sleep had fled me), 'Why not let us go down, and search out whether anything is hidden there?' Without delay, suitable instruments having been seized and the servant-boys roused, we went to the place; and with not much earth dug away, we found a subterranean structure, and this being somewhat broken open, we beheld a vaulted edifice. Searching it through, we found nothing but rubble — except bones, those of a human corpse indeed, but of such length and size that it was plain they had been a Giant's. From here, digging out another chamber (for there were several, connected to one another), we dug up nothing but bones of this kind — shins, that is, legs, arms, and ribs of the same bulk. At last, catching sight of something round, not unlike a large apothecaries' scale-pan, and striving with all my strength to break it loose with a two-pronged mattock, I noticed that it was the top of the skull of that same corpse. Whereupon, being thus taught that we had stumbled upon a Giant's tomb, we placed the bones back in the same spot, threw the earth back to level with the ground, and departed satisfied."

[Margin: A Giant's tomb.] *Hearing these things, it was asked among us: of what Giant were these ashes, and to what times could they be referred? Then I [said]: as far as one may conjecture from the histories, with the place of the tomb added, I would believe that these were of Marducchus the Salernitan, formerly a Giant. For we read in the Book of the Deeds Bravely Done by Giovanni Calà of Hedua [?], printed 1509, the author being Joannes Bonatius, from the relation of Martinus Schener the Englishman... ..the Englishman [Angli,], a disciple of this same Joannes Calà — that during the siege of the city of Salerno by the army of the Emperor Henry VI, there lived there a man of monstrous stature whom they called Marducchus, or the Salernitan Giant. When this man heard the report of Joannes's bravery, he challenged him to single combat, in which he was killed by Joannes himself, and seems to have been buried on this very spot afterward.*

On giant bones of this kind various authors offer various accounts. The reader may consult them all in Goropius [Goropius Becanus] and in the commentators on Sacred Scripture, where they treat of the giants (*Genesis* ch. 7 [recte: ch. 6]) and of the giants Og and Goliath — accounts I have thought it superfluous to repeat here.

Pliny [the Elder] asserts (*Natural History*) that in Crete, when a mountain was split open, a standing body of forty-six cubits was found. Fulgosus [Battista Fregoso] says it was thirty-three cubits; some judge it to have been the body of

Orion, others of Otus. The body of Orestes, dug up at the command of an oracle, is held by ancient records to have been seven cubits. The annals do not record the height of Naevius Pollio, but because he was nearly killed in a crush of the crowd he was regarded as a kind of prodigy. Our own age, in the reign of the deified Claudius, saw a most lofty man named Gabbara, brought from Arabia, who was nine feet and as many inches tall. Under the deified Augustus there were two who were a half-foot taller; their bodies were preserved, for the sake of the marvel, in the vault of the Sallustian Gardens. Their names were Pusio and Secundilla.

Dalechampius [Jacques Daléchamps], in his notes on Pliny, asserts that in the bed of the river Orontes a corpse was found of eleven cubits and more. Caelius Rhodiginus [Lodovico Ricchieri] says that in the territory of Valence among the Allobroges, in the torrent that waters the village of Saint-Péray [pagum Divi Peratii], in the reign of Louis XI of France, the corpse of a giant was dug up, of astonishing and unusual size — one which, as is gathered from various pictures and from the bones themselves, would have approached eighteen feet. On the testimony of Pausanias, in the corpse of Ajax the kneecap was the size of the discus used by competitors in the pentathlon. And Asterius records that the corpse of the son of Anactus was ten cubits in length. Plutarch says the body of Theseus was of unusual size.

"Recently," says Licetus [Fortunio Liceti], "at Julia Caesarea in Africa a skull was dug up twelve handbreadths [spithama] in circumference, on the authority of Magius; [Margin: A skull-cap of 12 handbreadths.] but after the victory that he won under King Louis at Laudum Pompeiam [Lodi], having gone on to Milan, he came upon in the youths' hospital one of such tallness that he could not stand: for it had not been possible, from a sufficient maturity of nourishment, to supply the corresponding thickness, strength, and proportion; and so he lay there and filled two joined beds. In him one must not blame nature simply, but the unhealthy and feeble temperament and constitution of this single individual — or, if you like, his particular nature." The deified Augustine [Augustine of Hippo] says: "But concerning the great size of bodies, the tombs, laid bare for the most part by age, or by the force of rivers, or by various accidents, refute the incredulous, wherever there have appeared, or whence there have fallen, bones of the dead of incredible size. I myself saw — and not I alone, but several with me — on the shore at Utica a man's molar tooth so huge that, had it been cut up into small pieces of the size of our own teeth, it seemed to me it could have made a hundred of them. But that one I would believe to have belonged to some giant; for besides the fact that the bodies of men of old were much larger than our bodies now, the giants of that time far surpassed all others, just as afterward, and in our own

times, there have been some — rare indeed, but scarcely ever wholly lacking — who exceeded the measure of others by a great deal." [Margin: The tooth of St Christopher.] Vives [Juan Luis Vives], in his commentary on this passage, adds to this effect: "On the feast of St Christopher, when we had gone to greet him at the greatest church of our city, there was shown to us a tooth bigger than a fist, which they said was his. Hieronymus Burgarinus was there with me." Faleotus [Faleotti] likewise affirms, in his work on Plutarch and Strabo, that at Tangier, a city of Mauretania, a tomb was opened by Sertorius in which a human body was found that measured out sixty cubits — and it was thought to have been Antaeus's. [Margin: A skeleton of 60 cubits.]

"In the reign of Charles VII," adds Fulgosus, "king of the French, in the mountainous part of Gallia Narbonensis near the city of Valence, the Rhône uncovered a tomb whose great size drew very many people to view it; for when the mound was opened there were found in it the bones of a man whose measurement filled thirty feet, and as we ourselves were making a journey in that direction, we saw the tomb and some part of the bones, which is kept by the inhabitants as a marvel." Boccaccio [Giovanni Boccaccio], in his *Genealogy of the Gods* [*Genealogia Deorum*], writes: "But that there were indeed giants — that is, men exceeding all others beyond measure in form or stature — is not at all a fiction; indeed it stands as most certain, and a chance event clearly demonstrated it in these recent days near Drepanum [Trapani], a town of Sicily. For when some peasants, at the roots of the mountain that overlooks Drepanum, not far from the town, were digging foundations for the building of a shepherd's hut, the entrance of a certain cavern appeared. Having seen it, they entered it eagerly with lit torches to discover what was inside, and found a cave of the utmost height and breadth, through which, as they walked, they saw on the opposite side a man of enormous size sitting down. Terrified at this, they at once took to flight, fled the cave, and did not stop running until they had reached the town, telling those they met what they had seen. The townsfolk, marveling and wishing to see what evil this might be, with torches lit and weapons taken up, went out from the city all together as though against an enemy; and more than three hundred of them entered the cavern, [Margin: An enormous skeleton found near Drepanum, 200 cubits.] and saw something no less than what the first stunned witnesses had reported. Drawing nearer, after they knew that the man was not alive, they saw a certain figure sitting on a seat, leaning his left hand on a staff of such height and thickness that it would surpass the mast of any very large ship: a man of unseen and unheard-of size, in no part decayed or diminished. And when one of them, reaching out his hand, touched the standing mast, at once the mast collapsed into ash, and there remained, stripped truly bare, the other staff, of lead, rising to the

very hand of the seated figure; and, as they were able to perceive well enough..." ...the lead was being added to increase its weight, an apple stuffed inside, which those who weighed it assert it could be — those who saw it report it to have been fifteen *cantaria* [hundredweights] of Drepanum, each of which is a hundred common pounds. Finally, when the body, touched, likewise collapsed into dust — and Aristotle too knew of this, when he says somewhere that the bodies of the long-dead, which suddenly become ash in their tombs, have lost all their substance and retained only their shape. [The author here returns to the marvelous-strength anecdote:] Twelve porters, six on each side, with all their effort were dragging the opposite way against this man; yet, drawing his arms gradually to his chest against their will and resistance, he stood motionless and drew them, and, unperturbed, ate the apples he was holding in his hands over a notable span of time, mocking the sweating porters and those who tried in vain to wrench his hands from his mouth.

[Margin: A marvel of the giant's strength.] [Above, Kircher had cited:] As Fortunio Liceti relates in his book *On the Spontaneous Origin of Things* [*De spontaneo rerum ortu*], he saw at Venice a Lusitanian [Portuguese] giant of vast size, so robust that, when ropes were tied to each arm — which twelve porters, six on each side, dragged the opposite way — he drew them in.

When some men were handling the corpse of the Drepanum giant, three teeth still solid were found, of monstrous size; and they were of the weight of three *rotuli*, that is, a hundred common ounces. The people of Drepanum, in testimony of the giant they had discovered and as an everlasting memorial to posterity, bound these teeth with an iron wire and hung them up in a certain church of the city built in honor of the Annunciation of the Virgin and marked with that same title.

Moreover — that there were giants of vast size — the skeleton which is exhibited to be viewed, to this very day, in the town hall [Praetorium] of Lucerne among the Helvetians [Swiss], abundantly proves; concerning which Cysatus [Renward Cysat] treats at length in his work on the four chief cities of Etruria; and the matter, as it occurred, is even now recorded in the said council chamber [Margin: A skeleton of a giant in the town hall of Lucerne is on view.] in these words:

A delineation of a giant's skeleton, of which some portions of the bones — such as of the thigh, the shin, the shoulder-blades, the vertebrae, the sacrum, the coccyx, the navicular bone, a rib, fragments of the skull, also the second bone of the thumb and the heel — almost whole (out of which, and as it were from those parts which in men are formed otherwise than in the rest of the animals, these bones of a human

body were judged to have been, the evidence being drawn chiefly from this) were found in the territory of Lucerne in Helvetia, near the village of Reyden, an ancient oak having been thrown down, beneath which they were discovered. They were sent to the Senate of Lucerne; and, in order to bring the dimensions of the giant to completion, the remaining bones of the whole skeleton — those which were missing or were not intact — were delineated by Felix Plater [Felix Platter], ordinary physician of Basel, in imitation of the true skeleton, and were painted by Joannes Bock, a painter of Basel; and they were presented to the most illustrious Senate of Lucerne in the year 1584.

This skeleton was found in the year 1577, in the county of Willisau, within the jurisdiction of Lucerne, beneath an aged oak, as the inscription [epigraphe] records. Cysatus, on Plater's judgment, from the proportion of the limbs, states the height of this giant to have been forty-two times greater than the line written below.

[Margin: Beatus [Beatus Rhenanus?] — Odoricus of Udine [Odoric of Pordenone].] Beatus — Odoricus Utinensis [Odoric of Pordenone], in the second account of his journey to the Indies, testifies that he saw, at the court of the Great Khan [Magnus Cham], a giant twenty feet tall. [Margin: A giant at the court of the Great Khan.] Johannes and Olaus Magnus [Johannes Magnus and Olaus Magnus], archbishops of Uppsala, in their History of the Northern Kingdoms, especially celebrate among others Rollo and Starchater as giants of most lofty stature and most robust strength. [Margin: Olaus Magnus, on giants.] Joannes Cossaeus, a man remarkable for the highest probity and learning — as Fortunio Liceti relates in his book *On the Spontaneous Origin of Things* — [the text here resumes on the recto, Fol. 55].

[Margin: A line below.] *This line, taken forty-two times, equals the height of the giant preserved at Lucerne.*

[Fol. 55, lower columns]

But when he lived, or whence he came into these regions, has never become known to any historian. Certainly from this geometrical reasoning it is clear that this giant was more than three times taller than an ordinary, well-proportioned man — to whose stature architects and sculptors assign at most six palms. There are in my Museum bones petrified into stone [literally, hardened into rock], bequeathed to the Roman College by the most noble Alphonsus Doninus [Alfonso Donini] together with many other things pertaining to antiquity and nature. Whoever sees them, on account of their excessive size, judge them to have been the bones of some giant, since their magnitude — according to the proportion of

the shin-bones and vertebrae that I have observed — certainly yields little to that Helvetian giant.

Wonderful too are the things that Boccaccio and Philippus Bergomas [Jacopo Filippo Foresti of Bergamo] relate concerning the body of Pallas. The matter stands thus: In the time of the Emperor Henry III — that is, in the year 1401 [recte: an apparent error for the era of Henry III; "1401" does not match] — it was found by a certain farmer not far from the city of Rome, while he was...

[continues at Fol. 56]

[Fol. 56]

digging his little field somewhat deeper than usual, that there was a stone tomb adorned with an inscription; and in the tomb the body of a dead man of stature so lofty that it exceeded the walls of the city. The corpse was whole, as if it had been given burial a little while before; in its chest it bore a very broad wound. Above the head of the deceased body there was found a lamp burning with a perpetual fire, which could not be extinguished by any blast of air, nor by the pouring on of water or any other liquid; but, its bottom being pierced and broken, it at once vanished. [Margin: The body of Pallas.] Now this was held to be the body of the great Pallas the Arcadian, son of King Evander, a companion of Aeneas, who was killed long ago in the war and in single combat by Turnus, king of the Rutuli — much earlier, before Rome was founded. All this is confirmed by Volaterranus [Raffaele Maffei of Volterra].

And these are the things which we have thought worth bringing forward concerning the giants and their immense vastness. [Margin: All these things are confirmed by Volaterranus.] It remains, finally, at this point, to show whether men of so prodigious a stature ever existed in the world.

DISQUISITIO PRIMA.

Whether nature has ever truly brought forth men of so monstrous a size as the cited authors report.

That in tombs and subterranean places bones are from time to time found, which bones are said to be those of giants, I do not deny; for, as we noted above, that giants were men of vast body is testified by Sacred Scripture itself, *Genesis* 7 [recte: 6] and 1 Kings [*1 Samuel*] ch. 17. To the Emperor Maximilian [Maximilian I], in the year 1511, on the testimony of Surius [Laurentius Surius], a man of giant

size, born in Poland, was presented, who, in proportion to the size of his body, with food correspondingly...

[lower of facing page, after the figure:]...consumed, at each meal, a calf and a sheep. Similar to him in our own times was the man presented to Ferdinand II, at the Diet of Regensburg [comitia Ratisponensia], in the year 1623; so that on this account I have no doubt at all concerning men of unusual size of either sex, since no age has failed to produce such men.

[Margin (manuscript hand, not part of the printed text): "...discursum /...Barclaij Arge[nis] /...idem pag. 28 et 210" — an early reader's cross-reference, apparently to John Barclay's *Argenis*. [Illegible: cursive annotation partly trimmed at the gutter.]]

Diagram. A full-page engraving showing a comparative scale of giant statures. At the left, dominating the page, stands a colossal bearded nude man wreathed in oak/laurel and girded with a garland of leaves, his right hand resting on a tall club-like staff (a tree-trunk) — the "Giant's Skeleton" of Mount Eryx near Trapani. The engraved caption beside his shoulder reads:

Gygantis Sceleton / *in monte Erice prope Drepanum / inventum Boccatio teste 200 cubitus* ("The Giant's Skeleton, found on Mount Eryx near Drepanum [Trapani], on Boccaccio's testimony, 200 cubits.")

To the lower right, four progressively smaller figures stand on the same ground-line for scale comparison, each captioned:

- (far left, tiny) **Homo Ordinarius** — "Ordinary man" (a minute standing figure).
- (next) **Goliath** — a small bearded figure with a leaf-skirt and wreath.
- (next, larger) **Helvetus Gygaz** — "The Helvetian [Swiss] Giant," a bearded wreathed figure.
- (largest of the four) **Gygaz Mauritaniae** — "The Giant of Mauretania" (the Antaeus figure of Tangier), the tallest of the comparison group.

All four labels and the main caption were read cleanly under magnification; no labels flagged [?].

[Fol. 57]

[Margin: The measure of giants.] But that there have ever been men who exceeded 30, 60, 100, or 200 cubits, I utterly deny. And so that I may prove this by the clearest reasons, I shall first set out what is meant by a cubit, a foot, a palm —

so that, from these known measures, the vastness and incredible size of the giant corpses may become more clearly evident.

A cubit, according to the common estimate of geometers, contains within itself two feet; and a geometric foot contains one Roman palm and a half — which nearly correspond to the sacred cubit. For by these, as the better-known measures, our reckoning concerning giants may be more clearly proven; and anyone may easily apply, in place of them as he sees fit, the measures proper to his own nation.

Goliath, on the testimony of Sacred Scripture, is said to have been of a height of six cubits and a palm; which, converted by the rule of proportion into our feet and palms, the following [table] shows.

	Cubits [Cubiti]	Feet [Pedes]	Palms [Palmi]
Goliath is said to have been tall	6½	13	19
The corpse of the giant found in Helvetia had a height of	9	18	27
The corpse of Orestes, dug up at the oracle's command, on Pliny's testimony	7	14	21
On the same testimony, the corpse of Asterius, son of Anactus	10	20	30
The corpse dug up from a Cretan mountain, on Pliny's testimony	46	92	138
The giant's corpse dug up at Tangier in Mauretania, on the same testimony	60	120	180
And finally, what surpasses all wonder — the one found seated on Mount Eryx near Trapani, on Boccaccio's testimony	200	400	138

And this is the magnitude of the giant corpses, which the cited authors report to have been found, at various times, in different crypts.

[Margin: A natural inquiry concerning the bodies of giants.] The question therefore is whether it is at least plausible that nature could have produced fleshly masses so vast. For my part, just as I would readily tolerate a moderate excess beyond the natural stature of men, so too I can only with difficulty be brought to believe that there were ever men of such great size (whose measurements we have set out here), excepting the first three. [Margin: The reasoning of these statements.] And this I demonstrate by these arguments: Since every material form by itself and by its own nature requires being the form of an organic body proportioned to itself, while an organic body greater and greater to infinity is repugnant to a body of excessive size — surely the conclusion is plainly evident. The reason is that such forms must necessarily be commensurate with their organ, on whose existence, just as they naturally depend for existing, so they depend upon its possibility. Since it cannot come about that an organic body, greater and greater to infinity, should be animated by a soul which has fixed limits set for it by Nature; and this is confirmed by the following argument: For since every animal is a substance and a nature, it cannot be that any substance or nature should be substantially badly and violently constituted. And if a man were constituted in such a mass that, by the weight of his parts and by their natural cohesion being dissolved, his limbs were torn apart by their own weight alone, he would be essentially badly constituted; because the very substantial constitution of a thing, if it had what is due to it, would turn out unfit for its end. For his limbs could not hold together — therefore it cannot come about that the provident Nature of things should produce such a thing. For the feet of such a being could not sustain so great a mass, nor could he exert any forcible action with his arms without a convulsion of the whole. We learn this from the marble colossi here at Rome, whose projecting limbs cannot stand without an added support, but at last are torn off by the weight. And if this is true in marble statues, how much more will it be verified in a human stature of prodigious size? Whoever desires this argument treated more clearly and more fully, let him read the *problema* on the limit of size and strength in animals, by Father Antonio Terillo, a priest of our Society [the Jesuits], published not long ago, where everything is beautifully demonstrated ἀποδεικτικῶς [Greek: apodeiktikōs, "demonstratively," by rigorous proof].

[Margin: Why nature has not willed that certain animals should grow beyond the common order.] Certainly sagacious Nature, just as for all living things, so also for men, in order that they may duly carry out their actions, has fixed a determinate

size of body, so that whatever is beyond it may deservedly seem monstrous. For among quadrupeds she has produced the elephant, the largest of all, which too — that it might be nourished with sufficient fodder — she willed to feed everywhere on the readily available nourishment, not of meats, but of hay, grasses, and leaves. Among birds, as far as we know, she has shown none larger than the eagle, vulture, ostrich, camel-bird [camelus, i.e. the ostrich], and the falcon-griffin [falcogryphis] — and that with the best counsel; for if she had produced birds of greater mass and excessive size, surely no animal would have been safe from such rapacity joined to the velocity of flight. So that this disadvantage to nature might be avoided, she constituted each thing, according to its own kind, under such and such a size suited to its character.

In the sea, however — since she furnished the Ocean, by a great water-bearing nature, with brine, seaweed, and an abundance of fish — she produced the largest of all animals: whales, orcas, and physeters [sperm whales]; to which, however, she gave a very slow motion, lest, by the speed of their swimming, while these immense beasts overturned everything with a kind of tyranny of sight and appetite, they should by their voracity quickly exhaust the whole supply of the ocean's economy. [Margin: Why she gave the largest beasts the fewest offspring.] She added also to the said vast and huge beasts a scarcity of offspring, lest, like the smaller ones, from too greatly multiplied offspring they should bring irremediable harm upon nature. [Margin: Why fish, or whales, are viviparous.] And for this reason she willed the whale to be viviparous, lest, if like other fish they were born from the hatching of eggs...

LIBER VIII ("Λιθογενής"), Sectio II ("De Transformatione")

CAPUT IV — On the genesis of subterranean bones and horns

§. I — Disquisitio Prima: Whether Nature ever truly produced men of such monstrous size

[Continued from the prior folio. The argument that Nature has fixed a determinate size for each kind concludes here.]

lest they should fill [the world] to its detriment. Just as provident Nature has established all things in weight, number, and measure, so too she has refused to let man grow beyond the size we have described — that is, beyond fifteen palms,

or at most eighteen palms. As for the fact that Holy Scripture testifies that Goliath stood six cubits and one palm tall, I take this to have come about by no other cause than the extraordinary providence of God, foreseen from eternity for the manifesting of His people's glory.

For if — as Boccaccio reports of the Drepanitan [Trapani] giant — a man of two hundred cubits, which make four hundred geometric feet, or six hundred palms, had ever existed in the world, he would without doubt have matched the height of any tower whatever. [Margin: The enormous size of the Drepanitan giant, displayed by Boccaccio in fabulous fashion, against the nature of things.] No colossus was ever erected in the world that he would not have surpassed by many parasangs. Let the curious reader draw from this the consequences regarding the dwelling, the nourishment, and the tyranny of such a monster. [Margin: How much harm giants of this kind could inflict.] For what dwelling could hold so vast a bulk? What nourishment could satisfy so vast a gullet? Surely an entire flock of sheep and goats would not have sufficed to feed him for a single day; for one mouthful he would have swallowed an ox, and for one drink he would beyond doubt have drained springs and rivers dry. What covering could fit so great a mass? Certainly no sail of a ship would serve him except as a small kerchief, and fifty such sewn together at once would barely make a garment; a beech or a pine would be no more to him than a slender little staff.

And what animal would have been safe from so monstrous a creature — one of such speed that he could cover in a single stride fifty paces of an ordinary man, who with the blow of a mere fist or heel would have leveled walls and houses however firm and solid, who would have mown down whole armies just as a reaper cuts hay — and countless other things besides, which I leave to the curious reader to work out by proportional reasoning, as also for the other giants whose vastness we displayed in the preceding table. [Margin: Fabulous narrative of the poets concerning giants of enormous size, set forth by profane authors.] But so that the reader may view the matter more closely, I have thought it right to append here a figure, from which you may learn the proportion of ordinary men to the magnitude of the aforesaid giants.

Therefore whatever is reported about giants of such prodigious size is fable and the ravings of old women. For if such a one had ever existed in the world, would he not long since have worn out the genius of all historians in describing the bulk and deeds of so great a prodigy? Compared with him, the twelve labors of Hercules would have been nothing but children's play. Indeed, when I was staying at Drepanum [Trapani] in the year 1637, I inquired very carefully of

experts about this discovered monster-giant; I entered the mountain cave where the corpse was said to have been found, but I found none of those things that the authors cited above relate about the vastness of the cavern. On the contrary, I scarcely think — as far as I recall — that the height amounted to thirty feet. [Margin: The author's investigation of the truth.] Nor were they ever able to show me either feet and hands, or a skull, or similar members from whose proportion to those of an ordinary man one might come to a knowledge of the true size of the alleged giant. [Margin: The cave in which the Drepanitan giant's corpse was found.] The same I would wish for in the case of the Helvetian [Swiss] giant, where, besides ribs, shinbones, and thigh-bones, they can show neither head, nor hands and feet — and just as these organized parts are missing, so too they render the truth of the matter suspect.

It happened at the same time that at Panormus [Palermo], with my great delight, I conferred about giants' bones of this kind with the most illustrious Marquis Carlo de Vintimiglia [Carlo di Ventimiglia], a most learned man and a most exacting historian of Sicily. When I showed him some teeth that certain antiquaries had given me as giants' teeth, he smiled modestly and said: "Do you suppose, my Father, that these are a giant's teeth?" I, in reply, added that I gave them only as much credence as the trustworthiness of the friends who had given them deserved. He then rejoined: "Come to me again tomorrow, and I will show you whose teeth these are." [Margin: Teeth supposed to be giants' teeth — the author's judgment.] No sooner said than done: as I had agreed, the next day I called on that most courteous man, who said, "Let us climb into the carriage." This done, he led me to a place about three thousand paces distant from Panormus [Palermo], which they call *mare dulce* ("sweet sea"). There stood an enormous mountain promontory, and opposite it a very large opening, through which lay an entrance into the dark hiding-places of an immense cavern.

"Let us descend," he said; "now I will show you, my Father, how much Nature can do in fashioning members like those of the human body." And lighting torches, with servants going before us, we entered the cave of that very long tract. When we had now penetrated somewhat into its interior, he showed me on the left wall of the cave a marvelous work of Nature, spread far and wide. [Margin: How Nature forms teeth.] It likewise reproduced teeth — small, middling, large, and excessive in size — set in just that arrangement in which Nature is accustomed to insert them in the jaws of animals, and in such abundance that I could readily believe a hundred carts could be loaded from it. So great was the likeness to natural teeth that you could scarcely distinguish these from those; above, indeed, they showed a translucent whiteness, while below they showed sharp roots, yet

all were converted into solid stone. "Look," said the most illustrious man to me, "these are the teeth that certain impostors, having extracted them from here, sell to the ignorant common folk as the teeth of giants or elephants (for some were of excessive size, as I said)." For my part, I procured for myself no small quantity of them, part of which I keep in my Museum to this very day, and part of which I have given as a gift to learned men for the exposing of the imposture.

But Nature's marvelous craftsmanship did not stop here. Going further on, in the walls of the underground passage we observed I know not what outlines of human members; for now they protruded in the form of shinbones, now there appeared traces of vertebrae and knees, though they were seen with no orderly connection. There also appeared certain huge clayey swellings which, when cut open, on one side...

[showed the shape] of knees, while on the other they left a concavity not unlike a skull; yet among all of them no trace of organized bony substance — such as a head, hands, and feet — was to be found. From this I first clearly recognized the wonderful industry of Nature in forming bones, or stones resembling bones.

The most illustrious Marquis added that many caves of this kind are found in Sicily, in which, when the ignorant common folk find these likenesses of bones — wonderful productions wrought by the power of Nature — they persuade not only themselves but others as well that they are the enormous bones of giants. He added, however, that in the territory of Solonium [the *ager Solonius*] near the sea, between Drepanum [Trapani] and Panormus [Palermo], true bones of elephants are still found by the farmers; these elephants, in the times of past ages, were brought into Sicily by the Africans against their enemies in war, and there killed and buried, and in later times at last uncovered. [Margin: Bones of elephants.] These too the ignorant commonly peddle as giants' bones; but those who compare the symmetry of these bones with that of men at once recognize that what is so persistently asserted cannot possibly accord with the truth. He added, too, that there is this distinction between true bones and those produced by mineral nature: the former always retain the channels of the shinbones and the passages once filled with marrow, whereas the latter counterfeit solid stone without any concavity of the shinbones. Such are the stony bones that are even now displayed in our Museum, from which I have always believed them to be a pure work of Nature.

Fazellus, the historian *On Sicilian Matters* [Tommaso Fazello, *De Rebus Siculis*], also mentions this cave, on folio 25. [Margin: Fazellus in the History of Sicily.] "In the Panormitan [Palermo] territory," he says, "there is a famous spring, very well

known by the name of *mare dulce* ('sweet sea'), facing south, receding about three thousand paces from the city; above it, in the very rock of the mountain, is a cave more or less 60 cubits in length and 20 in breadth, in which Paolo Leontino [Paolo of Lentini], intending to make saltpeter — while in the year 1547 he was digging out cow-dung earth to be boiled down in the niter-works — fortuitously came upon the corpse of a man, of monstrous size and the immense bulk of a giant's body, eighteen cubits, incompact and dissolved in all its members. At the report of this, the Panormitans [people of Palermo], roused by eagerness to see it, were struck with astonishment at the head and all the members; yet everything had turned to dust except the jawbone and the molar teeth, kept unmoved by their hardness. Each of these weighed nearly four ounces, like our own, whitish, with the surfaces hollowed out entirely by decay. Two of these were given to me by Simone Piglione of Nicosia [Simone Piglione Nicosiensis], both to vouch for the matter and to display its memory to the incredulous."

But if we examine each of this author's words individually, we shall find many contradictions in them, and that it was nothing other than what I, together with the Marquis Ventimiglia, examined — bones and teeth produced by Nature. This I demonstrate as follows.

First, he says the corpse was incompact and dissolved, and of nearly 18 cubits — that is, 36 palms, or, what comes to the same, 44 Roman palms. I ask, then, how...

how that subterranean passage, of such unequal height as I observed it — now 25, now 15, or even 10 palms, sometimes so constricted in height that we had to walk bent over — and in breadth with equal unevenness, where it was narrowest not exceeding a ten-foot span — how, I ask, could such a cave contain a giant 18 cubits, that is, 44 palms, tall? [Margin: Fazellus contradicted.] Surely no one will easily conceive it, where he could neither stand, nor sit, nor — owing to the narrowness of the place — lie down, and where this passage would stand in the same proportion to such a giant as a cat to a mouse's lair. But he says the corpse was found incompact and dissolved. If so, how did the discoverer of the corpse so quickly reckon its measurement from the bones? Or how, with the members thus scattered, did the city of Panormus [Palermo] marvel so greatly at the mass of the whole frame? As for its having dissolved into dust at a touch, I would believe that to have been added gratuitously, to win credence.

He says that nothing else appeared of the corpse except the jawbone, well furnished with molar teeth, one of which weighed four ounces — while of the skull, the feet, and the hands there is deep silence. I too would believe in a jawbone furnished with teeth, together with the remaining shinbones, joints, and

similar parts; for I myself saw with my own eyes all the same things found in the same cave — but I found them to be nothing other than a pure work of Nature. Indeed, I found teeth, one of which I saw to weigh not four ounces but four pounds. Shall I therefore assert that they were a giant's teeth? Far from it. And so Fazello's account does not agree with the truth, like the other giants' corpses found in various places in Sicily.

Thus he says that at Mazarum [Mazara] in the year 1516 a corpse was found in a field called Xyphi [Xiphi], of 20 cubits, with a head the size of a wine-cask, yet reduced to ashes; besides the teeth they found nothing else, weighing five ounces. [Margin: A skull the size of a wine-cask.] If it had been reduced to ashes, how did he find a head the size of a wine-cask? These conjectures are utterly trifling and rest on no foundation. Likewise he says that many bones and teeth of gigantic corpses were dug up at the foot of Mount Hybla [Hybla], at the spring of S. Cosmano. [Margin: Another fabulous account of a giant found in Sicily.] He also writes that near Syracuse, in the year 1538, in a deeper-dug crypt, a corpse of 20 cubits was found by Adorno, a Genoese knight, while he was searching out ancient monuments; but from this, dissolved into dust, nothing else was brought away except part of the skull, the ribs, and the legs, along with the teeth, to be offered as a gift to the Grand Master. Again, at Calabراسi [Calatabellotta], near Entella, in the year 1550, while gravediggers were preparing a tomb for a dead man in a church, they came upon a vaulted little chamber, and in it found the corpse of a man of 22 cubits — that is, 66 palms — which, set up for jest and laughter, they pelted with stones until it was dissolved into dust, and nothing was left except the teeth. Who, from this description...

does not detect a fable? How a vaulted little chamber could contain a corpse of 66 palms, I do not see; how, again, drawn out with such labor and with such shaking of the body, it did not dissolve into dust — as he says afterward happened from the throwing of stones — I cannot at all comprehend; and that they found nothing worthy of note besides the teeth easily shows that, deceived by the shape of mineral bones and teeth, they sold them as the true teeth of a giant. And so whatever Fazellus writes about similar corpses of giants is plainly fable, and to be reckoned as nothing — as is evident even from what has been demonstrated.

For if these [giants] were born and reared in Sicily, why does she not produce the same today? Nor does it suffice to allege "influence" as the cause, since the climate is the same today as of old, the aspect of the stars is the same, and she produces today the same fruits and the same animals, of the same bulk as of old. But let no one suppose at this point that I mean to deny that there were ever

Giants in the world — far from it; the Sacred Letters teach me otherwise, from that passage of *Genesis* 6: "There were giants upon the earth in those days; these are the mighty men of old, men of renown." [Margin: How it is to be understood that there were Giants in the world.] But what Berosus relates about giants and the city of Enon of the giants on Mount Lebanon — just as it deserves no credence among historians, so too what he writes is to be ascribed to fables rather than, more truthfully, to history — as is all that the ancient gentile historians and Homer write about Giants, Titans, and Cyclopes, born of heaven and earth by [Greek: γιγαντομαχίας (gigantomachias, "battles of the giants")]. Therefore, when mention is made of Giants, it must be understood of the strength and powers in which they excelled, and of their unusual bodily bulk — yet not of a bulk such as would exceed the just bounds of nature, like those seen in our own age at the Magellanic Sea [Strait of Magellan], who exceeded the stature of well-proportioned men by once and a half, or even more.

Giants of this kind, we said above, have been found in every age; and that there were giants of this kind both before and after the Flood — that is, more eminent than other men in size and strength, as in other respects — must be held for certain, yet not of that exotic vastness which we have described. [Margin: Arabs' fabulous tale of the giant Og.] For if men of prodigious size were the Enacim [Anakim], how did they inhabit the city of Enon, and dwell in houses or tents incapable of holding so great a mass? How did they couple — as Berosus says, and the Sacred Text does not deny — with mothers, daughters, and other human beings disproportionate to them in bodily mass? But what the Saracen history, or rather fabulous account of things, relates about the giant Og far surpasses all monstrous conceptions of the human imagination. The words, translated by me from the Arabic tongue into Latin, run thus: "Og, a giant surviving before and after the Flood, was engaged with Noah in a notable and irreconcilable feud of enmity, and continually sought him out for slaughter. When [Noah] hid himself in the caves of the mountains, [Og], hindered by the vast bulk of his body, could not penetrate them. It happened at one time that the giant, having attacked Noah, when he could not overtake him as he fled, hurled his torn-out beard after him, which at once filled the whole plain of the field like a forest of cedars, so that as many hairs as there were, so many cedars seemed to appear; from these, they relate by a truly ridiculous fiction, Noah afterward built the ark. And they tell fables that he was of such immense size that, when he sought Noah's ark in the Flood, the waters reached only to his knees; meanwhile, tortured by hunger, he hunted whales, which, roasted in the sun, he devoured in a single mouthful" — and the like, which both provoke laughter and, on account of their absurd lies,

even turn the stomach; but this much for amusement's sake. Vain, then, and ridiculous is the history of the [giants] here recounted.

These things thus recounted, nothing further remains except that we should show how Nature generates a bony substance of this kind in subterranean places. [Margin: How bones are generated in subterranean places.] From this it will clearly be evident that whatever similar bones have been found are nothing other than a pure work of Nature.

DISQUISITIO SECUNDA — On the origin of *Enostoi*, or subterranean bones

Just as the Earth in her womb generates rocks of every kind, coal (which they call *lithanthraces*), fossil wood, and the flesh of the earth (which they call *marga* [marl]), so too she generates bones in her own way. The mineral-workers call these *Enostoi* [Greek: ἔνοστοι (*enostoi*, "in-bones")], *bone-breakers* [Greek: ὀστεάκολλα and ὀστράκολλα (*osteakolla* / *ostrakolla*)], and in German — from the human members they resemble — they are called *Knochenstein* ("bone-stone"). [Margin: In what places bones grow.] For as Hector Boethius [Hector Boece] says in his book *On Stones*: "Sometimes ribs are dug up, or the form of a human thigh-bone, or of ribs and arms, and they are found in various places in Germany. They are found in the Palatinate not far from Spires [Speyer]; likewise near Heidelberg and near Jena in Saxony, in Silesia, and in other places. [The stone] grows at the foot of sandy mountains, and is often dug up in great number from underground."

The most illustrious Cianthes [Cianthes], Bishop of Potenza, told me that in his bishopric there is a subterranean place from which round rocks, of the size of bones, are dug up — some expressing the shape of a human skull, others a perfect figure; these Ambrosinus [Bartolomeo Ambrosini] also recounts, together with figures. [Margin: A wonderful structure of bone-stones.] He calls these kinds of stones *cephalites*, *cardites*, or *perficates*, from the figures, namely, which they reproduce; some are seen furnished with coats like those of onions. Of these also Agricola...

Agricola makes mention in book 2 *On Fossils*. [Margin: Mineral skulls.] "As many coats [as there are], so many bony skulls you may find; and these too are sometimes found on Mount Carpathus [Mount Karpathos] of such size that a single one could hold many bushels of grain," as Ercker [Lazarus Ercker] testifies in his German book *On Minerals*.

The question is asked, then, how she [Nature] produces such enormous skulls, such enormous members of the human body, after the likeness of thigh-bones, shinbones, ribs, and teeth. [Margin: The origin of bones of this kind.] I say: there lies hidden in the subterranean entrails, within the clefts of rocky mountains, a certain muddy earth, which above, together with Agricola, we have named *marga* [marl], mixed with gypseous material. When this earth has received the nitrous flux through the fissures of the mountains, it comes about that it is clothed, as it were, with a kind of gypseous rind, which, as it petrifies over time, so too in the splendor of saltpeter rivals the whiteness of bone in its own whiteness — being white, fissured, and friable. If, then, within the cavities of the earth this earth has found a place of rounded concavity, a round ball will be born, which, when broken open, closely resembles a skull. If the matrix has been disposed in the form of a human thigh-bone, or of a rib, or of some other member, the *marga* contained in it, with the saltpeter-bearing liquor poured over it, will express a human thigh-bone — smaller, larger, largest, and altogether gigantic — according to the size of the matrix.

These, then, are those bones which Nature produces, and which are commonly called giants' bones by the common persuasion of men; yet if you break them, in them is found neither marrow nor the fistulous passage of marrow — which ought to be the case if they were the bones of men. All this Ambrosinus confirms, when he displays several of the *Enostei* stones [Greek: ἐνόστεοι (enosteoî, "in-bony" stones)] in the form of teeth, a rib, shinbones, and feet, which he writes that he himself observed at Bononia [Bologna]; whose figures I have thought right to append here. He asserts, together with us, that all these bones are indeed offspring of the earth.

But let us hear Caesalpinus [Andrea Cesalpino], who in chapter 48 *On Metallic Matters* [*De Metallicis*] says: [Margin: Caesalpinus's judgment on bones is subscribed to.] "That bones, however, are born from the earth, and that bony stones are found, Theophrastus clearly shows. Today, near the town of S. Giovanni in Valdarno [San Giovanni Valdarno], stony bones of huge size are dug up, from which they suppose they were from the elephants led into Italy by Hannibal. There survives the head of a humerus, or of a hip-joint, of such size that two forearms could scarcely embrace it. In my possession are fragments of legs, spongy within, solid without, blacker in color than porphyry marble, which ring like marble; concerning which more has been treated by us in our *Etruria* [Tuscany], to which we refer the reader."

Now I shall show in a few words how those round stones, of which I spoke above, are formed by Nature. [Margin: How fossil globes are generated.] Where Nature has disposed clayey mountains, mixed with sandy clods, in the roots of these for the most part stones of this kind, expressing forms of every sort, are wont to be dug out. They are made by this artifice of Nature: in the time of rain and showers, when clayey material is wrapped around a round stone, it comes about that this mass picks up the muddy earth in its path and rolls it up together with itself. Hence it comes about that the agglomerated material of the muddy clay, in its rolling-down, is always clothed with ever-new rinds, as it were; and these, carried to the bottom and there in the course of time having their moisture consumed — the nature of the place cooperating — are at last converted into a stony lump, small, large, or largest, according to the greater or lesser agglomeration of material. These lumps, then, when cut apart and their rinds peeled away, express as many skulls as there are rinds; and these the ignorant of Nature's art, from their resemblance in bone and material, call giants' skulls.

Whoever has seen snowballs rolled down from the mountains, ever growing larger and larger from the agglomeration of snow, will easily form a judgment about the muddy agglomeration of stones — [snowballs] which in the Alps are sometimes so great that, like mountains, they overwhelm men and beasts, and fill rivers and valleys. [Margin: How these stony skulls are dug out.] As for the fact that stony skulls of this kind are dug out of subterranean places, I would suppose this comes about because globes of this kind, heaped up each year in great number in a valley, at last grow up into a heap piled on like a mountain — a thing I would not have believed, had not this, while I was surveying Etruria [Tuscany] in the mountains of Radicofani, convinced me by sensible experience of the truth of the matter, as we set forth in our *Etruria*. [Margin: How these clayey lumps are converted into stone.] Again, since this muddy and clayey material is not always shaped into globes, but sometimes into cylinders...

Diagram. A woodcut occupying the lower-middle of the right column, depicting two fossil specimens shaped like human extremities: above, an open human hand (palm and fingers, viewed from the back, with the wrist/forearm stump at lower left); below it, a human foot in profile (heel at left, toes at right, with cross-hatched striations along the upper surface suggesting the layered/banded texture of the petrified specimen). These illustrate the *Enostei* (bone-stones) that imitate human members, discussed in the surrounding text (drawn from Ambrosinus's Bologna specimens). No labels or caption are engraved on the figure.

it comes about that, when this round-bodied material is wrapped around a stake or a reed, or something similarly cylindrical, in great rollings-down...

Diagram. A small woodcut at the very foot of the right column (partly cut off at the page edge) showing an elongated, spirally-coiled or banded cylindrical fossil — a coiled tubular form rendered with diagonal hatching, illustrating the cylinder-shaped concretions (formed around a stake or reed) introduced in the adjacent text. The image is faint and partly trimmed at the gutter/foot. No caption or labels.

Diagram. A small woodcut at the foot of the right column showing a roughly circular concretion ("globe") rendered with concentric banding/hatching, illustrating the layered round fossil-globes discussed in the bone-genesis argument. Partly trimmed at the page edge; no caption or labels.

Diagram. A vertical group of three small woodcuts in the right column, each depicting a round or oval banded concretion ("bone-stone globe") with concentric rings/coats — the *cephalites* / *cardites* type figures attributed to Ambrosinus, showing the onion-like rinds described in the text. No captions or labels on any of the three.

[Reading order reconstructed from folio numbers and running headers: (Fol. 62v) → (Fol. 63r) → (Fol. 64v) → (Fol. 65r). The PDF presents the leaves in non-linear order; the translation below follows the textual sequence 62→63→64→65.] ...so that it grows up into cylinders along its own length. These, mixed with a pitchy and nitrous liquid, are at last by a petrifying force turned into what look like bony beams — now in the shape of shin-bones, now of hands, now of arms, now of feet. When these are dug up and present something bone-like, made of a friable substance, they are commonly taken — on account of the sheer size of the mass — for the bones of giants.

Here, then, you have the two ways Nature uses in forming bones of this kind. The first is within the cavities of mountains: according to the layout of the hollow, a gypseous marl is poured over with a salt-nitrous liquid and turned to stone, and so takes on whatever shapes the matrix supplies. The second is the rolling-down from the mountains of a clayey material mixed with gypsum and niter, as has been described.

As for fossil teeth, which I remember observing with great care in the Palermo grotto [antrum Panormitanum], Nature forms them in this way. The walls of the grotto are not made of any very hard stone, but rather of a sandy, chalky, or gypseous kind, and because of the abundance of moisture they are riddled with

cracks — as the nitrous icicles [stiriae nitrosae] there sufficiently show. The result is that the salt-nitrous, vitreous fluid, by its fineness, penetrates the soft substance of the stone all the way to its outermost surface. There, having nowhere to drain off, it is fixed in place and hardens into a light, white, bone-like material very similar to teeth. These "teeth," following the cracked arrangement of the walls, are set off one from another, each fixed as if within a jaw, and so very nearly counterfeit real toothed jaws. They vary enormously in size, so that some might not unreasonably be taken for the teeth of giants — and in such quantity that the place may rightly be called a mine of teeth. I would beg all naturalists of more inquiring mind to visit this grotto, examine each specimen for themselves, and I am quite convinced they will find nothing other than what I have described. But I have thought fit to set down here a few of the differences among these teeth, so that what I have said may become still clearer from them.

Diagram. Upper figure in the right margin: a single irregular, ridged object resembling a worn molar or a curved bone fragment, rendered in fine engraved hatching to suggest a hard, banded surface. Uncaptioned. It illustrates a fossil "tooth" / bone-like concretion of the kind described in the text.

Diagram. Lower figure in the right margin: a cluster of several rounded, knob-like fossil teeth grouped together, as though still set in a fragment of jaw, shaded to show rounded crowns. Uncaptioned. It illustrates the "differences among teeth" the text promises — fossil teeth seated side by side as if within a maxilla.

[Margin: Quomodo natura dentes formet. — How Nature forms teeth.]

CAPUT V.

Fossil horns, which have a great affinity with subterranean bones; and where the horn of the Unicorn [Monoceros] is chiefly treated.

After bones come horns, which Nature fashions with wondrous skill in subterranean places, and which everywhere fetch a high price as most potent remedies for repelling poisons of every kind. They are distinguished among themselves by a manifold variety. Some Nature herself produces in the bowels of the earth in the manner described above — such as those found in various German underground mountain caverns, on the testimony of Agricola: as in the Hercynian Forest [Sylva Hercynia, the Harz] near the village called Baumannsholz [Baumannshöhle], under the dominion of the Counts of Stolberg; and likewise near Heidelberg, Speyer [Spira], Hildesheim [Hildeshemium], and in Moravia, Silesia, and Saxony. These are nothing but a fossil *spodium* [spodium

fossile — calcined-bone-like ash]. They arise from a certain species of marl which, when it is soaked and dissolved by water charged with a petrifying power, passes in the form of a milky fluid through the cavities of the earth. Wherever it finds a horn-shaped matrix, the moisture is used up, and the more serous part, saturated with marl, is there converted to a horn-like hardness.

It sometimes happens that this milky liquid falls not into a cavity but onto some piece of wood already stripped of all moisture by age. Being porous, the wood quickly draws the serous humor into itself, and at last, by the coagulating force of the milky liquid, in proportion to the salt-nitrous humor mixed in, it is turned into stone — either hard, or soft and friable — yet in such a way that the appearance of wood can still be recognized and its smell from time to time detected. **Anselmus Boëtius** [Anselm Boëtius de Boodt] confirms this in his *History of Gems and Stones* [*Gemmarum et Lapidum Historia*], where he says, in these words:

Fossil horns differ greatly among themselves, and few show the same appearance: in some they resemble teeth, shin-bones, jaws, and other parts of the body. I have at home more than twenty different kinds, all of which were given to me as "unicorn's horn," though one plainly shows the outer bark of an ash-tree on its surface. Another specimen, found near Brno [Bruna], a city of Moravia, reproduces so exactly, inside and out, the figure of a walnut trunk, that no one but a blind man could fail to notice it had been the trunk of that tree and had undergone transmutation in the earth; its smell, too, exactly gives off the odor of the nut-tree. A fragment of this same trunk was given to me, under the title of "unicorn." In the same place a larger portion of the trunk and stock was sold for the "head of the animal" — so that no one ought to doubt the generation of these horns. And as these things are of a drying and astringent nature, so too they staunch fluxes, heal the eyes' tears, help to strengthen the heart, and are most present antidotes against poisons, plague, and malignant fevers — and the more potent, the more the material is by its own nature opposed to poisons, as are ash-wood, hartshorn [cornu cervinum], and ivory, when they have been more closely and tightly united by coagulation. For they wonderfully promote sweat, and together expel from the body the breath of the virulence of a poisonous humor — epilepsy, the cardiac passion [cardiaca passio], trembling of the heart, and other afflictions of the heart...

[Margin: Origo cornuum fossilium. — The origin of fossil horns.] [Margin: Varis differentis [recte: Variarum differentiarum]. — Various differences.] [Margin: Vis medica in ossibus [recte: ossibus] fossilibus. — The medicinal power in fossil bones.]

...taken with appropriate water, is a remedy against fever.

Of the Horn of the Unicorn [De Cornu Monocerotis].

There is nothing in all of nature held in such esteem by emperors, kings, princes, and the great men of the world as the horn of the Unicorn [cornu Monocerotis] — so much so that gold and gems are reckoned as nothing by comparison with it. Yet what that horn actually is, or from what animal it has fallen, no one is able to say. Hence to this very day physicians, natural philosophers, and most investigators of nature contend among themselves about it in extraordinary fashion, the question still undecided.

I will say, however, that if anyone should too boldly deny that such an animal — one carrying a horn of such great efficacy and of so wondrous a virtue — either still exists or ever existed at all, that person would, with the same rashness, be calling into doubt not only the Sacred Scriptures but, along with them, the trustworthiness of all the historians.

[Margin: Descriptio Monocerotis. — Description of the Unicorn.]

That there is, then, a Unicorn or Monoceros is certain; but what sort of thing it is and was remains open to debate, and the matter is not without difficulty. **Pliny** [Plinius] and **Aelian** [Aelianus] describe a true unicorn with such marks that it readily appears it never existed in the form that is, wrapped in so many fables, set before the learned world. For if such a thing existed, then long ago — the whole globe of the earth having been so thoroughly explored — it would surely have been seen somewhere, or would have been known to the merchants who at all times are accustomed to traverse the vast solitudes of India, Tartary, and Africa, where it is said to make its lair. Add to this the diligence of our Fathers [the Jesuits], who — besides the winning of souls, which is their sole aim — do not cease, through continual exploration, to communicate to the world an exact knowledge of the exotic things produced by Nature in those regions. Yet it is astonishing that of the unicorn — which, among exotic animals, ought by right to hold the first place — they make no mention, not even a word.

[Margin: Unicornu nunquam visum fuit. — The unicorn has never been seen.]

Father **Pedro Páez** [P. Petrus Pais], who traversed the whole of Ethiopia [Aethiopia] together with the Emperor's army, and who searched out all the recesses of the Mountains of the Moon [montium Lunae anulos] in order to discover the source of the Nile, and who made mention of innumerable animals, makes none at all of the Unicorn — indicating by this very deep silence of his that it does not exist. The writers on natural things have indeed, it is true, seen various animals conspicuous for a single horn on the forehead or nose; this they teach of certain wild asses [onagri], oryxes [oryges], and finally of several rhinoceroses [Rhinocerotes].

[Margin: Animalia familia [recte: similia] monoceroti quae. — What animals are like the unicorn.]

The Indian wild asses [Onagri Indici] are single-horned, fitted with a rough horn on the forehead, broad at the root and tapering gradually toward a turbinate (top-like) form. The oryx, again, is that species of wild goat that roams in the solitudes of India, equipped with a single horn which, emerging from the head, is gradually twisted into helical lines and grooves in the manner of a snail-shell, contorted to a length of four palms, and at last ends in a very fine point — a thing found here and there. But on animals of this single-horned kind, see Father **Giovanni Filippo Marini** [P. Joan. Philippi Marinum] treating the matter more fully in his account of the kingdom of *Tonkin* [Tom Kin] and of Laos [Lao].

[Margin: Onager Indicus cornu in fronte spectabilis. — The Indian wild ass, remarkable for the horn on its forehead.] [Margin: Oryx monoceros. — The single-horned oryx.]

As for the horns of the rhinoceros — since nothing is more commonplace, and since we are accustomed to display three of them in our Museum — I say nothing. From all this I conclude that whatever has been said up to now about the horns of the true Monoceros is to be understood of the said horns of these animals. But the contrary seems to be the case: for those horns of such great price and esteem, kept among the treasures of kings and princes, have nothing in common with the said horns — whether you consider their form, their color, or their smell.

At Paris, in the Church of St. Denis [S. Dionysii], one is kept about five cubits long, twisted in the manner of a helix. Another of the kind is shown for viewing at Strasbourg [Argentina], in the treasury of the cathedral church: of the height of a full-grown man, but with grooves differing from the Parisian one, of great weight, of a yellow color verging on pallor; its end is of such thickness as a fist could fill. Likewise at Venice, at St. Mark's [Sanctum Marcum], similar horns of exquisite

splendor are to be seen, which are given out as the true and genuine horns of the Monoceros. Similar ones are said to be found in the possession of the Grand Duke [Magnum Ducem], and others of the princes of Italy are said to hold them — so everywhere prized by princes that a treasury is reckoned unworthy of the name where such horns are lacking.

[Margin: Loca quae Monocerotis cornu inter pretiosissima ponunt. — Places that rank the Unicorn's horn among their most precious things.]

Yet when I had examined these things with the utmost diligence, I could not be induced to believe that they were the horns of four-footed animals. For the horns of animals — as is clear from rhinoceroses — always have a notable breadth at the base below, and then taper gradually to a point, whether curved or straight; whereas those horns scarcely fill out a breadth of four fingers, of always equal thickness, until at last, growing slender, they end not in a sharp but in a blunt point. And it seems scarcely possible that an animal — especially a monoceros not exceeding a horse in size — could either sustain so long a horn, given the great weight against the thinness of the shaft, or use it among the dense trees of the forest without danger of striking or breaking it.

[Margin: Cornua quae passim monocerotis esse dicuntur, animalium quadrupedum non sunt. — The horns everywhere said to be the unicorn's are not those of four-footed animals.]

I say therefore — and, saving the judgment of others, I hold — that horns of this kind are not the horns of quadrupeds but of certain fishes; and by what evidence, I now set forth. Not long ago the most illustrious **Count of Ahlefeldt** [Comes de Alfeld], privy councillor to the King of Denmark, a man most thoroughly versed in the knowledge of various matters, reported the following, while in conversation mention was made of the monoceros horn in our Museum. He said that when his King sent an expedition to the northern island of Greenland [Groenlandia], to explore what advantage might come from it to his Kingdom, at last, after many hardships endured, those who returned reported that they had indeed traversed the shores of Greenland but had been unable to detect any trace either of dwellings or of men; yet there were huge heaps of long horns, some of which equaled a pike [sarissa] in size...

[Margin: Piscium spicula esse ostenditur. — It is shown that they are the spines of fishes.]

equaled a pike in size; and that they had further learned from the inhabitants of the neighboring islands that these were not horns but the snouts [promuscides —

proboscises/tusks] of certain very large fishes, with which they defend themselves against the ambushes of the whales [Balaenae], of which a vast multitude is harbored in the glacial Ocean; and that for this reason these beasts perpetually war upon one another. Yet it happens not infrequently that these pike-like (spear-shaped) snouts, violently locked together among the crags of the icy mountains, are at last washed up onto the shores of the neighboring islands, where they pile up; and many of them, buried under the sand of the sea, are found every year — so they testified. They testified too that they had themselves seen a fish, of the size of a great lance, equipped with such a snout, under the figure which we here append.

And so, that the truth might be plain to the King, they had presented to him a whole boatload of these, packed full, and had sent some on to princes as a rare gift.

[Margin: Cornu Monocerotis hic Romae. — A unicorn's horn here at Rome.]

I learned afterward that **Gisbert von der Pole** [Gisbertum von der Pole], a Belgian merchant and for the time a Roman citizen, kept in his workshop two unicorn horns of great price, sent to him from Batavia [the Netherlands]. I went to him, asking that he show them to me, eager as I am for such things, which he did not unwillingly. The horns are nine Roman palms in length; the thickness at the base such as a fist could fill; striated, with the spirals twisted in the manner of a snail-shell, ending in a blunt point; of a yellowish color, like ivory; very heavy in weight; and of wonderful virtue in medicines against poisons. For — he said — if one of them is placed inside some shell filled with spring water, it soon imbues that water with such virtue that water of this kind, drunk by a sick person, soon makes him better; and he testified that he had found this so by experience.

And when I had instituted the most diligent examination of the form and constitution of these horns, I found at last that they could by no means be the horns of quadrupeds, but were the horns — or rather the snouts — of those fishes which we have described. And so I began, now a little more boldly, to affirm that whatever horns of this kind lie hidden anywhere in the treasuries of princes draw their origin from nothing else than the said fishes.

[Margin: Cornu monocerotis ab Alberto Magno observatum. — A unicorn's horn observed by Albertus Magnus.]

Hence it is by no means false what **Albertus Magnus** writes that he saw — a horn of the Monoceros measured with his own hand, which was a palm and a half in thickness and ten feet in length. Since this could not belong even to the largest of

quadrupeds, for the reasons given above, it could be nothing else than the [snout] of some very large fish, of the species we have described, dug out of the sea-sand of the British shore [maritimo Angliae littoris sabulo], where that fish had deposited it, or had badly shed it.

[Margin: Cur in Anglia praecipue monocerotis cornua habeantur. — Why unicorn's horns are found chiefly in England.]

Indeed, I am led to believe this by an especially strong argument: that in no kingdom is so great an abundance of these horns said to be found as in England; for since no animal that would exhibit a horn of this form is found in the whole kingdom, and yet very many are said to be dug up along the seashores, it is readily plain to anyone that they have been either washed in from the neighboring glacial sea, or shed by those same fishes on the English shores, buried in the sand, found in their time, and sold off as the horn of the unicorn. Therefore, setting aside the fabulous tale of the monoceros described by **Pliny** and **Aelian** — since nowhere on earth has such an animal been seen — we shall more fittingly assert that horns of this kind, found here and there, are the remains [exuviae] not of quadrupeds but of fishes. But enough of this.

[Margin: Cornu monocerotis fossile. — Fossil unicorn's horn.]

That a fossil unicorn's horn is sometimes found, fashioned by Nature in subterranean burrows, the History of the Swiss [Helvetiorum historia] shows. For it relates that in the year 1520, on the bank of the river Aare [Arula], near Brugg [Bruck], in the domain of the Margrave of Baden [Marchionis Badensis], a unicorn's horn of considerable size was found. Since it could belong neither to any four-footed animal nor to the said fish, it remains for us to say that it was fashioned by nature in the bowels of the earth.

As for the utterly prodigious virtues which certain quacks [Agyrtae] and itinerant peddlers exalt to the point of miracle, I say that they are to be measured by the same steps as the monoceros animal itself — wholly fantastic and imaginary. For who has ever tested the powers of that horn, whose animal was never seen by anyone? As for the repelling of poisons, I say that all kinds of *spodium* — such as burnt hartshorn, ivory shavings, and the teeth of the *Rosmarus* (this likewise is in the farthest Ocean of the North an amphibious fish of the greatest size, furnished with very smooth teeth — on which see **Olaus** [Olaus Magnus] and the historical Accounts of others concerning the northern regions) — for these, whether horns or teeth, just as they contain in themselves, beyond the specific quality implanted in animals, that same virtue against poisons, so too it is everywhere agreed that

they are commonly employed by all as timely remedies against poisons and the diseases of a malignant nature. But let what has been said about fossil horns, and those dug out of subterranean places, suffice.

CAPUT VI.

Of Fossil Woods and Coals [De Lignis & Carbonibus fossilibus].

Fossil woods, which are sometimes found in the underground bowels of the earth, are considered under a twofold difference. Some are those which were once trees, and which in the course of time, by the force of a petrifying power, were converted into stone. Of this kind, **Anselm Boëtius** [de Boodt], in his book on gems and stones, reports that a great quantity was found beneath the earth at Saint-Omer [Andomarum] in his time; and such are found everywhere.

[Margin: Lignum fossile naturale. — Natural fossil wood.]

I myself have seen, in various places of Italy, the trunks of trees converted to stone, of such hardness that fire could be struck from them no differently than from the hardest flints; and when struck, like metal, they gave back a most clear ring. Some of these pieces our Museum displays. For some woods have a greater disposition than others for receiving the petrifying force: such as the alder [Alnus], whose trunks, buried for a long time under water or earth, are at last converted into stone of an iron hardness — concerning which fuller mention is made elsewhere. Oak [Quercus] too, holm-oak [Ilex], and walnut [Juglans] are easily hardened into stone, because of the abundance of saline spirits which dominate in them; these, being stirred up by even the slightest scent of a petrifying power lurking somewhere, and united by a certain magnetic confluence of similar bodies, harden into stone. But these things have been treated more fully elsewhere.

[Margin: Minera ligni fossilis in agro Aquaspartano. — A mine of fossil wood in the territory of Acquasparta.]

Furthermore, there are sometimes found, in the hidden bowels of the earth, certain woody masses in the form of a mineral mass, which have drawn their origin from a vegetable nature only very remotely — or not at all; rather, they are the pure and unalloyed work of Nature. For just as Nature, in the fruitful retreat of the womb, produces both bones and horns, so too she produces woods, imitating the industry of vegetable nature. A sign of this is that most things of this kind are found in the deepest bowels of the earth, within what they call the *virgin* earth [terra virgo] — unpolluted by any access of external matter, and where it is

likely that no tree-substance ever at any time penetrated. Such is the wood that was sent to me not long ago from Bohemia [Boemia]: found in the innermost recesses of the mountains and, as they say, in the chamber of virgin earth, it best expresses the form of black wood [ebony], but far surpasses it in hardness and weight.

About twenty years ago, in Roman territory, a mine of fossil wood was discovered, from which most beautiful crosses, tables, and small tables — that would yield nothing to ebony — were made, and are everywhere displayed, in the place of a rarity, both in the Roman Museums and in our own. The most excellent **Duke Cesi** [Dux Caesius — Federico Cesi] is said to have first discovered this mine, in the territory of Acquasparta [Ager Aquaspartanus] subject to his jurisdiction. He, just as throughout his life he showed himself a tireless investigator of natural things, so too did not cease both to admire Nature's industry in producing this wood and shrewdly to track down its cause.

[Margin: Minera à principe Caesio detecta. — A mine discovered by Prince Cesi.]

This was done through that most erudite man **Francesco Stelluti** [Franciscum Stellatum], a singular friend while he lived, who in the Duke's name published an outstanding little work on this fossil wood, in which he renders to the life the wondrous traces of the lineaments expressed by Nature in this wood. And when I would not infrequently confer with the said Stelluti about these matters, and had learned the place where the *xylotic* [xylotica — wood-forming] mine was said to be, an opportunity offering itself, I went to Acquasparta [Aquaspartam], some fifty miles distant from Rome. There, having hired a man knowledgeable of the locality, and having advanced about three miles toward the city of Todi [Tudertina urbs], he showed me, at the bridge of a certain stream — whose name does not now come to mind — within a small valley, various passages. Entering these, we saw a certain kind of earth, very rough, and roughened, as it were, with certain barks of trees. When these were removed, we came upon a vein, in earth somewhat harder and shining with I know not what smoothness; and this, he said, was the earth from which were made at Rome those precious tables of which we spoke a little before.

[Margin: Author mineram explorat. — The author explores the mine.]

Here there was no trace of a tree or of a rotted branch, but it appeared to be earth entirely — which, within the earth somewhat softer, yet exposed to the air, hardens utterly into a woody substance, so that, no differently than any other wood, it can easily be split, hewn, and polished, after the manner of ebony. For by

the variety of its grain it quite rivals the wood of the walnut or pear-tree, so that, at first sight of tables of this kind duly worked, no one could easily be induced to persuade himself that it was not wood — since, at least as to outward form, it seems to differ hardly at all from wood.

Diagram. A tall, narrow woodcut in the right column showing the figured grain of the fossil wood: a series of nested, wavering, mountain-like (chevron and flame-shaped) bands stacked vertically, mimicking the streaked, undulating grain of polished wood (or the "flame" figure of burr-wood). Uncaptioned. It illustrates the "variety of grain" by which the fossil wood (the *Acquasparta lignum fossile*) rivals walnut or pear, as described in the surrounding text.

[Margin: *Forma ligni fossilis*. — The form of the fossil wood.]

Nevertheless, it is only then believed to be primarily a mineral, when it puts forth effects proper to fossils. For, first, tables of this kind placed upon water do not know how to float, but at once seek the bottom; next, applied to fire, they conceive no flame — no differently than if you were to burn earth or any kind of turf; thirdly, they entirely lack fibers extended along the height of the tree, after the manner of other woods, by which they are wont to draw up nourishment, and show only a kind of agglomeration of I-know-not-what crushed fibers. In a word, it is neither earth...

Caput VI — De Lignis & Carbonibus fossilibus (conclusion)

**

•

- o ...it is, in fact, neither stone, nor tree. Not the former, because it is made of a material that is by no means friable, but so compact that it is not unsuited to the chisel. And not the latter, because it has nothing in it that would answer to the roughness of stone, either in weight or in hardness. [Margin: The origin of this fossil wood.] For

this reason, too, it cannot be counted among those things that have hardened into stone through a petrifying juice [succus lapidificus], since it has none of the fibers with which trees are equipped by nature — and the proof of this is that it can be cut in any direction without difficulty.

By what art, then, or by what ingenuity nature produced it, remains to be explained. For I do not think that anything similar has anywhere been observed by anyone in the whole class of fossils.

I say, therefore, that these were once trees — a fact that their very ancient bark sufficiently proves, found everywhere scattered throughout the mine. They were not, however, hardened into stone by some petrifying juice, but were dissolved into the smallest particles by a sharp and softening juice. An earthy mud — of whatever kind it may finally have been — mingled with these and flowed among them, and drew the minute particles of the now-dissolved trees together into a single earth-wood mass [massa terro-ligneæ]. The result is that it can be called neither pure wood (for the reasons given above), nor pure earth, nor any kind of stone, but a compound of them all — so compacted that it presents the striated surfaces of wood (because of the anomalous diffusion of the moisture that flowed through it), exactly as in a piece of wood skillfully planed. And yet in weight it surpasses wood, so that, weighed down by this, it cannot float on water as wood does. Likewise, when placed on the fire, on account of the whole admixture of earthy portions, it refuses to catch flame.

But so that the curious reader may see the striations of this wood more clearly, I have decided to include here a table [tabula] that we are accustomed to display in our museum, planed from this sort of fossil wood.

Diagram. An uncaptioned woodcut of a rectangular panel ("table") planed from the fossil wood, displaying its wood-like striated grain. No lettered labels are present on the figure. *[The figure referenced in the text is described here; the plate itself was not rendered with separate labels on this page.]*

That certain earthy juices have the property of turning some things entirely into stone, while transmuting others — the harder ones — once dissolved, into a soft substance, was shown in the preceding pages by many experiments, and will be taught at length in the *Book on the Marvelous Artifices Wrought with the Aid of Minerals* [*Liber de miris artefactis mineralium*].

Concerning **fossil coals** [carbones fossiles], which they call *lithanthraces* [Margin: λιθάνθραξ ([Greek: λιθάνθραξ (lithanthrax, "stone-coal" — fossil coal))], there is

no need for me to say much, since they are found everywhere — chiefly in the territory of Liège [Territorium Leodiense], in Bohemia, in Saxony, in various places in Italy, on the island of Elba, in Sicily. At Liège they build their furnaces and hearths with them. They are certain bituminous masses mixed with sulphur — which they smell of — and on account of the said power they possess, they make a fire of greater effectiveness than any wood does; yet, because of their noxious exhalations, they bring much harm to the head. The whole countryside — indeed the very city itself, as Anselmus Boëtius [Anselmus Boëtius de Boodt] attests — has been so honeycombed with diggings, for the sake of the profit they get from these coals, that it is at some risk of one day collapsing. Ground up and mixed with oil, this coal makes an ointment for farmers: the vines smeared with it come out immune from all gnawing by insects.

There are various kinds of such coals. Near Dresden in Meissen [Misnia] a soft, bituminous fossil coal is dug; and at the same place another, harder kind, which is commonly confused with the Thracian stone [lapis Thracius] or with jet [gagates]. In Scotland likewise — as Agricola attests — twenty thousand paces from Edinburgh [Edenburgum], where they call it a "coal-floor" [carbonum area], it is found in immense quantity; the ground there abounds in bitumen, which also from time to time, not without grave harm to the inhabitants, catches fire. In Meissen near the noble town of Zwickau [Zuicia], a mountain of coals presents itself to view, which always burns at the surface; and as the pits are gradually dug down — which, if anyone, as Agricola teaches, should see them, blazing furnaces appear — it kindles, by fire, material that is not even directly applied to it, but stands four feet off at an interval. But let what has been said about subterranean coals suffice.

SECTIO III

DE ASBESTO, SUCCINO

and the Other Bituminous Fluxes of Gums; and also concerning those fossils that are endowed with marvelous powers.

[Sectio III opening]

Caput I — De Asbesto, seu Amiantho

On Asbestos, or Amianthus

Among the other miracles of Nature with which the eternal and uncreated Wisdom of God plays in the Globe of the Earth, the stone **asbestos** [asbestus] stands out before all — of a nature untamable by fire and incombustible, most celebrated in the records of all authors, both ancient and modern. As it is entitled by various names, so too, out of the equivocation of those names, it has stirred up enormous disputes and controversies among authors. [Margin: The names of the stone asbestos.] Strabo calls it *Carystium* [the Carystian stone]...

**

Pausanias [calls it] *Carpasium*, Solinus *Carbasum*, Pliny [Pliny the Elder] "living flax" [linum vivum], Zoroaster *Bostrichites*, others *Corsoides*, some *Polia*, certain ones *Spartopolia*, Marco Polo [Marcus Venetus] "powder of the salamander," and most, finally, call it "fissile alum" [alumen scissile]. "The alum," says Cardanus [Girolamo Cardano], "which they call *Scaiola*, is the *astrum samium* of the ancients, and is not of the class of juices [succī], any more than is plume alum [alumen plumae], which is composed of earthy parts. And therefore, if it is finely rubbed and sprinkled on bedding, it stirs up a constant itching, for it has sharp and pricking parts; and if wicks are made from it, they do not burn, but the oil is forever consumed while the wicks themselves remain." Thus Cardanus.

[Margin: The custom of the ancients in burying their Kings.] With these the records, not only of modern but also of ancient writers, concerning asbestos — that is, the incombustible stone, which for that reason the Greeks call ἄσβεστον and ἀμύαντον [Greek: ἄσβεστον (asbeston, "unquenchable, incombustible"); ἀμύαντον (amianton, "undefiled, incorruptible")], that is, "incorruptible" — agree. Hence napkins, funeral linens, and small nets used to be made of it, in which the corpses of kings, wrapped and burned by fire, would be reduced to ash while the linens themselves remained uncorrupted. From these threads, too, household stuff of every kind of cambric [carbasina supellex] was made, which, when soiled, was cleansed not by water but by fire. But these things are well known, not only in ancient times among the Egyptians, Greeks, and Romans, but even in our own day, so that they are found at the court of practically every prince.

[Margin: A paper of asbestos belonging to the Author.] I too have in my museum a whole casket full of pieces of asbestos. I have paper made from these, which serves for writing letters; and when you cast it into the fire, the letters being soon consumed, the paper comes out whole and whiter, as if washed by the fire, and

serves for inscribing new letters — so that a single leaf could serve forever in the reciprocal correspondence of friends. [Margin: The asbestos wick lasting two years.] The most eminent Cardinal de Lugo [Juan de Lugo] also gave me a little band [redimiculum] twisted of asbestos thread, which, when thrown into the fire, if it has been soiled with filth, comes out from it most brilliant. I also remember that I kept a wick of this asbestine kind, set in a lamp, for two years without any consumption of itself — without doubt it would have lasted forever, had it not, by I know not what accident, been taken away from me. So it is most true, what the ancients handed down about a wick unconsumable by fire.

These few things I wished to point out to the reader, lest he should regard asbestos, and what the ancients handed down about it, as some sort of paradoxical thing. But the marvelous and almost incredible things that writers have reported about its nature and property, I have judged it superfluous to recount here. [Margin: The authors who have written about asbestos.] Whoever desires to know these things, let him consult Pliny, Aelian [Claudius Aelianus], Solinus, Cardanus, Scaliger [Julius Caesar Scaliger], Lodovico delle Fave [Ludovicus Fives — *recte* uncertain; possibly Juan Luis Vives, "Ludovicus Vives" [?], Aldrovandi [Ulisse Aldrovandi], Anselmus Boëtius de Boodt, Agricola [Georgius Agricola], Falloppio [Gabriele Falloppio], Cesalpino [Andrea Cesalpino], Gesner [Conrad Gessner], Liceti [Fortunio Liceti], and countless others. Since these authors do battle with one another in a remarkable manner, I have thought it my part to call them back into concord on the following questions — which I shall carry out with all due diligence, once I have first set down certain things necessary for fully thrashing out the subject.

[Margin: From where the dispute about asbestos arose.] The whole quarrel that has arisen among the authors seems to consist in nothing else than the varied naming of this mineral. As this naming is diverse, so too it has bred various and differing conceptions in the understanding of the writers — the origin of so many disputes and skirmishings. For since nature has produced asbestos in various parts of the earth's regions [in variis Orbis terrae portae(?)] [Margin: lit. "in various places of the earth's globe"], each writer inscribed it with a name from its native place: hence they named the *Carystium* from the city of Carystus, the *Carbasium* from the city of Carbasa, "Indian flax" from India, the *Cyprium* from Cyprus; "scaiola alum" from its likeness to alum; and, after the salamander — because it lives in fire — whence also Pliny called it "living flax," as we related above. Still, modern merchants assert that the finest is found in central India, in Arabia, and in Cyprus — although in the Ligurian mountains, as also on the island of Corsica, and likewise in Etruria, indeed in Germany (according to

Agricola), some traces of this mineral appear. But, leaving these matters aside, let us proceed to the proper subject of our undertaking.

[Margin: Whether the stone is incombustible of itself and by its own nature.] It is asked, therefore, first: what this stone is, how nature has made it, or by what means it composed it, and whether in truth, of itself and by its own nature, it is ἄσβεστος καὶ ἀμίαντος [Greek: ἄσβεστος (asbestos, "incombustible"); ἀμίαντος (amiantos, "incorruptible")] — that is, incombustible, and incorruptible in fire.

[Margin: The position of the asbestos stone.] This stone is usually formed by nature in a hair-like [capillary] shape, of color now white, then ashen, sometimes reddish, at other times iron-colored; it is dry as to its outer surface and resolvable into filaments. Yet it has in its center a kind of stabling [lodged] moisture — I know not what — viscid and oily, untamable by any fire. The filaments are so constituted that they can be both spun and woven, exactly like ordinary flax. I say therefore that this stone is composed of a certain species of alum or talc, so that for this reason many have thought it should be called "fissile alum" [alumen scissile] or "plume alum" [alumen plumae]; for it is furnished with much softer filaments than fissile alum, and you may split it apart with practically no effort, even with your very fingers. Its filaments, when spread out, always show something woolly, like cotton or threads of white silk, whence not unfittingly it is called "plume alum." Yet within the recesses of its property it has — I know not what — something viscous and oily, [Margin: The oil of the asbestos stone is so concentrated that it cannot be separated by fire.] so concentrated into the earthy material that it cannot be separated from it by any force of fire — a virtue that certain other minerals also possess, such as gold and selenite [selenitis], which they commonly call *talc* [talcum]; for that viscous matter by which it is joined to its native material so resists fire that it cannot be dissolved from it by any artifice. [Margin: Why they resist fire.] Their obstinacy, however, is greater in the one case, lesser in the other. For experience has long since taught that selenite, given the greatest time on the fire, is consumed; but gold and asbestos never are. And this truly marvelous virtue arises from nothing other than the perfectly balanced temperament of the well-mingled stone. By what skill, and by what ingenuity, nature, against the torments of fire, [composed this] aluminous...

**

this viscus, in so inseparable a manner and bond — that it far exceeds the limits of the weakness of our understanding; and likewise it is not the part of a wise man to explain such things in far-fetched words.

That **asbestos** — or amianthus — endures in fire and persists uncorrupted without any harm, I have learned by frequent experiment. Yet I cannot here pass over a notable error: that certain people — who either never saw the stone, or did not understand the authors writing about amianthus — supposed that this stone, with no other ingredient added, is set perpetually aflame by fire. Thus Camillus Leonardus [Camillo Leonardi], *On Stones* [*De lapidibus*], book V: "*Asbestos is an iron-colored stone, which Arabia produces; it is called Asbestos, that is, 'inextinguishable,' because, once kindled, it perpetually retains its flame without any liquid.*" In this account he committed a double error: first, being ignorant of the Greek tongue, he interpreted ἄσβεστος [Greek: ἄσβεστος (asbestos)] — that is, "incombustible" — as "inextinguishable"; and second, he supposed that asbestos, when brought near the fire, is set ablaze into a perpetual light with no addition of any other inflammable thing. [Margin: Asbestos without oil is not of itself inflammable.] How false this is, daily experience teaches me, since the effects of asbestos are demonstrated to visitors in my museum almost every day. For unless oil is supplied to the wick, you will waste all your effort in trying to set it ablaze.

Into the same error fell Dionysius Afer [Dionysius Periegetes] in his poem *On the Situation of the World* [*De situ orbis*]: he makes the asbestos of Arcadia inflammable, in these words:

Here is born a stone which, once kindled by fire, refuses to be
extinguished, which the Greeks by its true name call ἄσβεστον; it shines
with the color of iron.

This opinion had many followers ignorant and unversed in such matters. But now, back to my purpose.

Rightly, then, does the wonderful property of this stone vex to the utmost the wits of all philosophers, since they cannot conceive that there could exist, given in the nature of things, some mixed body immune from all the violence of fire. Leaving aside the opinions of others, I shall set forth in a few words what has occurred to my own mind concerning the admirable virtue and property of this stone.

[Margin: Asbestos placed in a glassmaker's furnace is drawn out uncorrupted by the fire.] Experience has taught me that a piece of this stone, set in a glassmaker's furnace, is always drawn out uncorrupted. This marvelous stubbornness in repelling the violence of fire must necessarily be constituted out of those things which are most contrary to fire — which seem to consist in three. [Margin: Whence the incombustibility of asbestos?] The first is the material itself, which, as it is furnished by nature with a tenacious, thick, and viscid moisture, so too

cannot be easily consumed by fire's most active nature. The second is that the said material is inexhalable, and (so to speak) inevaporable; for it is established by experience that any material resists fire the more, the less it is liable to evaporation; and, conversely, that it is the more easily seized and consumed by fire, the more it is resolvable into vapors and exhalations. The third is the sincerity of the material itself, adulterated by no admixture of any heterogeneous [Margin: ἑτερογενής, "of a different kind"] thing — so that for this reason it must be confessed to be a body of a pure, homogeneous nature.

[Margin: Why they resist fire.] And this is evident from the very fact that, since it is most proper to fire to segregate heterogeneous things and to congregate homogeneous ones — as Aristotle attests — and since in asbestos all the parts are homogeneous without the admixture of anything else, it is readily inferred that it possesses the greatest power and efficacy for resisting fire. And this is clear in certain other things, as we taught above — namely in gold, diamond, and selenite — because in all stones and metals, which, however vehemently they resist fire, can nonetheless only with difficulty be reduced by chemical art into a liquid, a calx, or a similar form differing from the prior one; and if they are dissolved, we see that the solid substance of which they previously consisted by no means remains. But this has no place in asbestos: for if you torture it in a furnace with fire even for a whole year, it will always be drawn out for you, with no alteration to itself, whole and entire, and will be beheld as sincere. Whence we give the following definition — or rather description — of the asbestos stone, by which it is essentially distinguished from all other fossils:

[Margin: Definition of asbestos.] *Asbestos is a fibrous stone, not unlike fissile alum [alumen schistum], consisting of a tenacious and thick viscosity — or rather a tenacious and viscid thickness — incapable, on account of the homogeneous texture of all its parts, of being resolved into vapor, alone immune from the most active nature of all things and incombustible.*

I said "not unlike fissile alum," even though it differs from it both in softness and in the arrangement of its fibers, which it has arranged not otherwise than in a kind of wood; and the whole thing seems to consist of these, so that many, deceived by the outer form, have supposed it to be wood. [Margin: Asbestos imitates the form of wood.] And likewise certain charlatans [Gnatones] have sold it to the ignorant common folk, and to superstitious little women, as wood of the holy Cross [lignum S. Crucis], according to Mercuriali [Girolamo Mercuriale]. Alum, too, has something not unlike asbestos in resisting fire, as is clear from Roman history, where men are said to have preserved their houses immune from

fire in conflagrations by means of linens smeared with alum. If this is understood of ordinary alum, I judge it false — as I have found experience to be contrary to it — but if it is said of the true fossil alum, or asbestos, I think it most consonant with the truth. [Margin: A marvelous story.] For in the *Life of Saint George* [vita Sancti Georgii] we read that, when the tyrants had condemned him to the fire, but feared lest the Christians [should attribute his immunity from fire to a miracle]...

**

•

[lest it should] emit perpetual flame? Here I behold a great contest of authors fighting it out. [Margin: An account of perpetually burning lamps.] There are those who stoutly contend that such lamps both existed of old and can be made to this very day. Others, on the contrary, with great weight of arguments, maintain the contrary opinion. The authors of the former view adduce countless histories of lamps shining with perpetual fire, and report marvelous things about the perpetually burning lamps of the ancient Egyptians: concerning the lamp of Tullia, the daughter of Cicero, found still burning in her tomb when Paul III sat [as pope] — which, however, was extinguished at the first whiff of the outer air; concerning the golden lamp of Callimachus, placed in the shrine of Minerva [Fanum Minervae], burning for a whole year, extinguishable by no force of rains or winds. Of a similar lamp Bernardino Scardeone [Bernardinus Scardeonius] tells, in his *On the Antiquities of Padua* [*De Antiquitate Patavini*]. Della Porta [Giovan Battista della Porta] [tells] of the lamp perpetually burning near Naples, by Nisida [insula Nisida]. Of the lamp of Pallas, see Volaterranus [Raffaele Maffei "Volaterranus"] and countless other authors who have written about the lamps of the ancients shining with perpetual fire — see them in Fortunio Liceti, in his *On the Lamps of the Ancients* [*De lucernis veterum*], which is wholly devoted to persuading the world of the invention of perpetual fire. Whether, then, a lamp can be contrived by the aid of an asbestos wick, or by some other liquor, I shall now disclose.

[Margin: What things are necessary for a perpetual lamp.] A perpetually burning lamp can be considered in three ways. First, insofar as, by God's miraculous operation, it can burn forever — [Margin: The lamp placed by Constantine, as found in the *Life of Sylvester* I, Pontiff.] as is recorded in the *Life of Sylvester*, in [the matter] of the lamp set up by the emperor Constantine; ...of the perpetual lamps arranged in the Baptistery of Constantine; and the other lamp set up in Antioch, a city of Syria, of which Nicephorus [Nicephorus Callistus] relates that it

shone perpetually above the door of the church. Of such miraculous lamps, since they exceed the powers of nature, we say nothing. In the second way they can be considered, insofar as some lamp can be designated that lasts a long time; and about this, too, there is no controversy, since there is no doubt that this can be done. Third: whether a truly and properly perpetual lamp, with a flame that will never die, can be made by the aid of asbestos, or of some other thing? Here is Rhodes, here leap! [hic Rhodus, hic saltus] — and about this, as a fitting place, I have judged that something should be discussed here.

To establish a perpetual fire, then, very many considerations, most worthy of attention, must concur. First, that the wick in the lamps be incorruptible, and that the oil by which it is fed be durable and indissoluble. Second, that the oil — or whatever inflammable liquor — be so constituted that it always acquires only as much new liquor as has vanished by exhalation, and that there be a perpetual ἀντιπερικύκλωσις [Greek: ἀντιπερικύκλωσις (antiperikyklōsis, "counter-circulation, circular replacement")] of the consumed liquor and of the newly arriving liquor. Third, that the lamp be so defended from the external air that the air should have not even the least commerce with it — and who does not know how difficult that is?

These things considered and weighed: [Margin: Why a perpetually burning lamp cannot be made.] I say, first, that it is not possible for such a lamp to be made. And as to the first point [the wick]: although an asbestos wick is indeed incombustible and can in no way be consumed by fire, as is established by the experiment adduced above, yet because such a wick requires a liquid similar to it in all respects — that is, inconsumable — and this has hitherto been discovered by no one, the whole contrivance of the perpetual lamp deservedly collapses.

To the second [the oil] I say that, by no artifice of human ingenuity, can a liquid be prepared that is (so to speak) inexhalable, and that, with the flame perpetually acting upon it, will not in the end be consumed — just as it cannot happen, without a miracle, that a man should live forever with no nourishment. For these things are so connected by nature that they cannot be separated from one another: wherever there is fire and moisture, there the moisture must be attenuated into vapor or exhalation; and wherever there is exhalation or evaporation, there too the thing from which it breathes forth must, with time, likewise be consumed. But to bring it about that some thing should, in the presence and activity of fiery heat, neither be consumed nor evaporate — that is the same as to put a bridle on the necessary operations of nature, and so it belongs to none but God, the founder of all things.

[Margin: A flame enclosed in glass cannot be preserved.] To the third I say that to preserve a perpetual flame in a glass vessel closed on all sides is contrary to all the principles of Nature; since the flame feeds not only on the oil but also on the air existing in the vessel — and since, by hypothesis, no other air can enter — it cannot happen that, the air being consumed and no other succeeding, the flame should last. And experience makes this so manifest that no one can doubt it. Nor is there any need to allege here that the flame must last for fear of a vacuum [metus vacui]: for who does not know that the vessel will sooner be burst than that Nature should tolerate so great an inconvenience? — and this is clear from the experiment, adduced in the preceding pages, of the bursting of an iron vessel for fear of a vacuum. Nature is so tenacious of her rights that she shows herself inexorable to the craftsman who tries to fashion such machines by art, lest she should seem to have granted to man what she has reserved for herself alone. The whole labor of human industry expended in constructing a lamp of perpetual fire is therefore in vain.

[Margin: Objections.] But you will object to me: What has once been done can still be done to this very day; but from the histories we have it that such lamps were discovered, furnished with a perpetual flame; therefore, by the effort of human ingenuity, those same lamps can be made today as well.

[Margin: Reply to the objection.] I reply, first: that not everything is true which authors — either to stir up admiration among men, or to propagate the memory of so unusual a thing — have not so much handed down about such lamps as invented. And to show this, I say first: either such lamps were constructed by divine art and through a miracle, of which we are not speaking — since to God nothing is easier than...[to make fire] ...to preserve fire without any fuel, with no wick added, in perpetuity, by the mere will of his pleasure.

Second point. Just as we have a true and authentic account of the lamps found in the tombs of the ancient Romans, so too many things—especially among superstitious grave-diggers—may well have happened from which they drew a false argument for their assertion.

[Margin: Objections and replies.]

But you will say: people have seen a living flame in the tombs. I grant it—but not one burning perpetually in lamps. Rather, it was kindled suddenly out of the putrefied air shut up there through the centuries of many years, or from the breath of those entering, or even from the access of outside air coming in, by a certain antiperistatic power. So testify all the grave-diggers who work at

investigating the underground monuments of the ancients or at digging out treasures. When I questioned them about this apparition, they consistently confirmed that they had seen such flames in newly-uncovered vaults and tombs. And I myself have learned by experience, more than once, in the cemeteries they call subterranean Rome [the Roman catacombs], that those who—soaked with sweat—enter through some narrow opening into the hidden chapels of the ancients, shut up from time immemorial, give off little flames or small lights from their heads, after the fashion of will-o'-the-wisps [fatui ignes]. And daily experience in cemeteries exposed in sunny spots teaches well enough, and more than enough, that this is not without superstition on the part of simple folk, who, when they see flickers of this kind, wrongly imagine to themselves that they are the souls of the people buried there.

[Margin: Why a will-o'-the-wisp [ignis fatuus] appears in cemeteries.]

There is also a deception not unlike this: just as in dark and gloomy subterranean places even the least bit of admitted external light, or of illumination from a torch, shines out wherever there is anything apt to reflect light, so too a reflected light arising easily either from some fragment of glass, or from some phosphorescent material (whether it be wood, or rotten bone, or a worm, or any other insect shining with native light), can readily deceive men struck dumb with wonder.

[Margin: Objection and reply.]

But here they object: they themselves saw a living flame. I grant it—but not one shining with a perpetual fire. They press further: they found lamps in that same place. I grant this too—but only ones filled up with dust. They add: they saw lamps still smoking. I grant the whole of it—but without any wick; for the smoke they saw by a false imagination could have been from a torch itself, or from the very breath of the man, which, condensed in the thick and rotten air, could easily deceive the eyes.

[Margin: Prudent men do not believe in perpetually-burning lamps. (Margin cites a folio reference: "...scriptores...2. p.[?]" — see QA.)]

Third point. Lamps said to have burned perpetually, which the ancient Egyptians, Greeks, and Romans used, have always been suspect to judicious writers, since no one is unaware how much men have always invented in order to perpetuate to posterity the memory of the marvels they discovered—with how many fabrications, with how many and how great lies, they wove these tales. There is also this: the enemy of the human race [the Devil], to foster the

superstitions conceived in their minds, has always mingled himself into all their oracles and sacrifices, and has deluded them in many and various ways—or, as our Delrio [Martín Del Río] thinks, by the magical art he fashioned both the statue of Memnon and lamps blazing with perpetual fire; for nothing could have been easier for the Devil than to supply such lamps with ever-new material, whether real or apparent.

[Margin: Delrio, *Disquisitiones Magicae* [?], 2.27, Sect.[?] — see QA. / "...314" page reference — see QA.]

On these matters, see how fully [I treat them] in the *Oedipus Aegyptiacus*, vol. 2, part 2, in the *Treatise on Hieroglyphic Magic*; likewise the last chapter of the third volume, *On Egyptian Lamps*. For if the Romans enjoyed the benefit of perpetual fire in lamps, why did they make use of whole flocks of Vestal Virgins appointed to preserve the fire?

[Margin: An argument by which perpetual fire is discovered [?].]

I am not unaware that very many people greatly long to find out and assign some physical cause for this perpetual fire. There are those who think that lamps of this kind lasted so long because the smoke, exhaling by the combustible power and by the action of the fire, can be condensed again and driven together into a liquid that is once more inflammable—by a perpetual circulation. We have refuted this above. Some, along with Francisco Citesius [Francesco Citesi/Citois?], think that in these lamps the wick was of amiantus, and the oil was drawn from metals by the chemical art. Others suppose that lamps fed by gold dissolved by art into a greasy liquid burned for a very long time, ventilated in the bosom of the earth by air entering through hidden passages.

[Margin: Various opinions by which perpetual lamps could be made.]

Libavius [Andreas Libavius] is of the opinion that they contained powders and filings of the stone jet [gagates], onto which a drop of water—or an aqueous vapor—forever distilling would perpetually excite the flame, and, once excited, would preserve it. The alchemists, just as they always invent ridiculous dreams for themselves about their Philosophers' Stone, so too suppose that by its aid lamps can be kept burning with a perpetual fire. But just as no stone of that kind ever existed in the nature of things, so too I judge it vain and pointless to set going more extended discussions about it.

Nor does that lamp of Olybius [the "Olybius lamp"]—which they so greatly exalt in order to establish their view, on account of the inscription engraved upon it—prove anything. The inscription runs in these words:

Touch not, you thieves, the offering sacred to Pluto; Unknown to you is this thing that lies hidden in the world. For the elements, gathered together with grievous labor, I have shut up; Beneath this small vessel [lies] the great Olybius. Let plenty's horn stand by as a second guardian for itself, Lest the prize of so great a fluid perish.

But what Scardeonius [Bernardino Scardeone] reports so cleverly about the lamp of Olybius, found at Padua [Patavium], must be understood not of the perpetual light by which it blazed, but of that liquid which turned everything into gold—if one may say so. Who does not know that the ancients, men of charming wit, inscribed many such things upon hidden monuments to delude posterity with a truly solemn cunning? Since this is so, the question at least is raised, whether by human art any lamp can be **built** that blazes with a perpetual fire—

[Now Fol. 71, recto, header "DE ASBESTO, SUCCINO, &c. 71." Reading order within this composite folio: the asbestos-oil paragraph in the left column continues Caput I; then the "Varii construendarum lucernarum" rubric introduces the survey of authors' methods, MODUS PRIMUS (Porta) and MODUS SECUNDUS (Trithemius/Korndorfer). The "construi possit. Fateor me..." paragraph picks up the catchword above.]

—**can be built. I confess** that I have indeed spent much time on this speculation, but that I was never able to find anything that met the test.

[Margin: Oil from asbestos [asbestus], if it could be extracted, would be the food of perpetual light.]

I subscribed above all to those who thought the thing was to be accomplished from an asbestos wick and oil. For if oil could be extracted from asbestos, it would surely be of the same power as the stone, and consequently incorruptible; and so, kindled at an asbestos wick, it would burn perpetually. For since it could not be resolved into vapors, it would maintain itself forever at an even rate against the unconsumable wick. Hence I concluded that if anyone could extract oil from asbestos for me, I would without doubt promise him the invention of perpetual light. So at once I dealt with the more skilled chemists about the possibility of the thing; indeed I supplied them with asbestos material to make the trial. In the end, having applied every diligence, they candidly confessed that they had accomplished nothing—so far is that oil concentrated within it from

allowing itself to be separated from its subject. For whatever could be extracted from it was either water, in no way fit to catch fire, or else a viscous material indeed, but so dense, stiff, and clotted [?] that it could not be liquefied by any fire, much less set alight. They added that the oil they call *talc* [oleum talci, "oil of talc"] is of similar stubbornness, and therefore, although it commonly serves for the softening of little women's [complexions], it is indeed called oil but is not oil, since a wick steeped in it never catches flame; and so it is nothing other than phlegm separated from talc by the chemical art.

[Margin: oil from asbestos, if it could be extracted, would be that food of perpetual light. (Margin partly duplicates the running gloss; see QA — left-margin Latin cursive annotations on Fol.71 are a reader's hand and are illegible at this resolution; flagged for review.)]

Various ways of constructing lamps that burn with a perpetual light.

Lest we seem to have reduced the construction of the lamps of the ancients utterly to nothing, in this place we shall bring forward the methods and devices of certain authors by which they thought lamps of this kind could be made, and at the same time we shall examine whether any success is to be hoped for from the prescribed experiments.

MODUS PRIMUS [Method One]

But erroneous, on producing a perpetual fire.

Giovanni Battista della Porta [Joannes Baptista Porta] held that a perpetually-burning lamp could be made. "It is known," he says, "to everyone, that the cause of all the marvels in this world is the fear of a vacuum [vacui metus], and that the Machine of the world would rather be torn apart than Nature admit it [a vacuum]. Hence if a flame be enclosed in glass, with all its vents shut off, then if it lasts even for a moment, there is nothing to prevent its lasting perpetually. But when a flame is to be kindled in closed glass—*this* is the work, *this* the labor: the liquid must be of the most tenuous substance and of the least evaporation; so that if a flame is introduced into the closed glass, which can easily be done by means of burning-mirrors [ustoria specula], it will remain." Thus Porta. But he would have done better to say that the glass, rather than the world, would be burst.

[Margin: A perpetual lamp from asbestos [?] — illegible annotation, see QA.]

Furthermore, a lamp enclosed in confined air will be suddenly extinguished, and experiment teaches this: if you place a candle under an inverted cup, so that, accordingly, all resolution of vapor into new nourishment vanishes—since the

flame is converted not so much into oil as into soot. But because we have refuted a contrivance of this sort above, we shall not dwell on it any longer.

MODUS SECUNDUS [Method Two]

Of Trithemius [Johannes Trithemius], but erroneous.

Bartholomäus Korndorfer [Bartholomeus Korndorferus], a chemist, thinks a perpetual lamp can be made in this way, and he makes Trithemius the author of it.

[Margin: Trithemius's mixture and composition.]

First he mixes 4 ounces of calcined sulphur and alum; from these, driven up into the sublime, he makes flowers. He joins a sextant [one-sixth] of the flowers, together with half an ounce, to crystalline Venetian borax; and onto these, ground up in a glass dish, he pours spirit of wine four times rectified. After making a digestion and drawing off that spirit, he replaces it with fresh, and repeats this two, three, four times, until the sulphur melts like wax on a heated brass plate without smoke; and this, he says, is the food of the perpetual lamp. Afterwards the wick too is to be prepared by this art: filaments of asbestos stone, nearly the length of the little finger and of middling thickness, are bound together with white silk; the wick thus made is first thoroughly cleaned in Venetian glass, or in [some other] purified vessel; it is sprinkled over, then heaped up, and is boiled down in hot sand for 24 hours, with the sulphur always bubbling. The wick, thus anointed and smeared, is so arranged in the glass dish that it projects a little; the prepared sulphur is heaped on; the dish is set into the hot sand so that the sulphur may melt and grip the wick. They say that this, once kindled, will burn with a continuous flame.

[Margin: No mineral by nature [is] apt for making a lamp.]

So then, if we call each ingredient of this experiment to the anvil, we shall find that they can by no means hold up. For who does not know that all minerals—such as sulphur, salt, alum, borax, and indeed even the quintessence of wine—once set aflame, are at last extinguished when the fatty moisture latent within them is consumed? Since all the said things are, both of themselves and by their own nature, corruptible, so too they cannot sustain a perpetual duration of a flame that feeds upon and consumes them. Nor let these people urge some "circulation" or other, since the very thing that is consumed by the flame is, by that very fact, incapable of any circulation. Nor does the circulation of liquids carried out in chemical vessels offer them any support; for the circulation of

liquids performed in a pelican [pelicanus, a circulatory vessel] is one thing, and the circulation of the fat in a lamp by fire—circulating, as they think, back into the same—is another, which, as we said above, will never yield the desired result; since everything that is generated and corruptible cannot be eternal.

[Now Fol. 72, verso, header "LIBER OCTAVUS, Sect.III. 72."]

MODUS TERTIUS [Method Three]

Of Libavius and others.

[Margin: The trick [fucus] of Libavius.]

Libavius thinks a burning lamp can be made in this way: if you kindle asbestos with *Alarbum*, it will indeed burn perpetually. But what this *Alarbum* monstrosity is, it has nowhere been possible to find out. So do those fanatical impostors who, in order to make their experiments look more like the truth, take on a certain appearance of some exotic name (which, however, does not exist in the nature of things) and so throw dust in the eyes of the simpler-minded. There are also others who say they can set a stone alight with spittle alone, and from this they peddle, with shameful boasting, a method of perpetual light. But since I shall dispute more fully about this stone elsewhere in our works, and in this volume in its proper place, I shall not dwell on these matters further.

CONSECTARIUM [Corollary]

From what has been said it is clear that all the industry of human ingenuity in constructing perpetually-burning lamps is vain and futile, and that no such lamp ever existed in the nature of things. Only he can fail to know this who is ignorant of the foundations of Nature and of the all-destroying power of the fiery element—whatever the most learned Licetus [Fortunio Liceti] may write to the contrary. For he holds, and is wholly bent on demonstrating, that some oil can be had, soaked into an asbestos wick, which resists fire to the point of equality [ad aequalitatem]; that is, [an oil] which would have an equal proportion of forces for resisting the fire, so that the fire could in no way overcome it.

[Margin: Of equal forces [there is] neither perpetual motion nor perpetual fire.]

That this is true of asbestos *thread* I freely grant; but that it can be said of *oil*, I deny, for the reasons brought forward above. For these things stand to one another by the same reasoning as a purely artificial perpetual motion stands to the things that produce perpetual motion. For many say that a certain wheel could be made which, by means of a pump [anthlia], would raise just as much

water above as would suffice for turning the wheel—so that, to turn the wheel, as much water would ascend as would be required; and that no one ought to doubt that this motion would be perpetual.

[Margin: Just as a purely artificial perpetual motion cannot be made, neither can a perpetual fire.]

But I, taught and led by experience, say that it is so far from a perpetual motion resulting from this, that rather a perpetual standstill necessarily follows—and the reason is plain to every legitimate philosopher. For since all natural actions are caused in [the moment of] victory, by which one thing overpowers another, where, under an equality of forces, not motion but rest follows—as is most clearly evident from the balancing of waters in channels, which is commonly called the *level* [livello], and as we have demonstrated more fully elsewhere—by a like reasoning [I say] that as much water would ascend as would be lacking, in the proportion of equality for turning the wheel; [and so where] not motion but rest follows.

Indeed, I say that just such an equality of the proportion of forces in acting and resisting was impossible in perpetual lamps, since equality, so far from being able to perpetuate a flame, rather causes that, as soon as they reach that very equality, the flame itself—as if impatient of this equality—goes out of its own accord. We say, therefore, that the persuasion about lamps burning with a perpetual fire is vain. For if any were ever seen, they were nothing other than either an illusion of evil demons [cacodaemons] or a deception of the senses. Nor do we believe Trithemius, that he displayed such contrivances to a wondering world; but since they are of the same flour as the preceding ones, we pass them over. For if he supposes some such power to be in the flame, it will be in it not by the condition of the material, as most suppose, but from the degree of mixture and composition of the ingredients—a degree which, as it has not yet been explained by any of the philosophers, so it still lies hidden in the deep and inaccessible majesty of Nature.

[Margin: The fable of perpetual fire took its origin from the illusion of the grave-diggers.]

That, moreover, this art of producing an oil invincible by fire was not found among the ancients can be shown—besides the arguments that demonstrate it to be impossible—on this ground: that without doubt someone would be found who would make mention of it; and yet there is no one who speaks of it. In the age of Plutarch it certainly ought not to have been lost, if it ever existed in the world, since the barbarians had not yet flooded Europe, and the Roman empire

flourished at its height, and consequently all the arts; and he himself, who was seen to be endowed with such great wisdom and was a most curious investigator of things, would have had at least some knowledge of it. Why then does he himself so greatly marvel that certain lamps lasted whole years without the addition of oil, and try to discover various explanations, when he could have had one ready to hand from this art [if it existed]? How is it that Aristotle—he too, who lived while all the arts flourished in Greece, and who treats frequently of fire and of its nourishment and preservation—never made mention of the matter at hand? How is it that Pliny, most curious and most diligent, treating in Book 7, chapter 56 [*Natural History* VII.56], of the inventors of arts and of even quite ordinary things—such as the mixing of water with wine—made no mention of the inventors of so marvelous an art? How is it that St. Augustine, who lived in an age in which the memory of this art could not yet have been extinct, when dealing with those lamps, says they belong to no other art than the demonic? How is it that those priests, who said that their lamps were kept a whole year without the addition of oil, referred this to something marvelous, [as] if that art of preserving [fire] forever were present? And why did they use lamps of this kind that were yearly rather than perpetual?

[Margin: Aristotle makes no mention of perpetual fire. / Reference to Pliny [recte: *Naturalis Historia* VII.56]. (Additional left-margin page-references in a reader's hand — "l.2 c.20", "p.450", "p.314", etc. — are illegible/uncertain; see QA.)]

And from these things it is clearer than the noonday light that this tradition of perpetually-burning lamps is a sheer and utter fiction, and [arose] from the grave-diggers—

[Now Fol. 73, recto, header "DE ASBESTO, SUCCINO, &c. 73."]

—from the grave-diggers of the monuments, or from a diabolical illusion, or from the persuasion of their own fancy, or finally, in order that it might be said they had discovered something great, was spread abroad among the too-credulous common people; and so they dragged all posterity into a chain of errors, to the point that they even won applause in the chairs of the wise Philosophers.

We have said, then, that lamps shining with a perpetual fire cannot be made by human art at all; and the grounds are so irrefutable that no one can rightfully contradict them.

The question is therefore raised: whether by some other way lamps of this kind—in which the natural is joined to the artificial—might attain the desired effect, [and] could be constructed? I reply that they can.

[Margin: How a perpetual fire can be made, and perpetually-burning lamps.]

But that the assertion may be rightly grasped, I say that, just as perpetual motion can be considered in two ways—purely artificial, and mixed, that is, composed of a natural Principle and an artificial one—so too perpetual fire can be considered in two ways: namely, purely natural, and composed of the natural and the artificial. Just as, therefore, a purely artificial perpetual mobile cannot be granted in the nature of things, so neither can a purely [artificial] perpetual fire, whose reasons we have shown a little before. But that a *composite* perpetual motion, composed of the natural and the artificial, can be granted—as also a [composite] perpetual fire—ought to be in doubt to no one. This I teach by the following experiment.

EXPERIMENTUM [Experiment]

Of perpetual fire.

If anyone finds a place, or a mine or vein, in which bitumen, or any other inflammable liquid, gushes forth perpetually as if from a natural matrix—of which kind are found in not a few regions, as we showed in the First Volume, Book V, on bituminous places [*Mundus Subterraneus*, vol. 1, Book V]—

Diagram. A landscape engraving titled *De igne subterraneo machina* ("Machine of subterranean fire"). At the left, a masonry vaulted chamber (an arched, brick-lined cellar) opens toward the viewer; inside it stands a tall cylindrical vessel labeled **A** with a lit flame on its rim. To the right rises a mountainous landscape in cross-section; near the upper right a spring is labeled, and a conduit/pipe runs down the slope from a basin to the lamp-vessel.

- *De igne subterraneo / Machina* (banner, upper-center): "Machine of subterranean fire" — the figure's title, repeated within the image.
- *Fons petrolei* (upper right, at the spring): "Spring of petroleum."
- **N** (basin, right-center): the reservoir vessel set within the natural matrix, receiving the gushing bitumen/petroleum/naphtha.
- *Canalis* (along the pipe, right): "Conduit/channel."
- *Plumbeus* (along the pipe, lower-center, with **M**): "Leadен" — i.e. the leaden conduit (*canalis plumbeus*, LMN); the letters **L**, **M**, **N** mark its course from the reservoir down to the lamp.
- **D** (at the lamp's rim, left): point on the cylindrical lamp-vessel (the wick/float assembly).
- **A** (the cylindrical vessel, lower left): the lamp-vessel itself.

- *Lucerna / subterranea* (caption beneath vessel A, lower left): "Subterranean lamp."

[Margin: A machine of subterranean fire.]

I say that by the aid of this anyone can keep a perpetual fire going, by this device. In some suitable place where you want a lamp to blaze with perpetual fire, let there be set a vessel—whether of glass, or of clay, or cast from metal—of cylindrical shape, a palm in diameter, as letter **A** shows in the Figure. Within this vessel [place] a wick made of asbestos thread, which is to be held up by an iron wire twisted into a little ring, and supported by a cork circle—so that the iron wire may not sink down together with the wick—so that it always floats on top of the liquid. This done: within the true [vein] or matrix let another vessel, **N**, be arranged, to receive into itself the bitumen, or petroleum, or naphtha gushing out there. From the bottom of this vessel, a leaden conduit, **LMN** (or one made of some other material that can hold the oil), is run all the way to vessel **A**, fitted with its wick, so that its outermost orifice continually drips in over the lip of the vessel. And you will have a perpetually-burning lamp. For since the oil never fails, but ever-new nourishment is supplied to the lamp through the conduit, and since the asbestos wick is also of itself and by its own nature unconsumable, the lamp will in this way shine with a perpetual fire.

But lest this seem new to anyone, let him know that the ancients—

Liber VIII "Λιθογενής," Sectio III — De Asbesto, Succino, &c.

[Caput I, conclusion — De Asbesto, seu Amiantho] ...that the ancient Egyptian lamps, which they kept perpetually burning with an undying flame in their sacred crypts and innermost shrines, were contrived by the very ingenuity here described. That this was so, an Arab author teaches in plain words in his history *Of the Memorable Things of Egypt*. [Margin: How the Egyptians made perpetually burning lamps.]

"There was in Egypt a field," he writes, "whose pits were full of pitch and liquid bitumen. The philosophers, knowing the power of nature, laid out certain channels from such places as far as the underground crypts in which they placed the lamp; this lamp was joined to the channels just mentioned. The lamp itself had a wick made of slime [*limus*] which cannot be consumed by fire, and in this

way, once lit, the lamp burned perpetually — both because of the perpetual inflow of bitumen, and because of the incombustible wick of slime."

Anyone who wishes more on this subject may read my *Oedipus Aegyptiacus*, vol. II, ch. 3, Syntagma XX, where he will find treated whatever one might wish to know about the lamps of the ancients (*Oedipus Aegyptiacus* II.3, Syntagma XX).

CAPUT II.

On the preparation of asbestos flax [linum asbestinum] for weaving into cloth and for making paper.

[Margin: How the texture of asbestos-flax cloth is made — a great secret.]

The monuments of the ancients teach us that cloths existed which were immune to every torment of fire; nor are such cloths lacking today, though those skilled in this art are exceedingly rare — men who, with enormous profit, know how to spin this downy stone and weave it into fabrics. We display specimens of this kind for viewing in our Museum.

The question, then, is how this is done. Certainly, just as it holds no mean place among the greatest secrets of nature, so too it should be kept under the strictest secrecy and communicated only by word of mouth to kings and princes — lest something that was prized so highly at every period should now become known even to the basest of men. I am well aware that various people have indeed attempted the art by various methods, but always with wasted labor. Anselmus Boetius [Anselmus Boëtius de Boodt], Libavius, della Porta [Giambattista della Porta], and others give a method, but, deceived by an utterly false account, they accomplished nothing — for by those methods it is impossible to achieve the desired result. So, leaving this secret aside, I turn my pen to describing another matter: namely, how paper can be made from this stone. [Margin: How asbestos paper can be made.]

Such paper remains forever the same among those who keep up a reciprocal correspondence by letters. For if I have written my mind to a distant friend in such paper by letters, and he, on opening the letter, has grasped the sense of my mind, then he will throw the paper into the fire and cleanse it of every mark of writing; and on the cleansed surface, where the writing was, he will write back his reply to me in the same sheet. And when the need to reply arises, I will throw the paper into the fire and clean it, in order to answer my friend's questions in it.

You will make such paper thus: In a mortar let asbestos stones be pounded in no small quantity, until nothing but a downy material appears. This done, let a sieve

be made in the fashion of a small grate, fashioned of iron wires — or better, of copper — so arranged that the wires are spaced as little apart from one another as possible, exactly in the manner that papermakers commonly use today. Then stir the downy material well, having put it into water; take up the stirred material with the sieve, and shake the sieve until the downy material is spread out into the form of a sheet conforming to the shape of the sieve. Note here that, after the material has been stirred in the water, it must be caught up with the sieve without any delay; for if you wait even the briefest time, the material — being mineral and by its innate gravity — will at once sink to the bottom, and so you will draw up nothing but water in the sieve. Having spread out the material according to the shape of the sieve, you will lay it out — taken up on the usual filter or cloth — in a shaded place until it dries, and you will have paper prepared for the said uses.

CAPUT III.

On amber [De Electro seu Succino], commonly Ambra.

Although in our *Ars Magnetica* I have set down many things worth considering concerning the nature and properties of amber, here I shall demonstrate its nature more fully. There are various opinions about its name; lest we waste effort on them, let the reader consult the writers on mineral matters — Caesius [Federico Cesi / Bernardino Caesius], Agricola [Georgius Agricola], Caesalpinus [Andrea Cesalpino], Fallopius [Gabriele Falloppio], and countless others. It is therefore called *succinum* [amber] because it hardens out of a bituminous juice [*succus*] into a stony substance; it is called ἤλεκτρον [Greek: ēlektron, "amber" / "electrum"] — *Electrum* — on Agricola's testimony, named so from its drawing of chaff [*paleae*]. And the Arabic word كهربا [Arabic: kahrubā, "amber" — lit. "straw-snatcher"] — *Carabe* — on the testimony of Abalali and Camus, likewise took its name from the drawing of chaff. It is also called *Ambra*, though only improperly, on account of a certain likeness and analogy that ambergris [*Ambra*] of precious scent has in its compound. But here our business is not with words, but with the very quiddity and essence of the thing.

It is asked, first, what amber properly is. [Margin: What amber is.] I am not unaware that there were some among the ancients who judged amber to be the tear of some tree or other — which is so far from being true that, on the contrary, almost daily...

we have drawn it [chaff] without any difficulty or resistance, so that I cannot wonder enough that there was no one who dared to make so easy an experiment with basil [*ocymum*], which is everywhere at hand. But similar things are read,

and at once, without consulting experience, are wrongly believed; so it is no wonder that so many chained-together errors have been propagated in the Schools right up to this day.

Amber, then, draws all light things, with absolutely no exception, provided that their innate gravity does not set an obstacle to the agent. Indeed, we have drawn not merely any light objects whatever, but even the heaviest metals of every kind — iron, gold, silver, lead of ten and twenty pounds; wooden staves, spears, gloves — with a fragment of amber, by a static experiment. The procedure is as follows.

[Margin: Definition of amber] — [The following passage is printed on fol. 75 and logically belongs to Caput III, before the experiment above.]

No one henceforth should suppose that amber draws its origin from a vegetable nature: a rash experience has persuaded him this without due thought. But let him hold for certain that it is nothing other than a certain earthy bitumen, which has its birth in the underground passages of the earth, through seepages set there by provident nature. And how it is produced, I shall explain in a few words.

We spoke in the first volume, Book V, of the veins of bituminous places, and how Nature produces each of the several distinct species of bitumen, each according to the property of its soil. Standing on these principles, we define amber thus: **Amber is an underground bitumen, welling up from an appropriated matrix of earthy material; entrusted to the sea through the seabed or by the wash of bank or river; and there, washed up on the shores, it grows by the inborn dryness of sun and air into a stony substance.**

We said it is an underground bitumen — for, like asphalt [*asphaltum*], naphtha, petroleum, and the like, it has its own modes of welling up. Anyone who has rightly grasped what we treated of bituminous places in Book V of this work will see at once, beyond doubt, that the inmost bowels of the Earth abound in such oily liquids, born of a natural, appropriated fatness of the earth — which is, as it were, a certain glue of mixed bodies, set into all and each of them for the solid binding of their parts. This bitumen is distinguished from the rest just cited by a certain specific difference, in that it acquires its property from some earthy material — whether sulphurous and duly purged, or from a vein of jet [*gagates*], or from a frankincense-bearing underground mineral material through which it distills. In a word, it takes its property according to the purity of the material through which it flows, as its very color, odor, and taste sufficiently show: in the white kinds it is most pleasing; in the tawny, less agreeable; in the ashen, it even

has the smell of burnt sulphur. Thus the purity of the material it flows through grants it powers more or less perfect.

We have, then, the origin of underground amber; now we must say how it hardens. Since bitumen of this kind, by its nature — like all oily things — is light and airy and seeks the surface above the water, it accordingly wells up from places beneath the water and, floating on the surface of the sea, is rolled to the shores by the impulse of the waves. There, in the form of a honey-like substance, it remains still soft and liquid, until little by little, growing sluggish in the dryness of the air, it hardens into stone as a hard material. Let us prove more clearly that this is indeed so.

CAPUT IV.

How little animals of various kinds have obtained their tomb in the heart [meditullium] of amber.

[Printed fol. 75 bottom, continuing to fol. 76.]

[Margin: Little creatures in amber.]

That transparent or clear amber displays, here and there, various little animals — not only does present-day experience teach this, but the ancient writers on natural matters have also attested it. Pliny [the Elder], book 37, ch. 3, says: "That amber drips out in liquid form at first is proved by certain things that show through within it, such as ants, gnats, and lizards, which were no doubt stuck to it while it was fresh, and were shut up as it hardened" (*Naturalis Historia* XXXVII.3). Dioscorides confirms this. Brasavolus [Antonio Musa Brasavola], in his examination of gums, says that he had at home a piece of amber in which there was an ant so wonderfully whole that not even the smallest leg was missing.

[Margin: They have obtained their own tomb.]

Agricola, subscribing to these statements, says: "Of these, the tawny and the wine-colored kinds are mostly transparent, and in them there sometimes show through small beasts — winged ones, such as the fly, gnats, bees, or wild ones, like the ant, little red worms, spiders, lizards, vipers; or swimming ones, like little fishes, or parts of beasts, such as the wings of flies, the eggs of fishes; or inanimate things, such as bits of herbs, leaves of plants — all of which had earlier flown, crept, or fallen into the sea; and afterwards, when that most excellent bitumen flowed out of the earth into the sea, it seized them and shut them within itself, and so, enclosed, they were turned into stone together with it."

To which Martial finely alludes, book 4 [*recte*: book 6], Epigram 15; book 4, Epigram 32 [?]; and book 4, Epigram 59 [the cited references — "l. 1. Epigram. 99. & 118. & l. 6. Epig. 12" as printed — are garbled; transcribed as printed and flagged]:

Epigram 12 [as printed]: *"And the drop fallen from Phaethon's tree both hides and shines, so that the bee seems shut up in its own nectar. A worthy reward she won for such great toils: one may well believe the bee herself wished to die thus."* (Martial, *Epigrams* IV.32)

ANOTHER: *"While a viper crept among the weeping branches of the Heliads, an amber drop flowed onto the beast that blocked it. While it wondered at being held by the rich dew, it suddenly stiffened, bound fast in the congealed ice. Take no pride, Cleopatra, in your royal tomb, if a viper lies in a nobler sepulchre."* (Martial, *Epigrams* IV.59)

ANOTHER: *"While an ant wandered in Phaethon's shade, an amber drop entangled the slender creature. So that, having been despised while life remained, it has now by its own funeral been made precious."* (Martial, *Epigrams* VI.15)

That all this is so, various fragments of amber in my Museum show — full of flies, ants, and the like; indeed, a string of beads, which they call a Rosary, is on display, in which as many amber globes are seen as there are different flies. In past years the Most Serene **Augustus, Duke of Brunswick and Lüneburg** [August the Younger, Duke of Brunswick-Lüneburg], a prince refined in every kind of learning by a rare example, sent me — out of his truly singular affection toward me and my studies — a piece of amber half a palm long, in which nature displays a little lizard so whole that there is no limb in it which is not most clearly seen, to the great wonder of those who behold it. Let the reader look at the figure placed here. [Margin: A piece of amber in the author's museum, in which a lizard is seen entire.] I recall that I once saw a similar piece in the Treasury [*Gazophylacium*] of Cardinal Francesco Barberini, in which a little frog had chosen for itself a tomb of undeserved honor.

It is asked, then, how little animals of this kind come to possess the heart of the amber; how they enter; and why they do not appear on the outermost surface. [Margin: How the said little animals are seen.] And although Agricola, cited a little above, assigns some sort of reason for it, yet since it does not satisfy the curious, I shall set out the manner a little more clearly.

When, therefore, the bitumen — still liquid and soft — is rolled by the waves of the sea to the shores, it happens that, gathered there among the sands and rocks, it grows sluggish in the dryness of the air. At this point little animals of this kind, drawn by its taste and smell, as soon as they have settled upon it, are at the same time seized by the stickiness of the material as if by some birdlime [*viscum*]; and being unable to free themselves from it, meanwhile — the material still being movable — they are little by little worked by the great sea-waves into globes or some other shape. And in this way, one wave thrusting and then another, the little animals, glued in, are wrapped about and withdraw into the heart of the mass. And I judge this to be the reason — saving the judgment of others — for the little animals appearing in the midst of amber. Thereafter, covered over with sand and rocks, in the course of time they harden into stone, honored with this noble amber monument of a sepulchre.

Diagram. A large engraved woodcut showing an upright, egg-shaped (ovoid) mass of amber, rendered as a translucent stone, standing on a flared, striated base resembling a turned pedestal or a fan of fine lines. Within the body of the amber, a lizard is depicted entire — head raised toward the top, body curving in an S-shape down through the center, the limbs and tail clearly delineated — the very specimen described in the text, sent to Kircher by Duke August.

- Caption (above the figure, in the right column): "*Non poterat tumulo nobiliore tegi.*" [It could not be covered by a nobler tomb.]
- Attribution (below the caption, above the figure): "*Donum Sereniss. principis & ducis Augusti Luneburg. & Brunsvicensis.*" [A gift of the Most Serene prince and duke August of Lüneburg and Brunswick.]

CAPUT V.

On the attractive power of amber [De attractiva Electri virtute].

[Printed fol. 76, lower; the experiment proper is printed on fol. 77 — see the EXPERIMENTUM section below.]

That amber draws to itself chaff, straw, and all light things was already known to the ancient writers on natural matters — Theophrastus, Pliny, Aelian, Solinus, and the rest — and present-day experience proves the truth of the matter more than abundantly. Yet I have always wondered that, from those times down to this present day, an opinion has been propagated: most people think, and firmly persuade themselves, that amber draws to itself all light things *except* basil [*ocimum*], or things smeared with oil, by some antipathy or aversion I cannot name. [Margin: A false opinion, that amber draws all things except basil.] A

plainly obvious error: a hundred times, in the sight of many, we have drawn basil with amber, and likewise any other small things whatever — whether chaff, or straws, even ones smeared with oil and grease — without any...

EXPERIMENTUM.

A marvelous experiment of electric attraction [Attractionis Electricae mirabile].

[Printed fol. 77.]

On a certain beam A B, let an iron arm be led out from H, from whose hook G let a thread hang down, which at the middle of any length whatever grasps, at point I, a balance-beam [*librile*] E, F made of any material. If you first bring a fragment of amber, warmed by heat, up to the unmoved end E F of this beam, at once the amber, leaving its station, will follow it. If you hang a weight on this balance E F, the threads of amber [?] will likewise follow in their turn. A truly fine experiment, with which the spectators of my Museum are often refreshed.

Diagram. A schematic illustration of the electric-attraction apparatus. At the top runs a horizontal beam labeled at its left and right ends. From a hook, a vertical thread descends (labeled at its lower point) to a small ring or pulley, below which hangs a horizontal balance-bar drawn as a narrow rectangular rod. A hand emerging at the side (an engraved pointing hand) indicates the apparatus.

- A, B: the ends of the upper horizontal beam (*trabs*).
- H: the point from which the iron arm is led out.
- G: the hook from which the thread depends.
- I: the point at the middle where the thread grasps the balance-beam.
- E, F: the two ends of the lower balance-beam (*librile*).

This too is worthy of wonder: that amber brought near to a flame, so far from drawing it, rather blows the flame away and disperses it. The cause of this is none other than that, when the very light flame cannot resist the spirits roused out of the amber by heat, it is driven off by their force into the opposite direction. But a little drop of water it draws so as to raise it into a cone. All those mixed bodies similar by natural kinship produce the same effect — such as jet [*gagates*], hard bitumen, and electric bodies of every kind whatsoever.

It is asked, then, what the reason for this is, and how this power is distinguished from the attraction of the magnet. [Margin: Whether it is a magnetic force.] I say there is a remarkable difference between the attraction of the magnet and that of amber:

- The magnet draws only determinate bodies, such as iron and the like; amber draws all things without distinction.
- The magnet not only draws iron, but also communicates its power to it — which amber does not do.
- The magnet exerts its force through determinate poles; amber exerts the same force everywhere and from every point.
- The magnet draws without preparation; amber, by contrast, [does not].
- The magnet's effluvium is immaterial, penetrating all things; amber's is material, ceasing to draw when the smallest objects are interposed.

I say, then, that amber's attractive power comes about thus: When the amber, having first been rubbed and warmed by heat, emits a most subtle effluvium, it happens that the surrounding [air], driven away as far as the chaff and repelled by the surrounding [medium], carries off with itself the lighter objects — up to the surface of the amber, where, glued by a thin fatness, it adheres. But since we have proved all this most fully and by various experiments in our *Ars Magnetica*, book 3, part 3, ch. 3, we refer the reader there, where he will find treated whatever one might wish to know concerning the electric attractive power.

CAPUT VI.

On the medicinal powers of amber [De Electri sive Succini medicis viribus].

[Printed fol. 77.]

That amber has an enormous use in medicine is everywhere agreed. For since it is endowed by its native faculty with the power of cutting, dispersing, warming, and gluing together, it accordingly confers a notable benefit for routing all the ills of the vital parts. [Margin: The diseases driven off by the help of amber.]

Hence, in the judgment of physicians, when bound to the neck it is a remedy for fevers; ground with honey, for dimness of the eyes; it stops blood flowing from anywhere; it removes vomiting of the stomach; it stops fluxes and discharges of the belly, by which ulcers are infested; it stops distillations of the head [catarrhs]; it helps the tonsils and ailments of the throat. And because it strengthens the viscera and the other parts of the body, provided they are not overflowing with humors, when drunk with wine it protects a man from epilepsy and from the loosening, convulsion, and distension of the nerves. It soothes pains of the stomach when one is bathed with amber oil [*oleum succineum*]; and because it is fragrant, it benefits the heart and remedies its trembling; its fumigation [*suffimentum*] dries up the phlegm of the head; it removes difficulty in childbirth; it weakens the rottenness of pestilential air — so that in time of plague no better

or nobler fumigation can be assigned. The oil, rubbed on the hips, frees one from sciatica and pains of the kidneys.

In external matters too it has an outstanding use: for its shavings, added to a lamp, make the flame both brighter and more lasting. That vessels and reliefs of every kind are carved from it is too well known to need saying; and it was once held in such high esteem among the ancient Romans that a tiny figure of a man carved in amber exceeded the prices of the other gems. Finally, for the prayer-beads which devout people for the most part use, nothing is more common. But let these things said about amber suffice.

BOOK EIGHT "Λιθογενής," Section III — *On Asbestos, Amber, and the Like*

A COMBINATORY TABLE

In which the forms and virtues of all precious stones are briefly set out, arranged in alphabetical order.

The table runs across four folios in alphabetical sequence of stone-names. Each entry gives the name, then a description (form, color, places of origin), then the stone's reputed powers and properties. The entries are transcribed below in their alphabetical order, which corresponds to folios 78, 79, 80, and 81 of the source. Throughout this table Kircher reports these "virtues" as traditional lore — note how often he himself flags a claim as mistaken (*perperam*, "wrongly") or as the fancy of magicians.

[Margin: handwritten reader's note at the head of folio 79, in cursive ink: "Calc Barias" [?] — an early annotation, reading uncertain.]

Folio 78 — A through Calcedonius

Name	Form, Color, Places of Origin	Powers and Properties
Adamant [Adamas] (diamond)	The most excellent of all gems, of unconquerable hardness, transparent; the true and genuine kind forms in India.	Taken internally it is a poison, because of its caustic power; when worn it is said to be a gem of reconciliation, of fortitude, and of

Name	Form, Color, Places of Origin	Powers and Properties
		constancy — but wrongly so, as we have noted elsewhere.
Aetites [Aetites] (eaglestone)	Named from the eagle [Aquila], because it is said to be found in eagles' nests; within its own body it carries another, loose stone.	There are various kinds, but all are "pregnant" with another stone inside. It is most praised when applied to women suffering difficult childbirth.
Agate [Achates]	A gem remarkable for its varied figures, tinged with differing colors. It is found in India and in various places in Europe, and commonly in Germany.	It is said to counteract pestilential poisons and the stings of vipers and scorpions; it calms the heat of fevers, and benefits the eyes.
Alabaster [Alabastrum]	A splendid marble of various colors — white, black, and honey-colored; found in Egypt, Sicily, and Etruria [Tuscany].	Burnt and mixed with resin, it dissolves hardness; mixed with wax it soothes stomach pains; drunk with milk it cures dysentery.
Amethyst [Amethystus]	It is of a violet color, and takes on various differences according to the differing conditions of the places where it is found.	It is thought to resist drunkenness — from which it takes its name [Greek: ἀμέθυστος (amethystos, "not drunken")]. The superstitious also believe it confers natural talent and the favor of princes.
Asteria [Asteria], or Astroites	It takes its name from the little stars with which its whole body is, as it were, painted. It	Poured over with vinegar, it moves of its own accord this way and that. Tied on children, it

Name	Form, Color, Places of Origin	Powers and Properties
	divides into various kinds and is found in various places in Italy.	is believed to cure smallpox.
Balanites [Balanites]	So called from the shape of an acorn [glans]; there are two kinds, greenish and yellowish, found in various places.	They are said to have an astringent power, and so to cure diarrhea.
Basalt [Basaltes]	It is reckoned among the marbles, because it takes the finest polish; hence it is also counted among the touchstones [Lydii lapides], well suited for testing gold and silver.	In Meissen, near Dresden, it is quarried in great quantity, and commonly serves the office of a touchstone.
Belemnite [Belemnites]	So called from the shape of an arrow [sagitta], which it resembles. It is found in various colors and is also called Lyncurius; from a broad base it grows up to a point.	Its powder heals wounds; it breaks up stones [calculi], and is said to ward off nocturnal apparitions.
Beryl [Beryllus]	A gem that counterfeits a bluish color out of green, like seawater; it divides into various kinds, and seems to be a species of crystal.	It is said to be especially good for the eyes, its powder mixed with rose-water or lily-water. It corrects ailments of the liver. The superstitious claim it wins over men's affections.
Toadstone [Bufonius Lapis], Batrachites	Found in a toad [Bufo], it has the figure of a star-stone, of various colors.	It is thought to resist poisons above all, applied to the affected parts; it prevents stones of the kidney and

Name	Form, Color, Places of Origin	Powers and Properties
Chalcedony [Calcedonius]	It shows various colors according as it is exposed to different light; it is semi-transparent, and is reckoned among the onyxes.	bladder. It is said to cure black bile and melancholic afflictions, as well as fear, sadness, and the hypochondriac disease.

Folio 79 — Carbunculus through Granatus

Name	Form, Color, Places of Origin	Powers and Properties
Carbuncle [Carbunculus], Pyropus, Rubinus (ruby)	So called from the light by which it shines like a glowing coal [carbo]; hence many wrongly suppose, falsely, that by its brilliance it gives light like a torch at night.	It resists poisons, restrains lust, gladdens the spirit, rouses to anger, and lessens sleep; when misfortune is impending, it is said to change color.
Carabe [Carabe], or Amber [Succinum]	It is not a stone, but a kind of bitumen, of which we have treated at length elsewhere.	It has great virtues for removing excess humors, as we have already shown elsewhere.
Ceraunia [Ceraunia] (thunderstone)	So called from the thunderbolt [fulmen], because it is supposedly cast down from the clouds — how that can be, we have discussed elsewhere. It has various kinds.	It is said to be effective against lightning, and for that reason is called Brontias; it is called Ombrias if it falls together with rain and showers.
Chrysoprase [Chrysoprasus]	So called from the splendor of gold [aurum] with which it shines; yet it has some greenness	It has a remarkable power for refreshing the eyes.

Name	Form, Color, Places of Origin	Powers and Properties
	mixed in.	
Conchites [Conchites]	It takes its name from seashells [conchae] turned into stone.	Its powder is said to cure the stone, by a certain sympathetic action.
Whetstone [Cos]	A very hard stone, suited for sharpening knives and other iron tools; there are various kinds of it.	A whetstone rubbed with iron is said to cure the loss of hair and to reduce the spleen.
Dendrites [Dendrites]	It is a stone that reproduces the figures of trees and shrubs; it is found commonly in Etruria [Tuscany].	Its use in medicine is not yet established; nevertheless it has a styptic property.
Dragonitia [Dracontia]	So called from the dragon [Draco], in whose heads it is said to be found.	It is said to have a wonderful power against every kind of poison.
Eneostis [Eneostis]	A stone that reproduces the figure of bones, of which [we have treated] at length above.	It has the power to knit together broken bones.
Enhydros [Enhydros]	It is called a stone from the water [aqua] that it holds within itself.	It is said to have power against weakness of the urine.
Entrochus [Entrochos]	So called from the resemblance to a wheel [rota], which its figure reproduces.	It has the same power as the sandy stones — an astringent one.
Enorchis [Enorchis]	So called from its resemblance to testicles, which its figure reproduces.	It is said to have the power of arousing lust, owing to the natural seal set upon it.
Jet [Gagates]	Not so much a stone as a kind of burnt bitumen; it	It draws up chaff, as amber does; it has a

Name	Form, Color, Places of Origin	Powers and Properties
	has a sulphurous odor; so called from the river Gages.	diuretic property; by fumigation it cures women's diseases, as also epileptics.
Galactites [Galactites]	So called from the milky [lacteus] color which it gives off when wetted with water.	It increases the supply of milk in women and swells the breasts, when ground to a paste with the milk of almonds.
Geodes [Geodes]	It is a round stone, named from the earth [terra] which it contains within itself; if that earth inside should be loose and rattling, then it is no longer called Geodes but Aetites.	It has the same power as Aetites, since it is nothing other than an unripe Aetites.
Glossopetra [Glossopetra]	It is a rock, so called from the figure of a tongue [lingua] which it reproduces; it is found in great quantity on Malta [Melita].	It is good against poisons, as is also the Maltese earth, and it has an astringent power; see the treatment of this elsewhere.
Grammatias [Grammatias]	It is a kind of jasper, so called from the letters and figures, or lines, which it reproduces; it is found in Meissen [Misnia].	It is good against poisons. The magicians dream up marvels about this stone, which you may see in Marbodeus [Marbode of Rennes].
Garnet [Granatus]	They are manifold, tinged with a deep-red [puniceus] color; they are found in great quantity in Bohemia, and of the better sort.	It has a drying power and strengthens the heart; garnets enter into the composition of the <i>elixir of life</i> and the <i>confection of hyacinth</i> .

Folio 80 — Haematites through Morochtus

Name	Form, Color, Places of Origin	Powers and Properties
Bloodstone [Haematites]	So called from the color of clotted blood [sanguis] with which it gleams; and there are various kinds: some are green, gleaming with blood-red points.	All these kinds are good for fluxes of blood, of whatever sort the flux may be.
Heliotrope [Heliotropium]	It takes its name from the Sun [Sol], because it reproduces the image of the Sun; it is found commonly in various places.	It has the same power as jasper and as bloodstone, about which the magicians invent many absurd tales.
Hyacinth [Hyacinthus]	According as it is of greater or lesser redness, it is referred now to the carbuncles, now to the garnets; it takes its name from the hyacinth flower.	It resists plague, gives strength to the heart, brings on sleep, and is said to confer cheerfulness of mind.
Jasper [Iaspis]	There are very many kinds, and according to the colors with which it is tinged it takes different names.	Hung at the neck it stanches blood; it relieves nausea; it benefits epileptics and sufferers from the stone.
Ictérias [Ictérias]	It takes its name from the jaundice-bird [icterus] or <i>Galgalus</i> , a bird of yellow color; for it too is of a yellow color.	It is said, when worn, to benefit the jaundiced in a wonderful way, by a certain natural likeness.
Iris [Iris]	It is called a gem from its resemblance to the colors of the rainbow [iris], which it	It is said to benefit the eyes, by a natural likeness and sympathy.

Name	Form, Color, Places of Origin	Powers and Properties
	reproduces; it is a species of crystal.	
Jew-stone [Judaicus Lapis]	It is a stone of oval shape, resembling an olive; it is found on the Mount of Olives [mons Oliveti].	Olives are supposed to have been turned into stone; it is wonderfully good for the stone and for difficulty of urine.
Lapis lazuli [Lazulus], Lapis Judaicus	It is a blue stone studded with golden points; it is opaque, and rivals the sapphire in color.	It is wonderfully good for quartan fever, strengthens the sight, brings on sleep, and soothes the pains of gout.
Leucophthalmus [Leucophthalmus], Cat's-eye [Oculus Catti]	So called from the figure of an eye [oculus], which it reproduces; it is a species of opal.	From the mark it bears, it is reputed to cure the eyes.
Lychnites [Lychnites]	It is a species of Parian marble, the whitest of all; it is found commonly in Etruria [Tuscany], as also in Sicily.	It has an astringent power, and so is good for moist infirmities.
Touchstone [Lydius Lapis]	It is a species of black marble, suited for testing gold and silver.	It has a cleansing [smectic] power, and an astringent one.
Lithanthrax [Lithanthrax] (mineral coal)	It is called fossil coal [carbo fossilis], and is commonly dug up in Belgium near Liège [Leodium] for feeding fires.	It is severely harmful to the head, even to the danger of apoplexy.
Magnet [Magnes] (lodestone)	It earned its name from the region of Magnesia, where it is found.	For its wonderful powers and properties, see our <i>Magnetic Art</i> [Kircher, <i>Ars Magnetica</i>].
Malachite [Malochites]	It is a species of prase; it	It has a laxative power; it

Name	Form, Color, Places of Origin	Powers and Properties
	earned its name from the mallow [malva], for it is green like the mallow, marked with various veins.	benefits the heart; it strengthens the stomach; and it helps epileptics and those with spasms.
Marble [Marmor]	All those hard, smooth, and splendid stones, painted with various colors, are called marbles.	According to their various color-tints, they are endowed with various virtues.
Melichrysus [Melichrysus]	It is a species of chrysolite, gleaming with a golden color; it is found in Bohemia.	It is good for fluxes of blood and for epilepsy; it drives off various diseases.
Morochtus [Morochtus], or Melites (so called from its taste of honey [mel])	It differs from Galactites, the milk-stone, in color alone. It is found commonly in Saxony; it is also called the black Galactites.	It is good for spitting of blood; it cures fluxes of the womb.

Folio 81 — Nephriticus through Thracius

Name	Form, Color, Places of Origin	Powers and Properties
Nephritic stone [Nephriticus Lapis] (kidney-stone)	It takes its name from the kidneys [renes], which it benefits; it is tinged with various colors, like jasper.	It is said to cure sciatica, and by a natural property it benefits the kidneys.
Cat's-eye [Oculus Catti]	It is a species of crystal; it takes its name from the cat's eye, which it reproduces; it is also counted among the kinds of Asteria.	It is said to drive away terrifying dreams.

Name	Form, Color, Places of Origin	Powers and Properties
Onyx [Onyx] (called <i>Camea</i> , cameo)	So called from its resemblance to a human fingernail [unguis]; it is tinged with a black-and-white color, and marked with lines of various colors; it is opaque.	It is good against epilepsy, and for the eyes; it is apt for striking fire; rubbed, it grows warm to a remarkable degree.
Opal [Opalus]	The most beautiful of gems, for the variety of colors it displays in its transparency, after the manner of the rainbow [Iris].	It has the powers of all gems; it refreshes the heart.
Phengites [Phengites]	So called from the transparency of its light; it is a species of transparent Oriental alabaster.	It has the common power of the marbles.
Phrygian stone [Phrygius Lapis]	So called from Phrygia, where it is found; it was formerly useful for dyeing garments.	It is astringent, it cleanses, it raises crusts [over wounds]; it benefits the eyes.
Porphyry [Porphyrites]	A very hard marble, sprinkled in red with white spots; it takes its name from its redness [rubedo].	It is of little use in medicine.
Prase [Prasius]	So called from the color of a leek [prasum]; it is mixed of green and yellow color.	It is good against poison; hence in the presence of poison it is said to lose its color, and when washed to recover it.
Pyrites [Pyrites]	It is a stone, which they also call <i>Mareasites</i> [Marcasite], apt for	It has a drying power, applied in the form of a plaster.

Name	Form, Color, Places of Origin	Powers and Properties
	striking fire.	
Ruby [Rubinus]	The ruby differs from the carbuncle and the pyropus in name only.	It is good for driving off poisons; it is a noble antidote.
Sapphire [Saphyrus]	It is a blue and transparent gem; it is found not only in India, but also in Europe.	A remedy for the heart; it is said to grow foul when worn by an impure man given over to luxury. It resists poisons.
Sarcophagus [Sarcophagus] Asius	So called because it quickly consumes the flesh of a corpse buried in it.	It soothes gout; licked, it benefits consumptives.
Sard [Sardius], or Carnelian [Corniolus]	So called from blood-red flesh [caro], whose color it resembles. It is semi-transparent; it is found of good quality in Sardinia.	It wonderfully stanches blood; it gladdens the spirit; it is good against malignant fever; it whitens the teeth.
Schist [Schistus Lapis], Selenites	Every stone that splits into flakes is called <i>Schistus</i> ; under this name especially the one from Lavagna [Lavagna] is meant.	Physicians do not know the use of this stone; it contains much copper.
Emerald [Smaragdus]	The most beautiful of green gems; the Scythian kind is of the better sort; there are many species.	It resists poisons; it heals diarrhea and all fluxes of blood; it is good for epileptics.
Smiris [Smiris] (emery)	It is reckoned among the species of bloodstone; of an iron-rust color, very hard; it takes its name from the polishing	It has no use except that it is employed for polishing gems.

Name	Form, Color, Places of Origin	Powers and Properties
	[poliendis] of gems.	
Talc [Talcum], Earth-star [Stella Terrae], Sideritis	It got its name from the Arabs; it is splitable into thin and very fine leaves, and is more transparent than any glass.	The water distilled from it serves to whiten women's skin; it resists fire; it is a species of sideritis and of asbestos.
Theamedes [Theamedes]	It is nothing other than a magnet [magnes]; for they supposed that iron does not attract but repel.	Both effects the magnet produces. See our <i>Magnetic Art</i> [Kircher, <i>Ars Magnetica</i>].
Thracian stone [Thracius Lapis]	It is scarcely distinguished from jet [Gagates].	About which [we have treated] more fully above.

The TABULA COMBINATORIA of gems continues from the preceding pages with its final entries.

Name	Form, Color, Native Places	Powers and Properties
Topazius [topaz]	It is a species of chrysolite; it reflects a color like water tinged with saffron. It is named from the island of Topaza in the Red Sea, where it is found.	Good for melancholy, epilepsy, and a flux of blood.
Tophus [tufa/pumice]	A common pumice stone, rough, and easily breaking down into sand; it is divided into various species.	Said to relieve gout [podagra].
Trochites [trochite]	So named from the shape of a wheel; found throughout the mountains.	Its use is not yet known to physicians.

Name	Form, Color, Native Places	Powers and Properties
Thurcois, Turchesia [turquoise]	Among the opaque gems the most noble, of a sky-blue color which they call ultramarine, and most brilliant; it is born in Samarkand [Samarcanda], a province of Hither Tartary.	Applied for the care of the head and the eyes. Magicians claim it wards off falls.

And these are the principal species of stones found in the natural world, to which all the rest are referred.

TABULA

Of those stones which take their name from the resemblance of the things they recall, or from the things themselves transformed into stones.

The following stones derive their name either from a resemblance to something, or from the very things that have been changed into stone:

- **Astroides**, from its resemblance to a star.
- **Amygdaloites**, so named from the shape of almonds, such as are found near Albula at Tibur [Tivoli].
- **Ammochrysus**, from its resemblance to golden sand.
- **Argyrites**, from the silver color it reflects.
- **Anthracitis**, from its resemblance to coals.
- **Bostrychites**, so named from the shape of women's tresses; also called **Callitriches**.
- **Bucardia**, a stone arising in Babylonia, so named from the horn of an ox — better called **Bucardia** [Greek: βεκαρδία (bekardia / boukardia, "ox-heart")].
- **Botritis**, so named from its resemblance to a budding grape-cluster.
- **Calamites**, takes its name from its resemblance to a reed [calamus].
- **Ceraunites**, ἀπὸ τῶν κεραυνῶν [Greek: apo tōn keraunōn, "from the thunderbolts"], named from the lightning-bolt.

- **Cantharias**, from its resemblance to a beetle [scarab], which it reproduces in shape.
- **Batrachias**, from its resemblance to frogs, which it reproduces.
- **Capnites**, named from the color of smoke.
- **Cardisce**, from the figure of a heart, which it renders in its natural shape.
- **Cerites**, from the color of wax, which it reflects.
- **Chalaxias**, from the figure and color of hailstones.
- **Carcinus**, from the figure of a crab, which it reproduces, turned into stone.
- **Cepoides**, from gardens, on account of the variety of its scents.
- **Catoptrices**, from mirrors, because it displays images of things.
- **Calcophonus**, because when struck it gives out the ringing of bronze.
- **Conchites**, from the shape of a shell.
- **Cissites**, from the leaf of ivy.
- **Corallites**, from the form of coral.
- **Chethrites**, from the pit of the alder or almond.
- **Clenites**, from its resemblance to a comb [pecten].
- **Chrysitis, Chrysolampis, Chrysolithus, Chrysophis, Chryselectron, Chrysoprasus, Chrysoberyllis** — all named from their golden form, resemblance, and color [Greek: χρυσοῦς (chrysous, "golden")].
- **Dendrites**, from its resemblance to trees, which it reproduces.
- **Daphnia**, from its resemblance to laurel [laurus] and its color.
- **Dactylus Idaeus** [Idaeon dactyl], from its resemblance to a thumb.

The list of stones named for resemblance continues:

- **Dryites**, from the trunks of oak-trees.
- **Echinites**, from its resemblance to the sea-urchin [echinus].
- **Echites**, from the color of a viper.
- **Elatites**, so called from the color of the fir-tree.
- **Hepatites**, from the color of the liver.
- **Geranites**, from its resemblance to a stork or crane, in beak or eye.
- **Galactites**, from its resemblance to milk.
- **Haematites**, from blood, whose color it reflects.
- **Hieracites**, from the eye of a hawk.
- **Hexagonus**, from its shape, and it is a species of crystal.
- **Leontias**, from the color of a lion's hide.
- **Lepidotes**, from the scales of the fish of this name.

- **Meconites**, from its resemblance to poppy seeds.
- **Molybdos**, from the form of lead.
- **Myrrhsimites** [Myrsimites], from the scent of myrrh.
- **Myrmecites**, from the form of an ant naturally set within it.
- **Myites**, from its resemblance to a mouse.
- **Narcissites**, from the form of the narcissus flower.
- **Ostreites**, from its resemblance to oysters.
- **Pyrene**, from its resemblance to the kernel of an olive.
- **Pangonius**, so named from its many angles.
- **Panis Daemonum** [demons' bread], from its resemblance to bread.
- **Pentexoche**, from its resemblance to the medlar [mespilus].
- **Pentagonus**, from its resemblance to five sides and angles.
- **Polytrix**, from the form of hair.
- **Polyzonos**, from its resemblance to belts [zonae].
- **Pisolithus**, from its resemblance to peas [pisa], whose likeness it expresses.
- **Pardalios**, from the spotted hide of the leopard [pardalis].
- **Polia Spartopo**, from the color of grey hair.
- **Perdicites**, from the color of partridges.
- **Phycites**, from the color of seaweed [alga].
- **Phoenicites**, from the color of the palm or date.
- **Rhodites**, from the color of roses.
- **Scarites**, from the color of the mullet fish [mullus].
- **Scalopendrites**, from the figure of the worm called scolopendra, which it displays.
- **Sycites**, from the figure of a fig [ficus].
- **Spongites**, from the figure of a sponge.
- **Syringites**, from the figure of a pipe [fistula].
- **Stelechites**, from the figure of a trunk or stem.
- **Steatites**, from its resemblance to fat [adepts].
- **Tillinites**, from the tellins, a species of oyster.
- **Triglites**, from the color of the mullet fish.
- **Taites**, from its resemblance to a peacock in its colors.

Almost all stones take their names either from the resemblance to the countless things which Nature paints within them; or from the solid figures of things changed into stone; or from the parts now of men, now of animals; or from the

color of things, with which they are imbued; or from sound, scent, taste, or touch; or from the effect they have on diseases; or finally from their contents — as those called *enhydros*, which hold water within themselves. For since there is almost nothing in the natural world that cannot, when a petrifying juice is added, be converted into stone, it is no wonder — given trees, flowers, branches, leaves, shrubs, herbs, fruits, seeds, animals and their parts, and various artificial things turned into stone, as is established from what precedes — that as many kinds of stones are found as there are different things that have been transformed into stones. From these things, too, they obtain their names, as the Table demonstrates.

CAPUT VII.

On the twelve stones set in the Breastplate [Rationale] of the High Priest, and in the foundations of the Apocalyptic City.

Lest anything should seem to be lacking in this Treatise on Stones, I have added this chapter on the twelve gems set in the High Priest's Breastplate [Rationale] in a fourfold order. Just as countless authors and interpreters of Sacred Scripture have treated these matters most fully, so too, since each one describes them according to his own opinion, they have fallen into such confusion

I shall be reckoned, and deservedly, to be wasting my time. How great the diversity is among the authors will be plain from the following table, in which I have arranged the opinions of the Latins, the Greeks, the Hebrews, and the Arabs.

Latini [Latins]	Rabbini [the Rabbis]	Graeca Lectio 70 Interpret. [the Greek reading of the 70 Translators]	Paraphrasis Chaldaica Onkelos & Jonathae [the Chaldee Paraphrase of Onkelos and Jonathan]	Nomina Arabica [Arabic Names]
Sardius.	האודם — Carniola.	σάρδιον [Greek: sardion]	סמך — Sardius,	احمر [Arabic: aḥmar, "red"]
Topazius .	הפטדה — Topazius.	τοπάζιον [Greek: topazion]	ירקן — Topazius,	احصص [Arabic: aḥṣaṣ [?]]
Smaragd	הברקת —	σμάραγδος	ברקן —	اصغس [Arabic:

Latini [Latins]	Rabbini [the Rabbis]	Graeca Lectio 70 Interpret. [the Greek reading of the 70 Translators]	Paraphrasis Chaldaica Onkelos & Jonathae [the Chaldee Paraphrase of Onkelos and Jonathan]	Nomina Arabica [Arabic Names]
us.	Ceraunia.	[Greek: smaragdus]	Smaragdus,	aṣghas [?]
Carbunculus.	— הנפך Carbunculus.	ἄνθραξ [Greek: anthrax]	— אזמרגדן Carbunculus,	اڤڤاك [Arabic: akḥak [?]]
Saphyrus.	— הספיר Saphyrus.	σάφειρος [Greek: sapheiros]	— שבזיו Saphyrus,	مها [Arabic: mahā]

Amethystus.	— האחלמה Onyx.	ἀμέθυστος [Greek: amethystos]	— עין אגלא Amethystus,	ازرق [Arabic: azraq, "blue"]
Chrysolithus.	— התרשיש Chrysolithus.	χρυσόλιθος [Greek: chrysolithos]	— כרום ימא Chrysolithus,	بلور [Arabic: billawr, "crystal"]
Onyx.	— השוהם Smaraldus.	βήρυλλος [Greek: bēryllos]	— בורלא Onyx. perla,	يسف [Arabic: yasf [?]]
Beryllus.	— היספרה Iaspis.	ὄνυχιον [Greek: onychion]	— פנתרי Beryllus.	بلور [Arabic: billawr, "crystal"]

The arrangement of the twelve stones in the Breastplate according to the mind of the Rabbis.

	1.	2.	3.
Primus Ordo [First Row]	אדם. Sardius — Ruben.	פטרה. Topazius — Simon.	ברקת. Ceraunia — Levi.
Secundus Ordo [Second Row]	נפך. Carbunculus — Judas.	ספיר. Saphyrus — Issachar.	חלום. Adamas — Zabulon.
Tertius Ordo [Third Row]	לשם. Turchesia — Dan.	שבו. Hyacinthus — Nephtali.	אחלמה. Onyx — Gad.
Quartus Ordo [Fourth Row]	תרשיש. Chrysolithus — Aser.	שהם. Smaragdus — Joseph.	ישפה. Iaspis — Benjamin.

And this is the arrangement of the twelve stones in the Breastplate, according to the names of the twelve tribes of Israel, following the mind of R. Abraham Ben Hanasse [Rabbi Abraham ben Hananiah / the *Shiltei ha-Gibborim* author], who sets out fully the mysteries of each in his book which he calls *Scutum Fortium* [*Shiltei ha-Gibborim*, "Shield of the Mighty"] — to which I refer the reader. The said author asserts that all the gems of the Breastplate were transparent and most resplendent. Since, therefore, many opaque gems are reckoned in this Breastplate — such as turquoise [Turchesia], jasper [Iaspis], and ceraunia — either it must be said that these were of another species among our own, namely transparent ones, or it must be judged that they were of such smoothness that they produced the same effect as the transparent ones. The reason for this they explain under the *Urim and Thummim*.

Now these were the effects of the stones, by whose illumination the Priest was led to the knowledge of a thing to come; and through the *Thummim* the matter was infallibly accomplished by divine revelation. But because few of the interpreters of Sacred Scripture have rightly grasped the effects of the *Urim and Thummim*, I have thought it well to unravel them here. R. Abraham Ben Hanasse, in the book cited just above, sets out the argument concerning the *Urim and Thummim*, gathered from the rabbis of better repute. This argument, which I myself have translated from Hebrew into Latin, I here present to the curious reader, in as few words as I am able. The *Urim and Thummim* under the old law are nothing other than the holy names of God, engraved on the twelve stones, by whose power and might the Priest knew things to come and announced them to everyone

that they may scarcely agree, one with another; and to whom one ought above all to subscribe, I can scarcely discern. The names of these stones I do indeed find aptly placed in the various texts of Sacred Scripture — Hebrew, Chaldee, Syriac, Arabic, Greek; yet what they really are, and how they may be compared with our own, is hard to conjecture. Out of all the rabbis whom I have consulted, I find that R. Abraham Ben Hanasse has written best on these matters, in the book which is entitled שלטי הגבורים *Schilte beggiborim* [*Shiltei ha-Gibborim*]. *Scutum Fortium* [*Shield of the Mighty*] it is titled; and from the Chaldee Targums and the other texts and authors of better repute, he determines very nearly the truth — although he himself seems to despair of penetrating the substance of the matter.

[Hebrew: ויראת מכל וכל מיני אבני הרציון לפי שאיני יודע (?) בעצמות מה הוא פטרה — a Hebrew citation; "Yet I am in doubt about all the kinds of stones of the Breastplate, since I do not know in their substance what this *Peteda* is..."]

Nevertheless, I am in doubt about all the kinds of stones of the Breastplate, since I do not know in substance what this אודם *Odām* is, what this word פטרה *Peteda* is. For when I examine Onkelos and Jonathan, the Chaldee paraphrasts, I have found them all perplexed in this argument.

[Hebrew: כל המפרשים ובעלי הקבלה אומרים (?) שאין ביניהם אלא הבדל מקרה — a Hebrew citation continuing the argument.]

Some of the interpreters hold that the stones are to be taken only according to their accidents, not according to their substance — namely, *Odām* and *Peteda* from their color, red and yellow. Many think that one of these stones is specifically distinguished from another, but they are mistaken, since the difference between them is only accidental, and a matter of more and less. He then enumerates all the precious stones, in that order in which they were placed in the Breastplate, and according to the mind not only of Sacred Scripture, but also of the paraphrasts and the rabbis of better repute.

[Margin: 10. / XI. / 12. — running marginal numerals keyed to the entries below.]

The twelve stones now follow, each headed by its Hebrew ordinal letter (א-יב):

[.1] א [Hebrew: האודם או הקרניאלה על שם הבשר דהיא אבן אדומה דומה לבשר האדם] The first stone of the Breastplate was *Odām*, that is, Carniola [carnelian], and it was a red stone, like the color of human flesh — flesh-colored.

[.2] ב [Hebrew: הפטדה או טופאציאו והיא של מינים הא' צבעו והוא ירוק] The second is called *Peteda*, or Topazius [topaz], and it is of two kinds: the first inclines toward a golden color, the second toward green.

[.3] ג [Hebrew: הברקת או כרבנוס שנקרא מפני שהוא יורד לארץ עם הברקים] The stone *Berecket*, that is, *κέραυνός* [Greek: *keraunos*, "thunderbolt"], *ceraunia*, beautiful and transparent, inclining from green toward sky-blue — so called because it is cast down to the earth with lightning and thunder.

[.4] ד [Hebrew: הנפך או כרבונקולוס ונקרא בשם זה על כי הוא דומה לאש המוצת בפחם] The stone is *Hanephech*, that is, *carbunculus* [carbuncle], so called because it is like the fire that comes from kindled coals.

[.5] ה [Hebrew: הספיר או הצאפירו וצבעו הוא נוטה לירקות הכרכוס ודומה להבונים] The fifth stone was *Saphir*, that is, *Saphirus* [sapphire], and its color inclines from saffron-yellow toward sky-blue, like the splendor of the firmament.

[.6] ו [Hebrew: ה[?]החלום או הדיאמנטו והיא אבן ירקה השובה ישבע הנם] *Hahalom*, that is, *Adamas* [diamond], is the most worthy and precious of all gems, uniquely desired.

[.7] ז [Hebrew: הלשם או הטורקואיס הוא במעלה כבה בין כל חפצי הא] *Halescham*, that is, *Thurcois* or *Turchina* [turquoise], is a green stone inclining toward a sky-blue color, a praiseworthy gem, in comparison with which gold and silver are nothing.

[.8] ח [Hebrew: השבו או ההיאצינטו הוא אבן הדומה כמען לפוח שחו היאינטו והוא משתה] *Haschabo*, or *Hiacynthus* [hyacinth], is a stone that took its name from the hyacinth flower, with a color of gold and grassy-green inclining toward sky-blue.

[.9] ט [Hebrew: התרשיש או קריסוליטו הוא אבן של ארבע מינים] The ninth stone is *Tharsis*, and it is *chrysolithus* [chrysolite], of which there are four species, that is: Arabian, German, Indian, Ethiopian — which he says are all imbued with differing colors.

[.10] י [Hebrew: השוהם או סמיראלדו והוא בכל האבנים הטובות השלי] The stone is *Hafchoham*, that is, *Smaraldus* [emerald], and among all stones, for price and dignity, it occupies the third place, on account of its most limpid greenness, most pleasing to the eyes.

[.11] יא [Hebrew: האחלמה או אוניקו הוא של מינים רבים והוא של חמי] The eleventh stone is *Haclamah*, *Onyx*, and it is of five kinds, all of which are imbued with diverse colors.

[.12] יב [Hebrew: היספרה או אספס והוא עשרה מינים] The twelfth stone is *Iaspis* [jasper], which is divided into ten kinds, of marvelous variety.

And these are the twelve stones inserted into the Breastplate according to the opinions of the rabbis. But which of these they properly are in their own substance is as hard to affirm as it is hard, among so many kinds into which they are distinguished, to determine the truth. And just as among the authors the dispute hangs unsettled to this very day, so too, together with St. Jerome [S. Hieronymo] and the other interpreters of Sacred Scripture, in unraveling an argument entangled with countless difficulties, deservedly...

[p. 86, conclusion of] CAPUT VII — Urim and Thummim

the things that were to come. Its power consisted chiefly in two things. The first was that, by its own intrinsic power, it illuminated the letters of the tribes engraved on the stones of the Breastplate [Rationale]—which is why it was called אורים [Hebrew: Urim], that is, "illuminations," because by the power implanted in it, it illuminated the eyes of the priest. The second was what was called תומים [Hebrew: Thummim], that is, "perfections," and consisted in this: that it exerted its powers upon the heart of the priest, who then, from what he had learned through the illumination of the stones, drew out by the secret reasoning of his mind—from the combination and fitting connection of words—voices proportioned, by way of answer, to the question that had been put. For by the power of these names the heart of the priest was made apt to recognize the letters; and in the power of the Holy Spirit, which came into him, there came into his heart the conjunction and linking of the letters, by which the work of prediction was accomplished in this manner.

The Urim did not illuminate all the letters in a single compartment, but, by the power of the Thummim, it illuminated only the first letter, and afterward the second letter, without any mixing or confusion. By considering them one after another according to the first, or the last, or the middle letter, the priest knew how to draw out voices, through the collection of the letters and the manner of their resemblance, so as to make manifest what was to happen.

For example: when Israel asked of the Lord, "Who of us shall go up against the Canaanite, to begin the war with him?", the Lord answered, יהודה יעלה, "Judah shall go up." And then the Urim illuminated, as it were, the whole name *Iehuda* [Judah] from the stones existing in the Breastplate. But the word יעלה was understood by the priest in this manner: first there was illuminated, in יעלה, the first letter י (*Iod*) of the name of the tribe יששכר *Issachar*; then the ץ in the middle of the name of the tribe שמעון *Simon* [Simeon]; then the third letter ל in the first letter of the name of the tribe Levi—and so on with the rest. In this way, from the

joint illumination of the names of the tribes of Israel, the priest gathered the voices that showed what was to be done.

But these things, since they are merely flimsy conjectures resting on no foundation, deserve no more credence than fables; so let it suffice merely to have set out their opinion here.

SECTIO IV — DE ANIMALIBUS SUBTERRANEIS

[Section IV — On Subterranean Animals]

PRAEFATIO [Preface]

The condition of subterranean animals can be considered under four heads. [Margin: The fourfold kind of subterranean animals.] There are some that always live in the bowels of the earth. There are others that do indeed dwell within the earth, but now and then break out to the surface to get the food they need, and presently return to their hidden lairs. There are still others that hide away in the winter season, but in summer burst out from their caves and pass a six-month span of life in sunny spots—whether in woods, in fields, or on inaccessible mountains. Nor are there lacking some that, after they have lain hidden for a while in the earth's secret passages, come out and never return to their abandoned dwellings. I shall treat of each, as far as may be, in few words.

CAPUT I

On certain animals which, just as they cannot live outside the earth, so dwell perpetually in its hidden bowels.

Among animals of this kind, first are certain ones that are easily born from putrid matter. The living things of this kind can be considered under a threefold class. First, all the genera of worms that they call earthworms [lumbrici terrestres], which take their origin from the slimy and putrid mud of the earth. Second, there are certain perfect animals, such as fish, serpents, and fossil frogs, which now and then are encountered in the heart of rocks when these are split open.

[Margin: Fish and frogs and fossil toads.]

There is, on the testimony of Agricola [Georgius Agricola], in the Narbonese region [Narbonensis Ager], which lies between the Pyrenees mountains, a maritime plain of fields, watered by various rivers, in which living fish are not

infrequently dug up near the surface. There is found there too a certain kind of exceedingly porous rock, from which millers are accustomed to make the grinding stones used for grinding grain; and in the middle of these, when they are split open, they very often find living toads. Hence great care must be taken not to fit such stones, at first, for the mill without proper examination, lest, when they have grown hot from continuous turning, the toad lurking somewhere inside spread its poison through the grain.

[p. 87] DE ANIMALIBUS SUBTERRANEIS

Agricola also teaches, in his book *On Subterranean Living Things* [*De Animantibus Subterraneis*], that fish of this fossil kind, and frogs, and even serpents, have been found in this way in Germany. [Margin: How animals of this kind are born within the rocks.] Since, then, experience shows that the matter is so, someone might rightly come to doubt at this point: how have animals of this kind penetrated into the very middle of the rocks and the earth, and how can they live there? To make this clear, I will begin with fossil fish, some of which are still found alive in certain places, while others have been turned into stony substance. About this kind of fish and their origin I have treated extensively in the preceding pages; it remains for me to say something about the living ones as well.

Fossil fish are most often found either on the seashore or on the sloping banks of great rivers, among heaps of sand. I say, then, that they can be born there in this way. At the time when the sea, by the force of the winds, rolls huge heaps of sand onto the shores, or when the floods of rivers cast up great masses of mud onto the shores, it can also happen that no small quantity of tiny fish is thrown out together, mixed with the mud and sand. Since these abound in moisture—because of the streams perpetually flowing down from the mountains and channeled there through subterranean veins—it comes about that the little fish, enclosed within the hovels of sand and mud, are in time both nourished and grow up there from sufficient moisture and from the juice of the earth.

But because, when the rivers or seas subside, the earth—mixed with mud and dried out by the heat of the Sun and the constitution of the warm air—puts on a stony crust, [Margin: How they are turned into stone.] hence it happens that certain empty spaces are left behind, as the nitrous mud is contracted and gradually turns to stone by the Sun's heat. And just as these spaces are perpetually filled through the veins of moisture gliding beneath, so too they acquire, together with the juice of the surrounding matter, nourishment sufficient for living. But if they are deprived of all moisture, wrapped about on every side with mud—then, as the mud in the course of time turns to stone (as I

showed in the preceding Book), at length they too are turned into stony substance, retaining nothing but their shape, as is plain from the figures adduced at the place cited above.

It also happens now and then that little ones insinuate themselves through narrow cracks into the rocks for the sake of food, until, settling in a more open place and gradually growing to such a bulk that they can no longer make their way back through those cracks, they are therefore forced to remain there. And this is the other way in which they are sometimes found among the rocks—though experience has taught that living fish are never found without moisture.

In the same way, frogs or toads [rubetae] are sometimes found in the heart of the rock; but I come to the βατραχογένεσιν [Greek: batrachogenesin, "the generation of frogs"], that is, the generation of frogs carried out within the rocks. [Margin: The origin of frogs within the rocks.] Such is the process of nature: if at some time the spawn of frogs is wrapped up in mud somewhere, and meanwhile, as the substance of the mud gradually turns to stone, it has obtained a warm-and-moist cell, fit and well-disposed, the spawn—animated there as in a womb by the force of the subterranean heat—at last brings forth the frog. And this, being supplied with sufficient nourishment, as moisture glides through the pores of the rock, could thus sustain its life for a long time within that cell, until, the stone being cut, it leapt out alive. It is established, however, that such animals, once entrusted to the air, die a little while afterward. What I have said, then, about fish and frogs is to be understood of fossil serpents as well.

Animals of the third kind, which always keep to a subterranean station, are the various genera of moles [Talpae], which have themselves disposed to the open air within the earth almost in the same way as fish to the air within the water: for just as fish cannot continue their life long outside the water, so neither can moles outside the earth. [Margin: The origin of moles.]

Now whether these animals are furnished by nature with eyes, I see many to doubt, for this reason: since they always inhabit the bowels of the earth, eyes would seem to have been granted them in vain, as they pass their days in perpetual darkness. To find out the truth of the matter, I intercepted a mole in my suburban garden and, having carefully shaved its whole head, examined it to see whether eyes could anywhere be detected; and at length I found two minute openings, as if made with a needle. Not yet satisfied with these, however, I stretched out a little the membrane by which they were covered, and then, applying a microscope—the instrument I usually use for examining the smaller things—I detected eyes, exceedingly bright, which had nothing at all different

from the eyes of other animals. [Margin: Moles, contrary to the common opinion, are not blind, but have eyes—exceedingly minute ones, however.]

From this I concluded that the membrane covering the eyes had been granted by Nature so that in their subterranean parts, where they have no need of them, they might not suffer some harm to the eyes from the dust of the earth and the scrapings of the parts they tunnel through; but because they are nevertheless sometimes forced to come up onto the earth, Nature did not wish to deprive them of eyes, for the sake of direction and the protection of life, as in the other animals.

Second. [Margin: What animals inhabit the crypts of the mountains.] There are certain animals which, in the winter season, lie hidden in subterranean crypts, in the caverns of mountains, in the hollows of trees, in the openings of the earth, but in the summer season first come out into the open light, occupied—with truly marvelous foresight—in gathering together the provision of nourishment needed for the winter season. These are either among the insects, or the kinds of mice, or the kinds of birds and quadrupeds. And of the insects—flies, ants, serpents, tortoises, and the rest—being everywhere known, I shall say nothing.

Various genera of mice are reported. [Margin: The various genera of mice.] Among the rest is the Alpine mouse [mus Alpestris, the marmot], an animal of the size of a medium-sized dog, which is found for the most part in the Alps. Throughout the whole winter season it lies hidden within the caverns of the mountains, sunk in sleep; in summer it finally comes out, intent on its provision. Into the caverns they carry a great quantity of hay, as a kind of bedding, so that the mice may rest more comfortably; [Margin: The nature of the Alpine mouse.] but the mouth of the cavern they block up with manifold art, by an interwoven plaiting of twigs, so as not to be harassed by the injuries of the air and the seasons, or by the ambushes of foxes and hares. In these...

[p. 88] LIBER OCTAVUS, Sect. IV

now and then four, five, or six are found asleep. Not undeservedly may the dormice [glires] be counted among these, of whom there is the common saying, "the whole winter is slept away." [Margin: Hedgehogs and porcupines.]

Hedgehogs [erinacei] too, and porcupines [hystrices]—of which the former lie hidden in the winter season not only within caverns but also within the hollows of trees, while the latter are scarcely seen by day, but by night are intent on their dealings. About bears it is everywhere agreed that, as winter approaches, they make for the crypts of the mountains, where for a span of forty days they even indulge in sleep. [Margin: The nature of bears.] That done, they put the toes of

their forefeet into their mouths and, for the rest of the winter, suck them without any other nourishment, growing fat by the sucking; but for the rest of the summertime they come out into the open and pursue the hunt. When they are about to enter their caverns again, they block them up with branches and twigs of trees; and lest their tracks be detected, they insinuate themselves with the body lying on its back through an opening deliberately left there, which they afterward block up from within, as I said of the Alpine mouse. The same is to be said of martens, weasels, squirrels, and countless other animals, for which see Agricola in his book *On Subterranean Living Things*.

Third, among the birds that delight in subterranean places are numbered chiefly screech-owls, eagle-owls [bubones], and night-owls [noctuae], which establish their habitation partly within the caves of rocks and the recesses of old and inaccessible towers and similar places, intent chiefly on their plunder by night. [Margin: Subterranean birds.] There is in the Apennine [range], where one goes from Florence toward Bologna, in a hidden recess of the mountain, a certain great chasm, into which, if you cast a stone, immediately a huge number of jackdaws [graculi]—which they call *cornacchie*—are found to fly out; but after a few flights outside the crater, they at once return to the place they came from. About these see our *Iter Hetruscum* [Etruscan Journey].

Fourth. [Margin: Swallows, and the wonderful things about how they hide.] Marvelous are the things reported about swallows [hirundines]. Most people think that in the autumn season, when the injuries of winter set in, these migrate to warmer regions toward the south; and I do not deny that this is true of some. For, as I have heard from the inhabitants of the Peloponnese and of the rest of the Archipelago, a huge multitude of them crosses the sea every year, together with storks, from the shores of Egypt and Libya; and they report that, when the swallows are wearied with flying, three, four, five, or six of them now and then settle on the backs of the storks; while the storks, in acknowledgment of the kindness, with a continual chattering and song, as it were caressing them, once this gentle and generous conveyance has been gained, make their way back to their former homes.

There are, then, some swallows—chiefly those that dwell not far from warmer places—that migrate from one region into another. But long-standing experience has taught, time out of mind, that those which dwell in regions near the North undertake no such distant journeys, but lie hidden during the winter either in the innermost caverns of the mountains, or in the bottom of lakes, or in the hollows

of trees, or on the reedy shores of rivers and seas. Of these particulars I shall adduce legitimate testimonies.

In Poland the matter is commonly known, and to fishermen nothing is more familiar: when in the winter season, the ice being cut, they let down their nets into the water for fishing, they not infrequently bring up, together with the fish, swallows rolled into a ball, [Margin: In Poland swallows in the bottom of the lakes.] so interlaced by their claws, by a certain marvelous skill, that they can scarcely be separated from one another. When they have brought these, sleeping and as if half-dead, into a heated room [hypocaustum], they are reported gradually to bestir themselves, as if waking from some deep sleep, and a little later even to attempt flight; yet all of them, drawn out before the time appointed for them by nature, do not continue their life.

Agricola too makes mention of this matter, in his *On Subterranean Animals*: that they have been found in the lakes of Germany in the winter season. Pliny [Gaius Plinius Secundus, the Elder] also mentions it, Book 12 [recte: Book 10], chapter 25. [Margin: In the hidden places of the mountains they are found.] "Swallows depart," he says, "in the winter months—the only one, of the birds that feed on flesh, that does so [recte: of the flesh-eating birds, the only one that hibernates]; but in the spring they return; they make for the hidden recesses of nearby mountains, and there they are found already bare and unfledged." [*Natural History* X.] And Olaus Magnus confirms it, Book 15 [recte: 19], chapter 10: "In the Septentrional [northern] regions swallows are often pulled out of the waters by fishermen, gathered into balls—the waters into which they had hidden themselves at the onset of autumn—with such skill that they appear to be linked to one another by their beaks, wings, and the little claws of their feet turned toward each other; and bound together in this fashion, they let themselves down among the reed-beds to the bottom of the lake. And at last, in the spring season, at the time again appointed for them by nature, returning to themselves, each one seeks out its own nest, or builds new ones—if at any time, having been caught, they are brought into heated rooms, they immediately appear to revive and to aim at flight; but these are not long-lived, since they were drawn out before the time. Hence the fishermen, when they have caught such swallows in the winter season, finally commit them back to the waters as an unripe fruit."

Nor are they found only in the waters in the winter season, but also—on the testimony of Pliny, cited above—in the caverns of the mountains. The truth of this matter the people of Tivoli [Tyburtini] taught me, who say that in that wonderful mountain which they call the "Cleft" [Scissum, Monte Scisso]—and which by

tradition they have received was split at the time of the Lord's Passion— [Margin: At Tivoli, in the cleft of Mount Scissum.] when they had led me to it and shown me all the marvels of that impenetrable abyss, they related that a great multitude of swallows nests there, which, by a perpetual circling of flight, enter the mountain on one side and finally go out on the other; nor do they ever withdraw from that mountain or, as the common folk suppose, migrate to other regions, but in the winter months remain there asleep; and a great quantity of them is found, gathered into balls, by boys who go down more deeply into the mountain's inner recesses. See what we set down, worthy of careful consideration, about the marvelous constitution of this mountain in our *Latium*.

There are also swallows which they call bank-swallows [riparias], because they mostly delight in the banks of rivers, [Margin: Bank-swallows.] and these for the most part dwell in the winter months within the fissures of rocky shores...

[p. 89] DE ANIMALIBUS SUBTERRANEIS

Agricola teaches, in the book cited, that they pass the time. [Margin: A wonderful occurrence in Switzerland.] And it has not infrequently been found, by those who seek out the nests of halcyons [kingfishers], that they are there in that very situation which we described above—namely, half-dead. It is a marvel that Cysat [Johann Leopold Cysat] relates in his description of Switzerland [Helvetia]: that when the people of Lucerne were digging the foundations for the building of their town hall, about the time of the festival of Christ's Nativity, they came upon a tunnel, out of which some twenty swallows flew up. This thing astonished everyone, since they could not find out where they had penetrated into so deep a pit. But just as to this very day it is unknown how and where they hide themselves, so too the hidden ways by which swallows tuck themselves away in subterranean places are known to Nature alone, the Mistress, by herself.

From all this, then, it is plain that not all swallows love migration, but only some; while the rest—according to the different species of swallows—hide some in the lurking-places of the mountains, some in the hollows of trees, and most, chiefly in northern regions, let themselves down into the bottom of lakes. So that I cannot sufficiently marvel at the providence of God, Best and Greatest, in directing and preserving animals of this kind. They know most exactly the time at which they ought to withdraw themselves and the time at which they ought to come back. [Margin: How swallows can live within the waters.] But how they can live within the waters or the caverns of the mountains for a six-month span is difficult to find out—unless we say that it is in exactly the same way in which we said above that bears, Alpine mice [marmots], and dormice live: namely, from both the

constitution of their own temperament and the natural juice with which they are swollen.

For even though they appear to have been found dead, they ought by no means to be reckoned dead, since there is no return from privation to possession; but they are only put to sleep, the radical heat within meanwhile working, by the means necessary for preserving the soul, just as we said above of bears and dormice. [Margin: Why they are found almost featherless.] But the reason they are found almost featherless is that the heat, drawn back from the circumference to the center, now destines that matter which otherwise is wont to pass into feathers for the inward nourishment of the animal. And as to their being able to preserve life in the waters, this is to be ascribed to the natural constitution of their temperament. For since life consists in a warm and moist temperament, and the bottom of the lakes is warm in winter—as are also the caves of the mountains—they easily, surrounded by warm moisture, pass their life (unfit and idle though it be for their usual activities) up to the appointed time, until, the external warmth prevailing, they are again roused to their usual activities.

It is a marvel, however, that something similar happens with storks [ciconiae]. [Margin: The same happens with storks as with swallows.] For as Gervase of Tilbury [Gervasius Tilburiensis], marshal of the Kingdom of Arles [Arelate], writes to the Emperor Otto IV [Otto IV], storks were found in a certain lake of Arles clustered together in the manner of swallows. [Margin: In a lake of Arles storks found under the waters.] With this agrees Fulgosus [Battista Fregoso / Fulgosius], Book 1, chapter 6, who reports that similar clusters of storks were found in a certain lake near Metz in Lorraine [Lotharingia].

And these are the things which I have thought ought to be said about the subterranean animals known to us. But about those which dwell in the vastest recesses of the subterranean regions—as being things of which we have nothing ascertained—I deliberately keep silent. Yet that there are both fish and other animals there, various examples teach us. [Margin: Fish in subterranean rivers.] For, as Pliny writes, when a great earthquake had arisen in Greece, the earth opened and cast out a huge quantity of fish together with a river; and these fish without doubt had their origin in some subterranean river. There is too, in Carniola [Carniolia], near Laibach [Labacum, Ljubljana], a vast plain, [Margin: The wonderful lake of Laibach.] out of which every year, in the spring season, so great a quantity of water bursts forth together with fish that within a few days it changes the plain into a lake filled with fish. But these things we have pursued more fully in the first Volume [primus Tomus].

Cysat, cited above, agrees with these things. "Rivers," he says, "such as there are in Switzerland, [Margin: When the rivers are filled with fish from the mountains.] which, rolled out from the caves of the mountains, flow continually from about May until September; but in the remaining time of the year they cease their flow." He adds that the rivers, after the first rolling-out of the waters from the mountains, are at once filled with fish—an open proof that they have burst out, together with the river, from the subterranean waters. Therefore, just as in the subterranean lakes or rivers fish of every kind live, so too we think it not unlikely that other land animals dwell there as well: all the genera of mice recounted above, serpents too, and little dragons [dracunculi], and finally all the rest that draw their birth from putrid matter.

CAPUT II

On Subterranean Dragons.

There is a great controversy among the authors about winged dragons [dracones alati]: whether such animals have really existed in the nature of things, or whether—like many other things—they are to be reckoned among fabulous tales. [Margin: On dragons—the least fabulous of arguments.] For I myself indeed long and greatly hung in doubt whether such animals ever existed; until at last, from the reading of various authors beyond all exception, and indeed from the testimony of eyewitnesses, I let myself be easily removed from this doubt. And since monstrous animals of this kind for the most part have their birth and their nests in subterranean caves, I have thought they ought, as a noble argument of our undertaking, deservedly and by right to be counted among the subterranean beasts.

I am not unaware that a twofold kind of this animal is reckoned by the authors: one winged, the other without wings. About the living things of the latter kind no one either can or ought to doubt—unless someone should perhaps dare to contradict the Sacred Scriptures, which it would be impious to say—since in Daniel 14 [*Daniel* 14, i.e. Bel and the Dragon] mention is openly made of *Bel*, the dragon honored with divine worship by the Babylonians, and in various other places of the Sacred Scriptures mention is made of dragons: "the dragons and all the deeps" [*Dracones et omnes abyssi*, cf. Psalm 148:7]. From which passage it is plainly gathered that animals of this kind... ..that animals of this kind stable in the hidden abysses of the earth, and that, when an exit is granted them, they sometimes emerge from their lairs to the great harm of men and animals.

I now come to profane histories. Aristotle [reports] that in the time of Philip of Macedon two dragons lurked in the caves of neighboring mountains, with such virulence of venom that no one could pass through there without danger to life. But there is no room for doubt about dragons of this enormous size — or rather serpents — since they are found in our own day by various sea-captains everywhere, and most of all in Ethiopia, India, and the other regions lying within the Torrid Zone. To this day a similar dragon, fifteen palms long, dangerous on one side with a double row of teeth, may still be seen at Rome in the Museum of Cardinal Francesco Barberini.

[Margin: A dragon in the Barberini Museum.]

[Margin: Histories of various sorts concerning dragons.]

Concerning winged dragons alone has a dispute arisen among authors, most of whom declare them to be fabulous. But these men are contradicted by the histories of every age and by eyewitness experience. There is no age that has not produced winged dragons — small, large, and very large — in various parts of the earth. See [Girolamo] Cardano (*De Subtilitate* VII.29) on winged dragons, which he says he himself saw in the Museum of Guglielmo Musito at Paris. To this should be added the testimony of [Pierre] Belon [Bellonius], who relates that he saw in Egypt whole carcasses of winged dragons most carefully preserved. They were, as he reports, thick about the belly, with two feet and as many wings, formed like those of bats, with a serpentine tail.

[Margin: Winged dragons of Egypt.]

Indeed, Aldrovandi [Aldrovandus] says that he keeps in his own museum preserved carcasses of dragons of this same stamp, communicated to him by Gabriele Barbaro and Francesco of Crete [Francisco Cretensi], in the year 1551. They were furnished with two feet armed with claws, and with as many small ears; they were covered with green and somewhat blackish scales, and moreover bore wings fit for flying, with a long, twisted tail covered in yellowish scales. Their jaws were armed with sharp teeth; and although these were not of any unusual size, they could nonetheless in time grow to that bulk which we shall describe a little later — for just as crocodiles do, so too monsters of this kind are said to grow continually.

[Margin: Dragons slain by the saints.]

Whoever desires more about dragons, let him read Aelian, Olaus Magnus, Pausanias, and Pliny. And dragons either put to flight or slain by the merits of the

saints, let the reader see among the hagiographers. On the dragon slain in the Tauric Chersonese by the merits of Deipara [the Mother of God], see in Matthias à Michon. In the life of Saint Margaret, on the horrendous dragon killed by her merits, see in [Laurentius] Surius. In the life of Saint Hilarion, on the huge dragon committed by him to the fire, see in Saint Jerome. In the lives of Saints Donatus the Bishop, Joannicius the Abbot, Sylvester and Leo IV, Pontiffs at Rome; Arsacius at Nicomedia; Theodore, Marcellus, Crescentius — in Surius, Metaphrastes, Sozomen, and others, who are all reported to have been destroyers of monsters. Consult likewise Fulgosius, Diodorus, Orosius (IV.8), and Augustine (on Psalm 348 [recte: 348? — Ps. 148 likely intended]). Yet whether all dragons of this kind were winged is not established. Therefore let us now proceed to the histories in which winged dragons are described exactly as being not merely two-footed, but also four-footed.

[Margin: Switzerland once abounded in dragons.]

Gessner first teaches that Switzerland [Helvetia], on account of the very remote recesses of the Alps and the inaccessible nature of its caves, in places never trodden by men and unfrequented — in which [the dragons] take delight — was once inhabited by dragons; and that they were still seen within the memory of our fathers. After him [Johann] Stumpf [Stumphius], and in our own time Cysat [Johann Cysat] in his *Description of the Swiss Towns*, teach the same, so that no one can doubt the incredible truth of these monsters.

[Margin: Switzerland abounded in winged dragons.]

But I come to the other part, concerning flying dragons, which the histories report cleave the air with a mighty rowing of their wings. And to begin with the smaller: that there are winged serpents became so well known to the Egyptians that they even inserted them into their hieroglyphics. Moreover, to this very day, winged serpents come from the regions of Arabia after the flooding of the Nile is over, to devour the insects which are wont to be born in great abundance from the rotting matter of the remaining mud — and Pliny, Aelian, and Solinus confirm this.

[Margin: A winged dragon slain by a hunter in the Roman countryside.]

In the year 1660, in the month of November, a certain butcher of Rome, while he had betaken himself for the sake of fowling to the marshy parts of the maritime shore, suddenly, in the haunt of the marsh-birds, came upon a dragon of the size of a rather large vulture. Taking it for a bird, he discharged his gun against it; and having wounded its wing, he so enraged the beast that at once, partly running,

partly flying, it rushed upon the hunter to avenge itself on its enemy. He then, firing his gun again, so burst open its throat that it immediately fell dead. But whether infected by the virulent flow of its blood or by its breath, the man returned home and died that same night, his whole body suffused with the spreading of green venom. This unusual event, just as it befell the whole city [with wonder], so too a certain more curious person, informed by the report of the dying man, went to the place of the contest and found the dragon already putrefied. Nevertheless, that on his return he might attest to the truth of the deed, he carried off with him the dragon's head — which, while I write this, was brought to me by the most expert Lord Hieronymus Lancia, prefect of the Museum of Cardinal Barberini; and this head, on being diligently examined by me, was found to be the head of a true dragon. [The text continues at the foot of the column and resumes at the next page-top — see below.]

[Margin: A basilisk born from a cock's egg.]

That basilisks are born winged from the egg of an old cock has become so well known in our day that anyone would be reckoned reckless who should too insolently wish to deny it. See what I have treated at length about these in my *Diatribes on the Prodigious Crosses*. Just as some tiny grubs are animated into wings, so too some worms, while by continual eating they grow into a huge bulk, at length — when wings are assumed through the disposition of the matter — pass their lives as four-footed creatures among the winged. And these are those horrendous, winged dragons of which we are speaking. It is read in the life of Saint Mary Magdalene, when she sought a more hidden retreat of solitude...

[The basilisk-head description completing the 1660 Roman dragon — running over from the left column: the head was] furnished with a double row of serpentine teeth set into its jaws; it was two-footed, but, with a contrary position, monstrous, and equipped with cartilaginous feet like those of geese; and it is displayed for inspection, with all [its parts], in my Museum. The Figure of the Dragon is here.

[she] sought [a cave], and, having left Marseille, withdrew to a certain rocky and rugged tract, five leagues distant from there, which today they call Sainte-Baume [Saint Beaume], into the cave of a lofty mountain, into which one could be carried only by the aid of angels. There, when she had come upon a horrendous dragon of unusual size, she straightway commanded it, in the name of Christ, to depart from that place. And it, struck with awe by the holy command, flew off to a deserted spot by the Rhône, where Saint Martha [Sancta Martha] was then dwelling.

[Margin: The cave of Sainte-Baume was at first the lair of the dragon of St. Mary Magdalene.]

[The dragon] departed, and by the help of the same Saint — the inhabitants pressing their prayers because of the enormous harms it was inflicting — it was captured by the Saint, bound with ropes, and led to that place which was afterward called Tarascon [Tarascum]. There it is said to have been killed by the inhabitants — whose history, very skillfully painted in the Cathedral Church, I remember seeing at Tarascon in the year 1632, while I was passing through there.

[Margin: It was killed at Tarascon by the help of St. Martha.]

At this point I shall add two historical relations concerning flying dragons, which are confirmed by so many and such great testimonies that I think no one is of so brazen a brow as to be able to deny them — unless perhaps someone who has resolved to do away entirely with all human credence, which does not befall a man of sound brain. One is found in the *History of Religion of Jerusalem* composed by Saint [recte: not a saint — Giacomo] Bosio [Iohannes Bosio]; the other in the description of Switzerland related by Johann Cysat [Ioanne Cysato]. I shall here briefly recount both.

From Bosio, who in Book 2, page 45, speaks thus:

[Margin: A wondrous history of a winged dragon in the island of Rhodes, slain by Brother Deodatus de Gozon, Knight of Jerusalem.]

In the year 1345, in the pontificate of Clement VI, while Hélión de Villeneuve [Elione de Villanova] was Grand Master of the Order, there happened a thing wonderful and altogether memorable for all ages. There was in the island of Rhodes, not far from the Church of St. Stephen, a huge crag furnished with a vast subterranean cave, from which a stream flowed. In this cave there kept watch a dragon — a monster horrendous, huge, and dreadful to behold — which not only infested the greater part of the Eastern island with great ruin of men and beasts, with unheard-of savagery and enormous destruction, but also so corrupted the air with its venomous breath that no one could approach this shore without manifest danger to life. And so it was decreed by the Grand Master, by public edict, that no one of whatever condition or order he might be should approach the place; the Knights too were forbidden, under penalty of life and of loss of the habit. Hence not undeservedly the name *Malpasso* [Bad Passage] has clung to the place. There was at that time at Rhodes a Knight, a most noble youth, endowed with great fortitude of soul and body, whose name was Deodatus de Gozon [Deodatus de Gozon], sprung from Gascony. He, deeming it unworthy that of so

many high-born soldiers and Knights there should be none who would dare to set himself against the monster to repair such great harms, spurred no less by curiosity than by love of winning immortality for his name, judged that he could never obtain a better occasion than if, by entering upon a new and unheard-of combat with this horrendous beast and savage monster, and by slaying it, he should free the island — oppressed by so many and such great evils — from so great a plague. And he held his mind so firmly fixed upon the resolve of this undertaking that he seemed unable to rest day or night until he had carried into effect the thing he had set himself.

Diagram. A full-length engraved plate of the Rhodes dragon, occupying the lower half of the page. The creature is shown in profile facing left: an elongated, scaled, four-legged body like a crocodile, with a long serpentine tail curling up at the end on the right. The neck is long and serpentine, ending in a head with open jaws from which radiates a large fan-like crest or spray of bristles/spines. A prominent webbed, fan-ribbed wing rises from the mid-back. The legs end in clawed feet. The body is rendered in overlapping scales.

Engraved caption (cursive script, above the figure), verbatim and translated:

- "Hic est Draco ille alatus et quadripes omni ævo memorabilis, quem Deodatus de Gozon Eques Hierosolimitanus, in insula Rhodo eo quo descripsimus stratagemate confecit; qui et ob beneficium in Insulam collatum postmodum Magnus Ord. Magister Creatus est."
- Translation: "This is that winged and four-footed dragon, memorable for all ages, which Deodatus de Gozon, Knight of Jerusalem, dispatched in the island of Rhodes by the stratagem we have described; and who, on account of the benefit conferred upon the island, was afterward created Grand Master of the Order."

[The body text resumes in the two columns below the plate:]

But since he feared the Grand Master's rigid and capital edict, he was wholly occupied with this: by what way and means he might obtain his aim, with no one privy to the secret of his mind. He therefore began the business in this manner: first [he made] the form...

[Margin: The form of the dragon.]

[the form] of the dragon's whole bodily constitution, the diversity of the colors with which it was imbued, he observed by a clandestine approach to the place. The dragon's form was this: its body had the thickness of a great horse or ox; its

long and rough neck ended in a serpent's head; it had ears, rather long, like those of a mule; it was armed with a horrendous gape and very sharp teeth; it had very large eyes, exceedingly bright and as if breathing fire; it walked on four feet equipped with very sharp claws like a bear's; as to its tail and remaining limbs it was altogether like a crocodile. Its whole body was armored and fortified with a crust of very hard scales intricately arranged. It was equipped with two cartilaginous wings extended at the sides, of a color not unlike the gills of a dolphin — bluish on the upper part, and on the lower imbued with a reddish-yellow mixture — with which color the whole rest of the body too was variously tinged.

[Margin: Swiftness of its running.]

It was borne along with so swift and rapid a motion that there was no horse of such speed as could, by however swift a run, escape its swiftiness; so that it seemed partly to fly, partly to walk on its feet — which, when it happened in the search for food, both by the rattling of its shell-like scales and by a horrendous hiss, perceptible far and wide, almost killed with fear and dread even those at the greatest distance. You have here the form and actions of the dragon, in the manner in which I have recounted them, observed most exactly by Brother Deodatus of Gozon, the Knight.

[Margin: Deodatus's wonderful ingenuity.]

And so the Knight, without delay, having sought leave from the Grand Master, departed to his homeland under the pretext of settling domestic affairs. There, without postponement, he made a dragon of paper and Rhodian tow [stuppa Rhodensi] — whether you regard the variety of the colors or the lines of the limbs of the whole body — utterly similar and equal in size [to the real one]. Then to this end he bought a horse, as high-spirited and fit for war as he could, to which he joined two very powerful dogs, which they call English [mastiffs]. These things being now prepared, he ordered the tow-dragon to be entered by servants appointed to this office, and to be moved aptly now here, now there; by whose help, by means of little cords, now the horrid gape of its mouth was opened, now its tail was twisted in various directions, now by the clapping together of its wings it offered a wondrous spectacle of itself, like a living dragon. Deodatus meanwhile, with a feigned and pretended assault against the dragon, urged on now the horse, now the dogs.

[Margin: Preparation of the knight for the contest against the dragon.]

And when he had drilled himself in this exercise for the space of two months, the horse and dogs, trained to every effort, were held by so great a desire and itch for fighting that, at the sight of the fictitious dragon, they could scarcely any longer be restrained by the reins. Whence, now confident of the happy outcome [Greek: δρακοντομαχίας (drakontomachias, "dragon-fight")], he put an end to the masquerade combat, and without any delay began his journey toward Rhodes together with the horse, dogs, and servants. Scarcely had he reached Rhodes when, behold, putting his long-conceived design into execution without delay...

[Margin: Speed of its course.] ...with great fortitude of soul, he entered the cave, the dragon's lair; and when he perceived nothing stir, by a shout and din raised to rouse the beast — and when from that horrid hiss and the rattling of scales he had noticed the deadly monster approaching from the inner recess of the cave — he at the same time also advanced into a plain, a place suited for the fight, and awaited the monster. At length, the monster, on seeing the Knight, enticed by hope of rich prey, began to rush upon him with great force at a most furious run and flight. But the Knight's adversaries [the dogs and horse], trained and habituated to overpowering the dragon and thus also fearing nothing of the horrid sharpness of the monster, attacked the dragon at the part where it was possible. The Knight meanwhile, charging, drove his brandished lance so forcefully against the hard crust of the dragon that, at the very first blow, the lance was shattered and he was deprived of the chief support of his arms.

[Margin: The dragon's lair is entered.]

And since the dogs, having seized its genitals, were tormenting the beast in a wondrous manner, and since the beast, in defending itself against the dogs, thereby also left the Knight some little time to renew the contest, he therefore, armed with sword and shield, judging it more convenient to attack in a foot-combat, dismounted from his horse. When the monster noticed this, it at once stood on its hind feet, and, reared up, tried to crush the Knight with its left and the shield with its right, with the horrendous claws with which it was equipped. The Knight, having found out the softer part of its neck, drove his sword in so forcefully that thereupon he at once drew out a great quantity of blood. And since, from the pain by which it was oppressed, the beast was driven into a frenzy, the closer it brought itself to its competitor, the deeper he drove the sword into its vitals, until, with the sword cutting like a saw by repeated slashing here and there, he opened up the whole neck.

[Margin: The combat with the dragon.]

[Margin: The death of the dragon.]

And this done, the monster, weakened by an enormous flow of blood, falling down, with its own bulk so pressed down upon the Knight — exhausted both by the labors of the horrendous combat and intoxicated by the great stench which it exhaled from its opened body, and now failing in strength — that he seemed almost lifeless. Seeing this, the servants, mindful of the instructions given them, immediately left the crag and, with horse and dogs, [hastened to their] laboring [master]...

[Margin: ...the master laboring with the dragon.]

flew to bring help to their laboring master, and now drew out their lord, almost lifeless and oppressed, the beast having been removed; and because they still noted some signs of life in him, they continually poured cold water, brought in their caps from the neighboring stream, over the whole body of their master. He, then restored with cordial fomentations, when at last, his strength gradually recovered, he had come to himself, mounted his horse, and, returned to the city after a glorious victory, narrated the deed in order to the Grand Master.

[Margin: Deodatus de Gozon is restored by cold water.]

And where he hoped for great glory and reward from a deed so profitable to the public good, there he met with the contrary throw of fortune's die. For the Grand Master, having convened a council, with public reproof both of his rash and presumptuous audacity and of his violation of the rigid edict, and, having stripped him of his Knight's habit as an example to others, consigned him to a grim prison. Meanwhile, the killing of the dragon having been published throughout the island, there arose everywhere great applause at the high-born Knight's resolve, and congratulation at the island's deliverance from so great a calamity as the horrid and insuperable monster had inflicted on it; the Knight's praise resounded through the whole island. Moved by these things, the Grand Master, having considered the Knight's immense merits, not only restored his habit, releasing him from prison, but advanced him to the first grades of the Order's dignity.

[Margin: Deodatus de Gozon is chosen Grand Master of the Order.]

Raised to which station of dignity, he gave such proofs of prudence and of fortitude of judgment and spirit in dexterously expediting difficult affairs that, after four years, when the Grand Master Hélión de Villeneuve had departed [this life] for the [debt owed by] all, he was chosen by all the votes and ballots as

successor in the Grand Mastership. In whose praise these inscriptions are even now carried around, on the testimony of Hieronymus de Megistero [Girolamo Maggi]: "Deodatus de Gozano, slayer of the dragon — Master of Province III. After the dragon was destroyed, before he became Master." The other, subscribed beneath his effigy, runs thus: "Brother Deodatus de Gozano. This man strenuously slew the snakes of immense bulk, which were terribly devouring the wretched inhabitants of Rhodes in their coils; thereafter he was created Master, in the Year of the Lord 1349." These things, perhaps more fully than was fitting, I have thought should be set forth, so that, from a history known to all, men of stupid head [the skeptical] might learn to believe that winged dragons both have existed in the nature of things, and even now exist.

The figure of the dragon together with the contest, which the most illustrious Knight of Malta communicated to me, I have thought should be appended here.

[Margin: Deodatus is chosen Grand Master of the Order.]

Aldrovandi relates that, a little before Hugo Boncompagni [Boncompagnus], Cardinal, raised to the Pontificate, shone forth to the Christian world under the name of Gregory XIII, a dragon was found in the territory of Bologna [Agro Bononiensi], of the figure that follows — concerning whose origin and genesis we shall reason more fully elsewhere in this work.

Diagram. An engraved plate of the Bologna dragon, occupying the central portion of the page. The creature is shown in profile facing left: a long, slender, serpentine body with a single pair of legs (two feet) and a long neck. The back and body are covered with overlapping scale-plates rendered in detail; the underside of the neck shows ridged/banded scaling. The tail is long, slender, and serpentine, looping behind. No wings are shown — consistent with the caption's "wingless and two-footed."

Engraved caption (cursive script, above the figure), verbatim and translated:

- "Hic Dracunculus ἄπτερος καὶ δίπους paulo antequam Hugo Boncompagnus Card. ad Pontificatum assumeretur sub nomine Gregorij XIII. Bononiæ captus etiamnum in Musæo Aldrovandi tomento fartus spectatur."
- Greek terms in the caption: [Greek: ἄπτερος (apteros, "wingless"); δίπους (dipous, "two-footed")].
- Translation: "This little dragon, wingless and two-footed, captured at Bologna a little before Hugo Boncompagni, Cardinal, was raised to the

Pontificate under the name of Gregory XIII, is still to be seen in the Museum of Aldrovandi, stuffed with padding."

[The body text resumes in the two columns below the plate:]

And since for the incredulous one history heard does not suffice, I shall append another, no less worthy of admiration, which Cysat teaches in his description of the four Swiss forest-cantons [*De quatuor Helvetiorum Sylvaniarum civitatum descriptione*], in a book printed in the German language, which Johann Cysat the Swiss [Ioannes Cysatus Helvetus] some time ago made public. There he teaches by many examples that nowhere has a greater abundance of dragons of this kind appeared than in Switzerland.

[Margin: A flying dragon seen in Switzerland in the year 1619.]

And when, not long ago, I consulted by letter the noble man Christoph Schorer [Christophorum Schorerum], prefect of the territory of Solothurn [Soloduri], concerning the truth of these histories, he confirmed — not only on the strength of that experience of affairs in which he is skilled — that they are most true, but also wrote that he had ascertained the truth of the matter with his own eyes, in these words:

"On a night in the year 1619, while I was contemplating the serenity of the sky, behold, I saw a brightly-glowing dragon, from an immense cave of the mountain which the natives commonly call Pilatus [Pilati], fly across with very swift motion of its wings to another part on the opposite side of the lake, to the cave which they call Flue. Its form was very large, with a long tail and an outstretched neck; its head ended in a serpent's jagged gape; while it flew, it scattered sparks from itself, not otherwise than when men beat glowing iron on the anvil. At first I supposed I was seeing some sort of meteor, but after [I had] diligently..."

— from which it cut through the softer part [of the beast's body] with a blow and at last finished off the beast. But when, in his joy, he was now flinging high into the air the sword still wet with the dragon's blood, the venomous blood, flowing down inside the bared flesh, proved to be of such virulence that the man—who already believed himself the victor—was instead overcome by the dragon's own blood, and shortly afterward died. I have judged it fitting to insert here a depiction of the dragon sent to me from Switzerland.

Diagram. A full engraved plate of a Swiss dragon: a two-legged, winged creature in profile facing left, with a long-jawed crested head and gaping toothed maw, a serpentine neck and body covered in scales, a broad ribbed bat-like wing raised

over the back, two clawed forelegs, and a long coiling scaled tail. The figure bears only its engraved caption and no internal point-labels.

- Caption (engraved, above figure): *Draco Helveticus bipes et alatus* — "The Helvetic dragon, two-footed and winged."

[Margin: A remarkable account of two winged dragons.]

A remarkable account of a certain cooper who lived for half a year together with two dragons.

I shall add in this place an account from the Cysat already cited [Renward Cysat], one to which I would scarcely give credence—were I not compelled, by so many testimonies, and indeed by a public votive offering [*Anathema*] still preserved in the Church of Saint Leodegar at Lucerne as witness to the matter, to admit it to be true. The affair runs as follows:

There was in the city of Lucerne among the Swiss a cooper who, going out one day to seek wood [*ad fabricanda dolia*, for making barrels] among the dense recesses of the woods and crags of the Alps, by some fate I cannot explain became entangled in those labyrinthine windings of the vast wilderness. He no longer knew where he was, nor how to find again the path he had left, and wandered to and fro the whole day. He roamed through a great part of the night as well; then, indulging himself a little in rest from the weariness he had accumulated, he pressed on with his way as twilight came on. In the dim light he failed to see a huge chasm yawning before him at the bottom of the gorge, and fell into it—yet in such a way that, landing on soft mud, he suffered no other bodily harm beyond a fainting fit, which he had incurred from excessive mental dread and fear of falling.

When he came to himself, and saw that the depth of the chasm was insurmountable by human skill—for it was shut in on every side like a well or pit, with high and rocky walls all around—he despaired of any human help and turned with great fervor of spirit to the divine, ceaselessly importuning God and his Mother with continual prayers and vows to free him from so wretched a state. But it pleased the Divine Majesty to exercise him with a greater affliction, to the fuller heaping-up of his merits. In the sides of that chasm were deep crypts [*cryptae*], stretching far in length and breadth on every side. As he entered them, looking for a suitable dwelling-place, he suddenly met two horrid dragons coming toward him. At the sight of them he was nearly lifeless, and as he made for the pit again, he did not cease, with a great pouring-out of tears, to implore God and his Mother again and again against such monstrous creatures. And the

dragons, though they sometimes coiled about his body, now with the tail, now with the neck, nevertheless inflicted on him no harm or violence whatsoever. What state of mind the wretched man must have had in so dreadful and unheard-of a fellowship of dragons, anyone can more easily imagine in his own mind than describe in adequate words. Here you would have seen a Daniel dwelling not in a den of lions but of dragons.

Yet he dwelt there—not one day or a week, but six whole months, from the sixth of November until the tenth of April. But on what food do you suppose he sustained his life? Listen and be astonished. He had observed that those dragons fed on no other food at all, the whole winter long, but a certain salty liquid that oozed from the rock walls. So, when he was destitute of all the necessities of life, he followed the dragons' example, and himself set about licking and lapping that liquid from the walls; somewhat revived by it, he eked out his life by this kind of nourishment for the space of half a year. And so, as the Sun crossed the equinoctial line and the air was now felt to grow milder with the Sun's warmth, the monsters too perceived that the time had now come for them to emerge from their subterranean lairs and that it was fit for seeking food. The first sped off and flew at once out of the pit with a great beating of its wings; and as the second attempted the same, the cooper—reckoning this his best chance of escape—seized the beast by the tail and was carried out of the pit, in a spectacle the like of which had never been seen. There, once the dragons had been let go, he found by divine guidance the path at once, and returning by it to Lucerne, he visited his own people, who had long believed him lost. To the astonishment of all, and the amazement of those struck dumb at a story which they judged the most terrifying that had ever occurred, he set forth in order all that had befallen him.

And because he had obtained, through the intercession of the great Mother of God, his deliverance from so horrendous a state, he wished—as a perpetual memorial of the event and an object of wonder for posterity—a priestly vestment, which they call a *casula* or chasuble, to bear witness. On it he had the whole course of the affair embroidered with the needle; and this vestment, surviving at Lucerne in the Church of St. Leodegar to this very day, is customarily shown to all pilgrims. But the cooper himself, wholly turned to God, since because of the corruption of his stomach he could no longer take his accustomed food, two months after his deliverance from the dragons' den fell asleep piously in the Lord.

Many things, I admit, are contained in this history which far surpass the powers of nature; and so it must be wholly granted that the state of his life in so

horrendous an abyss was supernatural. From these and similar accounts anyone may easily gather that the things found here and there in authors about winged dragons are not false. But that nothing may seem lacking to the reader's curiosity, let us now set forth the origin and generation of dragons.

On the Generation of Dragons.

[Margin: A remarkable account of two winged dragons.]

One might justly raise a doubt as to whence, and from what matter, the generation of such great monsters takes its origin. And since up to now no one has been found who has handed down anything about this in writing, I have thought it our part to explain in this place, as far as our weakness of understanding permits—

—to unfold this *δρακοντογένεια* [Greek: drakontogeneia, "generation of dragons"].

[Margin: Why monsters are for the most part generated from a confluence of diverse seeds.]

It is acknowledged by all physicians and physiologists that from a confluence of diverse seeds an animal of mixed species is generated. This happens not only among perfect animals—as in mules, mongrels [*tragelaphis*, lit. "goat-stags," hybrids], camelopards [giraffes], and the like—but also in the production of a human fetus from the seeds of a different species, coalesced in the womb of a wild beast or a woman, of which as many examples occur as there are *ἄνθρωπόμορφα* [Greek: anthrōpomorpha, "human-shaped" monsters] found in Lycosthenes and other writers on these matters. But that this also happens most especially and most frequently in insects, their wondrous metamorphosis testifies abundantly and to spare. For a bee is born from cow dung, and if anyone examines its head more closely, he will be forced to assert that it exactly resembles the head of a cow—as we have shown at length in the *Chapter on the Hieroglyphic of the Ox* in the *Obeliscus Pamphilius*.

[Margin: Bees reproduce the head of an ox.]

[Margin: Beetles, the head of a horse.]

The same is plain in the horned-headed beetles, whose head is not unlike that of a horse, from whose excrement they are born; and the *bruchus* [a kind of locust or weevil] too, which, because of its resemblance to the horns of a stag, they call *tragelaphus* [goat-stag], clearly testifies it by its horns. In a word, the excrements

of perfect animals always generate some insect similar—if not in the whole, at least in some part—to the animals from which they are generated; about which I treat more fully elsewhere.

These things premised, let us now explain in a few words how dragons can be generated in inaccessible mountain caves and in vast solitudes. It is established by frequent observation that places of this kind, where dragons have ever been seen, are full of eagles, vultures, and similar birds of prey. Dominicus Niger, in his *Geographia*, reports that Rhodes abounded in robust eagles.

[Margin: Vultures and eagles hunt animals of every kind.]

These birds, by their very nature perpetually intent on rapine, carry off in their hunting animals of every kind—hares, lambs, dogs, indeed sometimes children too, snatched away—into the inner caves of the mountains for food. There, by continued hunting, they pile them up little by little into a great mass, as many testify; and just as they cannot consume so great a multitude of carcasses, so these too must gradually be turned into a putrefaction suited for generation.

[Margin: How carcasses are gradually consumed by putrefaction in the mountain caves.]

And since in the carcasses of any animals whatever there always remains some portion of seed—as will be demonstrated in *Book XII*—it comes about that little by little, from the various confluence of seeds in the matter now disposed and fermented by putrefaction, an animal is born. This happens in such a way that from the putrid matter a worm is first produced, and then, from the seed latent in the carcass of a quadruped, the worm is shaped into something resembling a quadruped animal. It may obtain, perhaps, long hare-like ears from the formative idea of the seed radiating together to fashion the ears; and because the seed of a bird also—

[Margin: Whence comes the diversity of limbs in dragons, for the most part.]

[Margin: How an animal is generated from diverse seeds.]

—whatever seed at last is in the rotting place, it comes about that this seed, since it cannot do otherwise, joins to it something winged, or some quadruped part, if not feathered then at least cartilaginous. In the same way, when a great supply of serpentine [seed] has been gathered there, from the serpentine seed a tail, neck, and head of a serpent are joined to it; and thus a serpent-embryo is formed from the mixture of diverse seeds, which in the course of time grows into a dragon of huge size. And if several are born of different sex, then just as they first obtained

their origin from the putrid matter, so afterward they can also propagate themselves by natural coition—like the rest of the insects that are born from putrefaction. But lest so great a multiplication of this plague should turn to the immense damage of Nature, Nature seems to have provided for this with the best of right, so that for the most part only one dragon is born in the subterranean caves of the mountains, from the differing seeds of various living creatures. That this spermatic power still remains in carcasses will then be demonstrated, when in *Book XI* the wondrous power of seed is treated of professedly.

[Margin: Why the seeds do not produce some whole thing.]

[Margin: How an animal is generated from diverse seeds.]

The question therefore arises: why do the seeds not produce something whole? I reply that this comes about because of the confusion of the seeds. While each one acts as much as it can, it happens nonetheless, from the confusion, that the individual seeds—since they cannot, from the resistance of the matter, produce the whole—at least produce a part similar to themselves; and so, while each contributes something of its own, from this is born that deformed and monstrous body of the dragon.

The question arises secondly: why do dragons seem to breathe fire? I reply that they consist of a certain viscous matter—of the kind of which certain fishes, and rotten wood, and glowworms consist—shining with an innate light that gleams most brightly in the dark; and so men, seeing dragons glittering with light, imagine to themselves that they consist of fiery bodies. You will ask: whence comes to them that very hard incrustation of scales? I reply that it comes from the same disposition of matter by which testaceous animals are armed—namely, from a humor of mucous and most tenacious viscosity, which, hardened on the outermost enveloping surface, gradually degenerates into a horny hardness.

From these things it is luminously clear that a manifold animal can be born from the fermentation of putrefaction arising from a diverse confusion of seeds. It is well known that a cock devouring a serpent's egg generates a basilisk—because the seed latent in the serpentine egg, gradually exerting its powers, brings forth an animal *δρακοντο-όφιομόρφον* [Greek: *drakonto-ophiomorphon*, "dragon-serpent-shaped"], that is, an animal composed of a serpent and a cock.

[Margin: A monstrous cock in the garden of the Grand Duke of Etruria.]

Such was that monstrous cock which Francesco, Grand Duke of Etruria [Tuscany], displayed for viewing in the Boboli Garden at Florence for many

years: it expressed in its crest, its leggings [feathered shanks], its spurs, and indeed in its whole body, a cock—but with a serpentine tail, flexuous and coiled into various spirals, displaying I know not what likeness to a dragon.

Diagram. A full-page engraved plate of the monstrous serpent-tailed cock. The figure shows a standing fowl with a feathered, plumed crest and long whisker-like feather quills projecting from the head, a hooked beak, scaled legs with spurs, and—in place of an ordinary tail—a long, scaly serpentine tail curling and coiling into spirals at lower right.

- Caption (engraved, beneath figure at left): *Gallus ὀφιομόρφος* [Greek: ophiomorphos, "serpent-shaped"], *Serpentina cauda conspicuus. Florentiae in horto Magni Ducis Hetruariae Francisci ea forma qua hic exprimitur omnium admiratione visus.* — "A serpent-shaped cock, conspicuous for its serpentine tail. Seen at Florence in the garden of Francesco, Grand Duke of Etruria, in the form here depicted, to the wonder of all."

So born, as it were, from a cock-serpentine egg. By this means barnacle-geese [*Berniclae*] too are born in the nearby places of Scotland.

[Margin: How geese are born in Scotland.]

For eggs in the icy sea, deposited by ducks and geese in countless multitude—as the Dutch [*Batavi*] relate in their voyage toward the North [*ad Arcton*, toward the Bear / the Arctic]—once the ice has melted and broken up, have their seed driven by the agitation of the sea against the neighboring shores of the Orkneys and Hebrides; and there, clinging to the slime [*mucor*] of ships, at last by a certain implanted property of the climate, it is animated from the presupposed matter of the seed into a duck or goose; and for producing these, even the smallest portion of seed suffices. But let this much suffice as said concerning dragons.

CAPUT III.

On Subterranean Men.

That there have been subterranean dwellings of men, and that there still are, the records of almost all historians are full of evidence. They can be considered in two ways. For either men inhabit hollow and rocky regions of the earth and crypts—and these have betaken themselves there either through want of resources or through the convenience of the place, to protect themselves against the injuries of the air and of the seasons; or else others, driven out in the

turbulent times of wars, have withdrawn into the safest regions within the valleys of the mountains, together with the things necessary for sustenance.

[Margin: How men first came to inhabit the subterranean regions.]

Of these latter, some afterward, when they could not find a way out, were compelled to remain there; and being perpetually shut in, and enticed by the convenience of the place for sowing and plowing the soil, they remained by the inescapable law of necessity, having multiplied by propagation. Of the former I shall speak first; of the latter we shall discuss afterward.

Gaffarellus [Jacques Gaffarel], in his book *On Crypts Celebrated throughout the Whole World*, describes subterranean cities at length. I would not have believed the truth of the matter, had I not myself surveyed habitations of this kind with my own eyes in three places of my own. For when in the year 1637 I was staying in Malta [*Melita*], it happened that one day, with the Master of the Order of Jerusalem, Giovanni Lascaris, I went to a certain villa of Malta filled with the charm and delights of men—which they call *Buschettum* [Buskett].

[Margin: An account of the subterranean dwelling of men at Malta.]

There, when concerning the nature and property of the island we were discussing back and forth with various reasonings—

LIBER VIII "Λιθογενής" — Sectio IV: De Animalibus Subterraneis [On Subterranean Animals]

Caput III: De Hominibus Subterraneis [On Subterranean Men] (continued)

(printed p. 98)

back and forth, the said Grand Master [Magnus Magister] added that there was, on a nearby hill, an underground dwelling of men subject to him, and that he wished me to go and inspect it — to observe the remarkable ingenuity of these people in fitting out such subterranean caves and arranging their dwellings. Since nothing could be more welcome to me, as I said, I joined a guide who knew the underground routes and the caves well, and I went up to the dwelling, which the island's natives in their domestic and familiar Arabic tongue call

[Margin: A great cave.]

غار كبير *Ghaar Kebir* — that is, "the great cave." Once I had entered the main gateway, which stood open far and wide, I found it full of people of both sexes, boys and girls dressed in peasant fashion. And although they appeared to live together in a confused way, each family nonetheless possessed its own quarters, or recesses, made either by craft or by nature. Within these, in a handsome arrangement laid out through one little cell after another, they were accustomed to store the various kinds of provisions.

[Margin: The layout of the dwellings.]

Here a bed was cut into the rock; there were nooks suitable for stowing loaves and cheeses; elsewhere appeared the stalls of cows, livestock, and donkeys; and there were even the nests of the hens. Earthenware vessels were not lacking, capacious enough to hold water in place of cisterns. Very long strings of onions and garlic, like so many clusters, adorned the walls. There were also ovens well suited for baking bread; into these subterranean cave-dwellings the light came through cracks in the rocks and through holes made deliberately for this purpose, contrived so cleverly that neither rain nor wind could easily harm them. Their ovens, too, had their own chimneys, so that when the fire was lit they would not be suffocated by smoke spreading through the caves without a flue.

[Margin: The customs of the inhabitants.]

By day the peasants busied themselves with their tasks outside the cave, and procured the necessities of life in the neighboring places; the women were assigned to the distaff, to cheese-making, and to similar tasks proper to women. Since they had no wood, in its place they fed their fire with the dung of beasts of burden dried in the sun. The men and women of this people were said to be of very large stature, robust and long-lived [Macrobii], living right up to a decrepit old age; and — remarkable to say — the women were not unhandsome in form. So strongly are they held by longing for their caves that, whenever the need to visit Malta presses upon them — whether to sell their goods or to buy other necessities — they could scarcely be kept there, as if condemned to a kind of exile, but at once, their business dispatched, they would return to their caves, not allowing themselves to be kept away from them even for a single night. They abstained entirely from the flesh of cows, livestock, and hens, since they reserved these only for profit, to be made by sale; they were content with bread, cheese, milk, onions, garlic, and herbs.

The Grand Master, in order to demonstrate the truth to me by experiment, ordered a table to be set. On one side he had placed all the kinds of meat, and whatever in the end was left over from the truly lavish and magnificent banquet by way of delicacies; on the other, cheese, onions, garlic, cabbage, and the dishes they call *Maccarones*. He then summoned his Troglodytes, whom he had had fetched from the caves to serve in the kitchen, and ordered them to sit at the table. They at once left the meat-delicacies untouched, and turning instead to those foods to which they were accustomed and which they gladly ate, they devoured them with full fists and a kind of canine greed. I have thought it worth describing this at some length, so that from it the reader may understand the character of the rest of the subterranean men. Hence what Solinus, Pliny, and Aelian write — truly most worthy of wonder — about the Troglodytes living beneath the earth by the Red Sea [mare Erythraeum] does not seem false.

[Margin: The Arabic language they use.]

There is, near the island of Malta, a place called Gaulos, commonly named *Gozo*, in which I found a wholly similar cave, packed with people who live by the same rite as those mentioned above. In both islands they use pure Arabic, without any admixture of Italian or any other tongue; and so the Maronites returning to Mount Lebanon, while they wait at Malta for a favorable time, often visit them, to read them the Mass in Arabic and to expound Christian doctrine — for they are not barbarians, nor deprived of the Catholic faith, but perform their daily prayers with the utmost devotion, continually tell their rosary-beads [precatorios globulos], and hear Mass on every feast-day in the nearer village. They keep, too, in their caves, images of the Crucified and of the Blessed Virgin set out in a fitting place. But let this much suffice concerning the Maltese Troglodytes.

[Margin: A subterranean dwelling in Etruria.]

In the year 1659, while I was exploring Etruria, it happened that, on a certain occasion, as I was about to examine the district of Viterbo, I crossed a meadow in which here and there continual columns of smoke were rising. Astonished, as it were, at such a spectacle, I supposed there were sulphurous pits in the place; so I asked my companion to explain what such smoke might portend. He, smiling, said: "These smokes that you see are not from earthly exhalations, but are the smoke that finds its way out into these meadows through the chimneys of the underground dwellings." And after a short interval he at once showed me a doorway through which there was an entrance into the said caves. We went in, then, and found everything arranged just as in the caves of the Maltese Troglodytes: bedchambers, seats, and nooks cut into the living rock, far more

spacious than the Maltese ones — for it was an underground village, which they call Meonianum, under the jurisdiction of the most excellent Prince Camillo Pamphili. A church could be seen outside; all the inhabitants devote themselves to agriculture. But I have pursued these matters more fully in our *Itinerarium Hetruscum* [Etruscan Itinerary], to which I refer the curious reader. And just as I surveyed these things with my own eyes, so too I have thought them worth setting out at somewhat greater length, so that if in other places — of which I have no doubt — similar

(printed p. 99)

dwellings are reported to exist, the reader may recognize that they are constituted in no other way than we have described. For that similar ones are found almost everywhere, the authors of geographical histories testify amply and to spare.

[Margin: Brahmans inhabiting subterranean caves.]

In the kingdom of Idalcan [Bijapur] in India, the members of our Society teach that very many people — both the Brahmans on the mountain of the Pagodas and the common folk — dwell in subterranean passages.

[Margin: Men dwelling underground in the Mountains of the Moon and the Caspian Mountains.]

In Africa, near the Mountains of the Moon [montes Lunae], Father Pedro Páez [P. Petrus Pais] relates that men live in the innermost recesses of the mountains, against the force of the Sun's heat. Marco Polo of Venice [Marcus Venetus] asserts the same of the mountains of the Caspian Sea, whose hollows, he reports, have been turned into the dwellings of men. I shall not speak here of the subterranean crypts of the city of Rome, where so many holy Martyrs, together with the holy Pontiffs, lay hidden during the time of persecution — on which let the reader consult the *Roma Subterranea*.

But since the dwellers in such caverns ought not properly to be called subterranean men — for a free exit is granted to them at all times, day and night — therefore in this place we must deal only with those subterranean places from which men, born and raised there, have never seen the light of either Sun or Moon, until at last, bursting out from their hiding-places by remarkable chances, they have recounted, to the wonder of all, what kind of life they had led. This history, exotic as it were and worthy of all wonder, William of Newburgh [Guilielmus Neubrigensis] tells in his *History of English Affairs* [*rerum Anglicarum*]

revolutiones], Book 1, Chapter 27, page 92. I shall set down his words here, translated from the German account.

A remarkable history of subterranean men, taken from William of Newburgh, the English writer.

"There is," he says, "a village in western England [*Occidentalis Anglia*], some four or five miles distant from the noble Monastery of St. Edmund, King and Martyr; near it certain very ancient caverns are to be seen, which in the common tongue are called

[Margin: Wolfpits.]

Wulfpites — that is, 'wolf-dens' — from which the aforesaid village took its name. From one of these caves, in the summer season, when the country folk were busy reaping the crops, two boys, their whole bodies tinged with a green color, emerged, covered in a material until then unknown.

[Margin: Two green-bodied boys emerge from the caves.]

And so, blinking as it were at the sight of the unfamiliar sky, they wandered through the fields, until at last they were seized by the reapers and brought into the village, with a great throng of people gathering, astonished at so unusual a spectacle. There for several days they lived without any food, nor could they be induced to take anything of those foods on which the village was accustomed to feed; and so, gradually failing, they were in danger of their lives for want of suitable nourishment.

[Margin: A wretched event.]

But it happened that at the same time someone passed by with a cart loaded with beans; as soon as they saw these, they at once rushed upon the cart with full force; and when, opening the pods, they found nothing inside, they bewailed their wretched lot with a copious flood of tears joined to wailing.

(printed p. 100 — Quaesita / Questions concerning the subterranean men)

But after the natives realized that they craved beans, they at once set fresh beans before them, which they ate with great joy and the utmost eagerness, as though it were their own proper nourishment.

[Margin: The food of the green ones becomes their accustomed food.]

And thereafter for several months they used no other nourishment than the one mentioned, until little by little they grew accustomed to bread. After they had gradually grown used to our foods, the green color with which they were imbued was seen to fade by degrees into the color of other human beings;

[Margin: The green color fades.]

then, initiated by holy baptism, they learned the English language.

[Margin: They are baptized.]

The male, who was believed to be the younger, died on the very day after he received the holy washing of baptism; but his sister, who differed in no way from other women as regards bodily proportion, long survived him, and — as is reported — having been joined in marriage near Lynn [Lenna], is said to have been still living not long ago. Now when she had already learned the English tongue and was asked who and from where she was,

[Margin: From where they took their origin.]

she replied that they were people from the land of St. Martin, where his cult was greatly esteemed. And when she was further asked where in the world that land lay, and how they had come up into our region, she answered that she did not know — she remembered only this much: that once, when they were watching over their father's flocks at pasture, they had perceived a certain sound like the one which is made in the church of St. Alban in that place by the pealing of the bells; and that, struck with wonder at this unfamiliar sound, as they went further on, they at last found themselves in the very field in which they had been captured.

And when she was again asked whether, in the land they spoke of, they believed in Christ, and whether the Sun ever shone upon them, she replied to the first that the land was Christian and provided with churches; to the second she said that the Sun was never seen by them, neither rising nor setting, nor were they ever illuminated by any rays of the Sun, but they enjoyed a certain dim light, much in the manner that, before the Sun's rising or after its setting, appears to us here at the time of twilight.

[Margin: The subterranean region not illuminated by the Sun.]

She said, too, that not far from there lay a region much brighter than her own, separated from her own land by the breadth of a river of no small size. These and similar things the woman told concerning the aforesaid subterranean region, as

she remembered them. To each I leave his own judgment about this history. Certainly it should not displease anyone that I have written down so wonderful a history. Now this marvelous event occurred under King Stephen, in the year 1140. I confess that I long held myself in much suspense over so unusual a case; but, convinced by so many and so conspicuous testimonies of men most worthy of belief that the matter was truly so, I believed it, marveling at that which reason seemed in no way able to grasp." Thus far William of Newburgh — who not without cause long remained doubtful about the truth of the matter, since it is indeed remarkable and contains many things that may seem ἄπιστα καὶ παράδοξα [Greek: apista kai paradoxa, "incredible and paradoxical"] to those inexperienced in the workings of nature. And we should scarcely have given the matter credence, had not many similar instances, met with in the authors, confirmed our mind. And so that this may be plain to the curious reader, let us now examine the history with the file of truth, with all the ἀκρίβεια [Greek: akribeia, "exactness"] that can be brought to bear.

It is asked, first: by what means and on what occasion could these men have penetrated into that subterranean region?

[Margin: How the said men entered the subterranean region.]

I answer that this happens in various ways. First, in times of plague and of raging wars, when most men, intending to look to the safety of their lives by flight, are accustomed to withdraw into some hidden caverns of the highest mountains, as into a safe refuge against the snares of their enemies; and lest they perish there for want of necessities, they are accustomed to bring along with them their livestock — cows, bread, seed, vegetables, and whatever in the end is necessary for sustaining life. Frequent experience in the tumults of our own times — to which Germany has now for nearly forty years been continuously subjected — makes this so manifest that no one can doubt it any longer.

[Margin: Those fleeing the savagery of war in time of war hid themselves within the caves.]

By a similar chance, then, those first men, fleeing the savagery of their persecutors, hid themselves in that labyrinth of caves, from which they could afterward not extricate themselves; and the more anxiously they thereafter sought a way out, the more and more they entangled themselves, as is likely — until at last, having entered into this far-and-wide-extending subterranean region, not without divine arrangement, they were compelled by the hard law of necessity to remain.

[Margin: The Jews shut up in the Caspian mountains.]

The very same thing, we read in the geographers, befell the Jews, shut up in the inaccessible recesses of the Caspian mountains. And do we not read that, in the mountains of Spain, in the time of King Philip III, a new colony of men was discovered — men who, by what chance is unknown, had betaken themselves there for some such reason and occasion, and who through many centuries of years, without any commerce with the rest of mankind, in a language much differing from Spanish, remained unknown to all up to that very day?

[Margin: In the mountains of Spain a new region discovered in our own times.]

This continued until, the region having been discovered by hunters, the inhabitants — destitute of all cultivation of life and morals — were converted to a better way by the Fathers of our Society, and now differ in nothing from the rest. Crusius [Cranzius] also relates that in Transylvania, in the year 900, a similar race of men burst forth from the windings of the mountains, who afterward inhabited the whole region, not yet everywhere cultivated.

[Margin: In Transylvania men burst forth from the caves.]

The curious reader will find countless instances similar to these, if he will consult the various revolutions of the world; for when men, oppressed by storms of misfortunes, have been compelled to seek the hidden recesses of the mountains, immune against the violence of their enemies, and tarrying there a long time, have at last with time grown accustomed to the places and remained there.

It is asked, second: how and from where could that light, similar to twilight, have arisen for them?

[Margin: From where that light in the subterranean region.]

I answer: from a fissure or a notable opening in the upper part of the mountains. For it can scarcely be believed how much clarity even the smallest ray of light, through even the smallest fissure, brings to subterranean places; and experience teaches this in the subterranean crypts, both the Roman ones and the other darker places, and is most especially evident in the Pantheon. Now it is likely that the opening of this subterranean region was quite notable, and stretched out lengthwise along the ridge of the mountains; whereby it came about that it not only received sufficient light for several hours of the day, but also, with the external warmth now insinuating itself, the subterranean earth was made fit for grasses and vegetables. For we saw above that beans and the nourishment of greens also grew there; nor were there lacking here springs, nor fish from the

subterranean river — with which we have shown elsewhere that the Subterranean World abounds. Nor does fire seem to have been lacking, since with the fire-strikers [ignitabula] they had brought with them — God surely directing it so — they could easily kindle a fire, and, when the tinder failed, easily prepare new tinder from any combustible material whatever (as nature is most resourceful in ingenuity in such cases), for the use of so necessary an element.

[Margin: In Megrelia a valley the Sun does not penetrate.]

Hayton [Haytho] relates, in his *History of the Tartars*, that in Megrelia [Mingrelia], and within the Caspian and Caucasus mountains, valleys are found so deep that the Sun never penetrates to their bottom, and that therefore a perpetual twilight reigns there even at midday; yet they abound in trees, herbs, plants, and streams, and are even inhabited by men. A region similarly enclosed within the walls of the highest mountains, from which there was no exit, could likewise have fallen to the lot of these men of ours.

It is asked, third: what was that unknown material with which the aforesaid boys were clothed?

[Margin: With what material the boys were clothed.]

I answer: they were clothed either with the skins of sheep, or with some other material growing in that subterranean territory. For just as we read of a certain people of India that they prepare their garments from twisted filaments of roots, others from moss growing on the walls, others from a certain thin and tenacious skin [cuticula] that usually grows on the walls of crags and rocks, others from the thin bark of shrubs and the like — these things which God, in His infinite goodness and mercy, does not fail to supply to the wretched when placed in such great need — so too we affirm that the said subterranean men were clothed.

It is asked, fourth: from where did that greenness of their bodies come?

[Margin: From where that greenness of the bodies.]

I say that it came from the native moisture of the place, and from the moist juice of the herbs on which they fed. For there are, as experience teaches, in hidden moist caverns, walls for the most part all imbued with a certain green color, which in the said region redounded also into the body — the very moist constitution of the foods contributing much to this. Hence, as soon as they used the customary foods in the region above the earth, that green color is said to have gradually changed into the natural one.

It is asked, fifth: how could they have dwelt for so long a time in a place of such intemperate moisture?

I say that the region was thoroughly purged, and reduced to some moderate temperature, by the perpetual fostering of fires. But you will perhaps ask: from where did they have a sufficient supply of combustible material? I say: from shrubs, roots,

(printed p. 101)

roots, clods of turf, and moss — sufficient material could have been provided.

It is asked, sixth: how can they be said to have believed in Christ?

I answer: since, before they became enveloped in this subterranean labyrinth, they had been imbued with the Christian mysteries, they preserved this faith also through the continual succession of propagation — though, with their minds running wild and being for the most part deprived of priests, in a very imperfect form. And the fact that a church consecrated in honor of St. Martin was there plainly proves it. And from these reasons it is clearly evident that this history related by William of Newburgh is not so impossible as anyone might persuade himself. Whoever desires more of this kind concerning subterranean dwellings, let him read the admirable work *Atlas Sinicus* [the *Atlas of China*] composed by Father Martino Martini, in which you will find wonderful things on such matters recounted.

Caput IV: De Daemonibus Subterraneis [On Subterranean Demons]

That there are subterranean demons, not only profane but also Sacred Writers assert by unanimous agreement — concerning whom, see Delrio [Delrigus].

[Margin: A subterranean place is fitting for the demons.]

For since these powers of darkness flee the light as the seal, as it were, of the divine countenance, surely no more fitting place ought to have been assigned to them than the subterranean pit [barathrum] of everlasting darkness, according to that saying of the Apostle Jude, verse 6: "But the angels who did not keep their own principdom, but forsook their own dwelling, He has reserved in chains of eternal darkness unto the judgment of the great God" (Jude 6). That subterranean demons, then, the powers of darkness, exist is so certain that no one can doubt it without loss of faith. And since, by the just dispensation of God, clad in the masks of human form, they from time to time appear to men — whether to tempt them

or to torment them — lest these too should be lacking in our subterranean world, which is constituted of every grade of creatures, I have thought it proper in this place to treat of them, so that it may be established what is to be thought of them, and how their wiles are to be resisted.

[Margin: In what places demons of this kind have been seen.]

Historians record that demons have been observed chiefly in three places: first, in the northern regions condemned to perpetual gloom; second, in dreadful wildernesses; third, in the subterranean tunnels [caniculi] of the metal-bearing mines. And since the said little demons [daemunculi] mostly appear under the form of a cubit-high dwarf [Nanus cubitalis], hence seems to have arisen the fable about the Pygmies fighting with cranes at the Rhiphaean mountains, whom the geographers place in the farthest kingdom of the North. The Arabic Geography places them in the kingdom of Gog and Magog, with which agree all the writers on northern affairs. Paolo Giovio [Paulus Iovius], in his book *On the Embassy of the Muscovites*, says: "That in the region between the West and the North, oppressed by perpetual gloom, Pygmies are found, certain witnesses of outstanding trustworthiness have reported — Pygmies who, after they have grown up to the full, do not exceed the measure of one of our boys of ten years; a timorous race of men, expressing their speech by a chattering, so that, both in their resemblance to apes and in their stature, they seem far removed from man in their senses and in a just height."

[Margin: The Pygmies were not men, but subterranean demons.]

Concerning these, see Olaus Magnus, who calls them *Screlingi* — that is, "Cubit-men." Authors of the greatest weight have also made mention of monsters of this kind: Plutarch, Ctesias, Pliny. And therefore, although I will not easily deny that such things have sometimes been seen, so too I will not easily affirm that these were true men, since, in so great a knowledge of the whole surveyed world, no nation has been found that is a nurse of such Pygmies. From which it is concluded that they were seen by rude and rustic men in the farthest corner of the North, condemned to almost perpetual darkness — that is certain.

[Margin: No nation of Pygmies has today been found on earth.]

For since the said men, on the testimony of Olaus, are prone to every kind of superstition and easily devote themselves to the demons, it ought surely to seem strange to no one that these demons are wont to appear under the human form of a Pygmy, both to propagate superstition in simpler minds, and to bind those men to themselves by the benefits with which they are sometimes favored. For if such

a race of little men existed in gloomy regions of this kind, why did it escape the notice of the most inquisitive Dutch [Batavi], who now for a span of sixty years have done practically nothing else than not to cease exploring — I will not say any most hidden corners of the North — but of the whole world; and yet have learned nothing of such a nation of Pygmies? Why was no dwarf of this kind ever carried off from Lapland, Biarmia, Cremesia, Finland, and the other nations neighboring on Germany — Sweden, Denmark, Holland? — when nonetheless they do not cease to bring home with them to their homeland monsters of lesser importance from the farthest parts of the Indies; nor is there anyone today found who would dare to assert that he has seen a similar cubit-high Pygmy in those parts. All those things, therefore, are fabulous which the old geographers handed down concerning Pygmies of this kind, described from the mere report of the common people; and just as one wave drives on another, so one fable drives on another, while they attach to such manikins, as a marvel, the γερανομαχίαν [Greek: geranomachian, "the crane-battle"] — that is, they imagine that, drawing up a battle-line against the cranes that have offended them, they are kept occupied in perpetual war. See Jornandes and Olaus, who treat of these matters more fully.

I say, therefore, that these — if indeed they were ever seen — were none other than demons, lovers of gloomy places of this kind, who from time to time, to the rustic people living without any law or religion,

[Liber VIII, Sectio IV, Caput IV "De Daemonibus Subterraneis" — continuing from the prior pages]

and deceiving them so as to bind them into servitude, they appeared. From this the fabulous tale of the Pygmies afterward not only filled the whole world, but — what is astonishing — even won credence in the minds of the wisest men. Hence I am firmly convinced that these phantom dwarves [pumiliones phantasticae] belong to the same class of beings that even to this day are not infrequently encountered in the mines of metals, beings that are called the mountain demon-imps [daemunculi montani].

[Margin: The mountain demon-imps.]

Concerning these, Georgius Agricola [Georg Agricola] writes thus in his book *On Subterranean Animals* [*De Animantibus Subterraneis*]:

"There are two kinds of these demon-imps. One is harsh, savage, and terrifying of face, which they call the *Sneberg* [Schneeberger]; whenever it is provoked, it brings the greatest ruin upon the miners. There are also certain milder demons,

which some of the Germans, and now also the Greeks, call *Cobali* [kobolds], because they are imitators of men. For, frolicking with a kind of mirth, they appear to do many things, when in fact they do nothing at all. Others name them little men of the mines, *Bergmännlein*, signifying their stature, which in most cases is that of dwarves — namely three palms [dodrantēs] tall. They appear, moreover, to be little old men, and are clad after the manner of miners, that is, in a girt smock with a leather apron hanging about the loins.

[Margin: The labors of the demon-imps in the mines.]

These do not usually harm the miners, but they wander through the shafts and tunnels, and although they do nothing, they appear to busy themselves in every kind of work: now they seem to dig veins, now to pour what has been dug out into vessels, now to turn the windlass [machina tractoria]. Yet although they sometimes pelt the workmen with bits of gravel, they very rarely injure them, and never injure them at all unless they have first been provoked by laughter or by a curse. They are not unlike those demons which the Germans call *Gütel* or *Trulli*, of feigned sex — now of a woman, now of a man — who are said to have served, both among other nations and especially among the Swedes, in the office of household servants." Thus far Agricola.

From all this it is plainly evident that these are the very same beings which he says, in the farthest reach of the North, performed the office of servants. It has been reported to me that these mountain demon-imps are also seen in the mines of the Tyrol.

[Margin: In the mines of the Tyrol.]

[Margin: They harass the miners in various ways.]

There, unless the miners deposit at a fixed spot a little portion of their daily provisions — made up of porridge, small cakes, and cheese — they are not without danger on that day. And so by such superstition the demon's craft so befools the miners that some of them do not even hesitate to ransom themselves from his harassment by a certain sacred rite, and they strive by every means to placate him — most of all when they hear certain blows of the demon-hammerer [daemon malleator]. For then they wholly persuade themselves that this is a favorable sign that new gold-bearing veins will soon be discovered.

And this is confirmed by Cysatus [Johann Leopold Cysat], already so often cited, in his description of the Swiss mountain which they call *Pilatus* [Mount Pilatus], in these words translated from German into Latin:

[Margin: The mountain demon-imps in Switzerland.]

"Among other wondrous things, certain accounts are given of little mountain men, whom they call *Bergmännlein*, endowed with the form and stature of men, who are said to have dwelt in the caverns and hidden tunnels of this mountain, and to have practiced mining marvels along with the miners; some they endowed with gold and showered with gifts, others they harassed in dreadful ways; indeed certain ones, [fol. continues at 103]..."

"...[stirred up] into a like rage, are said to have hurled headlong over the rocky crags of the mountains. That this happened not by means of these fabulous Pygmies, but by the contrivances and various deceptions of evil demons [cacodaemones], by the just judgment of GOD, is most likely."

Not long ago a man of no little learning wrote to me that diabolical apparitions of this kind, in the shape of dwarves, have often appeared to various people — both to peasants and to miners — and have given answers to questions put to them on various matters. Indeed, he himself one day, having entered a very long underground passage some distance for the sake of exposing the veins, found beside a certain rivulet, in the damp sand, the footprints of a three-year-old boy, and examined them carefully. And since he could not persuade himself that a boy of that age could ever have entered this dreadful subterranean passage, he finally learned from the neighbors that they were the footprints of the mountain demon-imps — who, in order to kindle the greed of miners, are accustomed to mislead men (for the most part superstitious) with such footprints.

Since not long ago I had inquired of the masters and overseers of the metal mines in Hungary whether subterranean demon-imps — which they call *Bergmännlein*, or mountain pygmies — from time to time appear in the mines, they answered me in a letter sent to me as follows:

[Margin: Subterranean demons in Hungary.]

"In times past there have been such spirits, encountered by the miners, which even drove the miners into flight and thrust them out of the shaft, and sometimes stirred up a great commotion and uproar — for the most part, whenever they were approaching a rich vein, a like portent went before." This from the account of Schapelmann [Schapelmann], overseer of mines at Herrengrund [Herrengrundt]. That truly outstanding man Bernardus à Brun [Bernhard von Prun], overseer of the Hungarian mines, writes to me about them thus:

[Margin: Various accounts of subterranean demons.]

"It is most certain that spirits or apparitions are perceived in the shafts, not only as if they were carrying out various labors — of which, however, no trace can be recognized — but they also assault the miners, throw stones at them, and several even harass them so fiercely that they can scarcely carry out their own work. So it happened a short while ago to a certain Schemnitz [Schemnitz] miner already well advanced in years, named Georgius Egger [Georg Egger], who, when he was alone in the mine, bore witness that he had seen apparitions of this kind. Nevertheless they are more often heard than seen; and when something of the sort happens, good or evil usually follows. The miners also superstitiously believe that if anyone has seen such a spirit and at once reveals the vision, the one who reveals it will soon die — of which there are many examples.

Among other things, something of this kind happened at Schemnitz: twenty years ago now, a certain man by the name of Symeon Krauss [Simon Krauss], who had related to his companions such things he had seen, perished by a sudden death. For greater confirmation there are several aged men, worthy of trust, who under oath and on their conscience have declared the following:

First. Martinus Lichy [Martin Lichy], a metalworker, says that sixteen years ago, on a certain Sunday, by night, in a certain mine called *Oberbieberstollen* [Oberbieberstollen], looking back he saw a little man [virulus] of the stature of a boy of six or eight years, dressed in leather clothing, [fol. continues at 103v]..... with a broad hat, with large and gleaming eyes; at the sight of him, since he was alone, he was seized with no small terror, and so, holding a club, he hurled it at the little man, who, vanishing, was thereafter seen no more.

Second. Paulus Wetzstein [Paul Wetzstein], a miner at *Oberbieberstollen*, says that twenty-five years ago, in a certain Schemnitz mine called *Mohrer Erbstollen*, on the Sabbath, he heard a violent working [as of labor], and so, believing it to be his companions, he approached but found no one. He supposed that his companions had hidden themselves and wished to make sport with him; but seeking further with his lamp, he was hailed with these words: "Ba, ba." At this, violently terrified and realizing that the matter was not right, he at once climbed up out of the mine, went to the inn, and sought his companions; he found them and began to tell them what had befallen him. They at once ordered him to be silent; nevertheless he straightway fell ill for the space of three weeks. A kind of scabby eruption broke out on his face, from which, however, he was not freed until the said three weeks had elapsed, after which he recovered his strength.

Third. Christianus Muller [Christian Müller], a miner in the same place, affirms that in the week following the one in which the said events occurred, the same

thing also happened to him: when his companion had left him alone in the mine, and had bidden him stay there longer, he heard a violent working above him. So, wishing to know who was working there, he searched but found no one; he returned to his own spot and again heard working; searching once more, he found no one. At this, struck with terror, he climbed up out of the mine. When his companion marveled that he had followed him so quickly, he began to relate what had happened; [and] feeble, he took to his bed.

These men could relate far more: how similar specters or pygmies carry out various activities in the shafts; how they turn everything upside down and topsy-turvy — uproars which are most often seen to be followed by a collapse [ruina], as though something were being hurled down within the waters with a great crash; and yet, when the collapses are sought out, not even the least trace of any labor or accident is found. Thus far from the Schemnitz account.

Schulzius [Georg Schultz] adds:

"After a long time had elapsed, the *pygmaeus* — or mountain little-man [virulus montanus] — was seen, and not without cause is he called by the diminutive 'little man,' since he is exceedingly small, as is evident from his footprints. For when he has crossed muddy and clinging ground, he leaves a footprint like that of a child of two or three years. The light which he carries in his hand is of a shining and clear brightness. If this little man precedes the miners as they enter the shafts, he gives good hope of riches and ore." This from Georgius Schultz [Georg Schultz].

The mountain little-man, or *pygmaeus*, is found only in the richer mines; in the copper mines of *Cur* [?], where they were flourishing, he too was seen. This from Philippus Bernardus à Prusn [Philipp Bernhard von Prusn] [?]. Many similar things were transmitted to me by Father Andreas Schaffer [Andreas Schaffer], who, just as he has remarkable knowledge of the Hungarian mines, so too has carefully investigated the explanation of the said specters. But since it agrees in all respects with what has already been related, I have judged it not worth repeating.

[End of Liber VIII.]

MUNDI SUBTERRANEI LIBER NONUS

OF THE VENOMOUS, or LETHAL, FRUITS OF THE SUBTERRANEAN WORLD

[DE VENENOSIS seu LETHIFERIS MUNDI SUBTERRANEI Fructibus]

SECTIO PRIMA — ON POISONS AND THEIR NATURE, Origin, and Wondrous Properties

[SECTIO PRIMA — DE VENENIS EORUMQUE NATURA, Origine &
admirandis proprietatibus]

PREFACE [Praefatio]

Since at no time has the admirable nature of poisons failed to torment, in a remarkable way, the minds of philosophers and physicians, however subtle they may be — nor has anyone been found, even today, who has uncovered the true and genuine causes of such great powers — I have judged it my part, to the extent that the weakness of my talent allows, to settle this pending dispute somewhat: not so much to resolve it, as to shed light on it by bringing forward new arguments. My aim is that the curious Reader may have it made plain from what source that untamable force draws its origin, and from what it obtains the principles of its composition.

[Margin: The greatest difficulty in assigning the origin of poisons.]

There are some who reckon this subject, on account of the hidden recesses of its powers, impenetrable, and therefore a lost cause. Certain others, even though they describe its causes somewhat, nonetheless derive the origin of poisons from nothing but a varied combination of the primary qualities; these are not to be heeded, because experience itself clearly demonstrates their opinion to be false. Something else, therefore, lies hidden — wholly divine [τὸ θεῖον, *to theion*, "the divine [thing]"] — beneath the wrappings of mixed bodies of this kind. What this may be, whence it arises, or how nature forms it in the different classes of bodies, we now set out to expound. May GOD, Best and Greatest, Father of lights, assist this undertaking.

CAPUT I

The Definition of Poison [Definitio Veneni]

Setting out, therefore, to treat of poisons as a subject properly belonging to the Subterranean World, we begin not rashly, nor as those do who are inexperienced in things, but rather, following the art by which Nature herself is the model, we take the starting point of our reasonings from that which by right claims for itself the chief place in every inquiry: namely, that once we have discovered the genus — by way of analysis [κατὰ τὴν σύνθεσιν καὶ ἀνάλυσιν, *kata tēn synthesin kai analysin*, "by composition and resolution"] — and the specific difference, we may then, [arriving] at the *what-it-is* [τὸ τί ἐστὶ, *to ti esti*, "the essence / the what-it-is"], that is, *what a thing is*, infer it by a sure and evident demonstration. But to the point [Sed ad Rhombum, idiom: "to the matter at hand"].

[Margin: The definition of poison.]

A poison, then, is nothing other than a thing not natural [Res non naturalis] which, in whatever manner it is at last applied to the human body, corrupts and destroys that body's nature by its own malignity, through a dissimilarity to its whole substance. I said "a thing not natural," because "not natural" in the definition set forth is the genus, and holds the place of the matter. Therefore, however many [poisons] can be assigned from the difference among the genus of poisons, they are to be reckoned material. It is called "not natural" because it is diametrically opposed to the human body. I say "to the human body," so as to exclude thereby certain animals which feed on venomous things, such as [fol. continues at 105]...

the starling [feeds] on hemlock [cicuta], the stork on toads [rubetae] and serpents, the warbler [ficedula] on scammony [scammonea], and the like.

[Margin: Toxic substances taken as wholesome.]

In the definition it is said "in whatever manner it is applied to the human body." This is so that the various scheme of the snares of poisons — both natural and artificial — may be conveyed to us. For Nature is wont sometimes to conceal poisons under a certain bland and friendly quality, by which men, enticed, imprudently swallow them. Thus a certain sweetness is found in aconite, in arsenic, and in the Colchian ephemeron [Colchicum], which, taken in pleasantly, hastens death in the end. Poisoners [venefici] are acquainted with qualities of this kind, who, by a similar artifice, make use of them in preparing food and drink for the poisoning of men.

There follows in the definition: "[which] corrupts and destroys human nature by the malignity of the poison." That is to say, it corrupts and destroys the mixture and the form of the mixed human body by a certain force wholly dissimilar and contrary to its entire substance. And although every morbid cause is in itself and by its own nature evil — because it produces an evil effect — yet, because the quality of poison is placed in the highest degree of malice, it has merited the name of "malice" *par excellence* [κατ' ἐξοχήν, *kat' exochēn*, "pre-eminently"]; in almost the same way that, in the book *On Plague* [*Libro de Peste*], we declared the highest and most excellent degree of putrefaction to be venomous and pestilential.

It is a grievous thing, in war, after many noble deeds, to be overcome by the enemy, and — most grievous of all — to be conquered and subdued [κρείττον καὶ ἀκρατῶς (?) ... "vinci & debellari"; the Greek phrase here is partly abraded and reads approximately κρείττονι καὶ ἀκρατήτῳ, "by a stronger and irresistible [force]"] [?] with no defense of valor left behind one. For even though the outcome of both kinds of affliction is one and the same — namely death — yet in poison the condition is worse, in that it suffers nature not only not to breathe again, but not even to fight back, since by its own malice it eludes and forestalls every effort of nature, as will become clear later in the case of several poisons. But by what means, or by what natural motion, poison gradually brings on corruption and destruction, will be explained later.

CAPUT II

On Certain Terrestrial Minerals, from which all Poisons are taught to draw their Origin, primordially, out of Subterranean things

[De Terrestribus quibusdam mineralibus, è quibus omnia venena ex Subterraneis originem suam primordialiter trahere docetur]

The unsearchable Height of Divine Wisdom so fashioned the World by its art that, just as it furnished the World with a certain infinite variety of things and species, so too it always arranged it with so great a blending [σύγκρασις, *synkrasis*, "blending / temperament"] of harmonious agreement, that — by setting consonant things with dissonant, good with evil, venomous with wholesome, bitter with sweet, precious with vile, all mingled together and bound by an indissoluble chain — the one could not subsist without the other.

[Margin: Why Nature willed good things to be mixed with evil.]

For if all things were good and wholesome, the World would necessarily perish — just as, if all in the World were Wise men or Kings, the political World would likewise necessarily perish. And so good things have been joined to evil by the most wise counsel of GOD in such a way that the one fosters the other. This the philosopher too recognized, when he asserted that the World is composed of contraries, and is driven by perpetual conflicts of things. Hence the alternations of day and night; hence so great a diversity of seasons; rains and showers follow fair weather; winter succeeds summer; dryness [succeeds] moisture, snow and hail.

[Margin: The diversity of things in nature.]

Hence the wondrous agreements and disagreements of the things existing within the fourfold realm of nature, which the Greeks call Sympathy and Antipathy [Sympathia, Antipathia] — since the nature of things cannot be preserved in its actions without strife and without friendship. All of which things have been aimed at by Nature's marvelous counsel toward the best end.

[Margin: The World is driven by the perpetual alternation of generation and corruption.]

For since the whole economy of inferior Nature consists in the perpetual alternation of generation and corruption — generation being followed by corruption, and corruption necessarily by putrefaction — and since [Nature] continually attempts to produce something living, it has come about that the malignant element inherent in putrefaction, and imbued with a venomous quality, [Nature] derives within itself, as it were, by a certain natural magnetism, and in this way frees the putrid body from which it is born of its own malignity. And unless this were done, the entire substance of the earth, infected with this venomous quality while it is continuously propagated, would inflict enormous and irreparable damage upon Nature.

[Margin: The minerals are the seedbed [variaturum (?)] of venomous things.]

Lest, then, plants or animals already imbued with the venomous quality should again infect the earth with their poisonous breath, [Nature] for the most part destined them to be the food of other animals — whence the venomous quality, dissipated and consumed, is turned into harmless nourishment for certain animals. Again, since the earth is the basis and foundation of all things, hence it comes about that the poison which arises in the innermost bowels of the earth, out of putrefaction and the confluence of malignant qualities, is imparted partly to the water, partly to the air.

[Margin: The minerals (?) [marginal note partly cropped at gutter] — Nature appointed certain plants and insects to draw poison; in earth, water, and air.]

And lest all the elements should be infested by this contagious putrefaction, Nature with remarkable sagacity has everywhere provided certain plants and insects which, just as they draw their origin from a different [source of] putrefaction, so too each, from an appetite implanted in them, draws and derives into itself that poison which is most agreeable and akin [σύγγειον (?), *synggeion* (recte σύγγενες, *syngenes*, "akin / kindred")] to it. Within the earth, indeed, [Nature] established innumerable worms, earthworms, mice, and moles; outside it, serpents of every kind, frogs, toads, and similar venom-bearing animals, which by continuous sucking would free the earth from its deadly quality. In the watery element, [Nature] established other animals of venomous quality — such as sea-hares [leporos marini], cuttlefish [lorigines], dragons [dracones, weever-fish], stingrays [pastinacae], sea-lungs [pulmones marini, jellyfish], and innumerable similar creatures — which would draw into themselves, as into living purses, whatever lethal thing existed within the water; and in this way, lest in time the whole [be infected]... ..so that they do not, as it were, lie idle and lack their own purpose, they serve as bait and nourishment for other fish.

In the air likewise, since a certain venomous thing is always nested there from the noxious exhalation of putrefaction, Nature again provided in the first place for certain insects which, by drawing into themselves the putrefactive influx from which they took their own origin, might in some way purge the air. Of this kind are flies, spiders, wasps, and all the genera of winged insects, which arise from the putrefaction of water and which afterward serve as food for swallows, bats, and similar animals.

[Margin: Why nature wished poisonous animals to exist.]

For this reason too, all plants, according to the diverse putrefaction of their malignant quality, generate different little creatures according to the diverse species of plant and tree — for no other purpose than to free the plant from the pernicious quality by means of the poison drawn off from it by these creatures. Again, there is no animal that does not generate worms from the putrefaction arising within it, and for no other purpose than this: that the harmful quality born of putrefaction somewhere within should be drawn off into these little creatures, as into living purses of the malignant quality, and so deliver the animals from the superfluous humor of their noxious quality. But I shall treat these matters of the productive power of putrefaction more fully in what follows, and expressly in Book XII.

[Margin: The poisons of minerals pass over into plants.]

Since therefore the body of the Earth teems with an innumerable variety of soils, minerals, and juices, it follows that these, altered in various ways by the subterranean heat, constitute as many genera of differing poisons as there are differing mixed bodies in the nature of things. And since these are of a malignant nature, then — lest they should infect the whole lower world — they degenerate partly into poisonous plants, partly into serpents and countless other animals swollen with poison, as will afterward be shown by the survey of particular cases. But three things above all are found in the subterranean realm which, mingled with the kindred parts of the earthy and mineral juices, constitute every variety of poison; and these are sulphur, mercury (that is, quicksilver), and salt.

[Margin: What the poisonous minerals are.]

Sulphur, burnt up by violent heat and as it were sublimated by the subterranean fire, wherever it finds earth suited to it, there produces a poison — either arsenic, or orpiment [auripigmentum], or sandarach [sandaraca], or realgar [risigallum], which are certain species of arsenic and take their origin from burnt sulphur. Mercury, however, sublimated by the subterranean fire, wherever it finds matter analogous and proportioned to itself, there produces either antimony, or white lead [cerussa], or litharge [litargirium], or something similar not unlike sublimated mercury — which is likewise a most efficacious poison of an almost insuperable malignity. Again, a varied mixture of salts, vitriol, niter, and alum with sulphureous, mercurial, bituminous, and naphtha-bearing liquids constitutes, according to the varied combination of its composition, a new seed-bed of poisons, all the more pernicious the more it has been fixed by the force of the subterranean heat.

These three principles of poison, according to the varied combination of mixture which they establish in earthy and mineral bodies, supply an innumerable variety of poisons. Hence there is no mineral, metallic, earthy body that does not abound in poisonous quality, one more than another. That this is so, perhaps only he will deny who is ignorant of the marvelous secrets of Nature drawn out by the operation of the spagyric art [ars spagyrica — alchemy/chemistry]. And let this much be said about the poisons generated in the mineral realm.

[Margin: Poisonous plants arise from poisonous and venomous juices.]

If now we examine the vegetable economy more exactly, we shall clearly find that all the offspring of poisonous plants and trees derives its origin from no other source than the poisonous juices of the earth itself. For from the fermented

putrefaction of a species of earthy or mineral poison — by however slight a movement of nature — a plant is born with a poisonous juice resembling it in its properties; or, if the putrefaction has reached a higher degree, an animal of the serpent or insect kind is born, entirely resembling the poisonous putrefaction in its properties and powers. From this it is clear that all the animals born from venomous putrefaction are themselves poisonous, and imbued with all the more dreadful a poison the greater the violence of the mineral poisons of which the putrefaction is composed.

[Margin: From the most poisonous minerals, namely the corrosive ones, sometimes a plant, sometimes a poisonous animal is generated.]

But let us make the matter clear by example. There are in the mineral realm, as we have said, arsenic and sublimated mercury, the most powerful of all earthy poisons, inasmuch as they corrode, gnaw, and reduce to corruption. The fermented putrefaction of arsenic produces napellus [monkshood] or aconite, entirely similar to it in arsenical virulence; but if it is sublimated into a more excellent putrefaction, then it generates either the asp [aspis] or the phthias [phtias — a poisonous serpent], dreadful in the ferocity of its venom. Nor does the poison of napellus seem to differ from the poison of the asp, except that the poison in napellus is somewhat blunted by moisture, whereas in the asp or phthias it is, as it were, exalted — being most spirituous, so most efficacious. For at their bite all the members of the human body are at once corroded and putrefied and dissolved into corruption, in exactly the same manner as when arsenic or napellus has been taken.

And if a certain putrefaction is imbued with mercurial virulence, then — brought from potency into act by external heat — it will generate either the venomous dracunculus [a small serpent], or, if the subject has been imbued with a more excellent putrefaction, the dipsas [dypsas]: which three genera of poison are of such power that, taken internally, they kill a man without remedy by corrosion and unquenchable thirst.

Again, if arsenic, mercury, and burnt vitriol are mingled in putrefaction, there will be born the plant haemorrhoids, or the serpent of the same name, the haemorrhous — each of which possesses this power among these three: that whoever is infected by it,

with all the veins and vessels corroded, dies in a flux of blood bursting forth from all the members of the whole body. Such serpents, they relate, are born in America with such virulence that a man bitten by the haemorrhous pours forth

both his blood and at once his life — through the mouth, ears, eyes, nose, the passage of the urine, the seat, the navel, and finally through all the pores — in a pitiable and terrifying death. Pliny [Plinius] relates that the plant haemorrhoids does the same.

COROLLARIUM I.

[Margin: All serpents correspond to herbs and to minerals.]

From these things it is plain that all the genera of serpents so correspond — as regards the likeness of their powers — to herbs and to mineral poisons, that, just as both vegetables and sensitive creatures draw their origin from them, so too they are endowed with the same powers. And just as the combination of poisonous qualities in the minerals from which they arise is most diverse, and they differ in species, so too the poisonous qualities, powers, and properties of herbs and of animals differ utterly in species — as will appear a little later from their effects. So much so that no combination of mineral poison arises which does not produce a herb or an animal of that same combination. For according as they partake more or less of the combination of earthy poisons, by so much do they likewise harm more or less; and hence arises that diverse property of poisons which we marvel at in the threefold realm — mineral, vegetable, and animal.

COROLLARIUM II.

[Margin: How poisonous animals are bred in the waters.]

From this it is clear how poisonous animals of corresponding mixture are bred in the waters. For if the putrefaction of earthy and mineral poisons is diffused through the waters, animals resembling that putrefaction must necessarily be born from it — animals which come forth in all the greater abundance the greater the proneness to generation that the foul mixture of the sea and of the other waters obtains. And from the subtle and thin vapor of the differing putrefaction, those infected, poisonous things — the various species of spiders and cantharides [Spanish flies] — are produced by spontaneous generation. Nevertheless, in the sea the least progeny of poisonous animals of all is observed, on account of the abundance of salt, which is contrary to putrefaction.

CAPUT III.

On the accidental generation of poison in the remaining vegetables and animals, both living and in the cadavers of the dead.

[*De accidentali veneni in caeteris vegetabilium, animaliumque tam vivorum, quam mortuorum cadaveribus genesi.*]

Since any plant and any animal whatever needs continual nourishment to preserve its life, and since all foods consist of sulphur (that is, natural heat), mercury (that is, the radical moisture), and salt (that is, the fixed or earthy substance), together with the aerial spirit — hence it comes about that no food is so wholesome that it does not have attached to it something corrupted from sulphur, mercury, and salt. This corrupted element, whether drawn in by plants or taken in by animals, being gradually actuated by the native heat, generates a certain putrefaction of malignant nature; and from this there is then born, in plants and trees, a little worm or caterpillar of similar powers. And this can be nothing other than a kind of animated purse, in which Nature, for the preservation of the whole, has stored up all the separated depravity and the latent malignity, as a sort of magnet for it.

[Margin: Plants are converted into worms... (left-margin note partly abraded) [?]]

These things are seen in all plants, even the most wholesome — indeed even in animals, which serve us as daily food. Who does not know that the maidenhair [maillratham / capillus Veneris (?)], or fennel and sage, are otherwise most wholesome plants, which nevertheless from an innate putrefaction generate a worm? Those who incautiously eat of them are tormented by the most atrocious symptoms even unto death — so that this saying may fittingly be applied to them: "the corruption of the best is the worst." Indeed, taught by experience (as will be shown in the following books), I assert that no herb, whether benign or malignant, is found that does not generate a caterpillar or little worm, differing according to the diversity and property and powers of the herbs, and imbued with all the more atrocious a poison the more malignant the herb —

for there is no combination of mineral mixture that does not produce a herb or animal of that same combination. For according as they partake more or less of the combination of earthy poisons, by so much also do they harm more or less; and hence arises that diverse property of poisons which we marvel at in the threefold realm — mineral, vegetable, and animal.

Any plant and animal whatever, then [resuming Caput III's argument] — hence so great a variety of worms, caterpillars, and butterflies, differing in species, arising in the several roots, leaves, seeds, flowers, and fruits of plants and trees; in apples too, pears, nuts, galls, acorns, pods, and legumes, each produce their own worms. These all, just as they are born from putrid matter, so too obtain a greater or lesser degree of poison — excepting, however, the acid fruits and those endowed with juices of the highest sharpness, such as citrons and pomegranates and the like, which, as long as they have their juice uncorrupted, cannot generate an animal. Yet as soon as they pass into putrefaction, they attempt to set about the same thing [generation of worms] — all of which I have established as observed and explored under the microscope [microscopium]. And although in the resinous trees and plants, such as pines and larches — that is, in the resin itself — no animal can be generated, because a certain balsamic virtue residing in them is contrary to putrefaction, yet in the other parts of such trees a certain noxious and poisonous kind of caterpillar, which they call the *buprestis* [Buprestis], is found to be born, and to inflict death on those who incautiously eat it, after dreadful symptoms have been roused.

[Margin: All animals generate worms proper to themselves.]

If now we explore the animal realm, we shall see that you may regard no genus — whether of quadrupeds, of birds, or of swimming creatures — that does not generate a worm appropriated to itself. In this way, horses, asses, dogs, cats, lions, stags, and whatever animals there finally are, generate worms: the excrement of horses [generates] beetles; bees, oxen; stags, tragelaphi [tragelaphus — fabulous goat-stag]; other animals generate *κάνθαριδας* [Greek: kantharidas, "cantharides," blister-beetles]; while in the subcutaneous recess [they generate] ticks, *cicubi* [?], moths,

moths, *acori* [?], lice, fleas, cockroaches, and similar creatures. What cause do you suppose it is that horses, hens, asses, and pigs delight — the former in wallowing in dust, the latter in mud? Nothing other than that they are infested by certain subcutaneous worms, and that the worm-bearing substance is destroyed by the sharpness of the dust no less than by the wallowing-place. And the same I would have you understand of the other animals that bathe in dust.

[Margin: Why pigs delight in the wallowing-place; why asses and hens delight in dust-baths.]

I shall say nothing here of the human body, all of whose inner vital-economy members, according to the *ἰδιοπάθεια* [Greek: idiopathea, "particular affection"]

— the proper disposition] of the putrefaction proper to those members, generate worms of differing species. Some of these introduce putrefaction; certain ones, by gnawing, gangrene; others, a deleterious quality into the vital members — so much so that from this worm-bearing substance neither the heart, nor the liver, nor the brain, nor the kidneys, the spleen, the bladder, and the lungs (to say nothing of the intestines and the stomach) are immune.

[Margin: Poisonous animals are born in all the members of animals, and of man too, from corrupted humors.]

I saw a sick man who, from the excessive malignity of putrefaction, vomited up a living frog. Schenk [Schenckius], too, in his *Observations*, reports that scorpions were born in the brain, and serpents in the intestines. But since all the monuments of the physicians are full of such cases, and since we have pursued them in our *Scrutinium Physico-Medicum de peste* [Physico-Medical Examination of the Plague] in an entire book, I refer the reader there.

[Margin: A sick man vomits up a living frog.]

The physicians wonder why gangrene admits so difficult a cure; and if they knew its cause, they could perhaps easily meet so great an evil with suitable remedies. For there are little worms imbued with a certain arsenical force, which under an imperceptible bulk do not cease to gnaw the neighboring parts of the living flesh, and by gnawing convert the flesh into corruption by their malignity.

[Margin: Why gangrene is difficult to cure.]

Not long ago August Hauptmann [Augustus Hauptmannus] wrote a little book *De viva mortis imagine* [On the Living Image of Death], in which he clearly demonstrates that all diseases arising from malignant putrefaction have their origin from a worm-bearing substance; and he adds that, in a gangrene arising from the venereal pox, there were observed through the microscope worms almost imperceptible, of the form of slugs, which within the gangrene-infected flesh turned everything topsy-turvy, just as worms do in burrowing through cheese —

[Margin: A remarkable observation concerning the worms seen in the putrefaction of gangrene.]

— and of such swift generation that one such little worm, placed upon paper, in the span in which the psalm *Miserere* could be recited, had cast off fifty others outside its body; and these, just as they are poisonous of themselves and by their own nature, so too, whatever particle of living flesh they touch, they reduce to

corruption by their innate malignity. Why, then — notwithstanding the cutting away of the living flesh in gangrenous cases — does the evil nonetheless creep on? The cause is that even a single such little worm remaining in the living flesh suddenly generates innumerable others like itself; whence these, by a kind of spreading rot, propagate the evil without measure. From which they conclude that the most acid and sharpest liquids are needed to destroy them.

[Margin: From what minerals are poisonous?]

If further we consider the putrefaction that shines forth in the cadavers of various animals, we shall find that poisonous animals — such as putrefied serpents — spring up again from their own proper putrefaction, as the phoenix from ashes; or, if the putrefaction undergoes a weaker fermentation, are transformed into some poisonous herb. For experience establishes that, in those places and pits into which carrion and the cadavers of various animals are thrown, for the most part poisonous herbs of every kind are born — such as hemlock, aconite, napellus, henbane [hyoscyamus], asafoetida, or cotula — which, being themselves born from putrefaction of a poisonous quality imbued with arsenical and mercurial qualities, likewise produce herbs of a similar quality.

[Margin: Poisonous serpents are reborn from a putrid carcass... (margin partly abraded) [?]]

The same holds even in herbs that are not deleterious. For [experience establishes] that from the seed of putrefied human or animal cadavers there are born satyrion [an orchid], philtric [aphrodisiac] herbs, and similar plants, which in their roots, bulbs, and flowers express those very members from whose putrefaction they grew.

[Margin:...from human cadavers herbs are born that express the genital members... (margin abraded) [?]]

[Margin (right): The seed... (abraded) [?]]

I could here unfold the mysteries of Nature, but since we hint at these in other places, we have judged it superfluous to dwell on them here. Since therefore almost nothing corporeal exists in the nature of things that is entirely immune from a malignant quality, hence arises that infinite diversity of poisons, which we shall pursue in the following chapter.

CAPUT IV.

On the differences of poisons.

[*De Venenorum differentiis.*]

[Margin: What things among the minerals are poisonous?]

1. There are as many differences of poisons as there are primary differences of mineral mixed-bodies — in such a way, however, that certain minerals are, of themselves and by their own nature, alone properly called poisons; and from these, as from a base and foundation, all the rest with which they are mixed acquire more or less of poisonousness according to the manner of their combination. Now there are, in the subterranean realm of minerals: arsenic, quicksilver (or mercury), cinnabar [Cinnabrium] — in Arabic *Uschar* [Usfar (?)] — quicklime, gypsum; red ochre of Sinope [Rubrica sinopica], litharge, white lead [cerussa], minium [red lead], verdigris [aerugo], pyrites, antimony, rust [rubigo], and the like — which take their origin from sulphur, as do the species of minerals already mentioned. These, mingled with various liquid, bituminous, and flowing juices through the fourfold difference of salts, lay down an immense seed-bed of poisons.
2. In the Vegetable Realm, the most powerful poisons are reckoned to be: napellus [monkshood], euphorbium, hemlock [cicuta], aconite, tithymal [Tithimallus, spurge], lathyrus (or cataputia), scammony, colocynth, hellebore, the wild cucumber [cucumis asininus], rhododendron, the laughing parsley [apium risus — sardonic-laughter herb], thapsia, haemorrhoids, stramonium [thorn-apple], maniacal nightshade [solanum maniacum], mandrake [mandragora],

[Margin: What plants are poisonous.]

A RESOLUTORY TABLE

A classification of all the poisons that can be distinguished in the Nature of things.

The following is a full-spread classification table presented as a branching tree. The top-level division is by natural realm (Minerals, Vegetables, Animals, Things produced from poisoned food). I render it as a nested pipe-table, reproducing the printed tree structure; the innermost lists are given in the rightmost cell. The

Latin plant, animal, and mineral names are kept as printed, with modern identifications in brackets at first occurrence where non-obvious.

Minerals [Mineralibus]

Division	Sub-group	Species / members
1st Class is	Arsenic [arsenicum], of which the species are	Orpiment [auripigmentum]; Realgar [sandaraca]; Risigallum [risigallum — red arsenic sulphide]; Ochre [ochra]; Antimony [antimonium].
2nd Class are	(lead-derived) species	Ceruse [cerussa — white lead]; Minium [red lead]; Cinnabar [cinnabaris]; Verdigris [aerugo]; Rust [ferrugo].
	(further)	Lead [plumbum]; Scum of silver [scuma argenti — silver dross]; Litharge [lithargyrium]; Quicklime [calx]; Gypsum [gypsum].
3rd Class are	—	Sulphur [sulphur], alum [alumen], natron/nitre [nitrum], in their corrupted state. — And these are the primordial origin of all the other poisons that follow. [Atque haec sunt omnium aliorum sequentium Venenorum primordialis origo.]

Vegetables [Vegetabilibus]

Used as to the whole [quoad totum]	Used as to parts [quoad partes], namely in:	Members
The whole plant , such as:	—	Aconite p[?] [aconitum — likely <i>aconitum</i>

Used as to the whole [quoad totum]	Used as to parts [quoad partes], namely in:	Members
		<i>pardalianches</i>, leopard's-bane, abbreviated]; Lycotonum [wolfsbane]; Napellus [monk's-hood aconite]; Cicuta [hemlock]; Hyoscyamus [henbane]; Several kinds of tithymal [titimallorum genera — spurges]; Cataputia [caper spurge]; Several kinds of nightshade [solanorum species]; Apium risus [the "laughing" celery, <i>Ranunculus sceleratus</i>]; Mandragora [mandrake]; Veratrum or hellebore [veratrum seu helleborus]; (and) from trees, the Yew [ex arboribus Taxus].
	In the seed [semine]	Henbane [hyoscyamus]; Coriander [coriandrum]; Hemlock [cicuta]; Nigella [fennel-flower]; Psyllium [fleawort].
	In the juice/sap [succo]	Poppy opium [papaverum opium]; Carpasum [carpasum — a poisonous juice]; Thapsia [thapsia]; Veratrum [hellebore]; Colocynth [colocynthis]; Scammony [scamonea]; Colchicum [colchicum — meadow saffron].

Used as to the whole [quoad totum]	Used as to parts [quoad partes], namely in:	Members
	In the roots [radicibus]	Chamaeleon-thistle [chamaeleontis]; Aconitum pardalianches [leopard's-bane]; Veratrum [hellebore]; Thapsia [thophae]; Hemlock [cicuta]; and the rest [caeterorumque].

The serpent group attached at the right of the vegetable/whole-substance spread (printed alongside the reptile leaders) lists: Vipera [viper]; Aspis [asp]; Dyspas [dipsas]; Phtias [phthias]; Dryinus; Amphisbaena; Scytala; Haemorrhoids [haemorrhoids]; and countless others [& innumera alia].

Animals [Animalibus]

From which poisons arise either:

(A) As to the whole substance of creeping things [quoad totam substantiam reptilium], namely:

Habitat	Members
Terrestrial [terrestria]	All kinds of caterpillar [omnia erucarum genera]; Salamander [salamandra]; Frogs, toads, the louse of the vulture [ranae, rubetae, bufones, pediculus vulturis]; the kinds of poisonous worm [scorpius virulenta vermium genera].
Aquatic [aquatica]	The marine hare or sea-lung [lepus seu pulmo marinus]; Leeches [hirudines]; Aquatic flies [muscae aquatiles]; the marine spider [araneus marinus].
Aerial [aëria]	Cantharides [blister-beetles]; Butterflies/moths [papiliones]; Heliocantharus [the "sun-beetle"]; the Bee [apis]. — Every kind of winged

Habitat	Members
	insect [omne aligerum infectorum genus].

(B) As to animals infected by putrefaction [quoad animalium infectorum ex putri], they are either:

- Bull's gall [fel taurinum]; the brain of a rabid cat [cerebrum catti rabiosi]; the bite of rabid dogs and of all rabid animals — even of man [morsus canis rabidi, caeterorumque animalium rabiosorum, etiam hominis]; the claws of any animal, whether four-footed or winged [ungues animalium tam quadrupedum quam volucrium]; the foam of any raving animal [spuma quorumcunque animalium furentium]; bats, owls, the hoopoe, and the like [noctuae, vespertiliones, upupae & similia].

(C) From the perfect parts of animals [animalium perfectorum partibus], such as:

Mode	Members
By the sting [aculeo], as	Bee [apis]; Scorpion [scorpius]; the sea pastinaca/stingray [pastinaca marina]; the spine of the sea [spina maris].
By projection or fluid [promiscide aut liquore], as	Flies [muscae]; Gnats [cyniphes]; Midges [culices]; Certain flies [certae muscae]; Hornets [crabrones].

From things used as food [Ex cibis usitatis]

Such as:

- Honey gathered by bees from poisoned flowers [mel ex floribus venenatis ab apibus collectum];
- Curd/rennet curdled in any way [coagulum lacti mixtum];
- Mushrooms of any kind whatever [fungorum quaecunque genus];
- The eating of marsh-frogs and of slugs/snails [ranarum palustrium & limacum comestio];
- Coriander and saffron taken in great quantity [coriandri & croci in magna quantitate sumptio];
- Fish from standing waters, such as eels, tench eaten cold after cooking [pisces stagnorum, uti anguillae, tinca post coctionem frigidi comesti];

- Dried meats, and meats afterward suffocated and then eaten cold [carnes assatae & postea suffocatae, deinde frigidae comestae];
- Anything at all in excess, finally, in whatever class of foods or drinks [omne nimium in quocunque tandem genere liquorum & ciborum].

[The text resumes from the body of folio 109, where Caput IV continues; the table above is referenced at the close of Caput IV ("See the following Table, where all things are displayed").]

— psyllium, and very many kinds of fungi. All these draw their origin, just as from the subterranean juices of minerals and from their various mixtures, so too each of them obtains its own properties from those things out of which they are born.

[Margin: Poisonous animals. (Animalia quae venenosa.)]

3. In the animal kingdom poison is found in a fourfold division — namely among quadrupeds, flyers, swimmers and creepers, or insects. These especially are reckoned among poisons. Among perfect animals I find no quadruped poisonous as to its whole substance, but only as to a part — such as the brain of cats, the gall of a bull, the sweat of certain animals (such as deer), the hairs of cats taken internally, the tail of shrews [cauda soricum], the rennet of a hare [coagulum leporis], bull's blood [sanguis taurinus], and the bite of rabid animals. And among the four-footed insects: dragons [i.e. large lizards], the stellio or salamander, the toad, the bramble-toad [rubeta], the crocodile, certain lizards, mice; and, midway between quadrupeds and flyers, the bat.

[Margin: Which among the flyers are poisonous? (Ex volucris quae venenosae?)]

4. Among the flyers, most of the nocturnal birds are of a saturnine nature; thus the various kinds of owl have something of poison in them. The winged tribe of insects is almost entirely poisonous, being as it were generated from the vapor of a deleterious matter — such as the cantharides, the bruchi [wingless locusts/grubs], butterflies, flies, locusts, gnats [cyniphes], silkworms [bombyces], and finally whatever is furnished with several feet besides wings.

Among the swimmers, these are counted poisonous: the sea-hare [lepus marinus], the water-snake [natix], the stingray [pastinaca], the leech or bloodsucker [hirudo sive sanguisuga], the sea-lung [pulmo marinus], certain squids [lorigines], eels born from the rotten mud of marshes [anguillae è putrido paludum limo]

natae], certain frogs or the aquatic toad [bufo aquaticus], water-serpents [serpentes aquatici], the torpedo-ray [torpedo], and so on.

[Margin: Which among the reptiles? (Ex reptilibus quae?)]

5. Among reptiles: all the kinds of serpent — the asp [aspis], the phthias, the dipsas [dypsas], the viper [vipera], the boa, the cerastes [horned viper], the haemorrhoids, all the kinds of worm, the amphisbaena, the caecilia [a blind serpent]; and among the many-footed, the scorpion, the spider, the millipede [millepeda], the scolopendra [centipede]. All of these are accustomed to poison human beings — whether by their breath, by their bite, by sting or stinger, by ejection of a poisonous fluid, by the foam of the mouth, or even by immediate contact.

The asps poison by breath, the vipers and the other serpents by their teeth; the scorpions by their stings or stingers; the toads by the ejection of poison; the rabid dog by the foam of its mouth. Some serpents are found to blast [siderare] people merely by the quality of their poison when trodden on; and some, too, infect by the diffusion of their poison through an intervening medium alone, as do the torpedo-rays, the asps, and the phthiades.

[Margin: Examples of poisoning by poison. (Exempla veneno intoxicatorum.)]

I myself knew one of our people who, when he struck an asp sitting in a tree, was so stricken by the creature's breath alone, by a kind of blasting [sideratio], that it rendered the man motionless for three whole years; and from this — no remedy availing against such a poison — he afterward died. There was also another who, having incautiously trodden on a serpent, perished a little later of paralysis, or rather of apoplexy.

[Margin: A poison proper to human beings. (Venenum hominibus proprium.)]

6. Among poisons there is also reckoned the lethal contagion of pestiferous bodies: the carcasses of any animals at length [animalium quorumcunque tandem cadavera], the carrion-flesh [moticina], the foul discharges of women's menses [menstruae mulierum sordes] — from which countless evils result; and lastly all those animals that are generated either from vegetable matter or from other animals.

Here, Reader, you have the six classes of poisonous bodies; out of whose malignant qualities, together with the foods in which they reside, all the kinds of disease arise. See the following Table, where all things are set out.

CAPUT V.

On the difference between Nourishment, Medicament and Poison; likewise on the agreement and disagreement of things — which they call Sympathy and Antipathy — in its various divisions; and on whether the strife and friendship of things is brought about through the primary or elementary qualities, or through the specific virtues of things.

[Margin: The difference between nourishment, medicament, and poison.
(Differentia inter alimentum, medicamentum & venenum.)]

All physicians assert that poison is diametrically opposed to nourishment. The medicament, however — the ἀλεξιφάρμακον [Greek: alexipharmakon, "antidote" or "remedy against poison"] — stands midway between nourishment and poison as between two extremes, partaking more or less of each. For things that are in the highest degree opposed to one another must necessarily share in the same genus; otherwise there could be no equal contest between accidents. Therefore poison, nourishment, and the alexipharmic [antidote] will, among the physicians, belong to the same genus — namely, they are placed among the non-natural things, which, by reason of their effect, they call efficient causes. For, as we noted above, those things are called non-natural which exist neither according to nature nor simply contrary to nature, but which can turn out to be such [as to produce an effect]: nourishments indeed by increasing and feeding; medicaments by correcting; and poisons by corrupting and destroying.

And those things which are appointed by nature for preservation — namely nourishments — must first be overcome by the innate heat, so that they may acquire a certain likeness to the thing nourished, before they can be converted within bodies into a substance similar [to it]. Medicaments, on the other hand, are first acted upon by heat and brought into act, and then in turn they themselves act upon the body and reduce that same body to a better state. But the case of poisons is different: for whether they are broken down by heat, as those that are cold, or are merely roused up, as those that are hot, they act upon the body not by preservation or restoration, but by total corruption. For just as nourishment is so called from the very fact that it can nourish [alere], so likewise medicaments — whether...

Liber IX, Sectio I — Caput V (continued)

(Folio 110, verso. Running header: "LIBER NONUS, Sect. I.")

or [sive] ἀλεξιφάρμακα [Greek: alexipharmaka, "antidotes"], because they are by their own nature fitted to heal; and poisons, [sive] δηλητήρια [Greek: dēlēteria, "destructive things, poisons"], because they are fitted of themselves and by their own nature to corrupt. And so, if they are ever found to do good and to help, this they do not in their own right but only incidentally. For although they may serve as a nourishment or a medicament, or at least do no harm with any malice, they can nevertheless incidentally bring on the utmost malignancy, capable of destroying the whole.

And although poisons are properly opposed to nourishment by a contrariety of nature, antidotes [alexipharmaca]—even though they too are counted among poisons—are so blunted by the admixture of other substances that they cannot exert their full force. This is clear, first, in the case of antimony, sandarac, and pyrites, which, being mixed with the not-unwholesome substances of earthy clods, cannot exercise their suppressed powers; and so, as will be shown later, once first corrected, they pass into medicinal use. The same must be said of colocynth, scammony, euphorbium, esula [spurge], and the like; for since they consist of a coarse humor, they are not so efficacious as the pure poisons are, and so they can be taken into medical use only after first being corrected.

[Margin: How a poison can serve as a medicament.]

I say further—**All corrected poisons pass into the use of medicine**—that there is no poison so potent and so pure that, once first corrected, it cannot be taken into medicinal use. So it is with vipers, toads, scorpions, and the other serpents, however venomous: the flesh of the viper, indeed, constitutes the base [hypostasis] of theriac; toads are taken as an effective antidote against the plague, as we showed in our book *On the Plague*. Nor is there any poison that cannot be applied as an antidote within the very species of poison by which one has been infected.

[Margin: A rare case.]

[Margin: Poison is the remedy for poison.]

Yet it is remarkable that one poison should be a poison to another. For example, the poison of the toad kills a man, but the spider [araneus] by its own venom kills the toad in turn; and the venom of the Tarantula of Apulia—as we showed in our *Art of Magnetism* [*Ars Magnetica*—rubbed in the manner of a plaster over an inflicted wound, extinguishes the poison itself; and so with the rest, the reasons for all of which we will try to give later. I myself saw an apothecary at Erfurt in Thuringia who had procured serpents of every kind, alive, destined for medical

use. When he handled them somewhat incautiously, having placed them in shells [conchas], he was bitten by one of them, and at once the injured limb swelled; then, struck as it were by a sudden stupor of the whole body from the serpent's venom, he trembled. Physicians were summoned, and although every kind of antidote was administered to him without any benefit, at last a more skilled physician among the rest asked the sick man which of these serpents had bitten him. He said an asp [aspis]. So they cooked that very one and gave him its prepared flesh to eat; scarcely had he taken it when—lo!—he at once began to feel better, and by continuing that food through a whole day, he at last completely recovered.

There are those who, fed on the flesh of a most venomous viper and on wine steeped with viper [vino viperato], not only suffered nothing harmful but—what is worthy of admiration—were, with every corrupt humor expelled, brought back from a leprosy otherwise incurable into a perfect state of health. Hence, that viper-flesh avails very greatly for the prolongation of life is so well known that it would be tiresome to say more about it. Let the reader see what truly wonderful things we set forth concerning the cave of serpents in the Third Book of the *Art of Magnetism*. But let us return to our intended purpose.

[Margin: All elements with time generate putrefaction.]

I say, then, that there is no element, however wholesome, that does not with time generate putrefaction, and no putrefaction that is not animated into some worm—which, as it does not lack its own venomousness, so neither is it free of all poison. The worms born of the lees of wine and of corrupted grain, with their intolerable stench, demonstrate this abundantly.

It must therefore be noted that every motion and effect is born from the discord and conflict of contraries. For Nature, when she subjected the whole frame of this World to continual change, at the same time necessarily sowed it, as if with seeds, with various kinds of discords; she established the four primordial things—Water and Fire, Earth and Air—as contraries, and to each thing that arose and proceeded from them she opposed something else by the law of discord. Thus to diseases that are contrary through an imbalance [intemperies] she opposed strengthening powers drawn from a balanced temperament; to diseases arising from matter she opposed the contrary properties of matter in some species; and as the secondary powers of medicaments, working through instruments, she opposed the powers that arise from the mixing of matter and temperament. Indeed—what is more wonderful—many things demonstrate that matter, in one and the same simple thing, sometimes combines this very contrariety of qualities.

[Margin: How milk both binds and loosens.]

In this way the serous and buttery part of milk relaxes the bowels, while the cheesy part checks and binds them.

[Margin: An antipathy of things through grief.]

Again, on the testimony of Galen [Caelio? — *Galeno teste*], a decoction of trefoil [trifolium], applied as a fomentation to the bites of a spider or a viper, at once soothes the pains and draws out the venom; yet the same, applied [to the part?], stirs up pains like those that the venom itself causes.

[Margin: An antipathy of things.]

The flowers of chamomile, by their smell, are good for headache; the leaves, by contrast, applied to it, are extremely harmful. The leaves of dock [lapathum] loosen, but the seed taken constipates. Aloe, taken internally, opens the veins of the hemorrhoids, while the same applied externally in the manner of a plaster closes them by staunching the blood. Eggs that are liquid and supping-soft produce a different effect from the same eggs roasted. The reason for this is that in herbs one part has a greater digestion of moisture than another; hence one part of a plant accordingly yields one effect in the human body, and the flowers of the same plant—of a purer and better-digested substance—another.

[Margin: Heat the craftsman of differing powers.]

For the craftsman of these differing powers is heat, which, according to the diversity of its degree, produces one effect in the root, another in the stem, another in the flower, and another finally in the fruits and seeds—as may be seen in...

(Folio 111, recto. Running header: "DE VENENIS.")

the citron-apple [pomum citrium], whose innermost pith, being of an astringent nature, presses out I know not what mineral juice, by which, through a certain corrosive force and coldness, it harms the stomach; whereas the rind, by its natural heat, contributes very much to that same stomach—indeed, just as by its natural mark [characterismus] it represents the heart, so too it is marvelously beneficial to it.

As, therefore, certain things are by their whole substance familiar and friendly to us, and as it were preservers of our nature—such as the nourishments suited to our nature—so certain things are by their whole substance hostile and inimical to us, namely poisons; whose qualities, for that reason, we call hidden [occultas], or

properties either of the form or of the whole substance. For nourishment nourishes us precisely because it is like us in its whole substance; and this likeness is neither a matter of temperament nor of the materials, but only of the forms, or indeed of all of these together—which likeness we call a likeness of the whole substance. For although wine, bread, and vegetable are, as to their matter, nourishments very unlike us, yet as to their form they become very familiar, friendly, and like to us, because they contain within themselves a certain kindly spirit of life and heat, exceedingly proportioned to our vital spirits; by whose arrival our spirit and heat are cherished and sustained, and which at last, together with the nourishment in which it resides, is converted by the likeness of nature into the substance of the thing nourished. This cannot be ascribed to the first elementary, or manifest, qualities; therefore that effect of nutrition is necessarily constituted in the spirit, or in that celestial heat of the innate form.

[Margin: Specific qualities act differently from manifest ones.]

[Margin: Nothing can nourish us unless it has first been imbued with life.]

Hence nothing can nourish us unless it too is nourished, and is, or once was, endowed with life—which does not hold for minerals. Hence most minerals, unless joined to vegetables, cannot be taken without harm, since they are inanimate and do not sustain nutrition. To this substance of nourishments, then, are diametrically opposed those things that are deleterious and poisonous in their whole substance, because, while what is in us is kindly and familiar, they—by their virulent and malignant force, when they strive to turn all the humors into their own likeness—utterly corrupt and destroy them. A middle place is held by the purging medicaments, which are partly like and partly unlike us, and which, although they do not pass into nourishment for us, nevertheless do not destroy our nature, but take a certain middle path, as will be declared in what follows. But let us now examine each of the things said up to this point concerning the effects of Sympathy and Antipathy by way of Questions.

QUAESTIO I.

On the Sympathy and Antipathy of poisons; and what precisely are those qualities which they call hidden [occultas] or specific [specificas], said to proceed from a likeness of the whole substance; and whether they can be comprehended by the human mind?

[Margin: The difficulty in knowing the Sympathy and Antipathy of things.]

There is one key to Nature in the most dissimilar materials, namely Unity; and he alone who embraces it must be reckoned to have found it—though no one possesses it unless he perfectly knows the forms of things and the spurs of natural motions, which result immediately from the strife and friendship, or the discordant accord, of things, and which the union and flight of bodies necessarily follow. For beneath these things lie hidden the treasure of all Nature, and the sacred mysteries of Divine Wisdom; imbued with the knowledge of which Solomon [Salomon] gloried so greatly that he judged it to be set far above kingdoms and scepters. Before we come, then, to the investigation of the things themselves, it seemed good first to examine what, of what kind, and how many are the causes of these marvelous operations of Nature.

[Margin: The Sympathy and Antipathy of things from the elementary qualities.]

The accord, then, or discord of things—the former of which the Greeks call συμπάθειαν [Greek: sympatheian, "sympathy, fellow-feeling"], the latter ἀντιπάθειαν [Greek: antipatheian, "antipathy"]—is not single, as some have supposed, but as manifold as the differences found among the entities in the nature of things. For there is no mixed body in the threefold kingdom of Nature—whether mineral, vegetable, or animal—that does not exercise these laws of hatred and love with some other; and these obtain the most diverse causes of their operations, and are referred either to these or to those, or to still other classes of Nature. In some, all of them concur; in some, several; in certain ones, one alone causes a prodigious effect. But lest we be swallowed up in a matter almost infinite, let us reduce all to certain definite classes.

[Margin: From the subtle emission of vapors.]

Of these, the first regards the first, second, and third qualities. The second results from the emission of subtle and imperceptible vapors. The third, from natural likeness and unlikeness, exercises the contrary acts of hatred and love. The fourth arises from the differing constitution of climates. The fifth, from the constitution of the pores in bodies, whereby one outflow of virtue emitted from some other source is received better than another. The sixth, from the vehement motion of the imaginative power, by which the fantastic force sometimes produces wondrous effects, both in the female womb and outside it upon various objects. The seventh, from the fear of a vacuum, by which sometimes wondrous effects arise in the nature of things. The eighth, from harmonic motion, by which certain admirable motions arise. The ninth, from the vehemence of the passions. The tenth, from the peculiar influence of the celestial bodies. The eleventh, from actinobolism [actinobolismus] or the co-radiation of bodies, which we properly

call magnetic—according to which, by a certain analogy [κατ' ἀναλογίαν — Greek: kat' analogian, "according to analogy"], we consider the reasons of all the other things already proposed through a magnetism existing as it were in all things; since attraction and repulsion, or strife and friendship, the consonant and the dissonant, must necessarily occur in every business of sympathy and antipathy.

[Margin: All things consist of friendship and strife.]

But let us now set forth each in fuller detail.

The first class regards the primary qualities—hot, moist, cold, dry; and the secondary qualities—hardness, softness, roughness...

(Folio 112, verso. Running header: "LIBER NONUS, Sect. I.")

smoothness, lightness, and the like. The third, by attraction, repulsion, and so on.

[Margin: How the elementary qualities make sympathy and antipathy.]

Since, then, among the four elementary humors certain strifes and friendships are experienced, it may rightly be asked how, or by what means, or for what cause these are carried out. Some hold that every humor is drawn by an elementary force—wrongly; for they have something else conjoined that sometimes produces the wondrous effects of this kind of attraction. Otherwise it would follow that all such prodigious effects could be ascribed to the four simple and manifest qualities—which is repugnant to experience.

I do not deny, however, in this place, the common rule of physicians, by which it is prescribed that contraries are to be cured by contraries: thus to hot diseases cold things are generally applied, to cold ones hot, to dry ones moist, to moist ones dry. But since these things are known even to the bleary-eyed and to barbers [lippis & tonsoribus], I would lose nothing but time by discussing them at greater length.

[Margin: By what force the ostrich [struthio camelus] digests iron.]

Yet because there is sometimes found in animals a certain heat that can do more than even the elementary woody heat—as when the ostrich digests within a single day iron that could not be consumed by fire except over a long time—it is asked, what is the reason of this? I say it is not done by heat alone, since the heat of the stomach in animals is quite temperate; but rather that there is in that bird something conjoined to the heat of the stomach, by whose power [it is performed], and that this is of the genus of salt—whether of niter, of alum, or of vitriol, in which animals of this kind greatly abound. This salt, excited by the

heat, performs the same in the ostrich's stomach that the said salts—especially vitriol—perform outside the stomach upon any iron plate. For the spirit of vitriol poured upon it gnaws and eats it away within a few hours, by an experiment commonly known. For the natural heat with which the stomach is imbued by nature, acting upon the saline material of the bird, sublimates as it were the saline spirit lying hidden in it, to such efficacy that it can perform this effect—that is, to consume iron. That this material is present in birds, their excrements clearly demonstrate, since with time they wholly effloresce into saltpeter. And from this we gather why all birds, even those accustomed to the water, have a hotter stomach than the other four-footed animals: namely, because they abound in more efficacious spirits of salts, by which they digest and concoct not only bones and every hard thing, but even iron and bronze coins—as do the hen, the duck, and the like. But of these things more in what follows.

[Margin: How an insensible vapor from a body fascinates.]

The second foundation of Sympathy and Antipathy consists in a certain subtle and wholly insensible vapor, which is emitted from some things into the presence of objects; and in this way arise all kinds of bewitchments [fascina]. In this way lovers mutually infect one another, by certain subtle spirits emitted from the eyes, which, raised from the corrupted blood, black bile, and yellow bile, are diffused through the philtric organ of the eye into the beloved thing, and excite savage symptoms—now of love, now of madness, a little after of indignation or fear, and suddenly of joy—all of which arise from spirits variously contaminated in an alien subject, and impelled and dissipated according to the varied conflict of the affections. But see what we have treated more fully concerning these things in the *Art of Magnetism* [*Ars Magnetica*], Book 3, fol. 576, last edition, and in Book X of the *Magia* [*Magurgia*? — Kircher's *Magnes*], on the bewitchment of love.

[Margin: The menses of women.]

To this class are referred the bewitchments of menstruating women, by which they both infect boys, stain mirrors, corrupt wines by their breath alone, kill dogs—wherever they have licked—with a horrible scab and a falling-out of the hairs: an unwonted venom, and to be shunned by all like the poison of the basilisk, with whose venom it corresponds in all respects; and Cardanus [Girolamo Cardano], Fernelius [Jean Fernel], and Andoynus [?] hold that a basilisk can be born from such [menstrual matter].

[Margin: How serpents kill at a distance by their breath.]

Moreover, certain most venomous serpents may rightly be seen to be referred here, which—being filled with this kind of subtle toxin alone—infect even at a distance: such as asps, the phthiades [?], and, according to Pliny [*Plinium*], basilisks. Hence asps blast [men] by their breath alone; the phthiades [phyades] corrupt and putrefy all things; and basilisks, if what is told of them is true, kill by sight alone—which surely can only be by the efficacy of a virulent spirit. But from where this corruption and putrefaction originally arise will be shown below, where it will be discussed concerning the specific and differing qualities of serpents, and the wondrous effects which they inflict by bite, by touch, or by breath.

[Margin: The accord and discord of things from the likeness and unlikeness of things.]

The third foundation of accord and discord consists for the most part in the likeness and unlikeness of things; and this likeness and unlikeness of things must be judged to lie not in temperament, but in the very substance, from whose form they proceed. For no other law of attraction and repulsion can be established. It is asked, then, how this attraction and repulsion come about in things? I say we can explain it no better than through the magnetism that shines forth both in all things and most of all in medicinal things.

[Margin: How rhubarb draws bile.]

Therefore, when medicaments taken internally—such as rhubarb [*reubarbarum*], scammony, senna, and the like—are said to draw the bad humors, they must not be reckoned to do this by any common and elementary force. For the hot acts upon the hot, the moist upon the moist, the dry upon the dry, inasmuch as they are homogeneous; and in the purgatives recited above, [being] analogous to the bile, they cannot act upon one another by an elementary power. Therefore, if rhubarb and the rest draw bile, they perform this by a certain hidden power, which consists in likeness and flows from the substantial form, by an innate familiarity belonging to both. But how this operation comes about, I disclose. As soon as a medicament has been taken into the body, it first seeks that which is most of all akin to it by a likeness of Nature; and presently, by its power diffused, it inquires after the friendly quality; the quality sought out, it moves; and having moved it, it draws it; the quality drawn, to it...

(Folio 113, recto. Running header: "DE VENENIS.")

[Margin: How agaric draws humors.]

and united everywhere, it leads out together with the other dregs through the stool, the vital spirits conspiring in the expulsion of the common enemy. In this way, then, the attraction in purging medicaments is completed and perfected by the property of likeness alone; and by what elementary quality this comes about cannot be conceived. For since the whole genus of cathartics is hot, it surely could not draw phlegm by likeness, inasmuch as phlegm is contrary to the qualities of the medicament; therefore the likeness of substance alone is the cause why rhubarb draws bile, jalap [scialappa] draws phlegm, and hellebore [veratrum] draws melancholy. Hence they are called by physicians cholagogues, hydragogues, and melanagogues [choligoga, hydragoga, melagoga].

You see, then, how agaric, although by its nature drawing bile, nevertheless draws phlegm; namely because, by its quality analogous to bile, it first moves the bile, which then vehemently stimulates the whole phlegmatic humor taken within, and by attenuating it dissolves it; whence the bile, since the phlegmatic humor is now exceedingly attenuated—being now a humor like itself—desires by an innate appetite to be joined to a like humor latent in the agaric; and so this [bile], drawn by the agaric, transmits along with itself, through the dregs and the stool, the flow of the now-dissolved copious phlegm. For there lies hidden in the corrupted phlegmatic humor something that answers by a likeness of nature to the humor of the agaric; whence at its presence the [bile] is at once agitated toward union—just as iron is suddenly agitated at the presence of a magnet. In this way all antidotes [alexipharmaca] are to be thought to move the humors of the human body.

The medicament, therefore, as soon as it is taken into the stomach and excited by the natural heat, at once bursting into act, is impelled to act; and its bonds as it were loosed, it flies forth, displays itself, and by diffusing itself produces new powers. But the vapor put forth by that very faculty of the medicament, springing thence, poured forth in every direction through the blind and hidden passages into all the recesses of the body, when it has reached the humor that is indeed inimical to Nature but friendly to itself, cuts and attenuates it by its sharpness; and by this action, as it strives to render it like to itself, so too it powerfully stimulates Nature and impels it to discharge. Hence it comes about that the medicament, which is stabled in the stomach and the intestines, by its innate force, and the battle now joined, on the one part by a natural appetite allures the humor like to itself; while Nature, on the other part, offended and stimulated by the lodging of the hostile guest, casts it out—wherever a door is given, not only through the accustomed passages, but through the hidden ducts of the body and the very fibers by which the body is permeable—derived into the intestines. But

concerning these things see *Art of Magnetism*, Book 3, p. 7, where you will find everything treated most fully.

[Margin: How the discord and accord of things arises from the differing constitution of the climate and the situation of the sky.]

Fourth. The accord and discord of things is founded sometimes in the differing constitution of the climates. For just as not every soil bears all things, so too under the torrid Zone, and in the other regions of the Indies and of America, different Animals are produced; and our own [animals], transplanted thither, almost change their species. Sheep acquire a humped form of body, and the other metamorphoses which we have recounted elsewhere; while most of the things brought from there to us cannot, because of the strangeness of the climate, live long; and not a few, soon after they have entered the Tropic of Cancer, die, offended as it were by the foreign region of the sky.

[Margin: The cause.]

In America too the natives suffer certain diseases proper to those regions, with which foreigners are never afflicted; yet the sons of foreigners, if born in that same place, are at once wont to be afflicted by them. These things proceed from no other cause than from the differing temperament which the differing sky, the differing manner of living, and the difference of nourishments produce in them.

[Margin: Where there is disease, there [is] the medicament.]

Hence too the immensity of Divine goodness has provided medicaments suited to those [diseases], which are not found in the regions of Europe, by which they are wont to remedy their own ills. Thus sagacious Nature, everywhere taking thought for the safety of men, has willed that where there is disease, there too the medicament appropriated to it should not be lacking. And—what I cannot sufficiently marvel at—she has produced even the very poisons out of wholesome substances: thus hemlock [cicuta] from corrupted and spoiled parsley [petroselinum]; thora [a poisonous aconite] from antora; from rue, wild rue of venomous substance; from horse-parsley [olusatrum], the horned poppy [papaver corniculatum] of the worst quality. And so the rest take their origin from one and the same thing, only by the corruption of the wholesome [part] intervening; so that the corruption of the best is convinced by the common proverb [to be the worst].

[Margin: Wheat changes its species when transplanted elsewhere.]

In this way wheat sown in unsuitable soil degenerates into spelt or oats; certain garden plants degenerate into turnips, with experience as teacher.

[Margin: Pepper, cinnamon, clove.]

By the same [token] we have come to know that the cinnamon plant sown in Europe has degenerated into laurel, pepper into ivy, the clove [chariophyllum] into something like the chestnut—and this surely for no other cause than because of the greater or lesser strength of the Sun, by whose defect they change the total form of substance when planted in foreign soil, with only certain obscure vestiges of the prior substance left behind. Again, the seedling of the cypress, planted in the Northern Regions in cold soil, [degenerates] into the Savin; the Tithymallus [a spurge], a plant, in Sicily degenerates into a tree. If, then, they undergo so great a change in neighboring regions, how much greater will they obtain when set under a torrid sky? But of these things expressly elsewhere.

[Margin: The accord and discord of things from the imaginative power.]

Fifth. The fantastic, or imaginative, faculty founds altogether prodigious laws of Sympathy and Antipathy. We marvel why not...

no people conceive a natural hatred against [certain] flowers, fruits, or animals: that some break into a sweat even at the presence of a hidden cat; that others faint at the scent of a rose, or are all but overcome by the fragrance of lilies. The same judgment is to be made about other antipathetic affections of this kind, on which a whole book could be written. These, however, draw their origin from nothing else than the mother, who, offended by such things at the time of pregnancy and stirred by various promptings of the imagination, transferred her aversion onto the foetus.

[Margin: The imaginative faculty in pregnant women is capable of it.]

To this same class belong also those marks that are impressed upon the foetus by mothers — and they are countless — which arise from a vehement craving for some thing the mother desires. The Latins call this *picae*, the Greeks κίσσα [Greek: kissa, "the craving (of pregnancy), the longing"]. When a pregnant woman, anxious with desire to have some thing, scratches herself in some spot, the animal spirit, roused by the power of fancy, rushes there and fashions the very thing she had conceived in imagination. From this come the origins of monstrous births; from this arise most of those exotic affections and inclinations that we find in certain people. But on these matters let the reader consult Book 3 of the *Ars*

Magnetica, in the section on the magnetism of imagination, where we have uncovered the genuine explanations of such hidden things.

Sixth. Sound, too, produces certain marvellous effects in the nature of things — as when a taut string sets in motion another equally taut string that it has not touched; and the sound of pipes moves any other object proportioned to it, such as statues in a church, candelabra, and the like, even to the point of a prodigy.

[Margin: From the marvellous power of sound.]

But since I have treated these matters expressly in various places of my *Musurgia*, I refer the reader there, where he will find all the marvels of sound unravelled through their genuine causes.

Seventh. The constitution of certain bodies with respect to their pores brings it about that some things, when thrown into fire, do not take in the heat — which people ignorant of the cause greatly marvel at; on these too in the preceding [discussion].

[Margin: From the constitution of the pores.]

For where, through the narrowness of the pores, no entry is granted to fire, there the thing necessarily remains cold, since fire produces heat not when received on the surface but in the inmost substance. Hence, although the heat acts to some degree on the outer surface, the cold lying hidden within, by its own power, the moment anything of heat is produced on the outside, immediately destroys it as something contrary to itself — as they report happens with the diamond [Adamas].

Eighth. That the cross-radiations [corradiationes] of natural bodies establish marvellous laws of consensus and dissension in the nature of things, only he can fail to know who is ignorant of the Magnetic Art.

[Margin: From cross-radiation.]

For since all natural bodies have been endowed by the most wise Architect of the world with this kind of ray-emission [actinobolismus], they certainly act marvellously through it. For these rays are like certain hands by which things, when they cannot always act with the immediate contact of their substance, seize one another, however distant, in a friendly or a hostile encounter. And such ray-emissions, or cross-radiations, are nothing else than certain subtle and imperceptible vapors, by which things cherish one another if they are friendly, and destroy one another if they are hostile.

[Margin: Friendships and enmities of plants.]

From this flow all those friendships and enmities of plants, whose catalogue you may see in the aforementioned *Ars Magnetica*.

It is a marvel that I observed not long ago in our own garden. A pomegranate-flower shrub [balaustia] had been planted between two rhododendrons, that is, oleander trees. Since this kind of shrub is marvellously destructive, swelling as it does with a venomous sap, it came about in time that the pomegranate-flower, as though seized by a kind of consumption, withered entirely and, consumed by dryness, presented an exotic effect to all who marvelled at it.

[Margin: A marvel concerning a pomegranate-flower planted between two rhododendrons.]

Suspecting the malice of the hostile plant, I advised that the oleanders be cut down — inasmuch as they had bewitched [fascinaverint] the tender pomegranate-flower with their venomous vapor. Once these were cut out, the pomegranate-flower at once, as though the causes had been removed, began to sprout anew from its lowest stock with an abundant crop of shoots. I found the same in the case of *satyrion* planted next to the chaste-tree [vitex]: for the *vitex*, or chaste-tree [agnus castus], in time seemed to have utterly destroyed the *satyrion*, as though at the encounter with a plant hostile to it.

[Margin: Enmity of the chaste-tree and satyrion.]

The reason for this is none other than that the chaste-tree, by its own fiery power, gradually dries up and destroys the generative humor lying hidden in the *satyrion*, as something contrary to it in the likeness of its whole substance.

To this cross-radiation, or ray-emission, all things — whether animals or plants — are referred. Of these, if any two are friendly, the one refreshes and cherishes the other by this circular outflow [ἀπόρροια / aporrhōia, "emanation"] or effluvium of like virtues; but if hostile, the one dissipates and consumes the other by the effluvium of unlike powers. And this magnetism is peculiar to all natural things in the three kingdoms of Nature, as we shall see hereafter.

CAPUT VI.

De Venenorum consensu, dissensuque, eorumque origine, & causis.

(On the consensus and dissension of poisons, and their origin and causes.)

Now that the reader has seen in how many ways the specific virtues of things — which people commonly, and ignorantly, call occult qualities — may be considered (as set forth in the preceding chapter), and what are the cradles of those admirable virtues with which they are imbued, and equipped with which, nothing remains but that we pursue the argument we proposed concerning poisons and their causes.

[Margin: A poison is defined by its property, distinct from its whole substance.]

Since, then, a poison is here nothing else than a certain force placed in some body, singularly harmful to the heart, wholly dissimilar to the life of living things, contrary to it, and directly corruptive — anyone might rightly doubt what this force is, or in what it consists. On this there is great strife and controversy among the authorities. There are those who think it acts merely through an excess of the primary qualities, so that some kill a person by intense and vehement cold, constricting the heart, stupefying it, and extinguishing the radical heat; others by dryness, consuming the vital humor; others by excessive moisture, putrefying and obstructing the passages — by a certain intemperateness, that is, a *δυσκρασία* [Greek: *dyskrasia*, "bad mixture, distemper"] of the primary qualities, peculiar to each. But in this they are greatly mistaken.

For if the action of poison consisted in an excess of the primary qualities alone, there would be no reason why pure water, pepper, or sublimated wine and the like should not be reckoned among poisons and lethal substances — since the coldest water is freezing-cold and pepper is exceedingly hot; yet these cannot be called poisons. Therefore, besides heat and cold, moisture and dryness, another quality is needed by which those vehement symptoms observed in the poisoned are produced — a quality that, on the very best grounds and on the testimony of Aristotle, corresponds by a certain proportion to the element of the stars. And so, that we may assign the genuine explanation of all those things that are called pure poisons, we shall begin the web we have started from the minerals.

DISQUISITIO I.

In which the nature, property, origin, cause of the effects, and the exotic symptoms are investigated.

I suppose, first: that there lies hidden in the subterranean bowels a certain *παντοσπερμία* [Greek: *pantospermia*, "all-seed, the universal seed-store"] of things, from which arise innumerable mixtures of innumerable species — as has been shown here and there throughout this whole work.

[Margin: The forms of natural things arise spontaneously from such-and-such material combination.]

These [mixtures], however, arise chiefly from salt, sulphur, the mercurial element, and from these mediately commingled into infinite combinations.

[Margin: The salts, and their infinite combinations, and the origin and causes of the consensus and dissension of mixtures.]

For the various species of salts — namely those of niter, of alum, of vitriol, and the rest — set in motion almost infinite combinations of mixtures, both wholesome and unwholesome, so that the forms of the most diverse things emanate from nothing other than this or that concurrence of combining materials. And these combined compounds of mixtures put on such a form as this or that combination has assigned to them.

I suppose, second: that the subterranean fire — the true Archeus [Archaeus] of Nature, the παντουργόν [Greek: pantourgon, "all-working (principle)"] — by its heat penetrating the inmost fibers of the Geocosm, transmutes the mixtures into as many different forms as there are degrees of remission and intensification within it.

[Margin: Heat variously intensified produces different properties in the mixtures.]

This we have sufficiently demonstrated in the preceding [parts] by experimental reasoning; and from these arise new seedbeds of combinations, which indeed result not immediately from the primary qualities, but from the very forms constituted by the law of this or that combination.

These things being thus supposed, let us now proceed to examine those combinations that give rise to pure poison. And first there is the fourfold genus of salts; then sulphur, quicksilver [argentum vivum], sublimate, mercurial juices, naphthas, and the half-metals [semimetalla] — cadmias, marcasites, antimony — from whose various permutation are born the infinite kinds of poisons.

[Margin: Of how many species is the poisonous sulphur?]

Sulphur first generates four species, born solely from a more intense or more remiss degree of fire; and they are: Arsenic, Orpiment [Auripigmentum], Sandarac, and Realgar [Risigallum]. These are so similar to one another in virtue that they may deservedly be taken for one. For from arsenic comes orpiment, differing not in substance but in color only; from this is born sandarac, likewise

differing from orpiment only in color, so that they may be taken for one and the same — which the Arabs too teach plainly: for what we call orpiment, they call زرنیخ [Arabic: zarnīkh] Sandarak [?]; and from this, finally, arises realgar — "the bad egg, the bad crow" [mali ovi, malus corvus]. For all these are pure and most efficacious poisons, as all metallurgists and chemists attest, as may be seen in Mattioli [Mathiolus], Falloppio [Fallopious], Agricola [Agricola], and Cardano [Cardanus]; and we ourselves have treated at length, in the preceding [parts], of imperfect metals of this kind.

[Margin: The threefold force of arsenic.]

But by what means it excites symptoms by its poisonous quality, and what is the force of arsenic and its threefold composition of species — from which such great evils proceed — must now be explained. Arsenic is sulphureous in nature, and arises from sulphur by various modifications of fire; it is endowed above all with a threefold power, so harmful to all men and other animals...

harmful. The **first** is its burning [adustive] force, which it obtains from the sublimation — effected by internal heat — of certain salts implanted in it that are endowed with a fiery power; with this it tortures and scorches all the parts of the body with a vast and intolerable burning. The **second** is its caustic, or corrosive, force, which, by dissolving, corrodes that which has already been dilated and attenuated by the burning — the flesh, the bones, and finally the nerves themselves — just as the strong waters, the so-called *aqua regia* and *aqua stygia* [royal water and Stygian water], gnaw at and consume metals. And just as these are for the most part composed of common salt, sal ammoniac, and vitriol, so in corroding and calcining metals arsenic has great power, since it swells with these same salts, and, already corrupted by the alteration of a more vehement fire, performs the same in the economy of the human body. The **third** quality is the putrefactive, which, as a shadow follows the sun, so continually follows the corrosive faculty; for this dissolves into corruption [tabum], by a certain septic force, all that has been corroded within.

[Margin: The symptoms produced in the human body by mineral poisons.]

These said deleterious faculties are necessarily followed by those unaccustomed symptoms by which the poisoned are agitated — namely: anxiety, languor, and a stupor of the heart from the oppression of the spirits; intolerable pain arising from the burning and caustic force; failing of the mind from the consumption of the vital spirits; finally, a clouding of the mind from the elevation into the brain

of fumes from the putrefaction of the humors; and at last inevitable death follows upon all these.

And these are, among the minerals, the chief and primitive poisons, from which all the other poisonous minerals — such as antimony, cadmias, magnesias, and the like, all of which savor of I-know-not-what arsenical quality — draw their origin; although, inasmuch as they are commingled from different mineral clods, they are also more and less contrary to nature.

[Margin: The deleterious force of quicksilver.]

The other primitive poison is **quicksilver** [Argentum vivum], on whose nature enough has been said above in the *Sectio on imperfect metals*. Quicksilver, so long as it remains undissolved in its natural fluidity, can obtain some use in medicine, if administered in a proportioned dose; for it is a great remedy against poison. Likewise it is usually administered to those afflicted with the iliac passion [colic], because by its great weight it presses upon and dislodges the matter obstructing the intestine. While I am writing this, it was administered with great benefit to a man suffering from the iliac passion, so that the whole quantity of mercury, having passed out through the bored-through dregs by stool and dispersed into globules, was gathered up entire without any loss. But if taken in great excess, it kills without remedy by coagulating the blood and spirits with a certain specific cold.

[Margin: The pernicious force of quicksilver.]

Mattioli [Mathiolus] relates that he knew an apothecary who, having been seized by a fever in the night, and tormented by intolerable thirst, had gone down into the cellar to slake his thirst with a draught of water, and by a foolish error drank no small amount, in place of water...

from a vessel of quicksilver. That it was an effect not of the primary quality, but of such a form as proceeds from the likeness of the whole mercurial substance, is clear from this — that I do not see how a draught of snow-water could not have produced the same. Therefore effects of this exotic kind must be said to proceed from no other cause than from salt, niter, or vitriol concentrated inwardly with the mercury — substances that coagulate not by cold but by heat. For once the spirits are consumed and the natural heat extinguished, the blood must necessarily coagulate, together with a cold constitution of the whole body. This is clear also from niter, vitriol, and salt, which in like manner — not by cold but by heat, the spirits existing in snow and water being consumed — necessarily

convert water into ice; an experiment than which nothing is more frequent here at Rome in summertime.

And so crude mercury, being oppressed by its natural moisture, cannot diffuse its poison; and likewise (unless taken in great quantity) it cannot do much harm. But once it has been sublimated and exalted by heat into a salt, then at last it loosens the reins of its poison with such force, and rages accompanied by so many and such great symptoms, that it seems to want to yield to no poison in the nature of things — especially if the sublimation is set up with vitriol, vinegar, and sal ammoniac. For if it has been taken inwardly, the tongue and throat are at once roughened, no otherwise than if one had drunk the juice of unripe sorb-apples; and descending into the stomach, it clings stubbornly there, soon exerting the powers of its malignity, and by corrosion and ulceration turns everything upside down, with an inexplicable burning of the whole body and an inextinguishable thirst. Upon these follow incredible anguish, swelling of the tongue, fainting, suppression of urine, difficulty of breathing, torments of the stomach and intestines — until at last, the stomach and intestines being eroded and perforated, they force the person to breathe out his soul along with the foulest stench.

[Margin: The horrid symptoms that proceed from sublimated mercury.]

All these things just said I have observed at Rome, not without horror, in a certain man who had rather incautiously taken only a third part of a drachma of sublimated mercury, and who, agitated by the said symptoms, was at last extinguished. It is asked: what is the cause of these symptoms? I say they proceed from the salt of sublimated mercury, which, stripped of moisture by the force of heat, is reduced to the utmost dryness. And the salts commingled with it — inasmuch as they incorporate into themselves whatever of malignant spirits lies hidden in the mercury — likewise, by their excessive dryness, constrict and strangle the throat, and, the humor being consumed, consequently torment with intolerable thirst. Added to this is the burning and supremely corrosive vehemence of the saline spirits, which, wherever they find a softer substance, at once gnaw it, dissolve the nerves, and, the vital spirits being at last consumed, bring on death. If anyone has seen tinder seized by a spark of fire — how quickly it pervades the whole mass...

[Margin: The burning force of antimony.]

and consumes it — he will form a not unfitting conception of the burning force of this poison. Mattioli [Mathiolus] testifies of himself that on one occasion, while testing the power of sublimated mercury by tasting it only with the very tip of his

tongue, his tongue at once swelled so far forward that there was need of sudden, extreme antidotes. Afterwards, on Mattioli's testimony, certain foolish little women experienced this kind of poison, to their own great harm: in order to be tinged with a fair complexion, [using] sublimate in place of acquired beauty, they soon vomited out their teeth, smelled with a stench fouler than a he-goat, fell from the brightness of their eyes into darkness [of sight], saw their soft, smooth, supple flesh soon transformed into the wrinkled face of old hags — indeed, as if seized by tetanus, they redeemed their foolish vanity by nothing less than an untimely death. We have now seen the deleterious effects of sublimated mercury, the cause of which is none other than the virulence of the salts which it holds folded up within its own body.

The **third** poison is stibium, or **antimony**, which, being constituted partly of arsenic, partly of mercury, even though it acts more mildly — because it is somewhat blunted by the medley of various substances — nevertheless yields the same effects as the said minerals. For by its violence and hostile force the stomach is so stirred up that, not without manifest danger, it strives to expel whatever is in it or flows into it; for it acts by a certain specific deleterious force, which, on the testimony of Erasto [Erastus], Smezio [Smetius], and Mattioli [Mathiolus], shares the nature of mercury, whether sublimated or precipitated — powers utterly maleficent and harmful, the more hostile to us the greater the quantity in which it is taken.

[Margin: The deleterious force of antimony.]

Hence, being most hostile and utterly contrary to the orifice of the stomach, snatched into the veins and distributed through the body, it marvellously harasses and plucks at the remaining parts, undermines the spirits, and with indiscriminate malice expels both the good and the malignant juices alike. And although in some it achieves its medicinal effect by a powerful purgation, yet I think few there are who, using this medicine, have reached early old age. But you will say it is taken harmlessly when corrected. I reply: since the purgative force consists properly in the various medley of pernicious salts saturated with mercurial spirits, then either it will still operate after these have been extinguished by the correction, or it will not. If the former, then — the same poison always remaining — the same effect must always follow. If the latter, then it will no longer act any more than any other floury powder. Thus the reason for the deleterious quality lying hidden in antimony is evident.

[Margin: The virulent force of misy, sory, and chalcitis.]

Fourth. To the class of poisons are also referred *misy*, *sory*, and the species of *chalcitis*, or marcasite, which — since they take their origin from vitriol, from the manifold species of the other burnt salts, and also from sulphur, as we have shown at length in the **Seventh Book** — are likewise so stuffed with arsenical spirits that they cannot be taken inwardly without manifest danger to life; for, being corrupted by the spirits of the primitive mineral poisons — sulphur, mercury, antimony, arsenic, and the like — they constitute as many different species of poison as there are diverse minerals arising from the aforesaid.

[Margin: The virulence of quicklime and gypsum.]

Fifth. From quicklime [calx viva] and gypsum a new species of poisons is constituted, which — inasmuch as they are taken both by themselves and mixed with the others already mentioned — likewise exhibit diverse species of poisons, although all of them are endowed with a certain caustic and burning faculty. And these are the matters concerning the causes and origin of mineral poisons that we thought should be set down beforehand.

DISQUISITIO II.

On the poisons of plants, and their causes, and from where they have drawn their origin.

I suppose, first, on the teaching of the botanists, that plants endowed with some deleterious property — especially those called pure poisons — are for the most part among the number of those said to be spontaneously generated; or, what is the same, that draw their origin from rot. For by experience — as we have shown in the **Seventh Book** and elsewhere — it is known to the learned that virgin earth, set in a lofty place to which the seeds of things can scarcely come, and watered with pure spring water, in time generates plants common to that country, such as various species of grass. Porta relates that he too performed an experiment on this matter, in Book 2 of his *Phytognomonica*, chapter 1, in these words:

EXPERIMENTUM

By which it is shown that herbs of every kind are born from earth without prior seed.

"For I myself have always judged it consonant with the truth that from the earth both plants and not a few animals are born — because there is in earth a moisture, in moisture a spirit, in [it] all a universal heat, so that all things are full of Jove. For this reason, without any pre-existing seedling, without any human

labor, just as the various tracts of the earth are diverse in soil, sap, sun, situation, and other constitutions, so too they have produced diverse plants, marked with diverse innate qualities. For such is wont to be the habit of the body, such the humors by which we are nourished, and such the juices that are engendered, as are the foods on which we feed. This kind of experiment turned my mind to it: when I had gathered up earth dug out from the deepest foundations of buildings — so that every suspicion of seed thrown in might be removed — and had exposed it to the open air in the highest places, lest the wind should have carried seeds from elsewhere, then, many days having elapsed afterward, and with the various qualities of the earth, in the said earth various kinds of herbs sprang up, familiar to the Neapolitan soil and sky. For one [kind of] clay produced one thing, the Neapolitan dust another, the ground-up pebble or tufa another. Thus each [kind of] earth..." ...the earth produced, according to its own quality, an herb of that same quality. For tufaceous earth [trophacea terra] yielded Neapolitan trefoil [trifolium Neapolitanum], other kinds of earth now nettles and brambles, others mercury-plants and the like. So far Porta. These results agree so precisely with the experiment I myself carried out that nothing further could be added to demonstrate the truth of the matter. For in plants the very same thing happens that happens above all in animals: depending on the disposition of the matter, now an herb, now some insect is born, as we showed above. But now to the next point [ad Rhombum].

The question therefore arises: why, and how, does so great a variety of poisonous herbs arise from the mixture of these earthy putrefactions? To untangle this, one must first understand — as was said above — that all classes of mixed bodies are primordially constituted from sulphur, mercury, and salt. But how plants that grow spontaneously arise from these; how insects can do so; and finally how plants and trees that derive their origin from a natural seed, as do animals, are constituted from those same three — this remains to be explained.

[Margin: The poisonous plants all arise primordially from minerals.]

So that no one may suppose that all things are constituted out of *material* sulphur, salt, and mercury, I say: these three principles of things must be understood according to a certain analogy. For hidden in the innermost recesses of Nature is something fiery and supremely active — call it natural heat, or whatever Nature-preserving thing corresponds to it — and this we call *sulphur*. And since that fiery force residing in things cannot subsist without a moist element to serve as its fuel, there is laid up in all mixed bodies that moist

principle — call it the radical moisture or by any other name you like — which the more secret philosophers name *Mercury*.

[Margin: What is meant by sulphur, mercury, salt.]

Again, since the warm-moist (that is, the sulphureo-mercurial) cannot subsist without fixation, that which gives subsistence to all things — inasmuch as it answers to the nature of the earthy element — they called *Salt*. And since the sulphureo-mercurio-saline compound still cannot rightly carry out its natural operations, they added to these a certain spirit that permeates all the substances of mixed bodies, which we designate by the name of *air*.

[Margin: How sulphur, mercury, and salt are to be understood in our sense.]

With these matters set out, let us now proceed to the δηλητηριωδῶν βοτανικῶν [Greek: *dēlēteriōdōn botanikōn*, "of the poisonous plants"] — that is, to the origin of poisonous plants.

Experience teaches that from the minerals adduced above in the subterranean fire-chambers [pyrophyllacia], certain fumes or exhalations breathe out perpetually through the inmost fibers of the earth up to its outermost surface. Hence it comes about that, if these fumes are joined to wholesome clods, they produce wholesome and good herbs; but if they are linked to a putrid soil tainted by malignant impressions, then in time, as those fumes ferment, they will lay down a putrefaction fit for generating poisonous herbs. And so, according to the diversity of the putrefaction — affected by one or another poisonous vapor — they will produce deleterious herbs of correspondingly differing power, as befits the disposition of the matter. But let us make the matter clear by examples.

[Margin: The origin of the poisonous herbs declared by examples.]

If an earthy putrefaction has been worked up by arsenical [arsenicalis] vapors carried through the subterranean channels, then from the already-fermented matter will be born either monk's-hood [Napellus] or aconite [Aconitum] — herbs whose properties in their powers are wholly like those of arsenic. Hence, once such an herb is taken inwardly, it at once excites those same symptoms suffered by people who have swallowed arsenic, orpiment [auripigmentum], or realgar [sandaraca]. To this class belong all the herbs endowed with caustic power, such as spurge [Lathyrus, or Cataputia], euphorbium, scammony, and the like.

[Margin: Comparison of the poisons with plants.]

But if the said disposed matter has been constituted by a mercurial vapor, then there arises either leopard's-bane [doronicum] or else the herb *hæmorrhoon* — which, like sublimate of mercury, has such efficacy that within a few hours, with all the channels of the veins eaten through, a person must die from a flux of blood pouring out of every member of the body. And if the disposed putrefaction has generated an herb from an arseno-mercurial source, then when that herb is drunk it will excite all those symptoms proper to arseno-mercurial mixtures. Of this kind are certain species of mushrooms, of such efficacy that, by their smell alone, they kill those who incautiously sniff them — as Pliny [Plinius] attests.

[Margin: The effects of veratrum and henbane.]

But if the earth, swelling with *melanteria* [a vitriolic earth], has been infected by the vapor of corrupt vitriol, then either henbane [hyoscyamus] or hellebore [veratrum] must be born, of the same property as the clods of that mineral. Whether veratrum or henbane is taken, besides the urge to vomit it hurls great globes of fumes into the brain, by which a person, first seized in mind, is driven into frenzy, and at last, struck with lethargy, ends his life in a wretched death. These herbs, according to the greater or lesser quantity of putrefaction, produce now more, now less efficacious effects. From this source spring thorn-apple [Stramonium], all the kinds of nightshade [solatra], mandrake [mandragora], asafoetida (or *cotula*), and countless other herbs of deleterious quality — all of which I have come to know by experience.

[Margin: A marvelous experiment.]

For if you take putrid earth from a place where many dead carcasses have rotted, and water it with poisonous mineral juices, then that earth, set in a vessel exposed to the sun, will in time produce either hemlock [cicuta], or henbane, or nightshade, or asafoetida, according to the condition of the juices of the minerals with which it is steeped; and these herbs thereafter propagate themselves by their own seed. But why wander further afield, when these very things are confirmed by Holy Scripture itself? When, in *Genesis* 1, God, after the separation of the earth from the waters, said: *Let the earth bring forth the green herb, that may bear seed according to its own kind*, etc. From this it plainly appears that the seeds of all vegetable things were first implanted in the earth, which then, sprouting forth from the earth, each according to its own species produced an herb conformable to the seed from which it was drawn; and these thereafter, through the seed natural to each, have propagated the species of plants to this very day.

And so the earth, struck by the divine command, out of the bounty of its omnipotence — the storehouse of every good — brought forth an innumerable variety of herbs along all the paths of the world, according to the situation of the sky and the various constitution of the climates. Then the whole ridges of the North produced the yew, the *Thutian* [?], and the *Celustum* [?]; under the torrid zone, the fragrant aromatics; Arabia, balsam, frankincense, myrrh; Egypt, the sycamore, cassia, colocasia; Rhodes, the *Aspalathus*; Babylonia, the date-palm; Lebanon, the cedar; Crete, the cypress; Pontus, wormwood [absinthium]; India, pepper, cinnamon, clove; America, sandalwood, guaiacum, and other exotic plants and trees. And so at last the whole surface of the Geocosm flowered with a certain infinite multitude of herbs, shrubs, and trees, of incredible diversity of powers. All of these, just as they consist of salt, mercury, and sulphur, so too, mixed with the earthy clods, brought forth — according to the combination of the concurring matter — now wholesome, now unwholesome plants, partly by the agency of the sun, partly by that of the subterranean fire.

It is therefore clear that plants of a deleterious quality drew their origin from no other source than from a certain fatty and mucilaginous matter, impregnated with a varied mixture of mineral juices. And this is clear even to the senses: since, after the manner of the said juices, all poisonous plants are imbued with a marked acrimony and with a certain fiery faculty by which they gnaw, corrupt, and destroy all things. And of those which are born from calcareous, gypseous, and tufaceous matter, all are powerful in acrimony — though less harmful than the rest. But of these matters more fully elsewhere.

DISQUISITIO III.

From where do serpents, insects, and the other imperfect poisonous animals draw their origin?

[Margin: All poisonous things arise primordially from earth — the same earth from which both animals are compounded by the union of the two sexes.]

Just as, then — as was said in the preceding passages — plants have their origin from the earth (since the earth, as Anaxilaus [Anaxilaüs] testifies, is the mother of all plants, and fire, whether solar or Vulcanian, is their father), so too I would have you understand the same of animals. For all those animals — both those called *insects* and the species of land, flying, and swimming creatures — have their origin from nowhere else than from the putrefaction of earthy matter, variously disposed by the marvelous industry of Nature. This putrefaction then, just like plants swelling with their own seed, propagates itself after the manner of

the other living things. Nor does this conflict with the sacred Text, when it says: *Let the earth bring forth the living soul in its kind, cattle and creeping things and beasts*, etc. — and at last also man; so much so that the primordial production of even the perfect animals, without any prior seed, by the command of the Divine power alone, proceeded out of the earth as out of an underlying matter.

[Margin: The opinion of Anaxilaus.]

And from among the ancients, Anaxilaus, the disciple of Euripides [Euripides] — though not without a sense contrary to the sacred page — asserted: "For when heaven and earth," he says, "had been received as one whole within themselves, the earth brought forth trees, birds, beasts, and the whole race of mortals" — not, as he himself supposes, by the command of the Creator, but by chance. "While the earth, putrid, soft, and made dense by the sun, produced swellings on its surface, each containing its own putrefactions; and, with night going round, the dew sprinkling, and the sun consolidating them, it at last carried the putrefaction to its peak — the time of birth, of course, having ripened — and, the bonds being broken, it brought forth all the kinds of living things." But this too daily experience teaches, when we see so many species of worms suddenly born.

[Margin: The origin of the testaceans.]

The ὀστρακόδερμα [Greek: ostrakoderma, "shell-skinned ones" — the testaceans], which is a class of shelled animals, when cast into the sea in earthen vessels, are generated from putrefying foamy slime; purple-fish [purpuræ] from slimy putrefaction exalted into a notable luster; in muddy matter, oysters, razor-shells [ungues], and scallops [pectines]; in sandy matter, the *conchæ*; and finally testaceans of various kinds are engendered from slime, according to the difference of the slime.

[Margin: The origin of eels.]

Eels are born without seed from the skin which they shed putrefied every year, or even from the shreds of that same skin worn off against rocks. You will discover the truth of this if you cast the skin of an eel, cut up small, into a slimy pond: for within a month's space you will find a new brood of eels.

[Margin: Fish arising from rains, by a mixture of earth.]

This too became known to us by a remarkable experiment: that a place enclosed on every side by valleys, which no spring waters and no lake washes, and which admits nothing but the rain from heaven, is straightway filled with various kinds of fish. Of this I can give testimony as an eyewitness. In a field which the most

eminent Cardinal Ursinus [Cardinal Orsini] had, near the sea, converted into a pond, as soon as the hollow of the dug-out field had been filled with the winter rains, we found it likewise filled, within a few months, with every kind of fish — even though as yet no fish had been brought into it.

[Margin: The origin of frogs.]

Again, frogs, which have their birthplace in marshes and other ditches, are generated from putrid slime — and not from slime alone do they arise of themselves: the dusty sands of marshy places being merely sprinkled with rain, whence they are also called "temporary" (frogs); concerning their artificial production, more in what follows.

I shall not speak here of the generation of mice from putrefaction; nothing of aquatic insects, nor of the other flying insects and of the earthly worms, scorpions, and so on — all of which, just as they are born from putrid earth and the mucilage of the waters, so too are not devoid of poison.

[Margin: All plants and animals generate their own animalcules out of putrefaction.]

Just as, then, plants and serpents are immediately generated from earth, so too there is no plant which does not produce out of its own putrefaction some peculiar insect; nor any perfect animal which, either immediately from the putrefaction of its own body, or by means of its excrements, does not procreate certain animalcules...

so much so that no member, whether internal or external, has been observed not to teem with worms — especially in the maladies of a more malignant quality. On these matters see Schenck [Schenckium], Valleriola [Valleriolam], Gesner [Gesnerum], Aldrovandi [Aldrovandum], and the rest, and our own reasonings (supported by manifold experimental demonstration) in the *Scrutinium physico-medicum de peste* [*Physico-Medical Examination of the Plague*].

But let us return to the purpose we have set ourselves. Since, then, poisonous animals — such as serpents — are for the most part born from the putrefaction of the earth, and afterward propagate the species by mating as well; and since the poison of some serpents is so deadly that some kill a person, with no remedy of safety, by their bite (as the dipsas-serpents [dypsades]), some by their breath alone (as the asps [aspides], by their *Chelidonia* [?]), and some by the discharge of their spittle (as the *phtiades* [spitting-snakes]) — it may rightly be asked: from what causes does so great a destruction arise?

[Margin: By what means do serpents kill a person?]

I answer: it derives its origin from a putrefaction of this kind, which emanates from the poisonous faculties of certain of the minerals we adduced above. For from the combination of these with certain earthy clods — calcareous, gypseous, sulphureous — and with the slimy matter of the earth worked together, there results a certain putrefaction; and from its fermentation, by the force of the heat of the sun, or of Vulcanian heat, a worm is hatched, which finally generates a serpent endowed with that property of poison which the putrefaction, combined from the deleterious minerals, possesses — a putrefaction which procreates as many differing species of serpents as it has differing kinds of combinations.

[Margin: The marvelous sympathy and antipathy of poisons.]

Hence arises that admirable sympathy of poison toward a poison like itself, and antipathy toward one unlike it. For just as a serpent lives only from that from which it drew its origin, or from little animals imbued with a similar poison, so too it alone craves that poison, and draws it magnetically — both for its nourishment and for its own preservation; for serpents consist of those very things by which they are nourished. But if the putrefaction has obtained, from one or another combination of things, a different temperament differing diametrically, then there arises also, in the serpents, an antipathy wholly opposed to the former poison — as in the dipsas and the *cherza*-asp [aspis cherza], which destroy one another by the contrariety of their poisons and by dire feuds. This is no otherwise than certain mineral juices and certain metallic bodies consume one another, as will be taught in its place — not by manifest qualities, but by specific properties, whether drawn from the whole substance, or from the form, or finally from the likeness or unlikeness of various accidents.

DISQUISITIO IV.

On the antipathies of poisons, and their causes.

Likewise:

How the poisons of all poisonous animals can be a remedy for the poison they have inflicted; and finally how all poisons draw to themselves poisons like to themselves, and are nourished by them.

First, that one poison is hostile and contrary to another by the unlikeness of its whole substance, the toad and the spider sufficiently show — a thing which, had I not seen it with my own eyes, I could scarcely have been induced to believe. For

when I had read in I-know-not-which author about the antipathy of these animals, I resolved to put the matter to the test by experiment. And so, when I had brought a spider hanging from a stick close to a toad shut in a pit, the spider, on sighting its enemy, at once descended along its thread and, inflicting a sting, not merely stunned the toad but utterly killed it; and then, as if having carried off the victory over its enemy, it withdrew along its thread back to the place from which it had let itself down.

[Margin: The marvelous antipathy of toad and spider.]

The cause of this is asked. I say the cause is the diversity of the poison of each animal. For since the poison of the toad, or of the *rubeta*, is wholly earthy — arisen from corrupt putrefaction and from the venomous slime of the earth — while the poison of the spider is airy, subtle, and swelling with spirit, having its birth from the air, or from the putrid pores and chinks of walls and timbers; hence it comes about that the spider, being full of deleterious spirits and mineral juices, engenders a not-dissimilar poison. As soon as it has injected this into the body of the toad, then, by the subtlety in which it excels, it converts the whole poison of the toad — now made subject to its own jurisdiction — into its own poison, and thus lays the toad low, infected with an alien poison wholly unlike its own substance.

Again, since the poison of the toad is humid-cold to the senses, not arisen from the primary qualities (for I judge that no poison is cold formally, but that all are warm, according to a certain specific property emanating from the form — otherwise the hottest things could overcome the coldest, and the coldest the hottest, contrary to experience; and I would have the same understood of the dry and the moist): the poison of the spider, on the other hand, being likewise by unlikeness of its whole substance dry and warm — inasmuch as it arose from a mineral vapor of deleterious quality, residing in the lime of walls and in the fissures of timbers — it is no wonder that, by the efficacy of this poison endowed with a certain fiery force, the toad's poison, being wholly contrary, is consumed and destroyed. I could prove this by various experiments, had I not reserved them for other places.

[Margin: The antipathy of vinegar and litharge.]

If someone precipitates in water the vinegar they call "radicated" [acetum radicatum] over litharge [lithargyrium], he will see how the water of the litharge, contrary to the vinegar, at once not only destroys the property of the poison latent in the litharge, but converts it utterly into a milky color, the whole poison

being consumed. You may reckon that the same thing happens, in just this way, in the antipathy of poisons.

[Margin: Asps and Argive serpents kill one another.]

Between asps and the Argive serpents [serpentes Argolici] there is so great a hatred that Nicander [Nicander] reports that serpents were deliberately carried over from Argos to Egypt to exterminate the asps. And this is to be seen, with wonder, among vegetables too: for if you plant the monk's-hood [napellus] around the roots of the poisonous yew tree [Taxus], you will find the yew consumed by the venom of the monk's-hood, as though by a kind of rot, within a single week. For that which among poisons — whether it be in animals...

or in vegetables — is more potent and more active, generally finishes off the other, weaker one. And hence is born that natural hatred of toad and spider. Since the toad, conscious of its own weakness, so dreads the spider that, at the season when spiders come forth — that is, in the dry season and at the noonday sun — it dares not appear (lest it fall in with its deadly enemy) unless armed with rue [ruta].

[Margin: The hatred of toad and spider.]

But the reason that toad is not opposed to toad, nor serpent to serpent of the same species, is that the poisons are of the same nature; and these poisons are so far from harming each other that rather they mutually cherish and preserve one another by the common poison of all of the same species. For just as plants and shrubs draw out of the earth that which is most agreeable to their nature, so too animals seek by a certain natural appetite the nourishment most suited to preserving their nature.

[Margin: Why poison of the same species is not contrary.]

[Margin: The poisonous juice of the earth is the food of the poisonous animals.]

Since, then, Nature has implanted poison in the poisonous animals as a kind of particular endowment — both for preserving themselves and for defending themselves against contraries and enemies — the attraction of poison seems to them to be a thoroughly natural nourishment, as something without which they cannot live; for they are nourished by those very things out of which they are made. Hence serpents, toads, and scorpions, sucking up by a certain natural appetite whatever in the earth is poisonous, putrid, and harmful, convert it into nourishment — no otherwise than a person turns food into the substance of the body that is nourished. This you may discover by the following experiment: if you

let loose a viper, for example, stripped of its poison, into earth steeped with poisonous quality, you will find it — which before lacked all poison — wholly venomous from the newly attracted poison.

[Margin: Poisonous animals draw to themselves from the earth the poison agreeable to them.]

Hence too vipers and the other venomous serpents, while they take from us what harms us, divert back into themselves — by the admirable providence of God, the Best and Greatest — what is beneficial, once drawn off; and so, where death was feared through the poison, there life is obtained through the medicine, to the great benefit of those so badly poisoned.

[Margin: The toad is a remedy for plague, and the scorpion for its own poison.]

In this way the toad, dried in the sun, applied to plague-buboes, while it draws to itself that which is pestilential, at the same time frees the person from the plague-affliction; concerning which see our *Tractatus de peste* [*Treatise on the Plague*]. So the poison of the scorpion, lodged in the body by its sting, is freed from the person by the application of the scorpion itself, crushed — by the attraction of its own poison. So the poison of the stingray [pastinaca] is drawn out by the application of the crushed tail of the stingray. But since we have dealt with these matters more fully in the preceding passages, we shall not linger over them; let this Rule suffice for the reader: that the poison of every animal whatsoever, of whatever sort in the end, when lodged in the body, is the medicine for its own poison. See Book 3 of the *Ars Magnetica* [*Magnetic Art*], where you will find numerous examples of this kind adduced concerning the magnetism of poisons, and also concerning the poison of the tarantulas.

CONSECTARIUM I.

From this it is clear that serpents of whatever kind draw to themselves, as nourishment, a poison akin to their own. Hence they not only suck up the putrid mucilage out of the earth, but also hunt, with the utmost cunning, for nourishment from the very poisonous herbs and animals which by a certain instinct of nature they know to be agreeable to them. Thus the viper, among herbs, eagerly preys upon hemlock [Cicuta]; among animals, upon mice, lizards, and worms of every kind — as appears from the dissection of vipers; and if they should ever die, they turn into that putrefaction which thereafter reproduces innumerable other serpents of the same species by a kind of marvelous re-cycling [pericyclosis]. But of these matters more fully in what follows.

[Margin: Poisonous animals hunt their poison as nourishment.]

CONSECTARIUM II.

From these things, too, it is gathered that almost all the poisons of deadly serpents differ only by intensification or remission of their venomous faculty — as is clear from the symptoms of each. Now this intensification or remission arises in no other way than either from places exposed to virulent evaporations; and the noxious evaporations do not arise except from the fumes of the above-mentioned minerals and from the noxious exhalations mixed with the earthy mucilage. And the subterranean fire raises that exhalation up within the earth; while outside, the sun's heat digests and ferments the putrefaction conceived from the said mixture. At last the heat animates the fermented putrefaction into a serpent — one all the more pernicious in proportion as the mixture of the putrefaction was scorched by a greater heat of the sun.

[Margin: Why serpents are more virulent in certain regions.]

Hence in places lying under the torrid zone, or near to it — as in India, Arabia, Africa, America — inasmuch as the southern regions are more exposed to mineral fumes, the serpents too are by many parasangs more virulent, and are found imbued with more prodigious properties, than in the regions lying toward the North. Hence in Italy there are few asps, and almost no dipsas-serpents [dypsades], *phtiades*, *sepes*, or *haemorrhoi*; much less are they found in Germany and the other regions lying further toward the North. The reason for this is none other than the temperature of the zone, which serpents necessarily follow, being born under it. For the more burning the sky, the greater the efficacy of the venomous animals, on account of the scorching; and so the most virulent serpents under the torrid zone stand to the serpents and vipers of Italy as the vipers of Italy stand to the vipers and serpents of Germany — whose venom, being much weaker than that with which the vipers of Italy are powerful, cannot likewise be taken up for the making of theriac [theriaca].

[Continuation of] CAPUT VI — Consectaria III–IV

CONSECTARIUM III.

[Margin: Serpents of a single species are solidified by the action of fire alone, and vary with the burning of the material; hence the differing serpents into which they degenerate.]

From this I conclude that the whole class of asps [asp genus] cannot, without distortion, be reduced to the vipers — to such a degree, indeed, that if Italian vipers were placed under the torrid zone, I judge they would degenerate, some into dipsades, some into ptyades, *sepes*, *haemorrhoi*, and the rest, exactly as I said above about the transformation of plants, which pass from one species into others through a mere change of climate. So great is the power, in transmuting genera and species, of a differing aspect of the heavens, a differing disposition of climates — and, finally, of the matter of putrefaction in venomous animals being scorched by the Sun in differing ways. For this reason, by the testimony of all historians, in no place on the globe is a greater abundance of venomous serpents and dragons found than in Egypt, and after that in Africa and the sandy deserts of Libya. So much so that — as the Abyssinians have told me — the peoples neighboring those fabled deserts are forced, every year, to muster an army out of many thousands of men and go to war against the incredible multitude of swarming serpents, to root them out with fire and with weapons.

[Margin: The incredible multitude of serpents in Africa.]

Were this not done, the region would shortly be emptied of its inhabitants. And this is no wonder, since even a single droplet of dew, as we have it from Rhamnusius [Giovanni Battista Ramusio], when mixed with suitable matter, produces a serpent.

[Margin: Sal ammoniac is produced in the sandy deserts; from this the serpents in Africa are produced in great number.]

Add to this that those fabled deserts produce a great deal of *sal nitri* [niter] and *sal ammoniacum* [sal ammoniac], which — once sublimated and scorched by the Sun's heat — produces, when the matter has met with the night-time cold, a most virulent putrefaction. From this a serpent is then born, which, according to the differing disposition of the matter, produces now an asp, now a *cerastes*, now a *ptyas*, now a *dipsas*, or a *seps*. Again, since in deserts of this kind whole armies — which they call *Caravanae* [caravans] — frequently perish from lack of water, from the putrefied corpses of the men and beasts of burden new seedbeds of serpents are founded.

CONSECTARIUM IV.

[Margin: The venom of serpents is hot by nature.]

From this too it is plainly evident — as we also hinted above — why the venoms of venomous serpents are hot by their nature, and none of them cold. For since

serpents of this kind are for the most part generated in the most scorching deserts, out of niter, sal ammoniac, and similar juices that have congealed within the sand and been scorched, and have been most powerfully mixed together with putrefaction, these serpents will certainly derive into themselves not only the property of the putrefaction from which they are born, but will also intensify their poisonous quality by feeding on venomous herbs. From this it necessarily follows that the supreme virulence in the said snakes arises. For just as sulphur, when violently scorched by subterranean fire, generates arsenic, sandarac, or *realgar* [red orpiment] — the most violent poisons — so too out of the efflorescence of these salts there are born salts of the same, indeed of more violent, poison, which when mixed with putrefaction then generate the serpents we have described.

[Margin: The heat of poisons is of a different nature from the heat of the elements.]

But the heat of the said poisons must by no means be reckoned the same as the heat of the elements. Rather it is of another quality, specifically different from the primary and manifest qualities — and I would have the same understood of the moist and the dry. This I prove as follows: All those things called cathartics and diaphoretics, since they are of a deleterious and caustic quality, and thin out and cut through the humors stagnating in the body, must necessarily be hot and dry — not by reason of the primary qualities, but by the properties of the forms from which they emanate. Hence those things which, as was said above, have been much worked over by fire, are hot poisons, provided they do not dissolve away. But if they do dissolve away, they take their origin from bitumen, naphtha, and similar juices of the earth.

[Margin: All dry things pass over into the nature of fire, all moist things into elementary heat without anything specific.]

All dry things pass over into the nature of fire — such as aromatics, metals and stones, sulphur, arsenic, and the rest mentioned above — which, if they are dissolved into oil, first take on an astringent taste, then present themselves as burning both in odor and in taste. Hence, taken internally, they disturb the parts of the animal. And so they are virulent. The hottest among the animal parts are the gall and the rennet; among plants, the seeds and roots; among minerals, whatever is made from a dry earthy substance, such as orpiment, lime, gypsum. Again, among vegetables the hottest are reckoned to be colocynth, black agaric, black hellebore, the milk of *lathyrus* [spurge] and the species of *tithymallus* [spurges], *chamelaena* [spurge-flax], and *thapsia* — and similar purgatives, as is

clear from their caustic effects, which, if they are corrupted, turn into an acrid poison.

[Margin: Objection.]

But here you will say: that poison is formally cold which induces formal cold; and this mercury accomplishes, as do many of the plant family; therefore poison is formally cold. For it coagulates the blood by its cold, as we recounted above in the case of the *seplasiarius* [apothecary] killed by drinking mercury [hydrargyrum]. It also damages the nerves and brain, and induces *siderationes* [strokes], tremors, and paralysis, which are nothing but effects of cold. And the same is to be understood of the narcotic or stupefying poisons — hemlock, mandrake, henbane, opium, nightshade, litharge of silver [spuma argenti] — which likewise give an indication of cold, and of intense cold at that.

[Margin: Reply.]

But against this I say, speaking generally, that no poison is to be granted as formally cold; nor, when we inspect them one by one, can any of those enumerated be proved cold, either by reasoning deduced from principles or from the senses. So when the poison of mercury, and the others, halt and coagulate the blood, this happens for this reason: that its force penetrates the whole of the blood — and this is the work of heat, not of cold. For cold, by the Philosopher's [Aristotle's] testimony, does not enter into the works of Nature, since it is reckoned only among the passive qualities.

[Margin: Mercury congeals the blood not by cold, but by heat, once the spirits are consumed.]

[Fol. 123 — running header "DE VENENIS."]

Every poison, therefore, which congeals and renders a man torpid, is hot. And the reason is plain: for when poisons of this kind, taken in, at once assail by their natural heat the natural warmth and the vital spirits lurking in the blood, they destroy them. It is luminously clear that, once the heat and the spirits are consumed, the blood is coagulated, and the man's cold constitution remains as a consequence — a constitution which is indeed cold, but deprived of blood, of spirits, and of vital heat. Its effects are these:

[Margin: Signs from the senses.]

A bitter taste is the effect of cold, but a bitter taste is not cold, but rather an effect of heat — by the Philosopher's testimony [Aristotle], since it is what cooks all

juices and decocts and parches them most vehemently from the Sun. This said, the alteration being made through thinning, and the sediment of the fixed salt remaining, he says they grow bitter. Again, hemlock, henbane, hellebore, taken in, drive [a man] to frenzy. Yet if this were the effect of cold things, there would be no reason why the less cold herbs — purslane, cucumbers, gourds, and the like — should produce the same effect; and this is contrary to experience. Since, therefore, this symptom of frenzy is non-existent in cold things, it is certain that it proceeds from heat with a specific quality. Moreover, a vehement odor — or better, I should say a stench, a foul and exotic stink — proceeds not from cold but from heat, as is proved by putrefaction's effect; since a malignant odor and stench is excited only by heat — water, however, ice, cucumbers, purslane, being formally cold, give off no odor unless they have been corrupted by putrefaction.

[Margin: Mercury [argenteum vivum] is the hottest of all poisons, especially when it has been sublimated.]

But I return to mercury [argenteum vivum], in which my adversaries glory, as though it were the coldest of all cold things, while in our view that is so far from the case that we would rather call it the hottest of all poisons. This I prove as follows: the more intense a thing's heat, the more resolvable it is into a finer substance; but mercury is more resolvable into a finer substance than any other mixed body whatever; therefore — the major premise is plain, since the smoothness and thinning of things proceeds from heat, just as condensation, by the Philosopher's testimony [Aristotle], proceeds from cold. The minor premise is proved: for mercury, taken whole and entire, with no sediment of itself left behind, passes by the agency of fire into the subtlest vapor, and by the surrounding cold returns into its first substance with no loss of its own substance whatever. Therefore it possesses the most vehement heat, and a specific heat at that. For if it be sublimated into a salt with vinegar and sal ammoniac, then indeed, with the acquisition of a new caustic faculty, it so rages and grows savage that it yields to no poison in all of nature. That it is caustic — who does not see it?

But you will say it is, in its natural consistency, actually cold, by the experiment of touch. I answer: that it is cold to the touch cannot be denied — but in the same way that pepper too is cold even in summertime, however much in itself and by its nature it is the hottest of things.

[Margin: How the poison of mercury induces cold, and how it can be called moist.]

Again you will say: mercury is moist and cold to the touch; therefore cold is present in it — we cannot deny it. I answer: it is not formally and aqueously moist; rather, it comes from the fluidity, implanted in it by nature, of a sulphureous fattiness. Hence it adheres to nothing, nor does it flow away as an elementary moist does, but it connects part to part in such a way that, however much its parts are separated, not even the least particle is lost; instead, rolled up at once into a globule, it studies its own preservation alone. But all fattiness is ascribed not to cold things but to hot ones, to inflammable ones, by number. From this it is plain that all poisons which partake of the things said — whether they come from the vegetable or the animal family — are either hot-dry or hot-moist, not by an elementary quality but by a certain specific virtue. The hot-dry ones, some of which are poisons, acquire the strength of their poison from the burning of fire; the hot-moist, however, from a certain fiery force by which they are imbued with fattiness and bitumen. The cold and moist, however, the elementary kind — since they arise from elementary contrariety — cannot have efficacy of operation in poisons, nor produce the effect of symptoms in those poisoned. Yet I do not deny that, from the elementary qualities, sometimes remotely, through the secondary and tertiary qualities combined under a certain combination, a specific quality may arise from the combination of the mixed body, and consequently, by a certain hidden force, may ground either a sympathy or an antipathy, producing a virulent effect.

SECTIO II.

DE VENENIS SENSITIVÆ & VEGETABILIS NATURÆ.

On the Poisons of Sentient and Vegetable Nature.

[Fol. 124 — running header "LIBER NONUS, Sect. II."]

CAPUT I.

Quomodo Venenum in humanis corporibus nascatur. — How Poison Is Born in Human Bodies.

[Margin: How poison arises in human bodies.]

I lay down as my first supposition: all things are born from the womb of the earth, as the miracles of Nature spring up, as was shown in the preceding sections — of fennel and sage, for instance. For out of the Earth, indeed, various species are born from various vapors, both from minerals and from putrefactions fermented at the surface; these, filled with the malignancy of putrefaction, generate either virulent herbs or poisonous animals. Wholesome herbs too are not so immune from all malignancy that they do not sometimes draw something noxious and harmful from a malign putrefaction.

[Margin: Why plants and fruits sometimes produce poisonous tiny creatures.]

This is luminously clear from caterpillars and the other worms which are sometimes produced even from the most wholesome herbs — as was said above about the poisonous offspring. These cannot come about except from some small portion of putrefaction, which, mingled with the juice of the herb, is animated into a caterpillar or worm — lest it should infect the whole mass of the herb's juice — so that the herb's wholesomeness may to some extent be vindicated from the evil threatening it. The same happens in nearly all fruits, apples, pears, nuts, and the others cited above, which teem with worms.

[Margin: Mixed bodies consist of three things.]

I lay down as my second supposition: all mixed bodies are composed not only of the four elements, but there also lie hidden beneath them three principles, distinct from the elements, of which all mixed bodies consist; and they are Sulphur, Mercury, and Salt. Sulphur, by analogy [Greek: κατὰ τὴν ἀναλογίαν (*kata tēn analogian*, "according to the analogy")], regards all things that are fiery, burning, combustible, and inflammable. Mercury, or quicksilver, contains all things liquid, watery, airy, the volatile spirits, and those which can be resolved into vapors and exhalations. Salt, however, [regards] the earthy element; just as it furnishes consistency to all things, so too all things earthy, fixed, and solid are referred back to it. These three, as the Spagyric Art [alchemy] teaches, belong to all things existing in the threefold Kingdom of Nature. For if you resolve into their principles, by the said art, any minerals, vegetables, or animals whatever, at once oil will appear under the species of Sulphur; Mercury will obtain the subtlest spirits under the form of a most acrid water; and under the earthy form you will find salt in the bottom of the vessel. These things are so true that no one, unless of senseless mind, could doubt them. If anyone kindles wood or an herb, in the flame he will recognize sulphur, in the acrid smoke mercury resolved, and in the ashes at last he will behold salt itself. So that, besides what has been said, in no mixed body is anything else found.

[Margin: What these three are in mixed bodies.]

The Sulphur of fire's nature, according to the intensity or remission of heat, modifies the virtues of all mixed bodies and procures vigor and activity for all. The Mercury of Nature, water, founds by its threefold action innumerable combinations of marvelous things — namely, by distillation, by sublimation, or by precipitation. Salt likewise, whether under a fixed or a volatile substance, when stirred up by heat, performs those things in the nature of things which — just as they are conceived under hidden properties, so too can scarcely be comprehended — and are everywhere called the miracles of Nature.

[Margin: All inferior things have their part in the threefold nature.]

From their admirable combination, therefore, made in things, all things whatever in this theater of the World — or of the Geocosm — that fall little by little under the senses, are constituted, whether they be wholesome for men and the other animals, or noxious and deadly. For the said four material principles, joined to the manifold species of salts which they generate, and these communicated to the rest of the earthy clods, transplant the virtues with which they are imbued into the vegetable family of herbs, plants, and trees; and these finally, falling into the economy and nutriment of animals, procreate that diversity of properties in each of the things enumerated — a diversity which we could not, I will not say count, but not even conceive in our mind. And in all these there is nothing left for us but to admire the ineffable wisdom, power, and majesty of God, the Best and Greatest, and to celebrate it with what praises we can — we who, out of the inexhaustible abyss of His goodness, providence, and wisdom, [behold that] it pleased Him to draw out of such tiny things so great a variety: things evil so marvelously connected with good, dissonant with consonant, wholesome with pernicious, that even out of evils themselves He has drawn an immense good of Nature, which belongs to His boundless power alone.

Since, then, it was said in the preceding sections how poisons, arisen from earthy and mineral substances, are communicated to plants and animals, nothing else now remains to be explained except that we should teach how these too have broken into the economy of the human body, and that we should expound, step by step, what they work within it.

Man, established in the original dignity and innocence of his nature, just as he perpetually enjoyed the good of blessedness

[Fol. 125 — running header "DE VENENIS SENSITIVÆ NATURÆ."]

[Margin: The original cause of evils is original sin.]

[Man, established in the original dignity and innocence of his nature, just as he perpetually enjoyed the good of] blessedness and felicity without any incursion of evils, so, after the stain of the sin he committed, when the lot of his felicity was reversed, he fell from the highest peak of felicity into the lowest abyss of calamities and miseries — with all the classes of natural things conspiring to his vexation and final ruin. From this was born the discordant antipathy of the elements, and from this the *dyscrasia* [Greek: δυσκρασία (*dyskrasia*, "bad temperament," imbalance of the humors)] of the humors out of which he is composed. Fire, indeed, armed with hidden engines, assaults the economy of the human body with the burning darts of fevers. Air — than which nothing is more necessary for sustaining life — does not cease to harass with various virulence of its corruption the spirit within us. Water, without which we cannot live, in the production of its unhappy spawn always brings something deadly therein.

[Margin: Why the Roman Sun is so harmful?]

Earth, finally, with its mineral fumes and pernicious vapors, so harasses plants, animals, and man himself, that whence — from the vegetative or sentient fruits of the earth — nourishment for his preservation flows, thence too there is prepared, in the greatest measure, his own gradual destruction. And so nothing is so sound and wholesome that there is not something connected to it which is contrary to our life and to the integrity of our health. Where there is honey, there is gall; where there is a teat, there is a tumor [*ubi uber, ibi tuber*] — so that, as advantages and necessary things proceed from individual things into the body of man, and into the uses and nourishment of man now made perfect, so too, to his destruction, both open assaults and hidden ones from those very same sources attack us, sometimes by wondrous mines. And those same things which had previously given life, when the laws of symmetry have been broken — the wheel now turned, as if war had been declared — destroy again and exterminate what they had built. These kinds of conflicts are too numerous to be enumerated, too well known to need to be.

Since, therefore, that consuming poison [virus] has flowed from fallen man, as from the head, into the rest of the members of the universe, deservedly are turned back upon them in turn the seeds of hatred and enmity, the scourges, crosses, and engines of every kind of disease and calamity, according to the inevitable law of Adrastia [Nemesis]. But that these things may be more luminously clear, I have thought it right to relate how the seeds of poisons spring up even in the individual members of men.

[Margin: Where there is disease, there is also remedy.]

But lest we should suspect that God, the Best and Greatest, the most kindly Father, willed to inflict on the human race the ultimate disaster without any remedy for such great evils, I shall at the same time show how the providence of the most pious heavenly Father has permitted no evil so great to be inflicted on man without at the same time joining to it the highest good, destructive of the whole evil — so that where there is disease, there is also a medicine suited to that disease and at hand, as, in His infinite goodness and clemency, He has willed it to be.

CAPUT II.

Quot modis in nobis venena nasci possint. — In How Many Ways Poisons Can Be Born in Us.

[Margin: In how many ways poisons can be born in us.]

Just as, by the benefit of fire, we defend ourselves against the violence of cold, are warmed by it, and are preserved — so too there are not lacking in it certain noxious impressions which may weaken, consume, and destroy the very native heat they ought to preserve. I do not speak here of the actual combustion of fire, by which all things are destroyed, but of those pernicious impressions which [a body] can receive into itself. A man walks about in the sun, sits beside the hearth-fire, handles [it] in cooking and digesting — yet he does not know that certain virulent exhalations are roused in the air by the fire's heat, which, once breathed in, [bring] poison immediately present and assault the radical heat with a substance wholly contrary to that poison. And how this happens I shall make clear by the manifold induction of examples.

[Margin: Why the Roman Sun is so harmful?]

It is asked, therefore, why those who have experienced the summer Sun here at Rome immediately fall into deadly diseases? I answer: there are malignant vapors drawn out by the force of the sun from the hollow places of the earth, and teeming with various putrefaction. These, taken up into the open pores of those who are sweating, as soon as they have been shut in by a cooler breeze or by the moisture of springs, are then exalted by the internal heat. First [Margin: What places struck by the Sun are pestilential?] — mixed with the blood and spirits — they kindle that malice of fevers which incautious mortals frequently experience with the loss of life. This, however, is not universal, but only in those places where the condition of the earth is teeming with corrupt and virulent vapors —

such as marshes, cemeteries, shady woods, the ditches of stagnant waters, places stuffed with corrupt sulphur and bitumen. Hence those who, glowing with heat, betake themselves to rest under a yew tree, have at once — infected by the deadly vapor — exchanged life for death, as various cases have shown. For the air of such shades takes on the qualities of which the exhalations of the trees consist: if these are wholesome, [they pour out] wholesome [qualities]; if poisonous, they pour out poisonous properties of their exhalations.

[Margin: The shades of certain trees are noxious and poisonous, such as the yew and the *napellus* [monkshood/aconite].]

In this way, at Tibur [Tivoli], two shepherds were, not long ago, found dead under a *napellus arboreus* [tree-like monkshood] on Mount January [Monte Gennaro] — killed by nothing other than the vapor of the poison with which the said shrub swells. It sometimes happens that sailors and farmers, having gathered up brushwood from all around, build a fire either for cooking food or for the sake of warming themselves; and so it happens that, the pyre once built, some were soon struck with a grievous headache and fell into madness and frenzy, while some were at once killed

[Reading order reconstructed from folio numbers]

LIBER NONUS, Sectio II — De Venenis Sensitivae Naturae

Caput II (continued) — Quot modis in nobis venena nasci possint

[How many ways poisons can arise in us — continued] So Porta reports of certain Neapolitan sailors (*Phytognomonica*). When the cause was investigated, they found at last that the sailors had contracted these symptoms from the burning branches of the rhododendron [Rhododendron] — which is a most poisonous kind of shrub. Its flowers are very pleasant to look at, white and red, yet of such virulence that if they are thrown into cisterns they can spread sickness through an entire community. I have also heard from sailors and fishermen that some men, after roasting fish skewered on dry hemlock stalks [cicuta], later ate the fish, and all who did so were eventually killed by various torturous symptoms. For the fire stirs up and rouses the poison lurking in the hemlock stalks; once roused, it is communicated to the flesh of the fish, and the fish, thus poisoned, inevitably poisons the human being as well.

[Margin: The rhododendron, a poisonous kind of shrub.] [Margin: Hemlock stalks, when dried, become poisonous.]

How greatly the vapor of pit-coal [lithanthrax], stirred up from the fire, harms those sitting nearby is attested by the people of Liège [Leodienses] and others who build their fires from this sort of fossil coal. Countless examples show how easily charcoal burning in a closed room, or the fumes of wax, can suffocate a person.

[Margin: The pestilential fumes of pit-coal.]

I will say nothing here of those who devote themselves to alchemical operations, and the savage symptoms they incur from metallic vapors unless they carry out their procedures with the utmost caution and the best protection. Experience has certainly taught that most of them are in the end worn down by consumption [phthisis], wasting [atrophia], or paralysis — of which I have written more fully elsewhere. Fire, then, can do the greatest harm. I have known painters who, because they had the bad habit of holding in their mouths for too long a brush stained with orpiment [auripigmentum] while painting, contracted horrible and utterly fatal diseases.

Secondly, I proceed to the Air, which breeds in us so many and such great offspring of poisonous brood — as epidemic diseases and plagues sufficiently demonstrate. Since I treated these at length and on purpose in my *Scrutinium Physico-Medicum* [*Scrutinium Pestis*], I refer the reader there; he will find that nothing can be more receptive to poisonous impressions than the air. For whatever is exhaled from the earth that is virulent and deadly is immediately communicated to the air; and since we are forced to breathe it in and out continually, there are necessarily founded in us as many different kinds of malignant disease as there are different species of various poisonous vapors.

[Margin: Poisonous accidents from the air.]

Now the things that usually infect the air with their vapor are reduced to roughly six headings. They are, **first**, stagnant waters teeming with frogs, serpents, and various pestilential insects. **Second**, places filled with sulphurous or arsenical vapors and other noxious mineral exhalations. **Third**, places foul with the virulent putrefaction of carrion and corpses. **Fourth**, places exposed to noxious gusts of wind. **Fifth**, places where there flourishes an abundant growth of poisonous plants — such as monkshood [napellus], hemlock [cicuta], henbane [hyoscyamus], hellebore [veratrum], nightshade [solanum], and thorn-apple [stramonium]; for these, struck by the Sun's rays and dissolved into vapor, infect the air wonderfully, especially if such places are approached after sunset. **Sixth**, epidemic plagues, which now and then — as I taught in the *Book of the Plague*

[*Liber de Peste*] — leave whole provinces, with their cities, towns, and villages, bereft of their inhabitants.

Thirdly. Now follows the element of Water, which rages against the human race all the more savagely the more virulent the impressions it has received, both from subterranean exhalations and from the putrefactions of its own substance. So much so that one might reasonably doubt whether the Water — once it has entered into wedlock with the earth, with the Sun as best man — does not bring forth a greater abundance and variety of poisonous things than of wholesome ones. Tinged with their virulence, the Water continually tinges the air as well by its emission of vapors; and the air, breathed in by men, gradually plants the seeds of poison. And so, had the sea not by the disposition of divine providence been imbued with saltiness, the Geocosm would inevitably have perished from the abundance and variety of its putrefactions. The harms that I showed a little earlier as arising from the air can also be applied to the Water.

[Margin: Poisonous accidents from the water.] [Margin: In what places is the water poisonous?]

Hence countless illnesses arise from drinking water, especially in those who have drawn it imprudently from stagnant ditches. For when waters lie still, they at once conceive putrefaction, and from that putrefaction are born various poisonous animals — frogs, serpents, worms deadly in their virulence, such as leeches and the like. The spermatic corpuscles of these creatures, being diffused throughout the whole substance of the water, work great ruin within the body when taken in by the thirsty.

[Margin: A marvel observed by the author. / The wind.]

I myself once knew, in my native country, a hay-mower who, driven by thirst, recklessly gorged himself on water from a ditch in a neighboring meadow. After the space of half a year he felt, first, terrible gripings of the belly, and his stomach too as though pinched by some living creature; and he complained that he was tormented by continual, intense pain, adding that something alive was hiding inside him, which — especially when his stomach was empty — was attempting as it were to find a way out through the gullet [oesophagus], not without the nausea of vomiting. The physician, shrewdly sniffing out what the matter was, concluded from the signs laid before him that it could be nothing else than a serpent — one that the man had hatched within his stomach by his native heat, from the spermatic matter mixed in the water he had drunk. His conjecture proved a happy one. And since he knew that serpents delight above all other

foods in milk, he hit upon this plan: he ordered the sick man to be hung up by the feet, with his mouth open (because he believed the animal lay hidden inside), so that he might catch the vapor of milk breathed out by the heat of a fire set beneath it. Marvelous to relate — the serpent stabled within, lured by the dainty of that vapor, burst out through the gullet with such force that it nearly suffocated the man. For struggling not a little within the narrow passages, and getting nothing but its head out, that head was seized with forceps and drawn out with the greatest force, displaying, to the astonishment of all the bystanders, a serpent nearly a foot and a half long. The patient, **however**, was soon purged with suitable medicines, strengthened, and restored from exile, as it were, to his former health.

Schenck [Schenckius] relates similar cases in his distinguished work of *Observations*, concerning men who, after drinking waters teeming with the like spawn of marshes, had hatched within their stomachs frogs, toads, and various kinds of worms, which they later expelled by emetics administered on a physician's prescription. Great danger also threatens those who drink waters tinged with the poisonous qualities of minerals. Valleriola [Valleriola] reports in his *Observations* that a certain hunter found a spring in a forest, and tasting from its sharpness that the waters were acidulous, filled himself with a fairly generous draught. But he soon felt himself so overwhelmed by so many grave symptoms that, having scarcely returned home in his right mind, within two days he died of the virulence of that deadly spring.

[Margin: A deadly spring kills a hunter.]

Of this sort are all those pits potent with arsenical virulence, such as Pliny [Plinius] reports once existed at Terracina (formerly Anxur), from which all who drank perished by sudden death; and therefore — lest it should in future bring harm to anyone — it was filled up with stones and a huge heap of earthy rubbish.

[Margin: A deadly spring at Terracina.]

Fourthly. The Earth, being held to be the mother of all generation, likewise perpetually contrives evil for us by its exhalation. It is the origin of every poison and of the impressions of malignant Nature — so much so that one might call it not so much the mother as the stepmother of the human race, appointed such by Nature. For with its virulent mineral vapors it perpetually infests both the airy and the watery element; and not content with these, once it has insinuated itself into the innermost fibers of plants, it rages there, allied with a host of noxious qualities. The result is that from the very source where we ought to expect

preservation through nourishment, from that same source we run into death. For as I said above, there is scarcely a little plant that does not have something virulent attached to it, born with it; and this is sufficiently shown by the worms and caterpillars that each plant generates as its own. When these are taken by us as food, the efficacy of our native heat does not so consume them that they do not always leave behind something contrary and pernicious to the nourishing substance — something which, increased by frequent use, finally breaks out into malignant fevers and exotic diseases, according to the condition of its malignant nature.

[Margin: All foods bring us some harm.]

The reason for this is none other than a certain wormy substance which Nature keeps hidden under the imperceptible covering of the putrefaction of plants and fruits — a substance all the more pernicious the more virulent its nature. This happens with poisonous plants, which some people, foolishly rash, take for wholesome herbs; not infrequently they pay for it by exchanging life for death. For nothing is easier than for inexperienced cooks, deceived by the resemblance of the said herbs, to seize hemlock for parsley, henbane for blessed thistle, mandrake for cowslip, hellebore for plantain, houseleek [barba Iovis, "Jove's beard"] for bugloss. Examples of these you may see in our little work *On the Plague*.

Fifthly. There remain the harms done by animals that come into our use. If these conceive even the slightest putrefaction, then when taken as food, by the innate fecundity of putrefaction they swarm with a host of imperceptible worms in the stomach. These are by no means free of poison; and though at first we do not notice it — the thing lying hidden, as it were, among certain embers — yet with the passage of time, gradually acquiring strength, it kindles so great a conflagration that the whole workshop of Machaon [Machaon, the physician] would scarcely suffice to extinguish it. Hence the eating of all putrid flesh is to be avoided — above all those parts of animals in which the poison, for the most part driven there by nature, tends to make its nest, such as the tails and brains of animals roused to madness [rabies]. For the bile, boiling up when it is burnt, is always disposed toward a certain pernicious quality, as the examples teach of those who, having eaten the brains of cats served at table in place of rabbits by a dishonest innkeeper, were themselves driven to madness the next day, and — by a truly unhappy fate — ended their lives in a raving death.

[Margin: Dogs and other animals which have something putrid about them readily breed pernicious diseases.] [Margin: Cat brains drive men to madness.]

How great an evil threatens us from insects which, through the carelessness of cooks, now and then fall into the cooking-pots of our food, frequent cases teach. Moreover, if pots, frying-pans, and kettles contract verdigris [aerugo] from vinegar poured over meat, it can scarcely be told how greatly symptoms not unlike those of minerals arise in us. I will say nothing here of the poisonous bite of animals, such as serpents, scorpions, and other insects; nothing of the eating of certain unclean birds, and of those fish that are fed on the putrid slime of pools — for these, since they are not free of virulence, are to be shunned with all speed [velis remisque, "with sails and oars"]; and so it is not without reason that they are forbidden in Holy Scripture. And these are the things that afflict the wretched condition of mankind with so many and so great evils.

Caput III

Quomodo venena animalium hominem inficiant & interficiant, sive de causis venenorum

[How the poisons of animals infect and kill a man, or concerning the causes of poisons]

It was abundantly demonstrated in the preceding chapters that all kinds of things capable of being generated draw their origin from the primitive principles of minerals — that is, from sulphur, mercury, and salt, and from their spirit. When these are tempered together by a certain harmonious proportion in the mixed bodies, they are said to constitute a man in the best state of health. But if at any time, through the contrariety and excess of heat or cold, dryness or moisture, the one against the other, they sink into a discordant constitution, then indeed at once the seeds of discord are born.

For where heat and moisture have taken on their right measure, they conceive, and from these two all things arise; and though fire is at war with water, the moist vapor creates all things, and discordant concord is fit for begetting.

[Margin: Ovid, *Metamorphoses* [I].]

[The verse is Ovid, *Metamorphoses* I.430–433, on spontaneous generation.]

Nor let anyone here suppose that all things take their origin from the four elemental humors. For there lies hidden beneath these something else, since the four [recte: three?] principles of things are only certain vehicles, as it were; and they are the three principles recounted above, which we have designated by the

names of Sulphur, Mercury, and Salt, whose spirits may deservedly be compared to air. From these, as from a material cause, we say all things consist. For how simple elements and bodies devoid of all composition could cause those exotic effects, both in the nature of things and in the microcosm, cannot be discerned.

[Margin: The elements are the vehicles of the three principles of nature.]

Therefore when we speak of elemental fire, there must always be conceived to lie hidden beneath it something distinct from the elements, which confers on it heat and dryness — and this we call by the name of Sulphur. If we bring forward water, we always conceive that something underlies it which procures for it moisture — and this is called by the name of Mercury. Salt, finally, is present in the element of earth, inasmuch as it furnishes it with its fixed consistency from itself. Each of these things is potent with its own spirit, diffused into all things, which we not unfittingly compare to air. And from these we maintain that all the kinds of mixed bodies that are in the world derive the basis of their composition, joined with the auxiliary supplies of the elements. For since in the nature of things no pure element is granted, but bodies are elementated — mixed from sulphur, mercury, salt, and their spirits — surely only the man will deny that all things consist of them who has never seen, by the spagyric art, the separation of individual things resolved out of all mixtures into their principles.

[Margin: The earth infects the water and the air with its exhalations.]

From the earth, then, these principles first draw their power through exhalations, which are nothing but a kind of effluvium [ἀπόρροια, *aporrhoia*, "emanation"] of the minutest corpuscles that are perpetually exalted from the primitive bodies of Nature by the force of the subterranean fire. Each of these holds the virtue of the whole [body] from which it takes its origin, and confers it on the airy and watery elements. From the union of both of these, the effluvium of diffused virtue first [passes] into the vegetable nature; vegetables, when they pass into the nourishment of animals, communicate to them the properties of the things they consist of. And in this way all things have obtained their origin from the things said — as is made known even from the very pages of Holy Scripture; since we showed above that not only vegetables but the whole kind of animals, and indeed man himself, was made by GOD as first-fashioner [protoplastes] from the slime of the earth; and that He marked the chaotic mass — not without mystery, in that threefold origin of the primitive bodies within it — as a kind of universal panspermia, with the most holy seal of the Sacrosanct and Triune, Divine and Supereminent Triad.

[Margin: The three principles signify the Holy Trinity in our notation.]

But to return to our purpose: it may rightly be asked how these three, with their spirits, beget poison in the body of the microcosm. That this may be elucidated as exactly as possible —

Be it known that if these three, together with the four humors of which they are the vehicles, subsist in perfect union and concordant temperament, then it is certain that health consists in its full vigor; and they are called by the spagyric philosophers the Sulphur of Nature, the Mercury of Nature, and the Salt of Nature. Of these, the common Sulphur, Mercury, and the usual and mineral Salt are only certain husks. But when the right blending [εὐκρασία, eukrasia, "good mixture"] of the said principles passes, through the admixture of various external things, into a bad blending [δυσκρασία, dyskrasia, "ill mixture"], then at last that savage confluence of contrary things begins to set in motion the Lerna of evils [malorum lerna, "swamp of evils"] which we shall now describe.

Sulphur, when it subsists in its purity, is not a poison — nor is mercury or salt. But when by the force of fire they are altered and reduced as it were into another character, the Sulphur — transmuted into Arsenic, Orpiment, Realgar [Risigallum], or some other such thing — having taken on a temperament [κράσις, krasis] contrary to life, pours out its venomous power into all the members of the world. Mercury, as soon as by the force of fire it has been distilled, sublimated, or precipitated, puts on an utterly worst and deadly substance — which same thing you may understand of the fourfold kind of salts, by means of their spirits.

And just as those three, pure and refined from all impurity, being congruent with nature, concur to the constitution of wholesome mixed bodies, so when impure and imbued with venomous qualities they may not undeservedly be called the boxes of death [pyxides mortis] — from which, namely, by means of the putrefaction of the earth, whatever in the sublunary world is found to be vicious, corrupt, and of deadly quality, derives its composition. Now, how within the microcosm these venomous properties just described operate, and how they dissolve the harmonious temperament of the humors, must be unraveled through questions.

You ask, then, first: How do deadly serpents produce in us poisons destructive of the whole vital substance? I answer: this comes about from the dissimilarity of the poison poured forth by the serpent, contrary in its whole substance to the vital substance of the microcosm. And this contrariety depends on the efficacy of the mercurial or arsenical spirits with which now this, now some other serpent is

potent — which spirits, being more efficacious than that our own vital or animal spirits could overcome them by their native heat, [recte: continues onto folio 129]

[Margin: How serpents produce poisons in us.] are able [to do so]; hence by a certain tyrannical violence, as soon as they have insinuated themselves into the body by a bite, by an exhalation, or by some other means, they turn everything upside down. And just as a fire, once it has gained strength, immediately corrupts everything, destroys everything, and turns it to ash — in just the same way, the poison of anything, once admitted, unless it is resisted at the very entrance of the gate, by the swift propagation of its power immediately makes for the citadel of the whole microcosm, that is, the heart; and once that is stormed, then triumphing as if over a victory, it makes all things subject to its own authority, with the final extermination of the microcosmic Kingdom.

[Margin: How the poison taken in operates.]

For since it is spirituous and of great subtlety, it penetrates all the passages, kindles, corrodes, and eats away everything with caustic force — with exactly those symptoms with which Arsenic or sublimate of Mercury, taken inwardly, rages in human bodies; so that even from the dreadful symptoms the rationale of the poison's constitution becomes plain. These things, however, are to be understood of poisons of the first class, for which scarcely any remedy remains — as is plain in the asp [aspis], the dipsas [dypsas], and the phthias [phthias].

There are, however, some poisonous animals and plants whose poisons, when taken in, likewise cause great symptoms, but whose mischief can in some way be subdued by suitable medicines — as in hemlock, opium, and the like — so that help can be given against them. These nevertheless afterward leave behind some lingering trace of their virulence, which, insinuated into the innermost fibers, sets up a kind of stealthy truce with the microcosm; but when it is reawakened according to the condition of the times and of the foods taken, then, emerging as it were from its lurking-places, it attacks the enemy unexpectedly with a new kind of weapons, with a slaughter which one can scarcely repair in the whole course of one's life. Of this sort is the poison of the Tarantula, which is a kind of phalangium [spider], whose prodigious operations I described in the *Ars Magnetica*, Book 3, *On the Magnetism of the Tarantula* [*de magnetismo Tarantulae*], with all the precision [ἀκρίβεια, akribeia, "exactness"] that was possible — which the curious reader may consult more closely. Its constitution, as it consists of saline spirits mixed with arseno-mercurial spirits in a certain temperament, when likewise brought into act by heat, by a perpetual twitching of the muscles produces that incessant appetite for dancing. The same effect, among

plants, is produced by *apium risus* ["laughing celery," a kind of crowfoot, *ranunculus*], whose poison, while it twitches the muscles of the mouth and chest rather violently, forces those infected to die as it were laughing.

[Margin: The poison of the Tarantula.] [Margin: *Apium risus* (laughing celery).]

You ask secondly: Do the individual members have a poison hostile to each of them? I answer that they do: for there are as many different poisons as there are different members and parts in the human body. Thus some poisons, especially of the first class, flow principally to the heart; certain ones attack the brain most of all, others the liver; nor are there lacking those which in a wondrous way attack the kidneys and bladder; others exercise their tyranny upon the blood. Those that make for the heart, the fount of life, are all the poisons of arseno-mercurial property, whether you regard plants or animals.

[Margin: The individual poisons natural to each member attack their own member.]

Those that attack the brain are hellebore, mandrake, the species of nightshades, henbane, thorn-apple; which, taken inwardly, by their innate virtue dissolve the mass of the humors and, with a vast accumulation of fumes, make for the brain — whence come lethargy, stupor of mind, cold sweat; and if these have any sharpness joined to them, by the twitching and inflammation of the meninges they provoke even into frenzy [phrenesis] and mania. Since the saturnine magnesia [magnesia saturnina] also produces this effect, it is likely that it too has shared in this through the tincture of such spirits.

Those that harm the lung are the sea-lung [pulmo marinus, the jellyfish], which by mere touch brings on difficulty of breathing [ἄπνοια, apnoia, "lack of breath" — i.e. respiratory distress]. When in the year 1632 I was surveying the Province of Narbonne [Narbonensis], and among other things had visited the inhabitants of that town which they call by the common name *Martaigne* [Martigues] from its "Martial waters," I found that most of them suffered from a defect of the lungs. When I asked the cause, they answered that it was from the great quantity of sea-lungs which a salt lake near the town — drawn from the sea by a channel twelve miles long — nourishes; so that while they handle these incautiously, they incur this sort of harm. It is indeed a foul and venomous animal, which produces nausea at the mere sight of it, floating on the waters like a wineskin, in which — as I most diligently examined — neither eyes nor mouth could be seen; you would call the whole thing a wineskin, of the bloodless [exsanguis] but poisonous kind.

[Margin: The sea-lung is hostile to the lungs.] [Margin: The poison hostile to the lung.]

It is asked, then, whence that virulent contagion comes to it, and how it attacks the lungs by mere touch. I answer that it is that foul vapor pregnant with the malignity of a burnt mercurial salt, which it emits from itself even when pressed by the fingers alone; and this vapor infects the neighboring air. Drawn in by the breath, it at once betakes itself to the member naturally kindred [συμπαθικόν, sympathikon, "sympathetic"] to it, where by its malignity, through an immediate dissolution of the moisture, it brings upon the lungs those symptoms which those afflicted by this evil experience. The same seems to be done by precipitated Mercury, mixed with a vehemently burnt salt, in the lungs; for from the vapor of this, those who are infected mostly fall into consumption [phthisis], as goldsmiths have more than once complained to me — although it does not harm the lungs with such violence as the former does, inasmuch as its virus is somewhat blunted by the slow and viscous body of the putrid animal. It is also said to be very harmful to the eyes; whence it is commonly called *mal d'occhio* [Italian: "eye-evil"] or *mal d'eulx* [French: "eye-evil"].

[Margin: The cause of the poison lurking in the sea-lung.]

It is asked thirdly: How is it that the Cantharides [Spanish flies], when either taken inwardly or even excited by the heat of the hand, at once make for the bladder and ulcerate it together with a discharge of bloody urine? I answer that it is a foul, subtle, and spirituous effluvium of burnt salt, with which the body of the cantharides is potent, roused by heat; which by a certain wondrous magnetism, as toward a body kindred [analo-

[Margin: How the cantharides attack the bladder, explained.]

[Text continues onto the following folio.]

is rendered more effective in that fluid of the bladder, so that, once it has made the fluid subject to its own jurisdiction, both a corrosion and—from that corrosion—a bloody urination must necessarily arise.

Whatever poisonous animal spirits, then, are diffused by a like action into the organs proportioned to them, achieve their effect by no other means than by a kind of magnetic action. Just as the magnet, among countless objects, seeks out iron alone, so too the cantharides [Spanish flies] do not seek the heart, the brain, or the lung, but the bladder—as something like, analogous, and proportioned to themselves—in the manner I have described. On these matters see what we

discuss more fully concerning like things in the *Ars Magnetica* [Kircher, *Magnes, sive de Arte Magnetica*], where we also assigned the manner and the cause why the torpedo [electric ray], by the mere touch of a reed touching it, as it were strikes numb and stupefies the hand—effects which must be ascribed to none other than a certain mercurial power innate in it, hostile to the nerves, by which it prevails.

[Margin: The sympathy of poisons toward particular organs.]

CONSECTARIUM. [Corollary]

And from this it is plain that the poisons which are diffused from venomous creatures toward certain particular organs, and not toward others, do so partly by force of sympathy [sympathia], partly by antipathy—or, what comes to the same thing, that they bear to certain organs a likeness, or proportion and analogy, and to others none at all. As for why the poison, attacking the said organs under the pretext of friendship, should stir up such great havoc in them, someone will rightly want its cause. I say this happens through an excess of power, by which it overcomes, suppresses, and converts into its own nature the analogous power in some sympathetic organ; and in this way it can be called antipathic. Yet sympathy can be considered to operate between the two, in that the organ contains within itself something analogous to the poison, toward which it naturally flows together. Thus saline bodies attract saline ones, of whatever species they may be; sulphureous bodies flow together toward sulphureous; and so on for the rest. So, for example, the saline poison of the cantharis [Spanish fly] naturally seeks by a kind of magnetic confluence the vessel of a property congenial to itself—that is, the bladder, which is endowed with saline force.

[Margin: How the cantharides [Spanish flies] ulcerate the bladder.]

And because that saline spirit in the cantharis is subtle and exceedingly hot, the result is that, penetrating everything, as soon as it has reached the organ analogous to itself, it undermines by the excess of its power the balance [temperies] of which that organ consists, while leaving untouched the rest, with which it has no analogy. Other poisons, by contrast—since they generally pour their venom through the blood or the vital spirits, and consist of a moist and subtly warm temperament—seize hold of a man at once, overwhelm him with their embrace, and stupefy him; whereupon, with heat and motion ceasing, the animal must necessarily perish.

Or again, some poisons so agitate the blood and the animal spirits that, while these flee what is contrary to them, the poisons—once received within the veins

and arteries and there intercepted by the malignity of the pursuing enemy—degenerate into malignant fevers, from which death follows. Or again, certain mercurial-arsenical poisons, since by their corrosive power they corrode and lacerate all the inner parts, must likewise procure death thereby, as is plain from the venom of hemorrhoids [a viper] that is endowed with the force of sublimated mercury [mercurius sublimatus].

[Margin: All poisons operate by magnetism.]

However the dreadful effects of poisons may at last be combined, it is certain that they arise only from a kind of magnetism [κατὰ τὸν μαγνητισμὸν (kata ton magnetismon, "by magnetism")] proceeding from depraved arsenic, mercury, and salts, in which venomous animals abound; and that their antipathy with the human body cannot be conceived otherwise—as infallible experience itself teaches: namely, that poisons infused into bodies by lethal animals cannot be extracted better than by a medicine made from that very animal. Thus the bite of a viper is healed by the viper, the sting of a scorpion by a scorpion laid over it, and innumerable other cases (of which more in what follows)—that is, by the attraction of like things. But antipathy, with respect to the said humors or infected organs, must not be considered except through the excess of power, by which the poison overwhelms its own analogue and converts it into the nature of the corrupted poison.

prepared by nature, it is conveyed and fully worked up into the vital spirit of the animal. And in this workshop, this laboratory, and in no other member of the body, did nature will that the poison of the viper be elaborated—instituted with a principal end in view: both for preserving the creature against adverse things, and for strengthening the vigor of its own natural powers, without which it would remain dull and sluggish. Hence both the viper and as many serpents as exist in nature are powerful by no other member than the mouth.

But let us now proceed to examine the body of the poison itself, which is nothing other than a thick and viscid stickiness, anointed with a nitrous-phlegmy ferment—much as bitter bile mixed with thicker phlegm—elaborated by nature beneath two fistulous, mobile, and somewhat upturned teeth. (As one may observe in the disemboweling of vipers, of which many thousands are killed every year in the Roman College for the preparation of theriac.) This sluggish matter, when it has boiled up through the creature's anger and the consequent influx of bile, and a bite follows, produces in the wounded victim the havoc we have described. So necessary is this sluggishness of the matter to the poison itself that without it the poison could not be contained at all, but would at once evaporate. That this same

sluggish humor is found also in the dypsas, the asp, and the rest, all who have written about them attest. For it is the kindling-stuff [fomes] of the poison; yet it turns into a most fine and subtle venom—just as quicksilver [argenteum vivum] is sublimated by the effervescence of salt. Indeed nothing in nature is so subtle that it does not build its nests of subtlety in the stickiness of bodies; and the spagyric art [Ars Spagyrica] teaches this plainly in the dissolution of minerals and salts—of niter, alum, and vitriol—from which bodies, though concrete, it nonetheless draws spirits so subtle and effective that scarcely anything seems able to resist their violence, as is plain from their vehement corrosive power. The same is evident also from the thick juices of poisonous plants, which, when taken inside and heated to boiling by warmth, at once put forth their subtle venom, with that train of symptoms which we recounted above in the case of monkshood [napellus], hemlock [cicuta], aconite, hellebore [veratrum], and the like. I say nothing here of animals. What can be subtler and finer than the spirits, whether vital or animal? Yet these nest only beneath the sluggish mass of the blood and the hard framework of the nerves. Hence, although—because of its earthy nature and its coldness to the eye—many suppose the poison of the viper to be cold, from these considerations it is nevertheless openly plain that the poison, that is, the spirituous liquor of the viper, is in the highest degree hot, being thoroughly concocted by the heat of the heart and the burning of the bile. For it is impossible that a thick liquor, coagulated by elemental cold, could be subtle and active; whereas, on the contrary, all subtle and penetrating things, since they proceed from heat, are likewise by their own nature hot. The reason for this see in the first

[Margin: Poisons do harm through an excess of diffused virtue.]

that this is by the power and property not only of elemental heat, but of the saline spirits, or of mercury and sulphur, in whose nature they share.

CONSECTARIUM I. [Corollary I]

From this follows the rationale of the antipathy of poisons, and it consists in this one point: that the poison of one animal is more efficacious and more potent than the poison of another. Hence the spider [araneus] kills the toad [bufo], because the spider's poison is subtler, more active, and more spirituous; and so perhaps—if it were established for us by experience—the asp, the dypsas, or the ptyas, which are armed with the most potent poisons of all, would kill vipers that had been bitten and steeped in a weaker venom; just as Nicander relates of the Argolic serpents, that they kill asps by their bite. From this too it is plain why a serpent of the same species does not harm another of its own kind [ὁμοειδέα

(homoeidea, "of the same kind")]: because in their natural power, proper to themselves, they are equal, without any excess. So far are they from harming one another that rather they cherish and preserve one another by this power, as by a kind of dowry assigned to them by nature.

[Margin: The spider kills the toad—why?]

CONSECTARIUM II. [Corollary II]

From this it is plain how the poison of the viper, by the propagation of itself, wreaks such great havoc. I say that, as soon as it has been put into a wound by a bite, it acts at once—no differently than if someone had thrown a spark of fire into tinder or kindling, which at once, by a most swift advance and within a brief moment, by the sudden spread of the fire destroys and consumes even a large part of the kindling, unless it is resisted. In exactly the same way the poison is to be reckoned to act; for since it is caustic, once taken inside it rushes wherever a door is given, turns everything upside down, gnaws everything, sets everything ablaze, until at last, the vital spirits being consumed by excessive heat, the poisons finish off the animal. And so its progress can be described in no better way than by the motion of acceleration of heavy bodies, as is plain from the line of points here drawn.

Diagram. [The figure, set in the right margin of the column, is a single vertical line (a falling-body trajectory) marked at intervals with short cross-strokes and lettered points. The line runs from A at the top down through B, C, D, E, to F at the bottom, with finer graduation tick-marks between the lettered points and an arrowhead at the foot. It illustrates the accelerating descent of a heavy body, used as an analogy for the accelerating progress of poison from the wound.]

- A (top of the line): the wound of the injured man; the starting point, where the descent is slowest
- B (next point down): the second interval; faster than at A
- C (third point down): faster still
- D (fourth point down): faster still
- E (fifth point down): the wounded man's site E—near the term of rest; fastest
- F (bottom, with arrowhead): the alternative site F; the term of rest, where death is

[Resuming the text:] The reason for this see described in the first Book of this work. For just as a stone, the nearer it is to the center, accomplishes the greater

spaces—that is, is the swifter, as may be seen in the spaces A–B, B–C, C–D, D–E: at A it is slowest; in the space A–B faster, and still faster in B–C; and in this fashion ever faster, all the way to the term of rest. In the same way, let A be the wound of the injured man, and the heart be at site E or F. I say, for example, that in the first hour, at E, the poison works more slowly; in the second hour, having now acquired its forces, it advances its power more swiftly

from A to B; in the third hour faster still from B to C; in the fourth hour faster still from C to D; in the fifth hour, swiftest of all, from D to E. Once propagated to E or F, it at last subjects everything to itself by its accustomed tyranny, and consequently terminates at E in that rest which death brings.

CAPUT V. [Chapter V]

How poisons do no harm to some animals, and how poisons—through the bite of a rabid dog or of the tarantula—do not put forth their force except at a determined time.

We know that storks, eagles, hens, ducks, pigs, deer, and the like delight in feeding on venomous animals, which nonetheless, once eaten, inflict no harm upon them. And, to dispatch the matter in few words, I say that this arises from the supreme and excessive heat in which the said animals—especially the birds—abound. But since an animal can by no means produce this effect by elemental heat, there is doubtless some other adjunct thing concealed, kept safe from all poison, which we shall now try to investigate.

[Margin: All birds abound in saltpeter [sal-niter].]

We have already shown elsewhere that every kind of bird abounds in a notable quantity of saltpeter [sal-nitrum]; and that this kind of salt, excited by natural heat, is destined partly to become excrement, partly to form the covering of feathers—as the very constitution of feathers, made from fixed niter under the appearance of purified glass, sufficiently demonstrates. This saltpeter, then, made fruitful with a sulphureous tincture, so wonderfully strengthens the natural heat, especially in the stomach, that whatever they have eaten—indeed even iron itself—some animals consume by an acrimony of this sort.

[Margin: Why serpents and toads taken as food by storks do no harm.]

From this it is deduced why no feeding on a venomous animal harms storks, hens, eagles, ducks, and the like. For since the stomach in such animals abounds in a sulphureous-salnitrous vigor, and consequently in a marvelous acrimony, it

follows that the poison of the serpent is consumed and transmuted before it can exert its forces—which is a clear indication that hens and storks far surpass, by their native heat, the heat of the diffused poison. And from this it is plain that heat of this sort exerts its force even upon metals themselves, by gnawing them—which the poison of serpents does not do. If you throw to hens a coin of silver or copper, they will greedily swallow it; but when they have voided it by stool, you will find it already half-eaten, which surely arises only from the salnitrous acrimony of the sulphureous spirit.

[Margin: Hens digest iron and bronze coins.]

The bone-breaking eagle [aquila offifraga, the lammergeier], having swallowed even the hardest bones of animals, soon digests them, by the heat of its stomach, into a soft and fluid excremental matter. I say nothing here of the ostrich [struthiocamelus], which—as is established by an experiment I myself made in Malta—digests swallowed iron by the heat of its stomach, and converts what it has digested into a ferruginous slag, just as if it had been placed in vitriolated water. With the same suffocating power of poison are endowed all those birds which feed on spiders, flies, caterpillars, putrid worms, locusts, and cantharides, and on poisonous herbs, such as the starling [sturnus] on hemlock [cicuta]. And so the reason is plain why the eating of venomous animals does no harm to some animals.

But why do men too feed on the flesh of vipers with impunity—indeed with the greatest benefit to their health? The reason is that the poison of the viper has established its seat in the head and in the tail, as in the extreme parts of the body. Hence, once the extreme parts have been cut off and the entrails removed, the remaining pulp of the flesh, cleansed with salt and dill and cooked, is not only not harmful, but turns into a wholesome medicine—as is plain from viper-salt and from viper-troches [trochisci] reduced to a powder. And viper-powder has so won applause, on account of the prolongation of life, that it has come, as a not unseemly condiment, to the tables of kings and princes.

[Margin: Why the flesh of vipers, when eaten, does no harm to man.]

But I come to resolving another doubt in this chapter, namely concerning the most virulent bite of the rabid dog, which—just as it produces, beyond the other poisons, symptoms that are more exotic [ἐξωτικώτερα (exōtikōtera, "more exotic")]—likewise has more recondite causes of this kind. In order to uncover them, let us first describe the symptoms themselves which it inflicts by its bite,

plainly horrendous and full of dread, so that from these astonishing effects we may at last find out the cause.

[Margin: The horrendous symptoms which the poison of the rabid dog inflicts by its bite.]

Andreas Baccius describes them in these words: "The accidents," he says, "which follow once the effect is confirmed, we have seen to be comparable even to the punishments of hell—especially from the dread of water, which they shudder at by sight alone, just as if they were to be cast into a blazing furnace, with shouts and wailings raised to heaven in the manner of dogs; so that, though bound with the strongest ropes, they drag along with them not only their bed but the bedclothes, and those who stand by suspect they will all but pull the very house down. Nay—and this is the more pitiable spectacle—although they shudder at water most of all, yet because of an intolerable thirst, and a burning by which they feel themselves consumed, gaping toward the water with throats open right down to the heart, or like the infernal three-throated Cerberus, while they gulp down water poured at a distance through a pipe [syphon], you would say they can find no place in heaven or on earth, so do they rage, so do they hurl and contort themselves, until at last they fall down like dead men, or like men struck by an evil spirit [cacodaemon]; and shortly afterward, their spirits dried out by the rage, they rise up again to the same torments and tortures." Thus far he.

Five accidents are to be set forth in this poison, so utterly unwonted and formidable; and the more hidden they are, the greater difficulty they present to the natural philosopher in detecting their causes.

[The first symptom...] confers upon the bitten person that which has been implanted in his own imaginative faculty. The second is slowness in operating, in that it does not exert itself at once, when the disposition is one of complete and best health, but after many days, months, or years—as the histories of physicians teach—it brings itself from potency into act; or at the sight of clear water, as in the case of a certain man who, when a basin had been set out by the barber to shave his chin, contemplated his own image in the clear water and imagined it to be a dog; suddenly seized with dread of water, he fell into rabies. Another fell into it beneath the shadow of a cornel tree. The third is the depravation of the imaginative faculty, by which—whether he looks into a mirror or into water—he always persuades himself that he has been transformed into a dog; and hence he imitates the dog's ways in everything: in barking, in his manner of moving forward, in biting. The fourth is a most vehement fear of water, on which account such persons are called hydrophobics [ὕδροφοβία (hydrophobia, "fear of water")],

as well as water-bitten. The fifth is an inexplicable thirst joined with an incredible burning of the whole body and with rage; and—what is wondrous to relate—that which ought to be the greatest remedy for extinguishing the burning and the thirst, this very thing they abhor in the highest degree and worse than death itself.

[Margin: The symptoms of rabid dogs.]

It is asked, then, first: whence does so exotic a property of poison arise in the dog? In order that this may be lucidly explained, the nature of the dog must first be explained—a nature to which this rabies is so peculiar that, as the foremost physicians attest, it befalls no other animal but the dog. Nor is Aristotle to be heeded, who in his *History of Animals* asserts that all animals except man are afflicted by rabies; though I cannot persuade myself that so great a philosopher asserted anything which is repugnant to common experience, so that I should reckon the fault or flaw to be of the text rather than an error of the author.

[Margin: The cause of the rabid dog's poison is investigated.]

That all dogs, then, are of a most hot and bilious temperament, their operations easily show—in which temperament, however, the vital principle of sulphur swells greatly; and this, by its strength and force, while it acts upon its own mercury, that is, the radical moisture [humidum radicale], gradually consumes that moisture, whence death arises. But from the abundance of innate heat and the abundance of radicated salt they are afflicted with rabies. For since that vehement natural heat in dogs consumes a great deal of moisture, many excrements too are born from it, which—just as they produce vast sootinesses—likewise obstruct the pores; and the pores being obstructed, they hinder the ventilation of the heat. This being hindered, while the heat is nonetheless gradually increased and burns strongly, the burnt-hot substance must necessarily degenerate by degrees from native heat into a preternatural heat; whence all those retained and heaped-up excrements, inflamed and burnt, generate that poison from which canine rabies derives its origin—a poison which they also communicate to all the animals they have bitten.

[Margin: The nature and temperament of dogs.]

It is asked, secondly: from what and from what causes does it produce so great an intemperance in the dog? I answer: from rancid nourishment imbued with a virulent putrefaction. Who does not know how foul the waters are that they drink? how filthy, how foul the things that dogs devour when hunger goads them, with what greed they gape after corpses tainted even with dire contagion? This

virulent putrefaction, together with the nourishment taken inside, produces in the animal the highest distemper [δυσκρασίαν (dyskrasian, "ill-temperament")], or intemperance. For this, once fermented and diffused into the inmost recesses of the fibers, lies hidden there as though in some clandestine station, until—with the summer heats coming on, stirred up at the rising of the Dog-star [Canicula]—it is exalted into that quality of poison which we described above. The sulphureous-saline force, by which the animal is predominantly constituted, joined with its black bile, so long as it is not solicited by external heat, takes a respite of some duration in the black bile, on account of the latter's tenacity which makes it hard to dissolve; but when it has now been fermented and incited by the goads of the dog-day heats, then indeed, as if with the reins loosened and a great accompanying throng of vapors, it assails the head, where it most exerts its saline virulence, by lacerating the meninges and goading them into furies. And as for why dogs are afflicted with rabies even in the winter months, when the cold is at its sharpest, the reason is that the heat, now compelled and concentrated by the external cold, resolves the poison into act. But among the other foods of virulent substance which they use, nothing conduces so much to generating rabies in dogs as if, given the occasion, they have licked of the menstrual flux of women; and so I would dare to say that the virulence of canine rabies arises from no other source than this—and that the pups of bitches are for the most part infected with this disease sufficiently indicates it. But how, or for what cause, religious modesty restrains me from disclosing. Physicians, as they will easily perceive my meaning, will likewise grant—from the historical accounts of women's diseases—that exotic kinds of diseases are produced not only in women themselves, but in those things too which have been contaminated by the breath of the virulent flux.

[Margin: The cause of the canine poison.]

It is asked, thirdly: how does this poison principally infect the imaginative faculty? I say that the canine poison, introduced into the body by a bite, prevails by the same power by which it exerts itself in the dog itself; and so nothing else can be said than that it is the venom transplanted into the man. This being laid down, I say that in this poison there always lurks something of the canine, transplanted into the man's body by a kind of ideal power; whence, at once fermented within the vessels of the human body, when it has gone into act, it thrusts up into the head huge sootinesses—from the burnt sulphureous-saline humor—mixed with an exotic vapor; where it is resolved into a certain glassy matter, fine, however, and subtle and translucent, which, as though in a mirror, presents to the fantasy or imagination the idea of a dog, or the analogous species

which we say lurks beneath the transmitted poison. Not otherwise than a pregnant woman suffering from pica—which the Greeks call κίσσαν (kissan, "pica/craving")—out of excessive desire of obtaining some thing, while she in some

[Margin: The cause why those bitten by a rabid dog imagine themselves to be dogs.]

Liber IX "De Venenis," Sectio II

[fol. 134, verso — continuation of Caput V]

it produces this effect, the spirits being stirred by the power of the imagination, and it imprints the form of the desired thing onto the fetus in the spot corresponding to the part that was touched. In just the same way, the rabid man, gazing at a dog as though in some mirror of the imagination, imagines that he himself has been transformed into a dog. As a result, whatever he sees—whether in a mirror or in water—he persuades himself, by the constant error of the fantasy that he contemplates within, that he too appears outwardly in that very form.

[Margin: The power of the imagination.]

To the intensity of the imagination is added the memory of the dog that had bitten him, so that the same thing happens to him as happens to certain people clouded by a hypochondriac or melancholic humor, who believe themselves to be what they are not—kings, monarchs, philosophers—some imagining themselves to be made of glass, others that they are dead. This is because the images of the things they turn over in their minds with intent attention and continual longing appear to shine back, as it were, in the humor with which the head is filled. Contemplating these images there, they come to believe that they truly are what they imagine themselves to be. As long as this confusion of humors has not yet acquired a solid consistency, it can easily be remedied; but once it has congealed into a glassy material, the patients become utterly mad, and die mad.

This too is worth marveling at: whatever poison—introduced either by the bite of an animal or by eating poisonous herbs—causes in the brain a certain image of a thing shining back in a humor of this kind, the patients imagine themselves to be that very thing. Thus those who eat the brain of a cat that has previously been driven into a frenzy imagine themselves to be cats, and so express the habits of cats by their voice, their shrieking, and their movements; indeed, with fingers

curved like claws, they attack the bystanders. In this way—on the testimony of Andoynus [?]*—those who have been bitten by the haemorrhoids* [Latin: *haemorrhous*, a viper whose bite causes hemorrhage] believe themselves to be a serpent swimming in blood.

[Margin: Those bitten by the *haemorrhous* imagine themselves to be swimming in blood.]

And here I recall a remarkable case involving two of our Fathers, missionaries in Germany, which I once witnessed myself. Returning exhausted from their labors and driven by hunger, they ate with great eagerness some roots of hemlock [Latin: *cicuta*] that the cook had through carelessness boiled in place of parsley roots. These had scarcely reached their stomachs when, as the vapors began to rise, their minds were clouded; they stripped off all their clothes and threw themselves into a nearby fishpond. Snatched from it and revived with antidotes, they were indeed saved from death, but afterward, their nerves having been overtaken by the poison, they lived a wretched, half-paralyzed life for three years. When asked later what they had imagined in their madness, they replied that they had believed themselves transformed into geese, and that they had thrown themselves into the water in order to swim among the geese.

[Margin: Those poisoned by hemlock imagine themselves to be geese.]

From all this it is therefore plain that all poisons—above all those that attack the brain—infect the intoxicated with the image of some particular thing, which they believe themselves to be, the image being projected in the glassy humor.

It is asked, fourthly: Why do rabid persons so greatly shun water?

I answer that this comes about because, in that glassy humor of the brain, the image of flowing water is projected, and in it the image of a dog swimming and pursuing them. As a result, through the memory of the dog that had bitten them—now swimming in the glassy fluid—they are so terrified that they loathe the water worse than the torments of hell. This is what those have told me who, while suffering from hydrophobia, were delivered by divine aid in answer to their vows.

[Margin: Why there is hydrophobia in rabies.]

It is asked, fifthly: From what source do the inexplicable symptoms peculiar to hydrophobics and rabid persons arise?

I answer that they arise from the sulphureous-saline scorched humor, by which all the internal organs are reduced to dryness and the meninges are torn, while the unceasing struggle of the vital and animal spirits with the poison racks them with incredible anguish of mind and restlessness. Hence, on the one hand, the extreme dread of water; on the other, from the fiery violence of the poison constricting everything, an inextinguishable thirst. From this contrariety of symptoms there afterward arises that rage which ends only in a pitiable death.

[Margin: Why there is such inexplicable thirst in hydrophobics.]

It is asked, sixthly: Why is the saliva so harmful that a person infected by it is driven into rabies just like a dog?

I say that, since the dog's saliva—like the spittle of certain serpents, which they accordingly call *phthiades* [?]¹—is most virulent, exceedingly well concocted and digested, moreover packed with deadly spirits, and is further made teeming with poison by a certain ideal power transmitted from the dog's imagination, it is no wonder that, instilled into the pores at the very first contact, it gradually creeps to the vital members, until at last, carried up into the head by the vehicle of the sooty exhalations, it produces the effects we have described.

[Margin: Why the saliva of a rabid dog infects.]

But as to the fact that certain people are brought to physicians afflicted with hydrophobia who nonetheless were not poisoned by a dog's bite: I say that the cause of this can be none other than that they have incautiously handled foodstuffs or kitchen utensils that a rabid dog had infected with its saliva, or have eaten bread and food infected by it.

[Margin: Why some without a bite become hydrophobic.]

CAPUT V.

De Origine morborum.

[On the Origin of Diseases]

[fol. 134 bottom → fol. 135, recto]

Since, then, we have shown above that all things in the Geocosm consist of sulphur, salt, and mercury, so too all those things that in any way draw their origin from the earth—plants and animals—and even (what is worthy of wonder) those very things that prolong our life, by which we are nourished and sustained,

all these are at last seen to conspire toward the final destruction of our body, as was said in what precedes...

it is, in the humors of the human body, some sulphureo-mercurio-saline thing stored up [?] which—

[fol. 135] —called [?], which draws its origin from the nutriments. As long as these three [principles] keep the harmonious laws of friendship in concord with the elements, they maintain a person in a whole and sound state of health. But if they are exalted beyond measure through a disordered mixture of the elements (or of the humors)—I mean sulphur, mercury, and salt—then indeed they bring forth, both according to the condition of the spirits and according to the condition of the parts and humors, that variety of diseases, and a great host of them, which to this very day no physician has been able to explain adequately.

[Margin: All nutriments are imbued from the earth with sulphur, mercury, and salt.]

Hence it is not without reason that the chemists [Chymici] refer every kind of disease to a threefold class: so that some diseases are sulphureous—that is, from sulphur; others mercurial, from mercury; and others, finally, saline or tartareous, their spirits being analogous to air. Here let the reader note that by "sulphur" in this place we understand not the elemental sulphur but the specific innate heat, of which sulphur is the vehicle; by "mercury," the radical moisture; and by "salt," finally, whatever in the Geocosm—or in the Microcosm—has an earthy savor. And since these three material principles, in the things in which they inhere, are most specifically determined according to the diversity of the members—just as sulphur, mercury, and salt, in the different mineral lumps to which they adhere, degenerate into properties differing specifically, as we have abundantly proven elsewhere—so too those same three principles in the members of the Microcosm are specifically determined according to the nature and property of the member in which they reside. For these three produce one effect in the vital members, another in the mass of the humors, another in the venous and nervous substance, and another in the external members.

[Margin: These three material principles are different in different members.]

But in order that these matters may be examined more deeply, let us unravel them by way of questions.

It is therefore asked, first: How is a person gradually disposed toward diseases so different in kind? I answer that it happens by exactly the same

principle, according to a certain analogy, by which sulphur, mercury, and salt acquire such different diseases in the economy of minerals. For the sulphur of nature, when it has been excellently tempered together with its associates, salt and mercury, produces not only harmless metals but even the most health-giving ones, as is evident in gold and silver. But when these have been scorched by the excessive heat of subterranean fire, then, just as they utterly degenerate from their native goodness, so too they produce an abominable offspring, contrary in the whole likeness of its substance to the principle of our life.

[Margin: How all diseases consist of sulphur, mercury, and salt.]

In exactly the same way: since plants obtain their nourishment and growth from the earth by a natural attraction, while that nourishment consists of sulphur, mercury, and salt, and plants are imbued with the native tincture of the said minerals, it comes about that animals take this in from plants, and that both animals and plants, taken as human food, draw into themselves this sulphureo-saline-mercurial progeny. As long as these keep, within the body, the laws of friendship intended by nature, so long do they preserve the body in its integrity. But if, through some excess of overfilling or of exertion, or through external causes—of the air, the Sun, water, the exhalation of the earth—they are torn apart into dissonance, then, according to the magnitude of the excess (which can be innumerable) and the condition of the members, innumerable species of diseases at once arise. Unless these are subdued in good time by appropriate and specific remedies, they finally threaten the person with death.

[Margin: Sulphureous diseases arise from sulphur.]

Sulphur, altered and exalted according to the varying condition of the humors and members in which it resides, soon stirs up all those different kinds of fevers that the physicians describe—and indeed all the more savage and malignant the more, when agitated by a greater force of heat, it has caused the more harmful putrefactions of the humors. Hence that sulphureous heat, kindled by the native heat, does not cease, wherever it finds moisture, to attack it with hostile assault. The moisture, setting itself against its enemy, flees to the extremities as though struck by a kind of horror, and causes that chill and that strange rigor which fever-sufferers experience in the first paroxysm. But when the moisture, feeling itself subdued by its powerful foe, can resist no longer, it likewise yields to the tyranny of the heat, its forces laid low [literally: its fasces submitted]. Then the insolent victor heat, its enemy subdued, gradually turns everything topsy-turvy with its blaze, to utter ruin. And I would have you understand that this cause of fevers comes from nowhere else than the sulphureous spirit variously exalted: if

it is mild, it will cause mild and not long-lasting fevers; if savage, savage ones; if malignant, pestilential fevers. And let this suffice as said about sulphureous diseases.

The second class of diseases depends on the **Mercury** of the microcosm, which can be the cause of foreign diseases by a threefold path: distillation, precipitation, and sublimation. These are caused by the various excess that a person can commit in food and drink, both through the taking in of harmful nutriments and through immoderate bodily exercise, together with the other concurrent external causes.

[Margin: Diseases from Mercury.]

And the **distillation** of exalted Mercury—since it is resolved into a most subtle vapor and so makes for the citadel of the whole microcosm—if it proves potent, produces mania, frenzy, and epilepsy, by more forcefully irritating the meninges with its excessive sharpness. But if, by the coldness of the brain, it is resolved into a fluid, then, should it fall into the lungs, by its usual sharpness it ulcerates the lungs and gradually destroys the person by consumption [phthisis] and wasting. If, joined with salt, it has been **precipitated**, it produces gout [podagra] in the feet, knee-gout [gonagra] in the knees, sciatica in the hips, hand-gout [chiragra] in the hands, head-gout [cephalagra] in the head, and finally, throughout the whole body, when it infests the nerves, it produces arthritis. But when **sublimated**, it produces in the head glassy, apoplectic catarrhs; in the liver, salty ones, where, the native heat being extinguished, it opens the way to dropsy. And when, by its diaphoretic power, it has assailed the external members, there, with its corrosive quality, it puts everything into a state of decay; hence—

[fol. 136, verso]

—hence [arise] *serpagines* [creeping skin eruptions], ulcers, condylomata, gangrenes, sphacelus [mortification], exanthemata, and similar monstrous forms of impetigo, according to the diverse quality with which it has been imbued. This too is worthy of wonder: that, by its septic power, when it has resolved a member into utter putrefaction, the infesting rot there at once raises up an animated offspring [i.e., maggots/vermin], which, being of the same condition as the putrefaction, by its gnawing produces a disease most difficult to cure—as experience has long since taught in pestilential buboes, in the venereal pox [lues venerea], and the like, and as we have abundantly demonstrated in our *Treatise on the Plague* [Kircher, *Scrutinium Pestis*]. For whatever in the human body is scabby, putrid, gangrenous, ulcerous, or impetiginous—no one should doubt that

it proceeds from the sharpness of the mercurial salt, not from bilious putrefaction, except insofar as the latter has been imbued with the said property of a malignant nature.

[Margin: Whence scabies and impetigo.]

The **third** class of diseases draws its origin from **salt and tartar**. That this may be understood, it must be explained what tartar properly is.

[Margin: Which diseases take their origin from salt and tartar.]

Tartar [Tartarus] is properly the name given to that coagulated matter which adheres in wine-casks or on their sides, or which is found at the bottom of a vessel as a kind of sediment, concreted into a stone. It is nothing other than vinous salt, that is, the tiny corpuscles dispersed through the substance of the wine, which, by their confluence to the sides of the cask, there grow together by a kind of magnetic attraction at last into a saline stone, which we call Tartar. And I would not have anyone suppose on this account that tartar forms in wine alone; by no means. Rather it must be held for certain that beer too, and any liquid whatever, has its own appropriate tartar by a certain analogy, as is evident from the lees of all liquids, which are a kind of species of tartar.

[Margin: What tartar is.]

How, then, or what sort of diseases tartar causes, must now be set forth. It must therefore be noted: the nutriment that a person takes is drawn either from the vegetable or from the animal kingdom. To the former belong all kinds of wholesome herbs, vegetables, fruits, and grains, and among drinkables the kinds of wine, beer [zithum], and mead; to the latter belong all the kinds of quadrupeds, fowl, and fish suited for nourishment, to which are added eggs and those milk-products derived from quadrupeds. Whatever is found beyond these is not suitable for nourishment—such as minerals and any inanimate elemental things, whether waters, earths, stones, or metals; for nothing can nourish a person that has not first had life. These things, then, being laid down beforehand:

Since no nutriment exists that is so purged of all the refuse of its lees that some sediment does not always cling to it, it comes about that, with the continued use of nutriments, the dregs are ingested together with the nutriments. These always leave behind them some viscous thing, or something not unlike an earthy sediment, after the separation of the pure from the impure—the former [the viscous] belonging chiefly to vegetables, the latter [the earthy] to meats and milk-products; and this is the proximate matter for generating tartar. As long as it is

not deprived of moisture, it brings no harm, since [the dregs] are expelled by the twofold evacuation of urine and feces. This separation of the dregs takes place first in the stomach, which sends out through the intestines the impure, earthy refuse of the matter separated from the nutriment; but whatever still clings to the nutriment as viscous is separated first in the mesaraic veins and transmitted to the liver, there to be further purified and concocted, where all the nutriment is first converted into blood and, thus dispersed through the whole body, is at last converted into the substance of what is nourished, the serous and viscid fluid being discharged through the kidneys and ureters into the bladder. Now these things, if the exits of the dregs are not impeded by overfillings, obstructions, and the like, are in good order and keep the person in a healthy state.

[Margin: A twofold dreg, thick and liquid, the cause of the stone.]

Yet it sometimes happens that either, through excessive heat, the parts where the said dregs are lodged become dry, or, with the intervention of the spirit of salt, the fixed matter turns to stone. For the spirit of salt, wherever it has detected this tartareous matter, at once fixes it, made subject to its own jurisdiction and nature. And from these principles arise the foreign births of calculous [stone-forming] diseases: in the intestines, indeed, dreggy and tartareous incrustations produce dysentery, colic disorders, convulsions, gripings, and spasms; and if at some point crusts of tartar, loosened by the slipperiness of the intestines and rolled into a ball, obstruct the passages, then the iliac disease [iliac passion, intestinal obstruction] arises—a most pernicious and desperate evil. In the kidneys, [it produces] sands, which, slipping down into the bladder, finally generate those stones which, unless extracted by cutting the bladder, bring death. In the remaining members it generates contractions, arthritis, and similar monstrous forms of evils.

[Margin: The spirit of salt fixes the tartareous matter.]

I myself observed in Germany certain places filled with a tartareo-nitrous soil, in which the vines planted there drew the tartareo-nitrous substance into their nourishment together with the fluid of the earthy clod; and likewise that whoever gorged themselves too freely on wine of this sort incurred the contraction of all [these] diseases, and that the tartareous matter, which they had drawn in by frequent drinking of the tartareous wine, was deposited through the very joints of their fingers, hands, and feet, in the manner of quicklime. From this it is plainly evident that viscous and dreggy things—such as the kinds of vegetables, milk-products too, and cheese, and especially the viscous and dreggy kinds of wines, which when spilled onto a table turn to stone over time—these, I say, are

the proximate matter of lithiasis [stone-formation], if they are taken by the unhealthy and the overfilled; so I judge.

[Margin: Tartar causes dreadful diseases.]

The maker of calculous diseases, then, is the spirit of salt, which, when it has found dreggy matter deprived of moisture, at once [turns] its powers—

[fol. 137, recto]

—turns its powers upon it, and converts it into a liquor similar to itself, exactly as in the case of things turning to stone in liquid, of which we spoke in *Liber VIII*. For plants, as long as they remain in water with the stone-forming spirit, do not petrify; but as soon as they are cast onto the shore or bank, they imbibe by the heat of the Sun and the surrounding air a stone-forming, drying humor, and are converted into rock. In just the same way [the spirit of salt] acts in the innermost members of the body. Hence it comes about that in the stomach, the intestines, the urinary passages, innumerable species of diseases are born; in the intestines and the stomach, besides what was said above, flatulence [arises]—

[Margin: The generation of stone in a person is the same as that by which things turn to stone.]

—from the resolution of dreadful tartar: convulsions, belchings, hiccups, burnings, and vomiting; in the mesaraic veins, obstructions; in the liver, scirrhus; in the gallbladder's sac, stones; in the bladder, various nephritic pains in the kidneys; in the spleen, smoky evaporations and hypochondriac flatulence. Tartar also raises up erysipelas in the external parts; in the very teeth, when they swell with tartar, it raises intense pains. In a word, if all the diseases that have their origin from tartar were here to be enumerated, there would be need of a whole Book. Therefore let these things suffice for the instruction of physicians.

CAPUT VI.

De Cura Venenatarum infirmitatum.

[On the Cure of Diseases caused by Poisons]

[fol. 137]

Since poisons for the most part act through specific qualities, or through ones emanating from a [substantial] form or from the likeness of the whole substance, as we said above, it cannot be that they are cured by the manifest qualities of things, unless these have something else conjoined to them—something similar in

substance, and proportionate, to the poison. All this has become so well known through long experience that no physician, unless inexperienced, could deny it: for there are four humors that serve as certain vehicles of the specific qualities, in which the foreign properties of things make their nests, so that in their own time, when they have been properly fermented, they may exert their powers.

[Margin: The four elements are the vehicles of the specific qualities.]

And **caustic** poisons of every kind, when taken—such as those that smack of arsenic, mercury, and the other minerals—are for the most part wont to be cured by very fatty things, such as oil of almonds, butter, milk, fatty broths, and the like (see these in the physicians [writers]); for by these the sharpness and caustic faculty is somehow blunted, suppressed, and smothered—especially if there be added clysters [enemas] and other things that belong rather to the surgeon than to the physician. I would have you understand the same of poison from herbs taken inwardly—although the more skilled physicians know how to prepare, even from minerals themselves, a medicine contrary to the poison and destructive of it.

But poisons that proceed from the bite of serpents—since they proceed from the life and the sense, indeed from the natural constitution of serpents—I think cannot be cured better than from the very parts of the serpent that bit: from its flesh, salt, and bones, duly prepared. And so all things are good [for some purpose] [?]. For example—to begin with minerals—just as in sulphur, mercury, and salt [there is medicine], so in those same things the poison resides; for in the same things both are present: for that very thing which can be of help to us has, besides, something else connected to it, which brings us death. You will ask: How [does this work]? I say: by the mere separation of the pure from the impure, in the manner that the Spagyric Art [Spagyric/alchemical art] teaches. And from what source so prodigious a cure arises, we have already said above—

[Margin: The magnetism of poisons.]

—namely, from the magnetism of Nature, by which every like rejoices and delights in its like; from this arises attraction and union, when the substance of the serpent, taken inwardly, however it has finally been prepared, by a certain natural instinct seeks again that [poison] which was transmitted from it, and, united to itself by a kind of attraction, sends it out through evacuation. From this is evident the reason why viper-flesh promises a prolongation of life to those who eat it: not indeed because it possesses anything for strengthening or for restoring the native heat, but because whatever putrid, poisonous, or malignant thing can

in time be stirred up in the body is attracted by the viper-flesh and thence frees the person from all the foul accumulation of harmful humors.

But that all these things may be better understood, I shall here append a few [rules], from which the curious reader may learn what is to be administered to those intoxicated by any poison whatever.

RULE I. All minerals that symbolize [correspond] in their properties with some mineral poison, when duly prepared, can be a medicine—an antidote [Greek: ἀντίδοτον (antidoton, "antidote")]—for the poison that was taken in. Hence gold, silver, and the rest, when purged of realgar or of the excremental impurities that smack of poison, and prepared by the Spagyric art, can be an antidote to mineral poison.

[Margin: Rule I.]

RULE II. All plants that, as to their natural properties, symbolize with the properties of the poison taken in—these, by a certain magnetism implanted in them, when duly and spagyrically prepared, are of service for driving out the poison.

RULE III. The parts of all serpents, insects, and the other venomous animals, prepared by the Spagyric art, are a remedy for their own poison transmitted into people, whether by bite or in any other way whatever.

RULE IV. All herbs that, as to their properties, symbolize with some animal poison—these too, when prepared, can be a remedy for the transmitted poison.

This, then, is that powerful magnetism of Nature by which the little bodies of mercury are joined to mercurial ones, sulphurous to sulphurous, arsenical to arsenical, saline to saline — out of which all things consist — bound together by a wonderful kind of connection; they flow together toward one another and eagerly seek each other out. From their confluence comes a man's health and well-being. For even when a poisonous body has been purged of all its impurities, it still, in that very state, seeks out what is connatural and kindred [σύγγενες (syngenes, "kindred," "of the same kind")] to it, and by a certain intimate appetite draws it to itself. Since I have set all this out very fully in the *Ars Magnetica* (Book III), I refer the reader there.

As for how poisons are to be corrected by the agency of fire, I will explain — or rather merely indicate — in a few words. No one is unaware that by the agency of fire poisons can be reduced to wholesome medicines. Yet not infrequently other correctives are also necessary — not only to strip away the poisonousness, but so

that the parts to which they make their way may either be traversed without harm, or so that a too-sluggish purgative force may be roused, or an unbridled one restrained.

[Margin: How these are corrected and amended.] The following are corrected and amended as shown:

- **Spurge** [esula] — with goat's milk.
- **Colocynth** and **elaterium** — with the juice of quinces, oil of almonds, butter.
- **Black hellebore** — with the most generous wine, Canary or Malvasia.
- **Scammony's** clinging and viscous malignity — by soaking it in the juice of pale roses, and with oil of vitriol.
- Likewise **antimony** — with sea salt in a wooden mortar.
- **Opium's** malignity, which issues from its own sulphur — with wine vinegar.
- **Sulphur** — purged with wax.
- **Sublimate of mercury** [mercurius sublimatus] — with fused salt.

Truly remarkable things are reported of the poisonous American plant which some call *Mandioca*, others *Hyucca* [yucca / manioc]. The juice of its root, when first pressed out, is so deadly and noxious that anyone who takes it must die without any remedy. But if it is cooked at a second degree of heat, the poison is now lost and it becomes a most sharp vinegar, fit for all uses; and if it is cooked still further, it passes wholly into a honey-like sweetness. Once all the juice has been pressed out, bread is kneaded from the dry pounded mass of root worked up with water — bread common to the whole region, not only to the natives but to foreigners as well. And so this most poisonous of all plants, properly prepared, furnishes mortals with a necessary and wholesome food, a vinegar, a honey, and a bread.

[Margin: The remarkable power and property of yucca.] This too is most worthy of admiration: that the virulence of this plant is noted only in the *island* yucca — that is, in Cuba, Hispaniola, and the other islands adjacent to America. On the mainland of New Spain [Novi Regni], by contrast, our Fathers — who lived for many years in those places — told me by word of mouth that this plant [is wholly wholesome].

[Margin: Why this plant is poisonous in some islands but wholesome on the mainland.] The question is therefore raised, first, why this plant is poisonous only

in the islands and not on the mainland of Santa Marta; and second, how, once the poison is removed, it becomes a wholesome food, that is, bread, for the natives.

I say, then, that its poison is not connatural to the plant but adventitious. For since the islands of Cuba and Hispaniola — which abound in gold — are filled with arsenical-mercurial exhalations, it comes about that this plant, by its own natural temperament, draws in the moisture by which it is nourished already infected with these deadly mineral qualities. From this it follows that the raw juice of the plant, infected for the most part by these noxious spirits, brings destruction on those who take it; for the poison compounded from such a mixture amply demonstrates the most savage symptoms incurred by those who are poisoned with it. But as for how it lays aside its poison in the customary preparation for use—

—this happens in the following way. Since the poison is exceedingly subtle, it comes about that the root under which the poison is chiefly hidden, once the spirits have been dissolved by cooking and have soon evaporated and vanished, leaves the rest immune from poison, converted into a most powerful vinegar. For just as it usually happens with wine — that as the spirits evaporate, vinegar results — we judge the same can happen here. When the portions of salt remain and the subtler spirits have been exhaled, an acidity is thereby acquired, as experience teaches in all those things which, after concoction, leave behind them a vinegar-like sharpness. And that after a more vigorous concoction all that remaining liquor is converted into a honey-like substance — the cause is that the saline spirits, exalted by the power of the fire, depart, while the fattier juice of the remaining substance, now that the sharpest saline spirits have escaped, acquires a certain honey-like sweetness. Once this is separated off, there remains that mass which, dried out and pounded into flour, is at last converted by a final baking in the oven into ordinary bread.

This, then, is my judgment about this plant; and it now remains to prove that it is indeed so. Since the juice of this herb, when drunk at once at the river of Santa Marta, holds nothing harmful or destructive, but on the island of Santo Domingo is poisonous, this is a plain sign that the poison is adventitious and contracted from the corruptness of its native soil, and thus too can easily be separated off by cooking. The poison in this plant, therefore, cannot possibly arise from a malign constitution of the air and waters; otherwise men could be infected by this most wretched constitution of the air — which experience teaches to be false. For, as our Fathers affirm, the air there is most excellent and most healthful. Nor can it arise from the aspects of the planets, since whether the aspects are favorable or

malign, this plant is always poisonous and destructive; nor from the heat of the torrid zone, since the mainland subject to that same zone is reported to be free from the malignity of this herb.

[Margin: Why polypody growing over a mineral soil is harmful.] Nothing therefore remains to be said except what we pointed out above: namely, that the islands are filled with arsenic, or orpiment, sandarach, or fossil cadmia, which infect with their virulent spirits the herb that, from its own natural disposition, draws in like nourishment around it. For it can scarcely be told how greatly a soil exposed to these destructive mineral exhalations infests even herbs otherwise wholesome. For, as Mesue [Mesuë] rightly teaches, polypody ought to be gathered not from stony and mineral places but from where it has grown upon a tree — for no other reason than that it acquires from the aforesaid vapors a certain malignity.

[Margin: Hermodactyl delights in the company of squill.] Hence too he advises that serpentary, arum, spurge, mezereon, squill, wormwood, hermodactyls, and colocynth — which always contain something poisonous — should not be gathered in mineral places or on the banks of thermal waters; otherwise, on account of their excessive virulence, they will be of no use in medicine. Therefore the places where they grow, free from these influences, must be inspected, and only what is gathered from such places should be put to use. One must also observe in the company of which herbs they thrive, for by association with these they are converted to a better growth. In this way hermodactyls, by the company of squill or radish, are greatly improved in their condition. Again, of colocynth, one should choose not that which grows in rotten and dusty soils, or near the lairs of serpents, or in the sulphurous places of hot springs, but that which is born in loose, sandy, and open ground. For experience indeed teaches that fungi in the vicinity of iron — from the rottenness of a dead serpent, or its den, or a noxious plant — become lethal from being wholesome, as Dioscorides attests.

[Margin: Bread of manioc.] As for the bread of yucca, which they call *Mandioca*: we preserve in our Museum a loaf baked from this root, which even now, after many years, still keeps its flavor. The Spaniards on long voyages prefer it to ship's biscuit, because it is not easily subject to spoilage. And let this suffice concerning the poison of yucca. Nothing therefore remains except that we present what has been said up to this point in the synopsis of a universal table.

Diagram. A woodcut of the yucca / manioc plant (*Yucca americana*), captioned "Typus Jucca seu Hiucca Americana" ("Figure of the American Yucca or Hiucca"). The engraving shows the whole plant: a tall central flowering stalk bearing

numerous pendent bell-shaped blossoms on lateral branches, rising from a basal rosette of long sword-shaped spiky leaves, with a cluster of large tuberous roots at the bottom. Three engraved labels:

- Lower left (beside the roots): *ex radice* — "from the root"
- Center bottom (on the tuberous root mass): *Radix* — "Root"
- Lower right (beside the roots): *panis fit* — "bread is made"

(Together the two flanking labels read "from the root ... bread is made.")

TABULA SYNOPTICA

A synoptic table of the principal poisons with which the threefold Kingdom of Nature — Mineral, Vegetable, and Animal — teems, together with the effects and symptoms they provoke, and along with the remedies appropriate to each.

PINAX I. — From the Minerals [Ex Mineralibus]

Names of the poisonous minerals	Property	Symptoms	Remedies and Antidotes
ARSENIC , and all species of sulphur [ἀρσενικόν (arsenikon) in Greek]	By nature sharp, subtle, caustic, malignant, putrefactive, suffocating to the spirit; whence—	Thirst, strong burning heat, paralysis, spasm, dry cough, ulceration of the inner viscera. The causes consist in [these] properties.	Drinking of milk, water of a decoction of mallow, greasy broths, oil of almonds drunk, provocation of vomiting, clysters; juleps, a decoction of mallow with honey, likewise of rice-seed and starch.
QUICKSILVER [argentum vivum, ὕδραργυρον (hydrargyron)]	Of a specific quality excessively hot and dry; sublimated, it ulcerates all the viscera, an enemy	Taken in its natural subsistence, it copiously suffocates the spirit. Sublimated: paralysis, falling-	Procuring of vomiting, or the taking of gold leaf, a drink of wine with wormwood, hyssop, and seeds of celery; ass's

Names of the poisonous minerals	Property	Symptoms	Remedies and Antidotes
	to the nerves.	out of the teeth, ulceration of the viscera, stench of the mouth.	milk, wolf's lard, goat's tallow, honey, and all fatty things taken as a drink; clysters.
ANTIMONY [antimonium, στίμμι (stimmi)]	Hot, dry, burning- ulcerative; excitative of the humors. Whence —	Vomiting, violent flux, wind, spasm, paralysis, dysentery.	Fatty decoctions from appropriate herbs; oil of almonds drunk, and all buttery things.
VERDIGRIS [ærugō]	By nature subtle, resolutive, corrosive, excessively hot, whence gnawing.	Dryness of the mouth and of the whole body, pain of the stomach and belly, vomiting and flux of the belly, difficulty of breathing.	Butter, drinking of milk, juice of sweet flag [acorus] with wine — its specific remedy is prepared red coral, taken in a drink, two drachms [3ij].
QUICKLIME [calx viva]	Excessively hot and dry, burning, inflaming, biting, and cauterizing.	Dryness of the whole body, pain of the stomach, dysentery, coldness of the extremities, fainting, and suffocation.	Drinking of oil of violets, of water- lily [nenuphar] or nymphaea, of milk, and of all greasy broths.
CERUSE [cerussa], Red lead [minium] — born of the same mother,	It is a calx made from lead dissolved by vinegar, of nearly the same nature	Whence the same symptoms befall those who take it inwardly.	The cure also, and the preservative, is entirely the same as the preceding ones.

Names of the poisonous minerals	Property	Symptoms	Remedies and Antidotes
distinguished only by being specified through fire	as the preceding.		
CINNABAR [cinnabari], or Vermilion [usitur]	Partly of arsenical nature, partly of sublimated quicksilver; whence—	The same symptoms befall those who take it as befall those who have taken arsenic or mercury.	The cure also is the same — namely, a drink of buttery and fatty broths, with the decoctions described above.

(Continuation of PINAX I — From the Minerals)

Names of the poisonous minerals	Property	Symptoms	Remedies and Antidotes
GYPSUM [gypsum]	By nature cold and dry; endowed with a conglutinative, constrictive, suffocating power. Whence—	Whiteness of the lips, mouth, and tongue; softening of the limbs; violent cough, hiccup, delirium, colic affliction [colica passio], difficulty of breathing [διαπνεΐα (diapneia), "transpiration / breathing- through"], black urine, fainting.	Vomiting is prescribed, with oil, fatty broths, and mucilages; a decoction of mallow in wine. The specific remedy is the dung of a mouse, ground and drunk, which acts by a natural sympathy with gypsum.
LITHARGE [lithargyrium], or Silver-foam [argenti spuma]	Shares the nature of lead, whence it is endowed with a conglutinative	It suffocates the spirits, congeals the blood, brings difficulty of	Wild celery [apium agreste] drunk with wine, three drachms of

Names of the poisonous minerals	Property	Symptoms	Remedies and Antidotes
	and styptic power.	breathing.	myrrh [ziii]; vomiting, water of a decoction of figs. Purgation by scammony [diagridion]. The specific and sympathetic remedy is the kernels of quinces, cleaned and ground, given in a drink with a decoction of sweet wine.
MARCASITE [marcasita]	Since marcasite has its origin from vitriol and sulphur, so too its nature is supremely hot, gnawing, and putrefactive.	Whence gnawings of the viscera, gripings, and colic pains in the intestines, or the iliac pain [Iliacus dolor], and the like — the symptoms that occur with arsenic, though not so intense.	The cure is the same as we described above: the taking of oily broths with spirit of vitriol; which is the specific and sympathetic remedy.

PINAX II. — Of the Deleterious Substances from the Vegetables [Deleteriorum ex Vegetabilibus]

Names of the plants that swell with poison	Symptoms	Cure and Remedies
CROWFOOT [apium risus, βατράχιον (batrachion)] — by	From the excessive twitching of the muscles stretched within the	— (<i>symptoms and cure given in adjacent column</i>)

Names of the plants that swell with poison	Symptoms	Cure and Remedies
nature sharp, burning, ulcerative, excoriative; endowed with a melancholic power. ACONITE [agonitum] — by nature putrefactive, corrosive in power.	jaws, it seems to provoke laughter, together with madness. It dissolves and extinguishes the native heat; causes dizziness, scotomia [dimming of sight], rumbling in the belly.	Oxymel, a remarkable secret remedy against this kind of poison.
SQUILL-BULB [bulbus squilla] — it is pungent, incisive, very sharp.	Taken in large quantity: pain of the stomach, vomiting; it ulcerates both the stomach and the liver.	All fatty things are beneficial; milk boiled with red-hot iron; yolks of eggs with seeds of purslane, with walnuts.
CAPER-SPURGE [catapucia], or LATHYRIS — it is endowed with a power subversive of the stomach, sharp and malign.	It subverts the stomach, causes dysentery if not corrected; with excessive flux of the belly it kills. It is healed [by]—	By vomiting, by the taking of oils; its specific remedy is St. John's wort [hypericon], or perfoliate [perfoliata].
HEMLOCK [cicuta]	It constricts the breath, subverts the stomach, stupefies the whole body; stilling of the pulse.	Wormwood and gentian drunk with wine is the specific remedy.
COLOCYNTH [colocynthis]	Laxative of copious phlegm, pain of the stomach, dysentery, tenesmus.	The specific remedy is emerald [smaragdus], ground into a powder and given in a drink, two drachms.

TABULA SYNOPTICA — PINAX II: Of poisons from the vegetable kingdom (*continued*)

[The vegetable-poison table continues from the preceding page. Columns: name of the poisonous plant | symptoms it induces | cure and remedies.]

Names of the plants that
swell with poison

Symptoms

Cure and remedies

Euphorbium
[euphorbia]

Inflames and bites the stomach, causes extreme constriction, hiccup, flux of the belly, and vomiting.

The specific remedy is kid's [goat's] rennet [coagulum hoedi], steeped in euphorbium together with oil of violets and of roses.

Fungi [poisonous mushrooms]

Difficulty of breathing, swelling of the face, colic, and pain in the pubic region; strangulation of the throat, retention of urine, apoplexy.

Aphronitrum
[aphronitum — natron foam] drunk with a draught — that is, with vinegar mixed in water; hen's dung taken with wine or honey, salt, and vinegar. Before eating, pyrethrum [pyrauna(?)] cooked with the mushrooms; after eating, raw garlic — a specific remedy.

Helleborum [hellebore]

It chokes, provokes vomiting, burns the tongue, brings on quinsy [angina], flux of the belly. It induces lethargy — a narcotic poison.

The specific remedies are flowers of the water-lily [nymphaea], i.e. the nenuphar, ground, two drachms [3ij]. Likewise pepper, ground, two drachms [3ij], with honey-water.

Hyoscyamus [henbane]

Provokes foaming at the mouth, dizziness, vertigo [scotomia]; brings on

The specific remedy is pistachio nuts, eaten and drunk, vomiting having

Names of the plants that swell with poison	Symptoms	Cure and remedies
	epilepsy, madness; the patient utters cries like a mule's bray; lethargy.	first been induced by means of cow's or sheep's milk; pepper with wine; castoreum with mint and rue; theriac.
Mandragora [mandrake]	Provokes lethargy, swells the face, makes the eyes protrude, brings on spasm, quinsy, deafness, and itching over the whole body.	The specific remedy is the continued eating of radish with bread and salt, vomiting having first been induced and a clyster made up with sharp things [acutis rebus].
Napellus [aconite / monkshood]. <i>It bears a flower in the shape of a human skull — a symbol of the death it inflicts by being eaten.</i>	Provokes dreadful symptoms; extinguishes the body's native heat — hence chill, horror, mania, lethargy.	The specific remedy is the mouse [<i>mus</i>] that feeds upon the roots of the <i>napellus</i> : dried, reduced to powder, and drunk down diluted in an appropriate water; all fatty things [pinguia] taken in broth [jure].
Oleander , or <i>Rhododendron</i> , <i>Rhododaphne</i> [oleander]	By its caustic force it gnaws the inner parts; brings on griping pains [tormina], colic, dysentery, and the iliac disease [morbus iliacus].	Oil of almonds; the root of tormentil chewed; emerald [smaragdus] ground and drunk.
Psilium herba [fleawort / <i>psyllium</i>]	Induces the same symptoms as the rhododendron, or rhododaphne.	Theriac taken; swallow-wort [vincetoxicum] taken; salt extracted from centaury.
Scammonea [scammony]	Excites symptoms similar to those who have taken verdigris	Copious draught of milk; the juice of quinces drunk down; juice of

Names of the plants that swell with poison	Symptoms	Cure and remedies
Solanum, Solatrum [nightshade]; <i>Opium and horned poppy [papaver corniculatum], all narcotics.</i>	[aerugo]. A narcotic and stupefying poison; induces lethargy, vertigo [scotomia], apoplexy.	bramble [rubus] drunk. The specific remedy is shellfish [conchilia], either raw or cooked; goat's or ass's milk drunk; broths prepared from cooked crabs.
Stramonium herba [thorn-apple / jimsonweed]. <i>Because of the poison [virus] latent in it, it touches no animal [i.e., no animal will touch it].</i>	It is endowed with a soporific power. It induces a lethargy by means of which thieves carry out their wicked deeds.	The same remedies are to be employed to suppress its poison as are wont to be applied against the toxin of the nightshades [Solanorum].
Tithimallus [tithymal / spurge]. <i>It has various species.</i>	By its caustic force it gnaws the viscera; causes intense pains of the intestines, colic, and dysentery.	The specific remedy is purslane [portulaca], houseleek [sempervivum], and a draught of oil of almonds.
Thapsia [deadly carrot]	The same symptoms as scammony induces.	Whey of milk [serum lactis]; sealed earth [terra sigillata].

PINAX III: From the animal kingdom [Ex Animalibus]

Names of the venomous animals	Symptoms they induce	Remedies
Aspis [asp]	Hiccup, alteration of color, numbing [sideration] of the limbs, chill through the whole body, lethargy, continual leaping [convulsive jerking]; the victim thrusts his fingers into	The specific remedy is lesser centaury [centaurea minor] and rue [ruta]; and a serpent laid upon the wound — besides the other things that cure serpent-bites — with scarification of the

Names of the venomous animals	Symptoms they induce	Remedies
	his throat to make himself vomit.	wound.
Araneus phalangius [the phalangium spider], <i>and there are various species.</i>	Induces flatulence of the belly, priapism, chill of the extremities, horripilation [gooseflesh].	The specific remedy is a spider crushed onto the wound. River-crab; ass's milk drunk; cock's brain drunk; man's [?] [<i>saevum hominis</i> — recte <i>sevum hominis</i> , human(?) tallow]; specific: grains of turpentine [<i>terebinth</i>] taken with wine.
Buprestis [a beetle], <i>a kind of caterpillar similar to the cantharides, which takes its origin from the pine.</i>	The symptoms are the same as those of the cantharides.	The specific remedy is niter [<i>nitrum</i>], very fine and spongy, in a sweet draught with oil of myrtle or of cypress. Likewise pine-kernels taken in great quantity.
Cantharides [Spanish-fly beetles] — <i>they possess a sharp, burning, biting, putrefactive, ulcerative, diuretic poison.</i>	They draw blood into the urine; pain in the members of the whole body; they cause ulceration of the pubic bone [<i>pecten</i>] and of the member [<i>virga</i> , the penis].	All fatty things [<i>pinguia</i>] swallowed are of benefit: milk, lard, butter, theriac. Fatty clysters; oils of every kind, both taken inwardly and injected externally through the member. The specific remedy is grains of <i>heliocacabum</i> [winter-cherry / <i>Physalis</i>], ten in number per dose.
Chersydrus , or the <i>water-serpent</i> [<i>Serpens aquaticus</i>]	Violent pain with inflammation and corrosion of the viscera; disordered movement;	The specific remedy is the taking of the serpent reduced to salt. The nut of the cypress with

Names of the venomous animals	Symptoms they induce	Remedies
	extinction of the native heat; vomiting of foul bile [cholera foetida].	grains of myrtle drunk with honey and wine.
Cerastes, the horned serpent [Serpens cornutus]	A pricking like a needle in the place of the bite; itching of the body; vertigo with derangement [amentia]; swelling of the shins; dimness of sight [scotomia].	Soft-boiled eggs [ova sorbilia]; pitch plastered on with salt; radish; specific: the serpent itself applied to the wound together with rue.
Dipsas anguis , or <i>Situla</i> — <i>it takes its name from the thirst [sitis] it excites.</i>	Burning of the belly; an appetite for drinking that cannot be satisfied, up to the bursting of the stomach and belly; inexplicable thirst and torment.	River-crabs crushed and drunk with goat's milk; a draught of oil, as much as they can take, to provoke vomiting — besides the medicaments customarily given for serpent-bites.
Dryinus serpens , or <i>the oak-serpent</i> [Serpens quercinus]	Induces the same symptoms as the asp [Aspis], of which it is a species.	The specific remedy is salt extracted from a serpent — above all, viper's salt [viperinum sal].
Draco marinus [the weever / sea-dragon]	Induces the same symptoms as the sea-hare [Lepus marinus].	The specific remedy is the <i>mullus</i> fish [red mullet] placed on the wound, and also cooked and eaten; oil of sulphur.
Haemorrhois [the bleeding-serpent], <i>so named from drawing out blood [a sanguine eliciendo].</i>	For the bite incurred from it brings on a flux of blood from all the hollow members of the human body: from the eyes, nose, ears, mouth, through the urine and	The specific and only remedy is bloodstone [haematites] ground up, and taken with the clotted blood of a he-goat.

Names of the venomous animals	Symptoms they induce	Remedies
	through the stool — indeed, bursting out through the very pores.	

PINAX III: From the animal kingdom [Ex Animalibus] (continued)

Names of the venomous animals	Symptoms	Remedies
Hirudo, Sanguisuga [the leech]	Putrefies, swells, causes vomiting, stupefies, induces lethargy.	Vitriol diluted with vinegar and gargled; brine [muria] given in sips [sorbitiunculis]; decoction of willow [salix].
Lepus marinus [the sea-hare], <i>of the same nature as the cantharides.</i>	Difficulty of breathing, asthma, spitting of blood, bloody discharge [from the nose], vomiting; the patient perceives the taste of the rotten fish itself and loathes it; just as a rabid dog at the sight of a fish [shrinks back] as from water [?], they die of consumption [phthisis].	They are cured by a draught of milk of any kind, especially woman's milk; theriac made of sealed earth; broth of river-crabs; the warm blood of a cock or goose drunk; man's urine. The specific remedy is a fox roasted and eaten.
Phtyas serpens [the spitting serpent], <i>killing by its spittle [sputo interficiens].</i>	Extinguishes the native heat; derangement [amentia], paralysis, apoplexy; it dissolves all the inner parts into a wasting decay [tabum].	Specific: lozenges of viper [trochisci viperini]; oil of scorpion; the juice of centaury root; all the things that are of benefit for viper-bites.
Pastinaca marina [the stingray / sea-pastinaca], <i>a fish in the shape of a</i>	Causes the same symptoms as the cantharides taken	Decoction of sage [salvia], wormwood [absinthium], or sulphur

Names of the venomous animals	Symptoms	Remedies
<i>rhombus [turbot], with a long tail in which the poison resides.</i>	[internally].	decocted from [with] vinegar, drunk. The specific remedy is the <i>mullus</i> fish cut open and applied.
Rubeta [the bramble-toad], <i>of an earthy nature, endowed with a putrefactive force, and stupefactive.</i>	Stupor, swelling of the limbs; it stupefies and benumbs by its vapor; by its spittle and urine it putrefies and inflames the infected member, whence [comes] gonorrhea.	The specific remedy is toadstone [lapis bufonius] and rue; indeed, let all the medicines be boiled and prepared with rue.
Vipera [the viper], [Greek: ἔχιδνα (<i>echidna</i> , "viper")].	Pain of the viscera, inflammation, chill and horripilation of the extremities, fainting [deliquium], derangement, extinction of the native heat.	Theriac; the specific medicaments are viper's flesh cooked and eaten, and likewise its powder; the bezoar stone [lapis Bezoar] taken; the viper's head applied to the wound — besides those things that serve to drive out poisons.
Salamandra [the salamander], <i>endowed with an ulcerative force.</i>	Pain in the groin, an abscess [apostema] beneath the hypochondria, spasm, retention of urine, derangement, swelling over the whole body, stupefaction, alopecia [baldness], or a falling-out of the hair.	Theriac; goose's milk drunk, and broths of fat meats and of crabs; frogs cooked with calamint [calamentha]. The specific remedy is the same as for the cantharides [grains of <i>heliocacabum</i>]; against salamander-poison.
Scorpius [the scorpion]	Swells, inflames, stupefies; vertigo [scotomia]; induces	Specific: the scorpion's own venom crushed upon the sting; its oil; the

Names of the venomous animals	Symptoms	Remedies
	dizziness and apoplexy; it attacks the nerves.	root of aconite <i>pardalianches</i> [leopard's-bane] applied. Basil [ocymum] eaten.
Seps , a putrefactive serpent [<i>serpens putrefactivus</i>].	Swift consumption of the flesh and bones; not only from the bite, but even from treading upon it, it brings sudden death.	The specific remedy prescribed by Pliny [the Elder] is oxymel.
Scolopendra , a serpent of various colors.	The symptoms are similar to those that arise from the viper.	The specific remedies are salt drunk with vinegar; juice of pennyroyal [pulegium], wild thyme [serpyllum], mint; the urine of pre-pubescent boys drunk.

After the table, the chapter concludes:

From all these things, then, it is plain that poisons are the more virulent the more they have derived their origin from the more excellent putrefactions — that is, the *arsenico-mercurio-saline* ones; and that they grow gradually milder the milder [those putrefactions] are. And since the degrees of this combination are infinite, so too innumerable kinds of poisons arise, and they may be considered in the same way. Just as Aristotle rightly teaches (*Metaphysics* VIII.7 [Arist. l. 7. met.]) that the species of things behave as number does: number, since it can be increased to infinity, must yet be reckoned to differ in every species — for if you add a unit to three [ternarius], not three but four [quaternarius] will result,

a number distinct in species; and if you subtract a unit from it, two [binarius] will remain, likewise distinct in species from three; and so on to infinity. I would have you understand that the same thing happens in the variety of poisons. For this combination of things depends, first, upon the varied concoction effected by nature's fire — so that there are as many distinct degrees of poison as there are degrees of heat; and second, upon the varied constitution, whether of minerals (one mixture of things and another), or of vegetables (according to one nature and property and another with which they are imbued), or of animals — terrestrial, winged, aquatic, and the insects — according to their temperament.

And since these are themselves innumerable, so according to the proportion of their nourishment they pour forth an innumerable variety of poisons. To wish to investigate all of these, or to attain to their innermost essence and perfection, is not the part of a wise man, nor [within the power] of the weakness of the human intellect. They are known to Him alone who furnished [things] with such great variety; reserved to Him alone, to whom therefore alone be honor, glory, and blessing for ever. AMEN.

SECTIO III.

DE IMPERFECTIS METALLICIS CORPORIBUS

On imperfect metallic bodies

which concur as the principal causes in the generation of metals. Wherein the poisons of minerals, and likewise their medicinal powers, are more fully set forth.

CAPUT I.

On the wonderful nature and property of sulphur. [De admiranda Sulphuris natura, & proprietate.]

[Margin: Why sulphur is called θεῖον (divine).]

Not without reason did sulphur earn from the ancient sages of Greece the name θεῖον [Greek: θεῖον (theion, "divine"; also the Greek word for "sulphur")], which denotes something divine. For its powers are so marvelous that, although for so many ages they have been examined by the study and scrutiny of all physicians, to this very day they have not yet been adequately explained by anyone. Plutarch says: "Sulphur, I think, was named θεῖον on account of the resemblance of the fiery, sharp odor which bodies struck by lightning give off — on account of which, I think, even dogs themselves abstain from eating the bodies struck by lightning." Hence they called the fire of the lightning-bolt sacred and divine, because bodies touched from heaven resist putrefaction for a long time — which also agreed with many other authorities: Aristotle, Dioscorides, and, among the more recent, Falloppio [Gabriele Falloppio], Mattioli [Pietro Andrea Mattioli], and Cesalpino [Andrea Cesalpino]. But since our chief care is concerned not with the etymology of the name but with the thing itself, and with unfolding the nature of sulphur, we shall therefore, with all possible diligence, endeavor to track down the nature

and properties of this so admirable mineral. And in doing so, neglecting those things which are set forth *ad nauseam* by countless writers, we shall follow only those tenets which irrefragable experience has taught us — beginning with a division.

[Margin: Division of sulphur.]

Following the Greeks, we divide sulphur into ἄπυρον [Greek: ἄπυρον (apyron, "unfired" — that which has not yet undergone fire)], that is, that which has not yet experienced fire; and πεπυρωμένον [Greek: πεπυρωμένον (pepyrōmenon, "fired" — that which has already undergone fire)], that is, that which has already experienced fire. By the former we understand nothing other than fossil sulphur [Sulphur fossile], just as it came forth from its own ore; the latter, however, is sometimes natural — as when, by subterranean fire, it is distilled into an oil, as is to be seen in many places of the burning sulphurous mountains and in caverns; and sometimes artificial, as when it is boiled down by fire and oil. The ἄπυρον [unfired] is called fire-untried, living, sincere, pure, unalloyed [putum], contaminated by no admixture of heterogeneous matters, shining, translucent — of which kind it is rarely found. But sulphur that is πεπυρωμένον [fired], that is, fire-tried, gleaming, of a green color and very fatty [praepingue], is regarded under a twofold difference. That which is pellucid and congealed in the shape of a cone or cylinder they call *virgineum* [virgin sulphur], used by maidens for tinting the hair to a golden color; it imparts whiteness and softness to wool; it was named *egula* by Pliny [the Elder]. But the green kind, transfused in cylindrical form into reed-pipes, is most useful for making lamp-wicks [elychnia]. And concerning the method of making artificial sulphur we shall here add a little first; afterwards we shall also reason at greater length about the nature, origin, and properties of natural, or fossil, sulphur, as being a richer subject.

[Margin: Sulphur is dug only in sunny places, and why.]

Sulphur is never dug and extracted in subterranean tunnels, but in places open to the sky on every side and in sunny spots, lest by its vehement heat and intolerable noxious vapor [mephitis] it destroy the miners. It is prepared, first, from sulphurous waters and veins, in this manner: sulphurous waters, gathered into leaden basins, are boiled down until they condense into sulphur. Second: if, however, the impure sulphur is variously [mix-]

so that the mixture is drawn off; then the sulphur ore is loaded into bulging earthenware vessels and boiled down. But since I will treat these matters fully in

the *Art of Metals* [*Ars Metallica*], I refer the reader there. Here our only task is to investigate the hidden nature of sulphur.

[Margin: The definition of sulphur.]

The first question, then, is this: **How, or from what matter, is sulphur generated?** Various opinions on this are put forward among the natural philosophers and the expositors of nature. But we, holding to our own principles established by long experience, say the following.

First, we say: There is scarcely any place free of sulphur — indeed the whole globe of the earth is so saturated with it that the innumerable hot springs (by the sulphurous odor they exhale), and the multitude of burning mountains and sulphurous pits, demonstrate this abundantly. That all these draw their origin from the abundance of subterranean sulphur is so certain that anyone who denied it could be thought out of his senses.

Second, we say: Wherever lakes are found filled with bituminous fatness, there too, by infallible inference, places saturated with sulphur are found — as I recall having observed in many places in Etruria [Tuscany], in the Albula at the lake of Tibur [Tivoli], in the territory of Puteoli [Pozzuoli], and in numerous places in Sicily. Hence Agricola [Georgius Agricola] (*On the Origin and Causes of Subterranean Things* [*De Ortu et Causis Subterraneorum*], book 3) says: "Sulphur is a fatness of the earth pressed out of it by the force of heat, for which reason it is generally found in burning places." Caesalpinus [Andrea Cesalpino] agrees, calling it the grease or oil of the earth; Theophrastus too calls it the resin of the earth. That it consists of four distinct substances is confirmed by its effects. For by heat it is dissolved and liquefies, and by cold it condenses again, so it must contain something moist within itself. And since it can be reduced to an impalpable powder, that is a clear sign of a drier earthy substance. And because it can easily be set on fire and adhere like glue, that plainly indicates a thoroughly viscous substance — through which, just as it readily adheres, so through its oily quality it can readily be ignited. These are clearly the signs of fire, air, water, and earth, in whose center is fire — that sulphur is born of fire, the fiery vigor — while the mercurial moisture (or mercury) and the earthy salt, which fixes everything, are stored within. The fetid smoke clearly indicates that it consists of an earthy matter still undigested, raw, and not yet brought to completion. Therefore, whatever in it is hot and dry and endowed with a fiery force, it has from its internal sulphur; whatever is liquefiable, from the mercurial liquor in which it abounds; whatever, once melted, easily coagulates again, must be

ascribed to the internal salt — as must its sharpness, and the fact that it easily penetrates all things, which it owes to its dryness.

[Margin: The nature and origin of sulphur explained.]

The second question: What is the difference between mineral sulphur and the sulphur they call the **sulphur of the philosophers** [Sulphur Philosophorum], and which of the two is said to contribute to the composition of things? Those who think that this mineral and fossil sulphur contributes to the generation of things are greatly mistaken. For I do not see how a sulphur of this kind could contribute, since it seems rather to destroy and consume the things to which it is applied than to compose them.

[Margin: Mineral sulphur is not the sulphur intended by the philosophers.]

Something else, therefore, seems to lie hidden under the name "sulphur," insofar as it denotes one of the universal material principles; and to explain it, **I say** it is a certain principle in nature — hot, supremely oily, subtle, penetrating, endowed with marvelous powers — which some call fire, the natural heat implanted in all things, and which some call the **sulphur of nature**. This is so because, just as elemental fire most displays itself, and makes itself visible, in flame and in burning things (although fire considered in this way can by no means be called an element — indeed, so far is it from contributing to the composition of things that it rather destroys everything), so too, I say, the sulphur of nature is an invisible fire. This material sulphur extracted from ores cannot be called that fire, nor, considered as such, can it contribute to the natural constitution of things. Yet there lies hidden beneath it, as beneath a kind of material covering or wrapper, that fire of nature, which by a certain analogy the alchemists [Spagyrici] have called sometimes the sulphur of nature, sometimes the life-giving seed of the World [vivificum Mundi semen] — because by its power all things are animated and made alive, since without it nothing in nature can subsist.

[Margin: The origin of mineral sulphur.]

Now since, among the subterranean mineral species, fire shines forth most in sulphur, and nothing more resembles fire than sulphur — on account of its heat, its sudden inflammability, and the other properties proper to fire — they have judged, not without good reason, that fire should be called by the name of sulphur, and have reckoned it among the first principles for composing things. And this fiery power is diffused by the Author of nature throughout all the pathways of the World, implanted in each and every thing; in sulphurous bodies it establishes its chambers as if in a center, and this is plain from the fact that

scarcely any body of a warmer nature is found which, when resolved into its elements, does not give off sulphur in odor and taste, whether under the guise of oil, bitumen, or salt. The perpetual fires of many mountains testify to this, as do baths of hot waters, which are never found without actual and mineral sulphur, and which derive their origin from a certain fatness of rich earth, in which those three natural principles of salt, sulphur, and mercury — united by means of the four elements to effect the composition of things — are found, and are regarded as the seeds, so to speak, of all nature. For whenever and wherever that fiery power finds rich and oily earth, composed of the refuse of the elements, it impregnates it in a certain way and imbues it with its own power, and at last cooks it into mineral sulphur. And since a strong and vigorous heat resides in it, in those places where it springs up in abundant yield it at once exerts its powers...

flaming up, it burns, as we said a little earlier. And since it is perpetually at work in the subterranean wombs, the result is that, sublimed through the fissures of the mountains and the cracks of the rocks, it blossoms out into sulphurous flakes, which they call the **flowers of sulphur** [flores sulphuris], as may be seen in the Phlegraean Fields. For the rocks, just as they abound in natural cold, so too they emit that exhalation and condense it into a sulphurous meal — which the alchemists, imitating the industry of Nature, work up into preparations of marvelous virtues, namely the flowers, milk, cream, butter, oil, and acid spirit, the genuine offspring of sulphur.

[Margin: The natural flowers and oil of sulphur.]

[Margin: Flowers, Milk, Oil — of sulphur.]

The **flowers**, which are also called the dew of sulphur, are of the greatest help in febrile, pestilential, and pleuritic impurities. The **milk of sulphur**, rightly called the balsam of the radical moisture, purifies the blood, increases the strength of the natural powers, and is a noble prophylactic against apoplexy, leprosy, asthma, and consumption. The **oil of sulphur** is so powerful that it allows neither a living nor a dead body to pass into putrefaction; in warts, scrofulous swellings, dropsy, colic, toothache, and epilepsy, with a suitable vehicle, it is used most conveniently. For consumptives, nothing more choice can be offered than **butter of sulphur**, or lozenges made of sulphur and sugar.

[Margin: The excrement of those who use sulphurous medicines gives off the odor of musk.]

This too is marvelous: that although sulphur is of a foul and intolerable odor, yet when taken internally it is by some hidden path so transformed that the

excrement of those who use it more frequently is said to carry the odor of musk. The **acid spirit of sulphur**, moreover, never catches flame; indeed it restrains gunpowder from igniting. In burning fevers...

[The remainder of this column continues at the head of the recto's first column above; the column wraps:]...in burning fevers, in asthma, and in suffocating catarrh and consumption, it is a noble remedy. But how all these things are to be prepared by art will be told elsewhere.

[Margin: (in margin, appears to be a cross-reference/shelfmark, partly cut off) "ad l. 8. 12. Sect. [?] / 5. part. 2 [?] / 268. [?]"]

Furthermore, sulphur has as many different virtues as it has different origins. For each metal or mineral contains within itself a sulphur different from that of another: the sulphur of gold is one thing, that of silver another, that of bronze, copper, tin, iron, lead another. Nor should this seem strange to anyone, since it takes on the nature of the metals with which it is mixed and, according to the condition of the metals, shines with different virtues.

[Margin: The marvelous virtues of sulphur.]

It tints crystals and beryls into the most precious gems (of which in their proper place); this sulphur exalts silver to such a degree that tin, with an equal weight of silver, sustains the test of the touchstone [lapis Lydius]. The sulphur of bronze so fixes copper that it withstands assay by lightning, though without producing a tincture. The sulphur of lead exalts tin into steel, and the sulphur of tin exalts steel into the finest iron. The sulphur of Mercury renders its own body fit for the hammer; sublimed with quicksilver, it is turned into a most ruddy pigment called **cinnabar** [Cinnabrium], very much used by painters. The same, by decoction, turns into an elegant blue; but with bronze it changes into violet; and if its flame is caught in a glass vessel, it turns into a most acrid liquor, which is called **oil of sulphur**. But of these matters in the *Experiments of the Art of Metals* [*Experimenta Artis Metallicae*]. Sulphur likewise differs according to the various properties of vegetables and animals, yet in their resolution it always leaves something analogous to the said sulphur.

CAPUT II.

On the other minerals which draw their origin from Sulphur.

§ I.

On Arsenic, Orpiment, Sandarach, and Realgar.

[Margin: Orpiment and Arsenic are the same as to substance.]

From sulphur, mercury, and salt, with the four elements as intermediaries, all things are composed and all are nourished; and consequently there are three principles which constitute all things, and three which destroy all things. The first are **arsenic** [Arsenicum], **orpiment** [Auripigmentum], **sandarach** [Sandaraca], **realgar** [Risogallum], and the other realgars — degenerate offspring of sulphur, which, although they derive their origin from sulphur, nonetheless decline from it by degrees, so that they may be called principles not so much of nature as of its opposite, of death and destruction.

Orpiment, or **arsenic** — which differ only accidentally — is a mineral that draws its birth from sulphur through the fatness of the earth. Hence, being an earthy combustible, oily substance, from the excessive combustion of fire it acquires (from I-know-not-what excrementitious dregs of the salt and mercury mixed with it) some corruption, which so degenerates from the vital and health-giving sulphur of Nature that it brings forth the most powerful poison of all things in the nature of things, and one utterly destructive — a poison which not only destroys metals but also extends its dominion over the economy of plants and animals.

[Margin: The poison most powerful.]

Hence, whatever is found virulent, deadly, and destructive in certain herbs — such as wolfsbane [Napellus] and aconite [Aconitum] — must be ascribed to the arsenical power of the earth drawn in through moisture; and whatever destructive thing lurks in vipers, asps, and other pestilential serpents must likewise be attributed to the innate corruption [putredo] of arsenical power, from which some such serpent has come forth, as we taught in the **Section on Poisons** [Sectio de Venenis].

[Margin: Herbs and serpents share this.]

The question is therefore asked: from where does so powerful a poison exist in the arsenical species? **I answer:** from the mercurial salt, together with sulphur more violently burned, by which they are raised to such a degree of power that there is scarcely anything that...

can withstand its sharpness and its subtle, virulent spirits. Hence it brings death to all animals, and it drives shrew-mice into such a frenzy that they do not cease to rage against other animals of their own kind, turning them rabid by the same poison they have implanted with their bite.

[Margin: The effects of arsenic.]

Plants tinged with arsenic by fumigation perish; men who drink waters in Egypt tinged with arsenical quality become bald; animals lose their hair, nails, and horns, their roots eaten away by the excessive sharpness. Indeed, arsenic — and its other species, antimony [stibium], verdigris [aerugo], and so forth — is a poison even to gold and silver. For it consumes the moisture of gold and silver so that they cannot be liquefied; but when fire is applied, since there is nothing to resist its dryness, the metal's substance is burned and goes off in smoke. And that this property comes to it from its violent sublimation, brought about by the combustion of fire, **realgar** [Risogallum] shows abundantly: for, extracted from sulphurous clods by art and not by nature, and burned by a more violent torment of fire, it turns into a poison such as is found in arsenic or orpiment. The same is taught by the experiment shown in the preparation of artificial orpiment.

[Margin: Realgar a fierce poison.]

EXPERIMENT.

[Margin: The making of orpiment.]

Take scrapings from crusts of fossil orpiment; when these have been ground to powder, you will add to them an [equal] part of the fossil, which you will load into a vessel coated with lead and stopped with clay. Then, placed on the fire, you will cook it to the point where the whole of what is within has risen on high and adhered to the vessel — and you will have artificial crystalline orpiment, which will turn out the purer and more efficacious the more often it has endured the torment of fire.

From this it is clear that all arsenical substances — such as orpiment, sandarach, realgar, ochre, and the realgars — differ only in colors, by the differing combustion of fire. Hence the alchemists call arsenic and orpiment yellow or "croceum," red sandarach; and white they call by the proper name arsenic, or **Arrhenium**, that is, "the male." But although, as we said, it is a kind of most powerful poison, yet when it has been purged of the superfluous impurities of its excrementitious dregs, it obtains some use in the treatment of the extremities of the limbs — as in curing the French disease [lues gallica, syphilis], ringworm [serpago], gangrene, and mortification [sphacelus]. It is also said to be a salutary prophylactic in time of plague; on which see our opinion in the treatise *On the Plague* [De Peste]. For there is in it a power of warming, dissolving, corroding, and an efficacious magnet for attracting to itself a virus of a like malignant quality.

[Margin: Arsenic a remedy against plague.]

§ II.

The origin, nature, and properties of Marcasites.

A remarkable abundance of **marcasites** [Marchesitae] — which the Greeks call **pyrites** [πυρίτας, pyritas] — is everywhere found in the veins of minerals. They derive their differentiation according to the diversity of the metals toward which they incline and from whose nature they partake. For some are called marcasites of gold, others of silver, others of iron, lead, copper, or bronze. And although all are composed, as to substance, of one and the same matter, they nonetheless have some diversity according to the degree of concoction. For through cooking, their sulphur and mercury are differently affected and corrupted, and this causes some difference among them, as the diverse colors — white, yellow, black, and leaden — with which they are everywhere imbued, demonstrate; for there is, as we said, a golden, a silvery, a bronze, and a leaden marcasite.

[Margin: The various species of marcasites.]

If you wish to know the composition of marcasites, **I say** they are composed of a great deal of white and red sulphur, infected and corrupted, with a great deal of arsenical salt, polluted, and the smallest portion of equally corrupted mercury. That they are composed of sulphur, the odor sufficiently shows; the contamination of their parts (which they call **realgars** [Realgares]) and the abundance of excrementitious dregs also demonstrate it. The copious salt mixed in them is shown by their alchemical resolution through vinegar; that this salt is corrupt and contaminated is sufficiently indicated by the deleterious power that resides in it. I said that little mercury is mixed in them, which is clear from the fact that they cannot be extended by the hammer, but are almost as readily reduced to powder, like stones. Hence some have not inappropriately called marcasite μεταλλόλιθον [Greek: metallolithon, "metal-stone" — a stone-metal] — midway between stones and metals — for it can be smelted and liquefied like metals, which does not suit stones, yet it can by no means be stretched by the hammer, like stones, which is proper only to metals.

[Margin: The origin and composition of marcasites.]

The cause of this is that the dry part is not perfectly united with the moisture residing in it, nor well tempered, nor mixed throughout in equal measure; for its dryness, being in excess, drives out and consumes a great portion of the moisture — hence it breaks with almost no effort. Whenever, therefore, that acid spirit of corrupted and burnt sulphur, together with a saline vapor, falls by subterranean fire into a suitable womb of the earth, the result is that, according to the condition

and nature of the womb, it is there condensed by the cold of the earth into the substance of marcasite — namely, on account of the deficiency of mercurial moisture, a substance by no means fixed.

[Margin: Why marcasites are easily broken.]

From this it is clear that those slag-mongers [ciniflones] roll the stone of Sisyphus who too confidently boast that they can extract either gold or a tincture of gold from marcasite. And if you should sometimes find a little gold along with marcasite, that nevertheless has nothing to do with the nature of marcasite, but has accrued to it by accident, as usually happens in earthy clods — you may convince yourself: for if you separate it with aqua fortis, you will acquire only as much as had been added of gold, no more, no less.

[Margin: Marcasites do not contain gold, except by accident.]

If you regard the virtues of marcasite, they are such as yield to none of the medical powers of minerals...

in their properties, especially if they are duly and lawfully prepared, and purged of the rubbish of their impurities by careful industry.

[Margin: The natural virtues of marcasites.]

I myself knew a physician who used to cure even the most desperate dropsical patients with an extract made from marcasites alone; and he proceeded thus. He made the extract from marcasites with vinegar, or the juice of lemons and pomegranates; then he let the juice evaporate over a small fire; the sediment that remained at the bottom he formed into small, very useful [polychrest] pills, which he offered to dropsical patients, and he affirmed that by them all the serosity of the humors stabled within the body was purged away, to the point of a miracle.

[Margin: They cure dropsy.]

And sometimes, too, with cream of tartar mixed with distilled wine, he performed not dissimilar operations with the marcasitic extract. And if anyone considers the rationale of this medicine more deeply, he will at once perceive the truth of the matters mentioned from the very magnetism of those things. For since marcasites — from which the virtues immediately emanate — are endowed not with fixed but with volatile spirits of sulphur and salt, for the reason indicated above; and since dropsical patients abound with the saline serosity of corrupted humors; hence, in order that the humor — which the burning power and sharpness of

marcasitic sulphur cuts, attenuates, and dries up — may be expelled, the saline spirits, attracted to themselves by the law of magnetism, drive it out with a powerful cathartic.

CAPUT III.

The origin, nature, and properties of Antimony, or Stibium.

Antimony, or **stibium** [Stibium], is so similar to marcasite in almost all its faculties that I would say it is nothing other than a Saturnine, or leaden, marcasite. Hence it is composed of the same materials as marcasites, though it has somewhat more mercury joined to it than marcasite does — for which reason, contrary to what many think, it can easily be melted into lead. It consists, then, of sulphur and a viscous earthy fatness, with a notable predominance of salt, so that, easily broken by the hammer, it escapes all extension; indeed, beaten longer with the hammer, it goes off into the finest dust.

[Margin: The nature and properties of antimony.]

It so savors of the nature of lead that it melts down into it, and so may rightly be called an imperfect species of lead — although in lead a larger supply of mercury shows itself than in stibium, which also renders the former sweeter and milder, the latter rougher and more acid, as is clear from its astringent faculty.

[Margin: Imperfect lead.]

But those who too anxiously seek a tincture of metals in it hunt nothing but smoke, since it eludes all the industry of the chemists for drawing out a philosophical tincture. For the sulphur and mercury of which it consists are so corrupted and infected that they can neither extricate themselves in any way from such infection, nor be freed by any artful preparation from their impurities for the said use, nor be dissolved — although from its various preparation marvelous things are drawn out.

[Margin: Tincture sought in stibium in vain.]

[Margin: The various things made from antimony.]

For from its calcination there come glass — red, yellow, of the regulus, hyacinthine, saffron-colored, and diaphoretic — from which, finally, the **regulus** is also drawn (of which in its proper place and time). But if you consider its faculty, it is most certain that, without correction, it is sheer poison, partaking

much of the arsenical-mercurial quality, as is clear enough from the symptoms by which it disturbs the economy of the whole human body in a wondrous manner.

[Margin: Antimony a poison.]

Hence a great controversy has arisen among physicians about its use: some execrating it, while others — chemists especially — embrace it, once its venomous qualities have been tamed and amended, as a kind of divine medicament.

That antimony, no less than arsenic, sandarach, orpiment, and mercury (whether precipitated or sublimed), is a most powerful and utterly deadly poison, various and horrendous cases have sufficiently taught — whenever it has been administered to the sick, uncorrected, by the fanatical crowd of unskilled quacks [Agyrtæ] and salve-mongers [Alyptæ] — as even the alchemists, philosophers of the first class, attest.

[Margin: How much harm unskilled physicians do with antimony.]

Libavius [Andreas Libavius] reports that he saw a shepherd seized with spasm from the use of four grains of antimony. **Erastus** [Thomas Erastus], the celebrated physician, says he knew a noblewoman whose soul left her body sooner than the vitrified antimony began to work. Again, a druggist's servant who had taken five grains of the same antimony, and shortly after, with blood bursting from his mouth and nostrils, lost sense and mind, and on the third day breathed out his soul.

[Margin: Various examples.]

And the physician of Philibert, Margrave of Baden [Marchio Badensis Philibertus], reports that he knew some who, from the use of the same, with the veins in their chest ruptured, perished of consumption. **Oberndorpius** [Oberndorpf], a distinguished physician, knew a certain matron who within about 24 hours was evacuated some two hundred times, to the point of eternal swooning, by an antimonial medicine. **Dessenius** likewise saw several who, from the use of antimony not properly prepared, fell into long illnesses from which they could never be extricated; and he reports others who, from its use, were brought into colic pains, diarrheas, convulsions, heart-distress [cardiaca], faintings, and premature deaths.

[Margin: Various examples of those who have used antimony.]

Bruno Seidel [Bruno Seidelius] mentions a certain barber who had given vitrified stibium to someone troubled by a pain in the shoulder from a flux; from which, on account of the intestines being corroded, a pain arose that he himself supposed to be colic, and he gave a most potent wine, anointed the belly with laurel oil, and all but deprived the man of life. Innumerable examples of this kind, which I myself saw at Rome [Romae], I could adduce...

[Margin: The atrocity of stibium.]

[I could adduce], but let these examples suffice to demonstrate the violence of the antimonial poison.

Nevertheless, certain physicians of our own day, of both schools, have arisen who not only do not reject antimony but extol it to the very stars, calling it [Margin: The usefulness of antimony in medicine] the "hand of God" [τὸ θεοῦ χεῖρά (to theou cheira, "the hand of God")]. They maintain that if any harm arises from its misuse, this is to be charged not to the antimony [stibium] but to the witless quack-chemists [Chimicastris], the mountebanks [agyrtis], and similar impostors upon the ignorant common folk — men who, being as full of crass ignorance as they are, can do harm with scammony, hellebore, and antimony alike, to the ruin of their patients. They cite countless cases of many people whom no other antidote [alexipharmacum] had helped, but who were freed from innumerable bodily ailments by antimony alone. On these matters, read, if you please, Andernacus [Johann Winter von Andernach], Matthiolus [Pietro Andrea Mattioli], Quercetanus [Joseph Duchesne], Gesnerus [Conrad Gesner], Croto [Croton], Rondoletius [Guillaume Rondelet], and many others. They also bring forward certain physicians who render antimony so mild that they have administered it even to infants, not rarely with the happiest success.

Paracelsus [Paracelsus] declares that antimony encloses within itself the secret of all minerals: it has, he says, ten sweetnesses, which yield ten virtues — the very virtues that the Earth holds divided among ten herbs, all of which (he asserts) lie hidden together in antimony. So great is its power that what ten herbs of potent virtue, applied each to its different use, contribute against various diseases, this single antimony alone supplies. [Margin: Antimony, in the opinion of many, the most excellent of medicaments against all diseases] Hence Crollius [Oswald Croll] says: if antimony [stibium] could be so prepared that it might operate, without vomiting, only through the lower passages, no more excellent purgative [catharticum] could exist in all nature. For taken internally it purges both biles with the highest efficacy; it is said to be wonderfully effective against epilepsy, dropsy, leprosy, quartan fever, apoplexy, alopecia, and jaundice; it opens

obstructions of the liver, the spleen, and the whole body; it heals the colicky pains of the intestines; it aids the gouty, the scabrous, and the asthmatic. In mania, in bewitchment [fascinatione], and in melancholic madness [philomania] he proclaims nothing to be more effective. Taken externally it cures cancers, elephantiasis, fistula, lupus, and other malignant ulcers; for closing and drying wounds men cannot commend it enough. From it are prepared innumerable medicines — namely an essence, a tincture, an oil, a vinegar, flowers, a diaphoretic powder, [the same] with sugar...

[combined], with which it binds itself by so close a bond that the two can scarcely be separated again — whence great and secret is its use in medicines.

And this is the view opposed to the former one. To which of these two I should subscribe, I do not know; nor do I think it is my place to touch this apple of strife [τὸ μῆλον Ἐριδος (to mēlon Eridos, "the apple of Eris/Strife")]. This only I say: [Margin: Judgment of the author concerning antimony] one must proceed with great caution and circumspection in a matter not free of danger; one should not trust just any quack-chemist, nor administer a medicine of this kind except in the more violent afflictions of disease. For since antimony, even in however large a dose, swells with arsenical and mercurial spirits (as is plain from the vomiting it provokes), it cannot but prey upon some part of the substance of our own body. This the ancients not only carefully recorded and their successors religiously observed, but experience too — the mistress of things — has confirmed: [Margin: The harmfulness of antimony] that we should scrupulously beware of purgatives that draw violently and excessively, since nothing is more virulent in undermining the strength, nothing nearer to death, than these. For they shatter the heart's vigor, consume the spirits, stupefy the mind, throw the humors into disorder, and produce thirst, nausea, and griping; in a word, when all the viscera have been ruined, they give occasion to death.

Therefore in antidotes of this antimonial kind, who does not see that great caution, singular skill, studious forethought, long practice, refined judgment, and perfect testing are required? Nor do I think physicians should ever resort to them except under the demand of the utmost necessity — and only when a disease has sometimes driven its roots too deep. For where human health is at stake, one must not abide by the judgment of each and every individual, but only of those who have, over long time, acquired authority. Hence I cannot but condemn the custom of those physicians who, at the slightest costiveness of the body — when they are not without milder and gentler remedies from the vegetable family — administer such enormous medicines out of indiscreet zeal, and who, to discover

the powers of the medicine, seem to be playing rashly and recklessly upon the skin of a sick man. Let the reader see more about antimony in the Section on Poisons.

CAPUT IV.

Of Quicksilver, that is, Mercury, and its nature and wonderful properties.

[Margin: The inexplicable powers of Mercury]

In no property of natural things does the ineffable wisdom, power, and glory of the majesty of GOD, the Best and Greatest, working in Nature, shine forth more conspicuously than in the certain yet incomprehensible nature of quicksilver, which men commonly call Mercury — by reason of its powers, effects, and singular composition. In it that living water, heavy, so greatly a friend to metals, in itself im...

[holds] within itself the supreme remedy against poisons; and so it can become the single and most excellent cure for all curable diseases. Mighty in this mineral lies hidden a Thaumaturge [Thaumaturgus, "worker of wonders"] of marvelous works; and though concerning its power everything might seem to have been said, yet far more still remains to be said. So convinced am I that in this life its power and the manifold variety of its virtues can neither be fully explored nor set forth in words, that it is better to admire in these things the immense wisdom of GOD, the Best and Greatest, than to promise oneself a full and perfect knowledge of the innermost properties of this so wondrous compound. Although many high priests of medicine and of natural science have written about it, yet always more and more secrets emerge from its dissolution — which he alone knows who has made trial of it. Nor are there lacking points that seem to need correcting in the opinions of earlier writers; these I shall pursue more fully in the following [book], on the transmutation of metals. But now to our undertaking.

§. I.

Of the wonderful properties of Mercury.

[Margin: The nature of quicksilver, or Mercury]

Quicksilver, or living silver [Argentum vivum] — called Mercury by the chemists on account of its mobility — is a mineral liquid drawn from a metallic water: viscous, earthy, exactly tempered with sulphur, spirituous, cold, moist, and openly white; yet hidden within it is hot, dry, red, and in short of every color. It

penetrates the metals to which it adheres and dissolves them intimately. It is the matter of all metals, required for their substance just as salt and sulphur are — a certain πανσπερμία [Greek: πανσπερμία (panspermia, "universal seed" — a seed-mixture of all things)], containing within itself all things metallic, as the innumerable colors it displays the moment it feels the fire bear witness. It is called living silver [Argentum vivum] because it resembles silver in color and is easily driven from one place to another by any impulse. Beyond all other minerals it has received a peculiar and wonderful nature that can hardly be penetrated, and it is endowed with certain admirable powers so contrary to one another that of it one might say: "cold things have been mingled with hot, wet with dry." Hence, from this contrariety of natures combined in a single compound, opinions so contrary and conflicting have sprung up in the minds of the chemists that there is scarcely anyone who can extricate himself from the impenetrable abyss of its nature and from its untamable force. And so, confused in mind, they leave nothing undone by which they might subdue this Mercury.

Thus, to make it more apt for fixation, one man — having robbed it of that fleeting spirit — macerates it buried in the juices of veins [in succis venosis]; another strives to suffocate it in the strongest, corrosive waters to wash away its superfluous moisture; some torment it miserably, smothered in dung, in the excrements of animals, and in hot smoke. Nor are there lacking those who, having shut up the poor and innocent thing in the strictest dungeon and bound it in fetters, even lop off its wings, and — exercising it with various precipitation, sublimation, calcination, fermentation, putrefaction, amalgamation, fixation, coagulation, and the like torments of the chemists — strive not only to deprive it of its wings, feet, and hands, but to take its life by every means. Yet imbued with a certain most subtle force, just when they least expect it, by its accustomed and deceitful fleetingness, rushing wherever a door is opened, it slips free of all such bonds, dungeons, and torments, and suddenly escaping from the hands of its tormentors, it vanishes into thin air, and — circumventing its adversaries by its cunning trickery — leaves them (not without indignation, as if smiling at them) with both their vessels and their purses empty. But, leaving these things aside, let us come to the matter.

The first property of quicksilver, then, is its fluidity [fluxibilitas]. Although it is truly something distinct and separate, yet unlike other things it does not hold together, nor is it hard; rather it is a liquid, fluid in every direction by its own innate power. [Margin: Properties of quicksilver] Nor can it be fixed except by a certain rare industry known to very few; and I judge that whoever has come to know that art will find nothing further difficult in the transmutation of metals,

having attained the goal of the work in the tincture of the Moon [tincture of silver].

The second property of Mercury is that, although it has taken on the substance of a liquid, it is nonetheless heavier and more ponderous than all the other metals, each and every one. [Margin: Quicksilver the heaviest] From this it comes about that, gold excepted, all the other metals float upon it, just as cork-bark floats upon water. For copper, iron, tin, and lead of whatever weight, cast upon it — as anyone who wishes to make the experiment will find — float upon it just as any piece of wood floats upon water; gold alone sinks within it, [Margin: Mercury, except for gold, floats] being at once resolved from a hard and solid substance into a liquid one.

The third property is that, as if scorning and neglecting the other metals, it seems to court the favor and fellowship of gold and silver alone; whereas the other metals, even if joined to it, are — I know not by what tyranny it is seized — penetrated, perforated, broken down, consumed, and utterly destroyed by its very presence, devoured and inwardly destroyed. [Margin: Except gold and silver, it consumes all the rest of the metals] Whence it is rightly called the poison of all things.

The fourth property is that, although it may be poured out and scattered into the tiniest and almost infinite particles, it nevertheless loses none of them easily; rather they all immediately gather themselves together again and coalesce into their former union and fellowship. [Margin: Mercury indestructible] So that for this reason, not without cause, it is called by the philosophers an "eternal substance" and an "eternal liquid," since there is nothing that can destroy or abolish it.

The fifth property is that, although gold and silver are separated from copper and the other metals by the help of quicksilver, yet for uniting and gluing these same metals together it is utterly necessary, as is plain in the gilding of metals. [Margin: Mercury joins all things] For Mercury, mixed with gold, like wax...

[for tinning], makes a soft mass; and when this has been smeared upon a plate to be gilded, by the aid of fire it so unites the gold to them that it can scarcely be separated again by any art. But Mercury itself, as soon as it feels the fire, as if it had duly performed its office, vanishes into thin air.

The sixth property is that, although quicksilver is the heaviest and most ponderous of all things, yet in a brief time it takes on a most subtle, most light, and most fleeting substance — or, at the touch of fire, having been converted, it

assumes wings. [Margin: Nothing heavier and nothing lighter than quicksilver] And if you should think it has entirely disappeared, then again, by a sudden metamorphosis, you may with wonder see it converted into a most heavy substance.

The seventh property seems to be magnetic. [Margin: It seeks and attracts gold] For this one thing has become known to us by experience: that quicksilver, by a certain secret instinct of nature, seeks out gold, embraces it, and receives it as into its own bosom; and its chief virtue is that, by a certain wonderful sympathy, it clings to gold and most readily penetrates it. For if it senses gold near it, it entangles itself with it so to the very marrow that, by that embrace, the gold once laid bare casts off and as it were shakes out the other metals with which it had been mixed.

§. II.

Of the mixed nature of Mercury, and where it is born.

Mercury is also a true hermaphrodite, of such a nature and property as we observe in no other compound in nature: of itself and by its own nature both hot and moist, earthy or rather cold and dry, constituted of opposite qualities. It shows heat and dryness in its sublimation; moistness and earthiness in its natural state; and moisture in its unstable fluidity; earthiness, because it moistens nothing. It is a metal and a non-metal: a non-metal because of its fluidity, by which it eludes every blow of the hammer — for of itself it flows like water, whereas the other metals do not flow unless melted; nor is it ductile, for it breaks into a thousand drops when it falls to the ground. [Margin: Mercury constituted of opposite qualities] Hence it also makes brittle the metals to which it is joined, even lead and gold. But that its moisture is metallic — indeed that it is a kind of potential metal — is plain from this: that it mixes with all metals, with one more than with another, and indeed is most greedily imbibed by all of them; yet it adheres only with difficulty to copper, and most difficultly to iron, because of its lesser similarity to these and its greater similarity to the rest. Hence too Mercury can be extracted from all metals by the spagyric art [Spagyrica arte], as will be taught in its place in the Experiments. But the question arises: why does it adhere more easily to some metals than to another? I say the cause is similarity, by which like bodies naturally seek and cherish one another, inasmuch as through these they attain the perfection intended for them by nature. Hence it readily adheres to gold, silver, lead, and tin, by I know not what laws of friendship, but not so to copper and iron; but gold and silver it not merely drinks in easily, but most greedily, like a glutton, because it seems to aspire through them to its own

perfection and to a state of higher dignity. But that its substance is impure and imperfect is plain from the blackness with which it stains the hands of those who handle it. And the reason it wholly flies off in sublimation is that it contains an exhalation that is not burnt but combustible, by which the substance is raised up in vapor. And the reason it is never burnt up is the perfect mixture of the earthy with the moist, by which it is defended from combustion.

There are two kinds: native and artificial [Nativum et factitium]. [Margin: Quicksilver twofold: native and artificial] The native is either virginal [Virgineum], which distills from the vaults of subterranean mines and is the most thoroughly purified of all; or it is drawn out by art from cinnabar [cinnabrio], which is its matrix — a method we shall teach elsewhere. In Spain the purest is found. At Hydria [Idria, in Carniola] it is pressed out from a somewhat reddish stone. [Margin: The mine of quicksilver at Idria in Carniola, where quicksilver is dug] But, in order to add here the manner, method, and industry by which the workmen extract and perfect it, I shall append a letter which P. Sigismundus Siserus [Father Sigismund Siserus] of our Society — who carefully inspected the said place — composed, describing everything no less skillfully than elegantly. He writes thus:

"Last year, [Margin: Idria described] while I was traveling from Goritia [Gorizia] to Clagenfurtum [Klagenfurt], it pleased me to make an excursion to Idria, and to satisfy a curiosity long since most ardently desired. And since I had for a long time most earnestly longed to learn the situation of that place and the rest, [Margin: A letter to the author on Idria] I made particular and more thorough inquiry into everything, Your Reverence, and I have thought it worth setting down the following about them.

"The place, which is at about the same elevation of the pole as Goritia, lies in a very deep valley, hemmed in on all sides by mountains; we scarcely reached its floor after a continuous descent of three quarters of an hour. A torrent conveniently flows through the village — from which perhaps comes the name Hydria [Idria; cf. Greek ὕδωρ, "water"]. Raised up by countless laborers' toils and variously and ingeniously diverted, it most easily supplies, with the greatest effort, various labors: for by its aid they most ingeniously drain off the subterranean waters, more than a hundred fathoms [orgyiae] deep, by means of several pumps [antliae] pouring from the bottom one into another, until [Margin: Description of Idria] the water is brought up to the top — waters which would otherwise hinder the workers in the pit. [Margin: Description of the mine of Idria, where quicksilver is dug] The excavated material is drawn up by hydraulics

alone (with only a single man directing the work), a rope being wound upon itself bearing a very heavy and huge mass, and is let down to the earth; and likewise the useless material, [now] filled with quicksilver, is very conveniently brought out, and the like. But more about the pit itself.

"There is a hillock, bare of trees but very thickly covered with grass, scarcely reaching (in my estimate) half a league in circuit, beneath which this treasure has hitherto lain almost wholly dug out. Here lies open an entrance, stretching straight ahead for some distance, sunk so low that it scarcely ever admits a man of ordinary stature walking with body erect; from there the descent gapes to the left, not however so steep...

"...[at first] from the start, in such a grade that it might deter one entering upon the journey — until, having been led on for some while, he reaches stairs set up to the vertical [ad perpendiculum]. There, truly shuddering with horror, I recall to myself that abyss, scarcely to be measured by the eye, into which one who so desires to feed his curiosity must let himself down. It is a pit reaching a depth of a hundred and some fathoms [orgyiae] from top to bottom; but as for its extent, I could not so easily reach it because of the various passages scattered to right and left. Yet something of it may be gathered from this: that from entrance to exit, if one does not linger beyond the usual, fully three hours are reckoned. In this continuous labor the inhabitants of the place — now as it were born to it — toil day and night by turns, and each now knows his own task to perform: so that some are diggers only; others carry the already-loosened material to the place from which it is drawn up into the open — and this even in darkness, by the aid of a channel laid throughout the whole way, in which a little cart [rotula curriculi] running along conducts the one who hauls it. To others it especially belongs to attend to the machines by which the water, as I said, is drawn up, and to have at hand everything that might supply a deficiency. There are also some who, with bellows, drive down fresher air from a place above into the lower parts, where there is a defect of air, [the air] drawn up [and] enclosed in pipes — without which the labors of those below could hardly last long. Moreover Mercury is not dug out only by continuous force, but in various places it sometimes trickles out of itself through openings, needing no fire nor any further effort to attain its purity, which it has in the most absolute degree — whence it is called virginal [virgineus]. Of this I have with me about a pound and a half, received there as a gift from the curator of the place. So much for what I either saw or heard at Idria."

These things about Idria, whether seen or there heard, are enough.

§. III.

Of the medicinal virtues of Mercury, and whether it is a poison.

Having now duly set out these things, let us come at last to the medicinal virtues of Mercury — which, although we describe them more fully in the Section on Poisons, let us here repeat a few things omitted there. Quicksilver, by the confession of all physicians, is reckoned among the pure poisons, especially if it has been precipitated or sublimated with diluted reins [haberis laxatis][?]. Whom, I ask, has it — which so greatly delights the ruined alchemists — hurled down into the lowest pit of miseries? Antarvetus [Antarvetus][?] says he would be richer than Croesus if he had as many coins as precipitated Mercury has carried off. Laurentius Hoffmannus [Lorenz Hoffmann] tells that a certain quack-doctor [Medic astrum] gave someone two pills made of Mercury, of which (he says) the man, having taken the first, fell into paralysis, and having taken the second also, into apoplexy. Libavius [Andreas Libavius] says he knows a man who had given to one afflicted with colicky pains a single mercurial pill; with the bowel obstinate, he gave a second and a third, and a little after the man voided his soul along with his excrements. [Margin: Deadly medicines of Mercury] Oberndorfius [Oberndorf] relates that he knew an anointer [Alyptam] who in the space of two years carried off sixty-three men by the use of quicksilver and its fume. I pass over the many who, anointed with Mercury, fell — in his very sight — into epilepsy, paralysis, and apoplexy.

Fernelius [Jean Fernel] reports that in a certain tanner, because of quicksilver he had taken, not only the crown of the head [sinciput] and both meninges of the brain rotted away, but also the underlying substance of the cerebellum was turned into an abscess. Many cases daily experience teaches: that those anointed with Mercury have fallen into paralysis, deafness, scrofulous swellings, colicky pains, dysenteries, convulsions, faintings, and tremors; that others have spat out their teeth; that some have lost their nails, hair, jawbone, uvula [columella], and limbs; that certain ones, racked by periosteal distensions, contractions, and diseases more dreadful than the pox itself, have lived on to the very last condition of life, tortured. I have heard men infected with the venereal pox confess that they were tormented so intolerably — no otherwise than those shut in the Bull of Perillus [Tauro Perilli, the brazen bull of Phalaris] — and tortured as if by an infernal fire. The question, then, is asked: what is the cause of such great symptoms? I answer: it is the arsenical spirits, joined to the spirits of the keenest salts, which — sublimated by the internal heat — are converted into a most subtle substance, and so likewise, as they penetrate all the passages of the body, gnaw at everything, pluck, and lacerate, and turn it into corruption [tabum] with the

ultimate ruin and destruction of the human body. See more of these things in the Section on Poisons.

We cannot sufficiently admire the disposition of the divine Wisdom regarding quicksilver: that although it is so dreadful a poison and altogether deadly, it has nonetheless not willed its kindness and wholesomeness to be excluded from it. [Margin: Corrected Mercury becomes the most wholesome medicine] For if it has come into the hands of a skilled craftsman and a prudent physician, it refuses to attack no kind of disease, while — by the subtraction of excess and the addition of what is lacking — it brings the disordered humors back to the proportion of equality. Hence Paracelsus does not fear to honor it, when legitimately prepared, with the title of the "balsam of Nature" and "natural theriac." Now the preparation of quicksilver consists not in purification — for many falsely persuade themselves that its malignity can be checked and it purged of all malignancy by straining it through leather, and by curbing its mobility with vinegar, urine, lye, or lemon-juice; for although it may seem mortified by these, yet, when warm water is poured over it, it soon rises again and will not cease to exercise its accustomed tyranny. Rather its perfect purgation consists in the subtraction of the sulphurous and leaden malignancies. [Margin: How it is corrected] For in this way the arsenical sulphur is removed by sublimation, the soul [is removed] by fiery fixation, and by the artifice of sublimation, precipitation, and various distillation it is deprived [of these] — which, properly speaking, is the Philosophical Mercury [Mercurius Philosophicus], and is wonderfully suited for curing various ailments, both internal and external. But so long as the corrosive sharpness of the salts lurking beneath it endures, so long must it be reckoned still imbued with a deadly quality; but once that is removed, then little by...

once its savagery has been laid aside, it grows mild. The sign of this is that when it has been reduced [?] to its former life, no further art can recall it. For the wonderful cures of desperate diseases worked by its agency, see Paracelsus, Libavius, Mylius, Quercetanus [Joseph Duchesne], and the other chymists. These are the miracles of the chymists, described with truly marvelous praises.

Whatever may be the case regarding the wonderful medicinal uses of properly prepared Mercury, I myself — examining the natures of things more deeply, according to their inmost essences — judge that Mercury, however it has been prepared (whether by precipitation, sublimation, or any other method), neither can nor ought to be applied against the savagery of such diseases, except where life has already been despaired of. For that deadly power and force of Mercury is

not elemental but a specific power and property; and since it flows and emanates immediately from the very form of Mercury, it is certain that this power can in no way and by no art be wholly separated from it, unless we wish to destroy the whole substance of the thing entirely. And if this is so, then Mercury will surely always keep hidden within itself some malignant something-or-other, working from within; and although it may seem from time to time to free the patient from the foul flood of the humors' malignant nature, yet it is always mindful of its own ferocity. Insinuating itself more deeply, it rises up again at an opportune moment, and by its hidden machinations turns everything upside down, right up to the final goal of death.

[Margin: The author's judgment on mercurial medicine.]

But here perhaps the chymists will object: that Mercury, once its malignancies have been tamed, then most of all possesses that wonderful power that cures all diseases. But I ask them this: will Mercury, so mortified, do something, or will it do nothing? Just as they will not deny the former, so they cannot grant the latter. For if it acts, it acts either by that specific power of its own, or by some other power newly acquired. If by the former, then — however tamed and restrained it is — it will always leave behind some traces of its virulent wickedness, since this corrosive power inheres essentially in the sublimate and cannot be wholly separated from it. If by the latter, then either it does nothing, or, if it does something — and indeed acts benevolently, without its accustomed ferocity, if that is the case — then I say that Mercury has then passed over, essentially, into a wholly new and distinct substance. Unless, however, we wish to say that in this new state it has been imbued with some magnetism, by which — just as viper's flesh draws to itself the venom that was poured out by the viper — so too Mercury (whether this happens by some diaphoretic or some purgative power) draws the virulent humors of the human body and, once drawn, expels them outward. And yet, since these things can be accomplished by other, far nobler medicines, we gain nothing by Mercury. [...]

§. IV.

On the wonderful power by which [Mercury] adheres to gold, and its cause.

It can therefore be asked, not uselessly in this place, how such a conjunction comes about. Certainly, since the powers mentioned have at no time failed to be a wonder to the philosophers, a great part of the chymists has judged that the associations of different metals come about only through a certain magnetism — as Paracelsus amply argues in his book *On Transmutation* [*De Transmutatione*].

Fallopious [Gabriele Falloppio] holds that the metals draw mercury in no other way than a magnet draws iron, or amber draws straws; and the chymist-philosophers maintain that even that Philosophers' Stone — known to the bleary-eyed and to the barbers — is to be compared only to magnetism. Whatever the case, it is truly remarkable to see quicksilver, alone, being sought after, as it were, by all the metals. What then this power is, and whether it belongs to the class of magnetic and electric attraction, now remains for us to declare.

[Margin: Whether Mercury draws magnetically.]

Against the cited authors, then, I say first: this conjunction of quicksilver with gold and silver comes about in no way through magnetic, electric, or elemental attraction. For if it were through magnetic attraction properly speaking, this appetite of the quicksilver for gold would have to do two things: first, to establish it in a fixed place suited to its own nature within this universe, as happens in magnetic bodies; second, the quicksilver and the gold would have to alter each other in such a way that, as soon as either one comes into the sphere of the other's power, it flows toward the other as quickly as possible — out of a certain likeness of nature and an appetite to acquire a new perfection — which we properly call magnetic coition or attraction. But the appetite by which the quicksilver seeks to join itself to those metals does not establish the quicksilver in any fixed place, since, owing to its fluidity, no fixed or stable place in nature can be assigned to it. Nor is it alterative: for when quicksilver is placed opposite gold and silver, or even balanced most exactly against a needle [obeli] of gold and silver, however close it is brought, it leaves behind no trace of alteration or attraction — as frequent experience has shown me — which nevertheless would have to happen if it were endowed with any magnetism.

[Margin: Mercury's attraction to gold and silver is not magnetic.]

For this same reason, certain people wrongly count its operations among the electric ones. For all electric bodies pour out certain effluvia, by which they move and attract only the very lightest bodies placed nearby. But quicksilver — besides being most heavy — also gives no sign whatever of an attractive quality in the gold toward it, or, conversely, in itself toward the gold, however subtly balanced; and so it can in no way be counted among electric bodies.

[Margin: It does not attract electrically.]

Nor can it be said that this conjunction comes about by reason of a vacuum, as in attraction in elemental [bodies]... [continues]

[Margin: Nor by reason of a vacuum is it drawn.]

since elemental attraction can serve no purpose, being ordained, as a potency toward its end, to nothing else but the union and continuity of the parts within a whole — which is not necessary in this metallic [Greek: συζυγία (syzygia, "conjunction" / "coupling")]. Nor can the said conjunction come about through a confluence of like things, as appears in homogeneous substances: for a drop of water, or of quicksilver, seizes another drop and joins it to itself — not by some hidden power, but by the law of homogeneous things, by which parts that are alike and of the same kind seek to be joined to one another, as if to defend themselves against a common enemy. So too oily substances, shunning the watery, mix readily with the oily; while watery substances, rejecting the oily, mix readily with the watery. So too the liquids we call gums: if they are of a watery nature — like cherry gum, gum tragacanth, and the like dissolved in water — they easily coalesce, out of a certain likeness of nature; whereas gums of a fiery nature — like mastic, frankincense, storax, resin, and the like — being of a different nature, cannot be made to mix with waters.

[Margin: The cause of metallic attraction.]

Nor can the said conjunction come about through a certain appetite of the gold and silver, by which it attracts quicksilver to itself as something good and suitable — as individual limbs are accustomed to draw to themselves the nourishment suited to them — since gold and silver, being established in their own perfection, no longer have any need of quicksilver.

I say, therefore, that this conjunction comes about through a certain beneficent and friendly outflowing of the gold and silver toward the quicksilver, by which the Mercury is apprehended; or rather through a natural appetite of the quicksilver toward gold and silver, in much the same way that matter naturally desires form, and, through prior dispositions, they coalesce into one physical compound. For as the Philosopher [Aristotle], speaking of this appetite, rightly says: [Greek: ἀλλὰ τὸ ἐστὶν ὕλη ὥσπερ ἄν τὸ θῆλυ ἄρρεν[?] καὶ αἰσχρὸν καλὸν[?]] (alla to estin hylē hōsper an to thēly arren kai aischron kalon, "but matter stands in the same relation [to form] as the female to the male, and the ugly to the beautiful") — *Matter stands to form as the female to the male, and the ugly to the beautiful*; and this appetite of matter is nothing else but its inclination to receive the form owed to it by nature. For since matter, of itself and by its own nature, is ugly and imperfect, deprived of all comeliness and beauty (as the Schools put it), it necessarily desires by nature that which can give it its ultimate complement and perfection.

So too I say: since quicksilver — the proximate matter of the metals — is a mineral, and, both on account of its excessive humidity and on account of the abundance of earthy impurities with which it teems, is so imperfect and defective that it can scarcely be corrected by any human art or industry; and since nevertheless it is ordained by nature to a further perfection, and of itself also strives after perfection and a solid consistency — it seems to have received from the Author of Nature this one prerogative: that when mixed with gold and silver, as with a more perfect form, with that excessive humidity somewhat suppressed, it is reduced [to perfection]. And indeed by the beneficence of the gold and silver — since unless by mutual embraces... [Greek: ...σύμφυτον?][?] — a pure thing flowing by natural appetite toward the impure, a beautiful toward the ugly, [the gold and silver] unite with it, until its humidity, blunted by the heat of the gold and the dryness of the silver, and its coldness checked, and stripped of that inconstant fluidity by their aid, it solidifies and at last attains the intended, consistent form. Quicksilver therefore runs to the said metals as the imperfect to the perfect, the ugly to the beautiful, potency to act, so that it may be perfected and adorned by it, and at last, according to the various dispositions, coalesces into one physical compound — into gold, I say, or silver.

[Margin: Quicksilver desires gold, as matter desires form.]

This adhesion, then, is accomplished by that viscosity in which quicksilver abounds, and by a certain subtle, most penetrating power, by which it suddenly permeates the inmost substance of the other metal — a power that is wonderfully promoted by its fluidity and mobility. Silver, by its very great dryness, somewhat blunts the excessive humidity of the quicksilver; gold rids it of its superfluous earthy parts; and these changes are then followed by the intended transmutation.

You see, therefore, that there is nothing magnetic in actions of this kind, but rather that the union of metals of this kind with quicksilver is accomplished by the said appropriated qualities. By the same reasoning, when we see gold coalesce with silver, with [Greek: χρυσοκόλλα (chrysokolla, "gold-solder" — borax)], that is, with borax; iron with iron, by means of chalk reduced to powder, moistened, and brought together by violent fire; tin combined into one with lead, copper, iron, [and] silver by means of Greek pitch alone — for this reason that action ought not, as many ignorant people wrongly suppose, to be counted among the magnetic ones, since these come about ordinarily not by hidden qualities but by primary or secondary ones.

[Margin: The cementation of quicksilver.]

Who would not marvel that, by the mere vapor, breath, or smoke of a material compounded of tin and lead, tin is so joined and hardened with quicksilver that, in color and hardness, if it does not surpass true silver, it at least equals it — bearing the hammer however much you strike? And had I not myself proved the truth of the matter by experiment, I could never have been brought to believe it. Since, then, by the same vapor and mercury — as experience teaches — gold, otherwise most solid, is reduced to powder, it must not be said that the quicksilver has gained entry into the gold, as a magnetic odor [enters] into the substance of iron (as certain of the chymists maintain), but rather in the manner we said above.

[Margin: Various experiences in the transmutations of metals.]

The like I would say of the metamorphosis of the other minerals: as when iron is turned into copper by the power of vitriol; tin into lead by the agency of sal ammoniac; quicksilver into cinnabar by the action of sulphur; lead into white lead [ceruse] by vinegar; and this [ceruse] into red lead [minium] by the force of fire. Nor can any magnetism intervene here, since experience teaches that in aqua regia silver dissolved adheres to copper, and copper liquefied [adheres] to iron, by a certain wonderful means — but all these things... [continues]

must necessarily come about through the qualities suited to each metal. Hence laughable are those who believe that the transmutation of metals can be carried out by some magnetic power, by means of certain herbs — as by the juice of monkshood [Napellus], leopard's-bane [pardalianches], or doronicum, infused [into the metal].

But how Mercury can be extracted from red lead [minium], and from the other metals, as well as from the soots of minerals and vegetables, will be set forth in what follows.

CAPUT V.

On bituminous bodies.

[Margin: Sulphur and bitumen are kindred minerals.]

Nature produces in her womb a certain kind of fatness, which, when not fixed by salt, grows into bitumen, but when fixed by its own salt degenerates into sulphur — to which bitumen is so closely akin that you could not unfittingly call bitumen liquid sulphur, and sulphur fixed and coagulated bitumen.

Bitumen, then — called by the Greeks [Greek: ἄσφαλτον (asphalton, "asphalt" / "bitumen")] — is a fatty juice, intensely hot, of an oily moisture, most apt for feeding fire on account of its nature, which is easily inflammable. It is varied and manifold according to the variety of the places in which it is naturally produced, and according to the diversity of the mixed bodies to which it adheres. For if it oozes out of rocks — as in the territory of Modena [Matinensi Agro] — then it is called petroleum; if it comes forth from the liquor of burnt sulphur, black in color and sulphurous in smell, it is called terrestrial pitch. The bitumen of Babylon they call naphtha, [Greek: νάφθα (naphtha, "naphtha")], that is, a bituminous liquor that enters into so great a friendship with fire that it catches flame at the mere approach of fire; and it is found in various places in Italy and Sicily — as at Naphtia, a place near the Sicilian city of Mineo, where I remember once having seen a species of this bitumen gushing out in abundance.

[Margin: What naphtha is.]

Again, if this unctuous juice, gushing up from the bottom of the sea out of a most purified clod of sulphur, is raised to the surface, and then driven by the impulse of the waves toward the shores, there, hardened by the dryness of the surrounding air, it is converted into amber [succinum]. If again the bituminous liquor is carried up from sulphurous lakes onto the surface of the water, it is properly called [Greek: μάλθα? (maltha)] *maltha* — as in the lake Albula in the territory of Tivoli [Tyburtini], and especially in the lake of Palestine, which they therefore call Asphaltites and the Dead Sea; and this, cast up onto the shore, takes on a stony hardness of a purple color.

Strabo: *Bitumen*, he says, *is a clod of earth which, liquefied by heat, is breathed out and diffused, and again is changed by cold water, as it were into the strongest ice — such as is the water of the lake — whence there is need of cutting [?] and incising.* If then it is fixed by the power of salt infused into the clod, a bituminous earth is born, which they either call *ampelitis* (because it kills worms on the vines), or — on the testimony of Theophrastus — name *pharmacitis*, on account of its notable use in medicine. If finally, like burnt charcoal, it is joined to a sulphurous mass, [Greek: λιθάνθραξ (lithanthrax, "stone-coal")], fossil coal, or jet [Gagates] is generated — concerning which [I spoke] in the preceding [chapters]. If a clayey clod is mixed in, it is called *maltha*.

Again, if a black [bitumen] coalesces with a white one, it is called *pissasphaltum*, that is, pitch-bitumen, and emanates from mountains in various places — as in Epirus — and this is native. The other kind is artificial, and is called mummy [mumia], because cadavers embalmed with pitch and bitumen, within the sands

of Libya, grow under the scorching heat of the Sun into a bituminous mixture, which they call mummy. But concerning the method and procedure of embalming cadavers, as practiced by the Egyptians, see the treatment given expressly in Volume III of the *Oedipus Aegyptiacus*, in the *Syntagma on Mummies*.

[Margin: That minerals are sulphur and bitumen.]

[Margin: How the varieties of bitumen arise.]

You see, then, reader, that bitumen is one and the same liquor, but that — from the diverse waters, clods, stones, mud, juices, and clays in which it grows — it has obtained so great a diversity among men. As they differ in various colors, so too it is established that a varied naming of the bitumen has flowed forth: white, black, red, yellow, ash-colored, purple. And since the things to which it adheres are imbued with varying faculty, with differing powers and properties, bitumen must necessarily be imbued and tinged with these powers and those.

[Margin: Bitumen is one and the same liquor, but takes its diversity from the things to which it adheres, and its naming from these.]

For the subterranean heat — as we have amply demonstrated in the preceding [chapters] — when it exalts that earthy fatness, can, according to the varying degree of combustion [adustion], now produce reddish and white juices, now yellow ones from the reddish, greens or blacks from the yellows: just as from sweet phlegm, by the power of concoction, blood is made; from blood, by immoderate heat, yellow bile; and from yellow bile, by the force of adustion, green or black [bile]. In this way, then, a certain liquid bitumen is white for this reason: that a mild heat has expressed it from the earth — as is plain in white amber, which possesses I know not what sweetness; whereas the yellow kind, being elaborated by a greater force of heat, also has a certain acrimony joined to it; and the black kind, because it is scorched by great heat, exhibits to the taste and smell I know not what of the empyreumatic [burnt quality].

[Margin: Whence the diversity of color in bitumen.]

These species of liquid bitumen, indeed, arise only from a differing degree of heat — and the same is to be said of the color and powers of the muds, clods, stones, and juices to which it adheres. For if pitch is mixed with bitumen, *pissasphaltum* must necessarily be born; and likewise, if it runs through salt, sulphurous, nitrous, aluminous, or vitriolated places, the bitumen is tinged with those powers with which the places through which... [continues]

[it flows] are endowed by nature. Whoever observes this rule will easily, with the aid of the senses, form a judgment about the powers and qualities of the bitumen. See what we discussed more fully concerning bituminous waters in the First Volume.

Hence one [bitumen] is hot, another cold, another lukewarm; one is thin, another thick and viscous like mud; one is dry, soft, and easily split, another hard and imbued with a certain stony substance — like jet [Gagates], fossil coal, the Thracian stone [lapis Thracius], [and] obsidian [obsidianus]. There are some, besides, that breathe out a pleasant smell, and some a disagreeable and foul one. Yet to all and each it is common that they are easily inflamed; and this is plain from the mountains that they call coal-abounding [carbones abundant] — as concerning the mountain near Zwickau [Ziccam] in Meissen [Misnia], which Agricola [Georgius Agricola] reports they say burns from time to time.

[Margin: The abundance of bituminous stones in the mountains.]

In this [mountain], on Agricola's testimony, the miners first dig up earth to the depth of a pace; then, having widened it, they find a vein of soft coals, nearly three and a half paces deep; then they cut out fairly thick rocks; soon they again find a vein of coals, but hard ones, to which they gave the name "pitch-coal" from the pitch — and these seem to be similar [to pitch] on account of their blackness and brilliance. Beneath this vein lies bituminous cadmia, and beneath this an aluminous pyrites, [and] pure copper. The coals that the fire feeds upon, extinguished when earth falls into the furnaces, are turned into a black powder.

Note also that whatever is fatty and unctuous in Sulphur, Salt, [or] Mercury, is to be ascribed primordially to this liquor. Therefore, since fatness of this kind is diffused throughout the whole body of the Earth, it comes about that the vegetable nature too partakes of it — which shines forth most of all in the pine, the larch, the turpentine-tree [Terebinthus], and the other resin-exuding trees; so much so that if you should call resin of this kind a vegetable bitumen, you would be judged to have spoken rightly. To this too can be referred all the kinds of trees that, besides pitch and resin, also exude gum — like the birch [Betula], the cherry [Cerasus], the plum [Prunus], and the like; so much so, indeed, that there is scarcely a plant that is not endowed with its own natural bitumen, whether you call it pitch, or resin, or gum, or any other fatty liquor. But of these things [I shall say] more in the *Disquisition on the Vegetable Kingdom* [*Disquisitio Regni Vegetabilis*]. Nor should you suppose that in the animal kingdom any animal is to be found that is not both nourished by fatness of this kind and constituted by it as by a certain gluey bond, by which parts are aptly connected to parts. For what

else is fat [adepts] but a certain coagulated bitumen? — all of which I would have you understand according to the analogy intended by us.

The Uses of Bitumen.

Bitumen has innumerable powers and an immense use in the things of nature; but I shall describe only the principal uses.

First. The cause of the perpetual subterranean fire is ascribed to nothing other than sulphur and bitumen — as we showed sufficiently in the First Volume — so that wherever either burning mountains or hot springs [thermae] are found, there sulphur and bitumen cannot be absent.

Second. Naphtha and camphor are certain species of bitumen, which, kindled upon waters, are not only not extinguished but nourished, and take on a greater increase of their brilliance. Concerning camphor, indeed — whether it emanates from a tree or from the bowels of the earth — there is great dispute among the mineralogists. I myself, by the instruction of our Fathers in the Indies, find a twofold camphor: one a vegetable gum [lachryma], which emanates from a certain tree growing in the Molucca islands, chiefly on the island of Borneo; the other brought from China, not so much natural as artificial. But concerning the powers of camphor [I treat] more fully in the *Pyroboic Experiments* [*Experimenta Pyroboica*].

[Margin: What camphor is.]

The Egyptians — as we showed in the *Syntagma on Mummies* of the *Oedipus Aegyptiacus* — used bitumen for embalming the dead, [and] fed a perpetual fire, concerning which [we treat] most copiously in our *Oedipus*. Ammianus [Marcellinus] relates that the Persians, hurling weapons smeared and coated with bitumen against the enemy, burned them up. Bronze vessels, weapons, [and] iron smeared with this remain incorrupt against the injuries of water.

Maltha — a species of bituminous mud — when it touches anything solid, adheres, and when touched follows the one fleeing; it is kindled by waters, [and] extinguished by earth, if we believe Pliny. Bitumen and naphtha burn upon waters and are nourished by their moisture; concerning which [we treat] in the *Pyroboic Experiments*.

[Margin: Maltha.]

As for what Pliny, Solinus, Tacitus, and from these Isidore, and Pererius write concerning Judaeian bitumen — namely, that the Judaeian bitumen, which is

collected in the lake Asphaltites, is of so tenacious a viscosity that it yields to nothing except women's menstrual fluid, and that, though it cannot be subdued by iron, it is easily torn apart and separated by their touch — these things must be reckoned among the fables, since they conflict with manifest experience, and those who have seen it extracted by the natives declare that they observed no such thing. Concerning these, see the *Itinerary* of Petrus Vallensis [Pietro della Valle], of Brocardus [Burchard of Mount Sion], and of others. In many places they use bitumen in place of oil for feeding lamps. Ships without bitumen cannot last long in the waters.

[Margin: The property of asphalt.]

If you desire its medicinal powers: it staunches, dispels, contracts, [and] glues together; its smell, when kindled, puts serpents to flight; it is shown to be of help to the laconicum [?] for blurred vision of the eyes; smeared on, it soothes the pain of the gouty; together with niter, smeared on, it heals toothaches; drunk with wine, it calms cough and dysentery; taken with vinegar, it dispels clotted blood; it mitigates the pains of the joints and loins; smeared on, it wonderfully helps the mange and scab of beasts of burden. As for how much bituminous waters, or hot springs, contribute to curing various kinds of diseases, it was treated in the First Volume.

CAPUT VI.

On Marine Fruits — Coral and Pearls.

[De Marinis fructibus, Corallio, & unionibus.]

Coral [Corallium] is defined by all natural philosophers as a marine tree, for it grows only on the sea floor, and like the tamarisk it spreads out into various branches. Within the water itself it occupies a middle ground between the softness of a shrub and the hardness of stone. Those who attribute to it some limp softness are therefore badly mistaken; not at all — within the water it behaves exactly like the stalk of a fern, or of a tamarisk, or of any herb with a fairly firm stem. For if it were softer than it ought to be, it could not rise up to any height, nor resist the more violent motion of the seawater, nor withstand the impact of the fish passing through it.

[Margin: Whether coral is soft while underwater.]

I know from experience that this plant raises itself firmly aloft on a perfectly straight stem, and that it has a stalk of such hardness and firmness that it

sometimes even tears the nets of fishermen. And since the sea of Drepanum [Drepanum, modern Trapani, Sicily] is exceedingly productive of coral, and a great profit accrues each year to the city of Drepanum from its harvesting, in years past that most distinguished and learned man Jacobus Staphylus [Giacomo Staffilo], the most worthy Secretary of the Republic of Drepanum, sent to me — out of his affection for me — an entire portion of rock covered over with coral, to enrich my Museum. In that rock, at the shores marked A, you may see, not without wonder, various kinds of shells grown onto the rock. Among them you may also see, set apart, the shells of oysters, from whose concave and smooth part the coral has been born without any root.

[Margin: A piece of coral-bearing rock cut out at Drepanum and sent to the Author at Rome.]

Diagram. A large engraved plate occupying the lower half of the page, displaying a collection of coral and pseudo-coral specimens, each separately captioned. The individual figures and their engraved captions:

- **C** (upper left): a human skull with coral branches growing from its crown. Caption: *In Gazophylacio M. Ducis Hetr.* ("In the Treasury of the Grand Duke of Etruria").
- (upper center): a dense, antler-like coral mass. Caption: *Pseudo-Corallum* ("false coral").
- **T** (left, below C): a small lobed/tuberous specimen with sprigs. Caption: *In Museo Auth.* ("In the Author's Museum").
- **S** (center): a small lobed specimen with branching sprigs. Caption: *In Museo Auth.* ("In the Author's Museum").
- **E** (right): a large, bare branching coral tree. Caption: *Corallum Verum* ("true coral").
- (lower left): a rounded rocky mass studded with coral sprigs, set on a base. Caption: *Rupes Corallis consita in Museo Authoris* ("A rock set with coral, in the Author's Museum").
- **H** (lower center): a finely branched coral tree. Caption: *Pseudo Corallum Lythophytum lapideum* ("false coral, a stony lithophyte").
- (lower right, upper): a stubby, warty, jointed branch cluster. Caption: *Corallum Verrucosum* ("warty coral").
- (lower right, lower): two short thick cut segments. Caption: *Pseudo Corallum* ("false coral").

In some shells you may see coral plants bursting out from the convex and roughened surface, while in some of them they burst from the bare rock.

I myself, in order to investigate the origin of coral more exactly, examined quite closely the little plants plucked from the shells, with the aim of discovering how they had grown together. But it could not be done: despite all my efforts I could find no root, nor anything resembling a root. Rather, they appeared glued to the trunk itself as if by wax, without any trace of a perforation — something I afterward observed also in those shining shells they call mother-of-pearl (as is plain in figure **S.T.** [?]), and indeed in polished and smoothed stones too. This left me no little perplexed.

[Margin: An experiment on the root of coral.]

Not long ago, however, it happened that I came to the acquaintance of an Arab merchant who, having for many years carried on trade at the Red Sea, had likewise acquired a great knowledge of that sea. He told me that whole forests of this plant are found on the floor of that sea, so densely packed with coral shrubs that they grant passage not only to no diver but not even to the fish. He added, moreover, that the fishermen had drawn up together with the plants such things as shells, bricks, rocks, bones, wooden boards, and iron tools — all of them covered over with the corals that had grown upon them — and even a dolphin, from whose tough hide a coral plant had grown.

[Margin: Whether coral has a seed. The Red Sea most productive of coral.]

When I marveled at this as a paradox and asked whether a plant of this sort had some seed by which it propagated itself into so great a multitude, he replied that long experience had made known that there is in the coral shrubs a certain spermatik liquor which they emit from themselves; and that this liquor, onto whatever thing it falls, at once thickens there and founds a new offshoot of coral. This, he said, is the reason why coral is seen to have grown upon all the things just recited; and this liquor, even after it has been extracted, is found in the form of coriander or of a cornel-berry, thick like fat.

[Margin: Coral emits from itself a generative liquor, from whose drops new plants are generated.]

The Grand Duke of Etruria has at Pisa, in his Treasury [Gazophylacium], a human skull (see Figure **C**) out of which a coral plant is seen to have grown — which surely, just as in our own shells, could have grown upon it in no other way than through the said generative liquor. Since this liquor is by its nature viscous and

heavy, easily penetrating water without any commingling, it forms a new plant in whatever thing it has fallen upon.

[Margin: A plant grown from a human cranium and from a living dolphin.]

But now that these things have been set forth, let us explain the nature of coral a little more fully. The first question, then, is: How, and from what, is this plant born? I answer: it has its origin from a fatty, viscous moisture and a sulphureous brine, mixed together in the depth of the sea among the rocks always covered by the waves. After the manner of trees it germinates within the water itself, somewhat soft and of a greenish color; but outside the water, or at the first contact with the air, it gradually coagulates by the stone-making spirit residing within it, and degenerates into a color either black, or white, or red. The red is obtained from a fatty, viscous, pure, and red sulphur, perfectly cooked and digested.

The white, although it abounds in pure moisture and white sulphur, nevertheless — because of the imperfect concoction of that sulphur — yields much to the red; yet some wrongly prefer it to the red. The black, finally, consists of fatty and viscous but corrupted and scorched sulphur, and so too —

Diagram. A single coral specimen rising on a foot, branching toward the top like a small bare tree. Engraved caption beneath: *Corallus in Gazophylacio Card. Barberini*. ("Coral in the Treasury of Cardinal Barberini"). Three labels are written vertically along the stem from base to tip, indicating the color zones described in the text:

- (base): *nigro* ("black")
- (middle): *albo* ("white")
- (upper stem): *rubro* ("red")

— it is held in no esteem, except for its rarity. There is in the Treasury of Cardinal Barberini a coral plant which around the root is imbued with a black color, in the middle with white, then afterward with black [recte: this passage in the text reads "nigro... albo... postea nigro," but the engraving's labels read black–white–red; the printed text appears to repeat "nigro" where "rubro" is expected — see QA], and finally extends out into branches very much like a sea-tamarisk. From this the degrees of the heat and concoction mentioned a little earlier are plainly discerned.

As regards the medical powers of coral, it is well known that it has the power of cooling, drying, and binding. I have certainly found by experience that a

preparation of coral (which they call a *conserva*) is a marvelous remedy in cases of *haemoptysis* — that is, for those spitting blood flowing from any part of the body whatever; for it stops the flux of blood wonderfully. It is moreover an excellent remedy against the *lithiasis* (stone). Paracelsus counts a medicament of coral among his panaceas; it strengthens the heart marvelously, and is of benefit in epilepsy and malignant fevers. But on these matters see the medical writers.

[Margin: The medical powers of coral.]

It is remarkable, what Anselmus Boëtius [Anselmus Boëtius de Boodt] observed about coral: that if it is worn by a healthy man it reddens more intensely than if it is carried by a woman subject to various impurities. The reason for this is plain: just as menstruating women foul a mirror by their menstrual flux, so too they infect the coral. Likewise it has been observed to grow pale upon the sick who are near to death.

Κοραλλομόρφωσις [Greek: Korallomorphōsis, "coral-formation" / the shaping of coral]

or, A fuller explanation of the origin of coral.

[De Coralli ortu, fusior explicatio.]

By what name I should call coral [Corallium], I can scarcely make out: for it cannot rightly be reckoned among the vegetable plants, nor —

— nor among the stony excrescences. More aptly, then, we judge that it should be called a λιθόφυτον [Greek: lithophyton, "stone-plant"] — that is, a plant-stone. I mean something midway between a stone and a plant, just as the natural philosophers are accustomed to call ζωόφυτον ἰχθυόφυτον [Greek: zōophyton ichthyophyton, "animal-plant fish-plant"] the thing midway between a plant and an animal. But in order that we may attain the truth about its origin, I shall set forth those things which I have learned partly with my own eyes — both in Sicily and near the Stoechades Islands [Stoechades, the Îles d'Hyères], not far distant from the Gallic coast — and partly from the account of trustworthy men.

[Margin: The genesis of coral.]

We do not, then, hold that coral grows the way vegetables do, by the taking-in of nourishment, but rather by the apposition of superadded saline corpuscles steeped in a sulphureous tincture — exactly as the other efflorescences of salts grow; and this happens not in all places, but on a suitable part of the sea floor

stocked with salts of various kinds and with sulphureous exhalations. For just as certain herbs seek out a determined and suitable place, in which they thrive more successfully, so too do the coral stocks. But let me explain the genesis in a few words. Where, through the pores of the sea floor, suitable exhalations of this sort and broods of salt burst forth, there the salts — tinged by the subterranean fire with sulphureous vapors — are sublimated; and when they have reached the seawaters, immediately, with both the cold of the waters and the brine of the sea concurring, through the hidden magnetism of nature a sympathetic attraction of like to like arises, and by the mediation of the stone-making spirit it is coagulated. And this is the first foundation of the κοράλλογένεσις [Greek: korallogenesis, "coral-generation"]. These corpuscles afterward, by an ever-new influx of saline corpuscles, are at length condensed into a trunk, and then, gradually spreading out into branches, they produce this marine plant that we are describing. And since the sulphureous vapors have a certain viscous fatness joined and innate to them, this fatness, conjoined to the salts, communicates to the plant a certain stickiness and viscosity, by which the saline corpuscles, as if glued together, confer upon the plant that solidity which we note. And this is the reason why, within the sea, they are not easily broken or torn apart, neither by the agitations of the waves nor by the violence of the sea-monsters.

[Margin: Why coral grows hard.]

And just as nearly all plants are furnished with fibers and little channels, so too the stalks of corals are equipped through the marrow with a certain channel set in them by nature, through which — as through the fibers of a bone or of herbs — nourishment is drawn to the plant. Again, just as in bones there is marrow, and in herbs an alimentary moisture, so too that spermatic liquor of which we spoke in the preceding passages — composed of a sulphureo-saline fatness — diffused through the middle of the trunk and of the coral branches, while it drips, forms a new little plant in whatever thing it has chanced to strike. For otherwise it could not be explained how coral could arise within a shell, in the root [recte: perhaps "in radice" = "at the root region"], and without any openings of pores.

[Margin: Coral has hollow branches through which it draws nourishment.]

And this is the genuine reason why it sometimes takes the first beginnings of its birth from a shell, a brick, a rock, an iron tool, or a cranium. It now remains to explain the branchiness of this plant, without which it could not otherwise be called a marine plant.

It was observed by the coral-fishers that there is always drawn up together with the corals a branching weed, which most people say is a tamarisk or seaweed growing up from the sea floor. And the sulphureo-saline corpuscles crave this weed by a certain wondrous law of friendship, so that wherever they have seized upon one nearby, they clothe the whole of it as if with a kind of coral garment — something I should never have believed, had I not, as I mentioned above, seen a similar specimen in the Treasury of Cardinal Barberini, which at the root was clothed with a black bark, then a white, afterward a red, and finally tapered off into the weed I called tamarisk-like, or seaweed — exactly as we showed in the preceding Book regarding many herbs clothed with a nitrous bark, which is the proper work of saline-sulphureo-nitrous bodies. But where weeds or tamarisks of this sort are lacking, there nonetheless it extends out into branches, in the same way in which the mineral efflorescences are spread out into various twigs by the continued superaddition of the said corpuscles.

[Margin: The branchiness of coral.]

It seemed good to display these species of coral in a figure, where at **A** a coral cut from the rock in my Museum is set out for viewing, together with the other shells onto which it is seen to have grown — as in figures **A. B. C. D.** we append the schematic.

There is also pure, solid red coral, which is approved above all by everyone, as is plain in Figure **E**. Another is spongy, tuberous, and lightly jointed, of a white color, as in **F**. Another, which they call *Savalia*, of a black color, is termed pseudo-coral; its inner part is usually wood, which extends through all the branches, and it is nothing other than a plant clothed with a coral bark, as you see in **H** — which, if it is rubbed, gives off a marine and fishy smell.

[Margin: The species of coral.]

Now that these things have been set out, nothing remains except for us to show whence so great a power as authors are unable sufficiently to extol is present in corals. I answer in a few words: it comes from the spirits of salts tinged with sulphureous vapors. For as was shown in the Sixth and Seventh Books, precious gems have no other cause of their rare powers than the spirits of the differing salts which are fixed within them. Since, then, coral has within itself a great deal of nitrous and nitro-sulphureous salt, and consequently also something vitriolated attached to it, it cannot but be that from such a medley of things it should obtain very many powers, such as those we described a little earlier. For how much power is present in salt, how much in niter, how much in vitriol and

sulphur, we have already shown in particular treatises; and who does not see that these powers, joined together in a single mixed body, take on for themselves a great increase of power?

[Margin: Whence the powers in coral.]

Nothing is more celebrated among physicians than the tincture of corals — which, however, much as it is celebrated, is just as unknown the method by which it is extracted. Some have supposed, like Quercetanus [Joseph Duchesne, "Quercetanus"], that if coral is reduced to a powder by the virtue of a sharp and acid solvent, it can come about that it is dissolved by its menstruum — which is duly purified by the power of fire by means of radicated [rectified] vinegar — into a liquor, just as any burning spirit, apt to catch flame, is dissolved; and this they call the tincture of corals. Some think the tincture is accomplished by means of a *magisterium* of amber [succinum]; but if these men examine the matter well, they will find a tincture not of corals but of amber. They labor in vain, too, who seek the tincture with the mineral salts — niter, alum, vitriol. The reason is that the violent acrimony of the minerals, just as it burns and erodes the corals, so too destroys every power latent within them.

[Margin: The various methods of coral tinctures.]

There are those who think the thing can be accomplished with pumice and emery-stone [smiris]; but these men too seem to be fishing in the air, since they suppose that the coral must first be calcined by fire — than which nothing is more contrary to the tincture. Perhaps from radicated vinegar, or from honey, the business might have a not-unhappy success. For my own part, so far as I have been able to gather from the secrets of nature, I judge that nothing can be more convenient and opportune for extracting the tincture than the spirits extracted from honey, or from oak-wood, or even from wild service-berry [sorbus]. But let it suffice to have merely hinted these things to the chemists. As for pearls [uniones], since it cannot conveniently be done in this place, we shall discuss them more fully elsewhere.

[Margin: The various methods of coral tinctures.]

MUNDI SUBTERRANEI LIBER DECIMUS — METALLURGIA, SIVE ARS METALLICA

BOOK TEN OF THE SUBTERRANEAN WORLD — METALLURGY, OR THE METALLIC ART

In which the nature, properties, principles, and causes of metals are treated, together with their matrices, that is, their mines; whatever can in any way be considered concerning this discipline is here examined as exactly as possible, with a remarkable array of experiments and the most abundant reasoning.

SECTIO I — DE ARTIS METALLICÆ REQUISITIS

SECTION I — On the Requisites of the Metallic Art, and the Condition of Mines

CAPUT I

Chapter I — On the Object of Metallurgy; and likewise on the Material and Formal Cause of Metals

Setting aside everything that the Scholastics are accustomed to teach about the object of the arts and sciences, and about the matter and form of the natural composite — taking these as commonly known — we extend our pen only to those things that concern the proximate causes of the generation of metals [Metallogenesis]. But in order to pursue the web of our undertaking once begun, we take up the thread of Ariadne and trust that, with God's help, we shall unravel above all those matters that until now have lain entangled and unresolved in the difficult labyrinth of natural philosophy.

The material object of our metallurgy is the perfect, purely metallic mixed body, excluding all the other minerals which we have already treated abundantly in what precedes. These [metallic bodies] are: gold, silver, bronze (or copper), iron, tin, and lead.

[Margin: The formal object of metallurgy.]

By the formal object we mean the manner and way in which Nature generates these things in the bowels of the Earth. From their native places they can be dug

up; they can be founded and shaped into statues; they can be transmuted one into another. Insofar as they can be extracted, smelted, melted down, cast, and figured into rings, collars, bracelets, coins, and utensils of every kind, they can be the object of various arts — namely of the metalworker's art, of statuary, of alchemy, of ironwork, of the goldsmith's craft, and of minting. And insofar as they are subject to the exchanges of merchants, they yield their proper subject to the art of the money-changers — of which matters there will be a full discussion in the course of this work.

[Margin: The matter of metals — what is it?]

We declare the proximate matter of metals to be neither the prime matter of the Peripatetics, nor the influx of the stars, nor the elements, but rather a vapor and exhalation, sulphureo-saline-mercurial in character, by which alone the metallic bodies — as though concreted from the seed of the chaotic mass — obtain their origin. The remote matter, however, we declare to be the *hyle*, the concurrence of the elementary qualities, and the influx of the stars. How all these are to be understood will become clear from what follows.

[Margin: The explanation of the generation of metals.]

It must therefore be noted that within the chaotic mass there lies hidden a certain rich, saline juice, congenital to the elements, which, driven into a vapor by the power of the subterranean fire, is dispersed through all the [fibers of the Earth.]

— **[continuation of Caput I, from Fol. 162]** — through all the fibers of the Earth; and where it finds a matrix proportioned to itself, it adheres to that, and, cooked over a long stretch of time, finally degenerates into a metal appropriated to the clod or matrix of the earth.

I said *juice* in the first place, by which I designate that mercurial liquor — that is, the spirituous substance — which we call the radical moisture inherent in all things. I said *rich juice* in the second place, that is, Sulphur, by which we mean that richness implanted in all things for the cohesion of their parts, shining forth most of all in sulphur itself. I said *saline*, because Salt is the earthy element, inasmuch as it supplies to all mixed bodies a firm consistency and a fixed substance — and this indeed has its origin not so much in the aforesaid juice as, most of all, in the very clod of the earth.

[Margin: Aristotle's opinion.]

These, then, are the three [principles] that concur in the composition of all metals, as will be shown later. And I demonstrate as follows that this our opinion

agrees with the first philosophers. Aristotle, in *Meteorology* III, expressly says that the matter of metals is a vapor. To show this, he premises a twofold exhalation: one vaporous, the other smoky. To the dry fossils — such as sandarach, ochre, minium, and stones, which cannot be liquefied — the dry exhalation belongs; but to metals — such as gold, iron, and bronze, inasmuch as these are ductile and capable of being melted — he assigns the vapor as the cause of their generation. He explains this more fully afterward in *On Generation and Corruption* II, in these words: "*Metals therefore have within themselves a great deal of moisture that is watery, yet so acted upon by the elements that it has become glutinous.*"

I should like you to know, however, that the Philosopher here did not understand a simple vapor arising from the pure element of water. This is plain from the fact that water, attenuated from the simple element of water, generates nothing differing from itself in species, but is finally resolved into what it was — as one sees in the vapor of boiling water, which on the lid passes back into drops, that is, into the very same water out of which it had passed into vapor. The same is plain in rains, snows, hailstones, and the like, of which we treated in the *Meteorology*. Therefore something else lies hidden beneath that vapor concerned with the generation of metals [μεταλλογονικῶ (metallogonikō, "metal-generating")], beyond the simple vapor of water. With a fine line of reasoning, agreeable to our own view, Albertus [Albertus Magnus], while explaining Aristotle's opinion, teaches this in these words:

[Margin: Albertus's opinion.]

"*The proximate matter of metals is a subtle, unctuous, and viscous moisture, excellently mingled with attenuated earthy [matter].*" What is meant by "subtle moisture" but the mercurial humor of Nature? What by "unctuous and viscous" but sulphur? (For, as we have shown elsewhere, sulphur is essentially rich, which is why it is so easily kindled and made to flow together.) And what else is "excellently mingled with attenuated dry earthy [matter]" but the salt of Nature, which connotes that which lends consistency and body to the composite?

And because that vapory exhalation always has joined to it a hot and dry exhalation — without which it could not be raised up — it comes about that whatever is dry in the metallic clods derives from the dry and hot exhalation, while whatever is vapory passes (on Aristotle's own testimony) into the matter of metals. And this is what Albertus means when he says "excellently mingled with attenuated subtle earthy [matter]."

Indeed, the opinions of various authors approve this view of ours. Gilgil the Arab [al-Jaldakī (?)] [?], as reported in Albertus, asserts that the matter of metals is lime and lye — that is, ashes soaked in water. Here let no one understand by "lime" or "ash" a lime or ash like our lime and ash; rather, he undoubtedly meant pulverized earth, or earthen powder, or the salt implanted in the nature of the earth, which, once infused with water (or impregnated with the mercurial vapor of sulphur), finally passes into metal.

For there is in the matter of metals a certain viscous moisture, the sign of which is that, when liquefied by the heat of fire, they flow, but by the cold of air and water they again condense. This happens, on the testimony of Agricola, in such a way that there is more of water in them and less of earth; for simple water is not their matter, but a mercurial liquor mixed with earth, inherent in the chaotic mass from the beginning, which various motions then bring forth: the flow of water softening the earth, the earth mingled with water, the force of heat acting upon the mixtures — out of which, finally, that metalliferous juice [μεταλλογονικός (metallogonikos, "metal-generating")] is elaborated and engendered. And this in such a way that the four elements are nothing but certain vehicles of the powers implanted in the aforesaid vapor; for without this complex of powers you may cook earth and water as much as you please, and yet you will extract from them nothing other than what they were before, namely water and earth. But if this spermatic vapor (for so I call it by a certain analogy to the seed of plants and animals) is added to the elements, then indeed they first exert their powers, and, according to the condition of the matter (that is, of the earthy clods), produce a metal differing in species. But all these things will be confirmed by various experiments in the books that follow.

From which it plainly appears that metals are by no means generated immediately from elementary and simple water, but from a vapor appropriated to each. But how they grow into such great hardness, one may rightly wonder.

[Margin: How metals grow into such great hardness.]

I say, then, that this comes about not from cold, nor from heat simply, but solely from the attenuation of the moist — that is, from evaporation or desiccation. For since there are in the nature of things two kinds of spirits, hot and cold — from the former indeed proceeds the principle of heat in things; the latter, no less than the former, even though cold by nature, are nonetheless most subtle and spirituous, as is evident from the north wind, and as is commonly known — whenever, therefore, hot spirits abound, such as the nitrous, the vitriolic, the

sulphureous, and the like, then the things they pervade acquire a warm [temperament].

— **[continuation of Caput I, from Fol. 163]** — acquire a warm temperament. But if [there pass through them] the breaths of the northern winds, which pass through snowy places, or subterranean winds which pervade the most frigid places of the clods (places that are by nature of a cold temperament), then the things they pervade acquire a cold temperament. From this it follows that each spirit, pervading the moist clod — the hot indeed by attenuating it into vapor, the cold by drying it out and freeing it from all superfluous moisture — induces the hardness proper to each thing, whether to stones or to metals.

The truth of this even the Philosopher himself acknowledged, who, in the passage cited above, after he had set forth the twofold exhalation, finally infers that *all things consist of a hot agent and a moderating cold heat*. Therefore it must be said that concrete bodies — whether they be stones or metals — solidify not by cold alone, but by heat, whereby the superfluous and impure moisture of the earthy clods is consumed, and the things, according to the condition of the vapor, turn out as this or that stone, or as some other metal intended by Nature.

All things, therefore, come to be by the force of heat as the principal instrument. From the metallic spirit, just as marble and any other stone is generated when proportioned moisture flows in [uti caetera proportionata affluente humido], so too from the same is metal generated.

[Margin: The form of metals.]

So, just as marble is not generated by cold alone, neither is metal — although, once it has been formed, it is melted by heat; but it is given firmness by the vigor of the metallic spirit, when it is united with the fixed [principle] by means of the moist, with heat always acting. But since we have explained these matters abundantly elsewhere, let us proceed to other things.

As for the form of metals: there are some who maintain that the forms of metals consist of the forms of the elements. But since the forms of the elements are accidental, it would follow that the forms of metals too are distinguished only accidentally. This being absurd and contrary to manifest experience, I judge that this opinion ought not to be refuted with superfluous words. Let us therefore philosophize more soundly.

I say, then, that the forms of metals are substantial, and are distinguished among themselves in species; that they give to each metal its proper being and proper

virtues, distinct from the rest. This is true not only in the manifold variety of gems and stones, but also in the species of metals. Thus the diamond [Adamas], the serpentine [Ophites], and the pumice [Pumex] is each what it is; for every stone and every gem has its own proper form, by which this and that gem is named and is distinguished in species from the others. But this form is not produced proximately from the mixture of elements, nor from cold, heat, moisture, and dryness, but from a seminary [seminarium] and an architectonic spirit [from the Liber Decimus, Sect. I.] inherent in the matter, which shapes the matter according as the seminary requires, and elaborates it according to a fixed and indivisible law of combination. By this seminary we understand nothing other than the sulphureo-saline-mercurial Chaos, out of which, from the first beginnings of things, all things were produced by the Divine Architect.

[Margin: The seminaries of Nature.]

Let the reader consult Book VI, Section I, where we have reasoned more fully concerning the seminaries of Nature. Now the seminaries were created by God as the principles of things, from which the individual species of things obtain their essential forms. These seminaries are not always enclosed within fixed and distinct bodies, as happens in the seeds of plants, but often remain in the matter in such a way that they can in no way be perceived. Thus in the branch of a willow the seminary of the tree is confused [i.e. indistinct]; for the willow produces no seeds, yet that it is present there the propagation of the tree amply and abundantly shows.

[Margin: An experiment.]

For if a branch is cut off and committed to the earth, a tree is produced from the branch, and from that tree countless others — as experience too demonstrates in the art of grafting [Phyteutica]. In the same way, in the generation of stones, gems, and metals, the seminary, even if it cannot be perceived, nevertheless furnishes the principle to gems and metals, and by the plastic faculty of the spirit passes into either gem or metal. For just as the plane tree, the mulberry, the linden, and the fir have different forms of branches, so the diverse kinds of metals — gold, silver, iron, bronze, and so on — produce, after the manner of trees, their flowerings or metallic plants out of their ores; and these, like those, have forms and virtues distinct in species. These things we shall confirm, God willing, by various and wonderful experiments in Book XI.

Since, therefore, metals are generated proximately from a sulphureo-saline-mercurial vapor mixed with a dry exhalation, we thus define metal in general:

[Margin: The definition of metal.]

Metal is a fossil body, hard, liquefiable by fire, and ductile by the hammer in every direction. I said *fossil body*, because it is dug out of mines; *hard*, because it is a concreted and most compact body; *liquefiable by fire*, because it coalesced from a sulphureous richness; *ductile*, because, possessing viscosity, its parts, joined as if by glue, are easily extended by the hammer. But if it had solidified from the simple element of water and from cold, then — like ice from excessive heat — by reason of its uncompacted hardness it would dissolve, and being melted by fire would grow watery, and would possess no ductility at all. Therefore [metals] cannot consist of the simple element of water, nor of cold.

From this definition we reject mercury, which is neither ductile nor flows in fire, but is resolved into an exhalation; yet it is a metallic body, concurring primarily toward the generation of metals [μεταλλογένεσιν (metallogenesin, "the generation of metals")].

CAPUT II

Chapter II — Whether the Heaven and the Stars concur in the generation of metals [μεταλλογονίαν (metallogonian, "the generation of metals")], and how the heavenly bodies can concur in the production of metals

The opinion which teaches that metals derive their origin and composition from the influx of the stars has so prevailed everywhere that it has found a place even in the minds of the wisest philosophers — at which I cannot sufficiently marvel. For they suppose the influxive power of the stars to be so subtle, and so equipped with rays of such penetrating force, that, hurled even into the inmost and deepest bowels of the Earth, it compels a proportioned clod, by the action of concurring elements, into this or that metal. Consequently, they hold that the seven species of metals took the beginnings of their names from the influx of the seven planets:

[Margin (planetary characters and metals):]

- ☉ Gold [Aurum]
- ☽ Silver [Argentum]
- ♄ Lead [Plumbum]
- ♃ Bronze [Æs]
- ♂ Iron [Ferrum]
- ♀ Tin [Stannum]

- ☿ Mercury [Mercurius]

They make the Sun preside over gold, the Moon over silver, Jupiter over bronze, Mars over iron, Venus over tin, Mercury over quicksilver, and Saturn over lead; and they call them the fathers and mothers of the metals. The alchemists, embracing this naming-scheme (as the saying goes) with both arms, did not for the same reason disdain to mark these metals with their planetary characters too, as may be seen in the margin.

But whoever weighs these matters on the finer balance of reason will see that the scheme rests on mere divination, and is received with great applause among the unlearned common folk, while in very truth it is mere trifles and old wives' fables, which crept into philosophy through the superstitious astrologers of the Chaldeans and Egyptians — as we set forth at length in our *Oedipus Aegyptiacus*, in the treatise on the astrology of the Egyptians.

Yet let no one, while I assert these things, suppose that I thereby deny the influences of the heavenly bodies and the stars; for to deny these I judge to belong not so much to an imprudent as to an ignorant philosopher. This much only I say: that it cannot be that the stars, by their *actinobolisms* [emissions of rays] — or, what is the same, by the immediate irradiation of their fiery light — produce metals in the deepest abysses of the Earth. For so far is it from the case that those rays penetrate the earth, that rather, as soon as they touch the Earth's surface, they are at once driven back and reflected into other and still other directions. For if they were to go further, no reflection would occur on the Earth's surface — which is contrary to all experience. It would also follow that no heat would be produced on the outermost surface of the Earth, since the greater or lesser intensity of heat in different climates comes from no other source than the altitude of the Sun, as we have amply demonstrated in *Ars Magna Lucis et Umbrae* [Kircher, *Ars Magna Lucis et Umbrae*].

But I have thought this matter should be demonstrated by a geometrical figure. Let the Sun be D. Let it project its rays — that is, its *actinobolism* — DC onto the surface of the Earth AB at the point C. I say then, supposing first (by an axiom received with the unanimous consent of all philosophers

[Margin: The rays of the stars do not penetrate the earth.]

Diagram. A geometrical optical figure occupying the lower half of the page, demonstrating that solar/stellar rays do not penetrate the Earth but reflect off its surface. At the upper left, the Sun is engraved as a radiant disc bearing a human face, emitting a dense fan of fine ray-lines downward. These rays strike the

convex arc of the Earth — drawn as a hatched, curved band across the lower page, with sketched coastlines/landmasses on it — and are reflected back upward, the incident and reflected ray-bundles crossing in an X above the Earth's surface. The construction letters named in the surrounding text are the Sun D, the surface AB, the incidence point C, and the angles DGE, EGA (incidence equal to reflection), and DGI, GIE (the total incident actinobolism equal to the total reflected). The point-letters A, B, C, D, E, G, I are referenced in the prose but are set very small on the plate and could not all be individually resolved against the hatching.

- Sun (upper left): radiant faced disc, emitting downward ray-fan (= point D in the text)
- Earth's arc (lower band): hatched convex surface with sketched landmasses (= surface AB)
- Incident ray-bundle: descends from Sun to the surface
- Reflected ray-bundle: rebounds upward, crossing the incident bundle
- Individual point-letters A, B, C, D, E, G, I as printed on the figure: [?] (too small / obscured by hatching to confirm placement on the plate)

[Below the figure, the text continues in two columns:]

by an axiom received with the unanimous consent of all philosophers and mathematicians, namely that all angles of incidence are equal to the angles of reflection) — thus the angle of the Sun's ray DGE is equal to the angle of reflection EGA, and so of all the other incident rays let the same judgment hold. And the angle of the whole incident actinobolism DGI is equal to the whole reflected actinobolism, the angle GIE. This being posited, I say that the rays of the Sun, or of any other star, as soon as they reach the Earth's [surface...] have struck the surface of the Earth, they do not penetrate any further but are at once reflected away at an angle equal to the angle of incidence. From this intersection of the incident and reflected rays — the region GHI — the air is intensely heated by the crowding-together of the rays, and this necessarily produces the heat we feel in summertime. For the higher the Sun stands, the more the intersection of the incident and reflected rays raises the heat at the Earth's surface; whereas the lower the Sun's altitude, the less heat it raises — as happens in the winter months, when the Sun is not far from the horizon. Indeed, the same becomes evident even within a single summer's day, from the Sun's rise toward the meridian and its decline from there toward setting. [Margin: Objection.] For in the morning, as the Sun has a lower elevation above the horizon, so too it produces less heat; and the same is plainly true of the Sun's descent toward the western horizon around evening. From all this it is clear that every degree of heat

at the Earth's surface is caused by the reflection of the Sun's rays — the *actinobolisms* — which would cease entirely if the solar rays passed into the Earth without being reflected, like so many darts piercing the body of the Earth. And that they raise no heat within the Earth is confirmed by experiment, since in summer the underground places are found to be far colder than in winter; which would not be the case if the fiery rays of the Sun penetrated the Earth.

But you will object: that this power of metal-generation [μεταλλόγονον, *metallogonon*, "metal-begetting"] consists not in the rays, but in the outflow of some hidden power — a force penetrating all things, which finally produces the metallic effect in suitably disposed matter. Yet since the power of all hidden influences is conveyed only by means of the heat and light that the rays always carry naturally within them (these being the vehicles, as it were, of the influential powers in question), it necessarily follows that, together with the reflected rays, the powers too are reflected and communicated to the neighboring air. For the air, once imbued with them, then communicates them to the waters, the plants, the animals, and to inanimate things — as we shall see shortly.

[Margin: How the rays of the Sun and Moon can be a cause of metals.]

From this it is clear how mistaken is the opinion of those who suppose that anything can be produced *within* the Earth by the heat, the light, or the radiation of the stars' influences. Since, then, I declared above that I by no means deny the light, the heat, and the influences of the heavens and the heavenly bodies, it now remains to explain *how* they can contribute to the production of underground things.

I say, then, that all the heavenly bodies of the stars and constellations — both the wandering and the fixed — act upon the lower (that is, the elemental) world not only through heat and luminous rays, but also through specific powers proper to each individual heavenly body. I have treated these at length in the first volume, Book IV [*Ars Magna Lucis et Umbrae*, Bk. IV], and in our *Itinerarium*, and so I have not thought it necessary to repeat them here. I say only this: that there lies hidden in each of the stars a certain specific power — implanted by God the Best and Greatest, the all-wise Architect, as a natural endowment of its body — which they pour into elemental bodies through a continual *aporrhoea* [ἀπόρροιαν, *aporrhoeian*, "emanation"] or effluvium; and that these influential powers always answer, by a certain analogy, to the powers that shine forth in sublunary compounds — just as, in the Fourth Book of this work, we sufficiently demonstrated regarding the Moon's influence upon the sea. These things being

laid down, I now explain how the stars contribute to the generation of subterranean things.

[Margin: How metals are generated by a heavenly power.]

These specific powers implanted in the Sun, the Moon, and the stars — which some call influences, but which we call *panspermia* [πανσπερμία, *panspermian*, "the seed of all things"] — are like seeds implanted, according to a certain analogy, for the producing of things. By their first influx they impart themselves to the air; the air, as if tinged with them, transmits them into the watery element; the watery element, made fertile by them and stirred by the Sun and Moon into its daily ebb and flow, conveys them through hidden underground channels into the secret tracts of the earth. The fire, or subterranean Sun, then resolves the cooked waters into vapors; and the resolved vapors, where any passage lies open, are diffused through the inmost cracks and fissures of the earth — like blood through the veins we call capillaries — and wherever they encounter a like and suitably disposed clod, they cling to it, and, drawn at last by a kind of magnetism through Nature's likeness, degenerate now into this gem or that stone, now into this or that mineral or metal. And in this way I judge that the heavens and the heavenly bodies can contribute to the generation of underground things — by means, that is, of the elements and of the Vulcanian subterranean Sun. But I shall develop this a little more fully.

When God brought forth the whole machine of the world, with all that it contains, out of that chaotic mass of the primordial world at the beginning, He furnished each of the heavenly bodies with its own solidity, with a fluid nature of moisture, and with a further fiery portion added to them. And just as, in those lofty tents of the heavens, He purged them utterly of all admixture with anything alien to themselves, so too it is likely that there is in them — out of that wonderful combination of things — something, according to a certain analogy, of those things by which we see all things in this sublunary world to consist: namely, besides the portions of the four elements, also something analogous to our sulphur, to our mercurial liquor, and to our salt. And these, while by their thinness and utmost subtlety they serve no other purpose than the preservation of their own body, yet, when communicated by an outflow to the sublunary world and to the grosser elements, finally acquire a body; and through the wondrous magnetism of heavenly and earthly things, they at last degenerate into that variety of things — both outside and within the most hidden storehouses of the elemental world — which we cannot sufficiently marvel at.

Since, then, the lower world (as Aristotle testifies) is governed by the upper, surely it is not by

motion, heat, and light alone that we ought to suppose it accomplishes this, but rather by the powers proper to each individual heavenly body — of which the *actinobolisms* of the stars are, as it were, the vehicles, and the carriers of all their powers. These powers, first communicated to the airy element, are what the air is impregnated with; and by their ministry, whatever arises in the sublunary world — whether in the air, in the waters, or in the lands — cannot in the least be preserved in its perfect and natural being without that heavenly outflow of powers [*aporrhoea*] which is present in the air in a peculiar way.

[Margin: The impregnation of the elements by heavenly influxes.]

[Margin: The simple elements do not contribute immediately to the production of metals.]

Finally, this air, made teeming with heavenly impressions — just as it perpetually lashes the watery element with its motion — likewise implants in that element the powers innate to itself, together with the heavenly outflow; and from this, by the heavenly and airy spirits, it gives birth to that countless variety of things which we behold in the ocean, the seas, the lakes, and the rivers. For since the air by itself and by its own nature can in no way serve for nutrition — being endowed with too thin a substance — it therefore communicates to the watery element the powers it has drawn from heaven, so that it may acquire some body fit for the nourishment of all things. For in this way no thing can lack water or moisture; indeed, without it the world would necessarily perish.

Therefore, lest that vast womb of the Geocosm should seem to be left destitute of this moisture in the generation of subterranean things, the supreme and ineffable wisdom of God brought it about that the air, by the subtlety of its nature, should be carried through the pores of the earth, and the water through the water-conducting channels [*canales hydragogi*] established by Nature, into the inmost bowels of the Earth and the deepest abysses; and that from there, by the agency of the subterranean Sun, it should — with vapors diffused through the whole mass of the Earth — make fertile, nourish, and preserve, both for the generation of fossils and metals, and for the generation of the plants that take their origin from the earth itself.

From all this it is plainly evident, first, that a pure and simple element cannot contribute to the composition of things; nor, so long as we make mention of the elements,

[Note: The right-hand column of this folio (fol. 167) carries the prose that continues into the second column. The text resumes:]

do we understand the elements [as pure]. On this reckoning, in any earthly body whatsoever, we say that salt is the predominant principle, whose marvelous faculty we declare to be the coagulating element of things among the other four — which indeed I should never have believed, had the spagyric [chemical] art not taught it me. For in the dissection or resolution of any earthly body whatsoever, I have seen it to contain a certain fiery, incombustible, fixed, and permanent salt-spirit, whose powers are so marvelous that they could scarcely seem credible to those ignorant of these hidden mysteries of Nature.

[Margin: The marvelous power of Salt.]

You will find, indeed, that the moist has so coalesced with the fiery fatness, and this with a certain earthy substance (which is the salt itself), in such equal proportion, that they can no longer be separated from one another. Hence it was not amiss that by this kind of moisture they understood the Mercury of Nature; by the fiery fatness, sulphur; and by the earthy substance itself, the salt of the chemists. Without these — unless the elements were impregnated by them — they could surely produce nothing heterogeneous of themselves and by their own nature: for pure earth joined to pure moisture would make nothing but mud, destitute of all power.

Secondly, it is evident that Heaven and the stars contribute as a universal and remote principle to the generation of metals and of the other minerals, insofar as they are, as it were, certain vehicles of the heavenly powers and the astral impressions; but that the proximate principles of metal-generation are the powers carried down through the air and the water into the inmost bowels of the earth — where, cooked and digested by the Vulcanian fire, they at last pass into the seed of all those things that take their origin from the earth. And so the proximate efficient cause is, properly speaking, the subterranean fire; the material cause is the sulphureo-saline-mercurial vapor and the proportion of the earthy clod for producing this or that metal or mineral; and finally, the final cause is the infinite usefulness for the needs of the human race and of Nature.

CAPUT III.

How that unctuous moisture, of which Metals are composed, is elaborated by Nature; and what in it Sulphur, Mercury, and Salt are.

We said in what preceded that the pure elements, water and earth, cannot contribute to the composition of metals unless they are altered by the seeds of the other things with which they are packed. For just as by their nature they are homogeneous, so they are always resolved into the homogeneous. This is clear from fire, which resolves the rarefied moist back into what it first was; and pure water joined to pure earth makes mud, which, when rarefied by heat, returns into those things it was before — namely, the powder of earth, and the water resolved by heat.

[Margin: The simple elements do not contribute immediately to the production of metals.]

Since, then, we have defined metals above as bodies hard, firm, solid, extensible under the hammer, and liquefiable by fire, they are surely recognized to have within themselves something else, hidden, into which they degenerate to take such forms. For how could they degenerate into that solid hardness merely by a mixture of simple earth with simple water? How could that inseparable fatness and viscosity — by which metals can be extended under the hammer without breaking, or melted without any flowing-away or moistening of their moisture — be brought about by the agency of the simple elements alone? No one can conceive this; since nothing gives what it does not have. In the inmost element, then, at the very center of the elements, there must necessarily lie hidden the cause of such great effects — that which furnishes metals their origin. And this we say is nothing other than that unctuous and viscid moisture, whose vapor, continually exhaling and diffused through the inmost fibers of the earth and the hidden ducts of the mountains, at last — wherever it encounters suitably disposed matter — there, according to the degree of its purity or impurity, generates now a stone or a gem, now a mineral or a metallic body.

[Margin: The origin of the viscous and unctuous moisture.]

But how this unctuous and viscid moisture is elaborated by Nature, one might rightly wonder. I say that it is derived from the outflow of the astral powers and the heavenly spirits. These spirits, being by their origin most pure and most thoroughly purged of all earthly dregs, do also — by reason of their supreme and inexpressible thinness and subtlety — at once penetrate all the elements, and by a certain magnetic attraction are joined, in a wonderful manner, to those things that in the primordial chaotic mass of things were one and the same. The elements air and water, made fertile by them through the sea's approach and recess (caused by the agency of the Sun and Moon), are diffused into the inmost

storehouses of the earth; there, cooked anew by the subterranean fire, and digested and purified through manifold and repeated cooking, they pass into that unctuous, fatty, and viscid moisture.

[Margin: How that unctuous moisture degenerates into metal.]

Its vapor, carried down through the hidden fibers of the earthly veins, is first — by the innate and invisible power of salt — dissolved into a salty earth [*terra salsuginosa*], moistened by the body's [?] sprinkling, and purified in many ways, both by sublimation and by filtration accomplished through the pores of the earth. And in this way, cleansed of all the earthly refuse mingled with it, it at last degenerates into a kind of most brilliant white sulphur. This pure and washed sulphur, enclosed in the matrices of the Earth, further cooked by the Vulcanian heat and by its own, is over the course of many years fixed into silver by the spirits of its own salt.

[Margin: The generation of gold.]

And if this white and incombustible sulphur is tormented by a still stronger fire to the point of redness, it is at last turned into the most thoroughly purged [?]... which, by the continual vapor of its own resolution

[Note: column break; text continues in the right column of fol. 168:]

under an equal portion of fatty moisture and earth, is transmuted by an inseparable union into pure gold. All of which will be shown in the Eleventh Book [*Liber XI*], in experiments adapted to the pattern of Nature. But if the vapor of this unctuous and viscid moisture has not yet been purged of all impurity and feculent dross, then, according to the degree of its purity or impurity, it is converted now into a more perfect, now into a more imperfect metal.

These things being set forth, one might rightly ask further: what, then, is that unctuous and viscid moisture?

[Margin: What the unctuous moisture is.]

I say it is nothing other than that radical moisture of Nature, which, just as it was implanted in things from the first beginnings of the chaotic mass by the ineffable wisdom of the Divine Architect, so it persists in all and each of the things down to this very day, and is everywhere called the Mercury of Nature. Its unctuous and viscid quality is nothing but that fatty warmth of Nature implanted in all things, which by a certain analogy the chemists call the sulphur of Nature; while the earthy part that lies hidden beneath it they call the salt of Nature, because it

furnishes all things a firm substance and body. And that all things consist of these, the spagyric art has long since learned by experiment. So that the four elements might not seem idle in the nature of things, Nature, from the beginning of things, grafted this Mercurial moisture into the watery element, the sulphureo-warm and inborn into the fiery and the airy, and the fixative salt of Nature into the earthy element — so that they might be, as it were, the vehicles of those material principles of which all things consist.

Hence nearly all the philosophers have set down, as the material principle of metals (in general only), a moist vapor mixed with earth — as appeared from the preceding chapter. But because they did not reach Nature's proximate procedure in the order of composing metals, I have judged it worth elucidating here, for the reader's benefit — somewhat more fully, perhaps, than was fitting — having been taught and led by experimental knowledge alone. For in physical matters, to philosophize without experiment is the same as if a blind man should foolishly presume to pass judgment on color.

CAPUT IV.

How all things are produced by the efficiency of the earthy and of the moist heat; and likewise, what that is which renders metals fluid in fire, but not stones, plants, and other things; and how Nature proceeds in dissolving and perfecting things.

Here I shall lay open a singular secret of Nature, which, since it unfolds the inmost mysteries of the composition of things, I hope will also be such that, once these things are rightly understood, the origin and causes of metals may become known to the reader most intimately. And although I shall propose it in other terms than those usually employed in the Schools, it will nonetheless be evident — if his words are rightly weighed — that Aristotle held the same view.

[Note: the right column of fol. 168 carries the opening of Caput IV's body:]

Two things there are in the nature of things (if matters be considered, setting aside all metaphysical contemplations, under strict physical rigor) which contribute to the *synthesis* [σύνθεσιν, *synthesin*, "putting-together"] of all things, are present in all, and are the cause of all generations and corruptions. And first there is the earthy, spiritous, concrete, corpulent matter, in whose center there lies hidden that which furnishes things their substance and corpulence — which we call the

fixed [salt]. We call it the fixed salt of Nature.

[Margin: The fixed salt of Nature fixes all things.]

And that the matter of the kind we have described should be such, it gets from the fixative element implanted in it. I said "matter," because, considered in itself, it lacks all active power; and it can be said to act only insofar as, by the innate appetite with which it is endowed — or, what amounts to the same, by a certain implanted magnetism — it draws to itself those parts most like and proportioned to itself.

[Margin: How the resolution of bodies takes place.]

I said that this earthy matter is spiritous, subtle, and active — that is, the central salt of Nature, the volatile salt, which by acting perfects and completes the other part when it is joined to it. And just as from that other part it receives corpulence and consistency, so too it communicates to it an active, formal, and specific power. And whenever these subtle and tenuous spirits evaporate, the matter is said to be dissolved, the fixed material substance remaining behind. And just as these formal parts are born for acting, so those material parts are born for being acted upon — as is evident from the artificial resolution of compounds, by which parts essentially diverse are extracted from diverse compounds. Thus the spirits of niter, of alum, of vitriol are utterly distinct from the spirits which are distilled and extracted from vegetables — of wine, of roses, of lilies, and of countless others. So that, not without reason, just as resolution into prime matter is not granted by the Peripatetics, so too no body whatsoever can be wholly devoid of spirit. For if you resolve bodies into ashes however far you please (which are believed the driest of all things), yet even these are further sublimated — partly into salt, and partly, if they are tortured by a more violent fire, they flow into glass.

[Margin: The moist glue of Nature.]

But these parts — namely matter and spiritous substance — being very diverse among themselves, have the greatest need of a bond by which to be united and coupled to one another under the strict laws of friendship. And this is nothing other than the moist: a sort of middle between the volatile and the fixed, between body and spirit — or, what amounts to the same, between the gross and the subtle. Yet because no change of things can take place without the rarefaction or dissolution of this moist, Nature has appointed heat as a kind of *Archeus*, by whose aid the rarefied moist glue of Nature is dissolved; and once it is dissolved, the parts too are dissolved, the spiritous things fly off, and the bodies fall together.

And the more easily this moist is resolved, the more readily too the body lies open to corruption; but the fatter, more viscous, and more compact the moist is, the more difficult it necessarily is to dissolve — and consequently, by reason of the close packing of its well-mingled parts, it is less subject to corruption. Hence it is clear why a watery moisture, having little viscosity, easily passes off into vapor when rarefied: namely, because vapor has a watery moisture that is very undigested and ill-knit in its parts.

[Note: text continues in the right column of fol. 169:]

By contrast, those things which have a more cooked and digested moisture, intimately mingled with their parts, are — by reason of the predominating fatness and viscosity — dissolved only with difficulty, as if by a more tenacious bond.

It is therefore clear from these things how our material principles, of which we have said all things consist, are to be understood. For what else does that spiritous substance denote but Sulphur? what else the fixed but Salt? and what else, finally, does that viscid moisture designate but Mercury? — as we said in what preceded, from the mind of the ancient sages.

[Margin: The principles of nature: sulphur, mercury, salt.]

In like manner, in plants and living things, the volatile part is called the soul, the fixed the body, and the moisture the true and physical union by which the soul is coupled to the body.

But why that moisture is so easily dissolved in vegetables and animals, yet so hard to dissolve in mineral and metallic bodies, one might rightly wonder. And since in this lies a great part of the knowledge of natural things, we shall unravel it somewhat more fully.

[Margin: Why moisture is so easily soluble in plants and animals, but not in metals.]

Nothing is better known than that moisture in certain things, when rarefied by heat, soon vanishes into vapor; while in others it cannot be resolved into vapor even by the most vehement fire. But how this comes about, I judge to be known to few. I say, then, that that Mercurial moisture is a kind of middle between sulphur — that is, the spiritous — and salt — that is, the fixed — as we hinted above. And this viscous moisture, the glue of Nature, according to the diversity of bodies, either clings to some things not at all, or is mixed in under a very small portion; while with others it is moderately and part by part commingled and joined.

Whence a threefold kind of moisture arises: the first is a certain watery moisture, wholly incompact and almost devoid of all viscosity; the second is more compact; the third is found most compact of all.

[Margin: Why metals can everywhere be melted by heat, but not resolved into vapor.]

The first is seen in the mud that is made from powder mixed with water; which, being incompact and consisting of slight viscosity, is dissolved into its elements by even the least rarefaction of external heat. But if you knead earthy powder with an oily matter,

[Margin: Why oil and wax flow when heated, but do not evaporate.]

then indeed a mass is made which is dissolved not so much by external heat — unless it be forced by a more vehement fire — because the fatty and viscous matter is more intimately knit to the powder, so that the spirits, unable to fly off, are held in. And daily experience teaches that the same happens in wax. For the reason why, when it flows rarefied and thinned by heat, the spirits do not fly off, is that viscid moisture by which the parts are so coupled to one another that the heat, when it does not allow it to evaporate into the air, at least resolves it into a flux — by reason of the bond of the more tenacious viscid moisture by which the parts are knit to one another. And from this it is also clear why wood and stones are consumed by fire — wood into ash, stones into lime — whereas metals flow when melted. [Margin: Why wood turns to ash, stones to lime, and metals melt in fire.] For wood and vegetables of every kind, since they do not possess a well-compacted moisture (lacking the viscosity required for it), have a moisture that is more watery in character. Stones, by contrast, possess only a scant moisture. Hence in both cases the spirituous parts, for want of the viscid moisture, dissolve the fixed parts — in vegetables into ash, in stones (because of the greasiness of their sulphur) into lime. Metals, however, since they possess a viscous moisture, also have their parts intimately mixed and compacted with one another. The result is that, through the action of fire, that moisture is thinned and swells to a considerable increase, yet is not separated off and does not withdraw from its own body; instead the whole passes over into a liquid.

[Margin: The source of the fusibility of metals in fire.] Whoever, therefore, considers this operation of Nature more deeply will necessarily be forced to admit that metals, when worked upon by fire, do not flow at all because they are governed by a predominance of water; rather, it is because of the remarkable viscosity of their radical moisture, by which the parts are so knit to one another

that it does not permit them to pass off into smoke and vapors. For if they consisted of a simple watery moisture, they would certainly not flow by the agency of fire but would be converted into lime, just as happens with stones roasted in fire. Metals, then, flow in fire because their moisture — by which the metallic spirits are bound together with their vapor — does not, under the force of heat, withdraw, but is so thinned and swells up that it also thins and rarefies the parts it binds; and herein lies the flowing of the metallic parts.

This is further evident as follows. If mixtures of heterogeneous parts and the dross of earthy clods have been mingled with metals, only the homogeneous parts of the metal will flow, while the other things of differing kinds pass off — as scoria, or as a pumice-like dross, and as soot — with some loss of the metal.

[Margin: Why metal becomes purer when roasted in fire.] And this is the reason why metals come out purer when roasted in fire: because the mixtures of heterogeneous parts, being not well compacted and abounding in watery moisture, fly off through the thinning action of the fire and the failure of their viscosity, while the metal — owing to its viscosity — remains, its moisture being irresoluble. That metals are rarefied in melting, smiths have established by experiment: for if they have made a hole in red-hot iron, they find it much wider while the iron is still glowing than when it has cooled — for just as iron expands with heat, so it contracts and takes up less room with cold. But more on these matters in Book XI, *On the Metallic Arts* [*De Metallicis artibus*], where you will also find all of this confirmed by experiment.

COROLLARY I [CONSECTARIUM I]

From this it is plainly to be gathered how all things are thinned and made to flow by heat — and this, indeed, by the most wise design of Nature, namely so that by the perpetual and never-ceasing alternation of things the whole face of the Geocosm may be changed. And since moisture is the bond by which the spirituous parts are joined to the body and the matter, when that bond is loosened the spirits withdraw from the body — yet without any perishing of them, the only thing accomplished being a separation — in such a way that nevertheless something of the spirits always remains in the matter, after the manner of Nature's seeds. [Margin: The wonderful constancy of Nature in this.] And if these are again carried back to a body of this sort, then, attracted by a certain magnetic law by those that remained within, and united to them, they are bound together by a new moisture. And this is the wonderful physical "circling-around" [Greek: περικύκλωσις (*perikyklōsis*, "circling-around," cycle)] in the nature of things.

COROLLARY II [CONSECTARIUM II]

From this it is also clear that the generation of all meteors comes about by the said industry of Nature, and that all the laws of generation and corruption, in the greater World as in the lesser, depend upon it. For although the varieties of all the spirituous effluvia are constituted in well-nigh innumerable differences, they can nevertheless all be reduced to two, as to their remaining genera — namely, to the moist and the dry, of which the former go by the name of "vapors" and the latter by the name of "exhalations." All these exert their powers in the threefold kingdom of Nature — the mineral, the vegetable, and the sensitive. [Margin: The circulation of meteors.] Mineral and metallic bodies, stirred up by the subterranean Vulcan and thinned and resolved into vapors or exhalations, are raised up to the outermost surface of the Earth, where, struck by the celestial rays and reduced to the utmost subtlety, they fill that great aerial sea. The spirituous substances of vegetables and of every kind of sensitive thing, likewise struck by the celestial light and resolved, are again committed to the aerial Ocean, where, dissolved by cold, they are restored to the earth anew through snows, hailstones, rains, mists, and dews — and each spirit, by a certain magnetic pull, flows together toward that body, native to it, from which it had flown off. But more fully on these matters in the Last Book, where I shall perhaps disclose a new physics, until now scarcely known.

These operations of Nature, art imitates — the artisan who, by distilling minerals, vegetables, and animals, extracts from them as many different waters, oils, and spirits as there are different mixtures in the nature of things. So it is that by "Salt" the old philosophers understood the fixed physical matter; by "Mercury," the moist principle, the glue of all things; and by "Sulphur," everything spirituous. Let anyone who pleases believe that from the mere confluence of the simple elements so great and so innumerable a diversity of things is born; for my part, taught otherwise by nature, I have judged it the wiser course here to set forth not the things that pertain to metaphysical concepts but those that pertain to physical experience.

SECTIO II [SECTIO II]

ON THE MINES OF METALS AND OTHER MINERALS, AND ON THE DISEASES AND REMEDIES OF MINERS

[DE METALLORUM, Cæterorumque Mineralium fodinis, Fossorumque morbis & remediis.]

CAPUT I [CAPUT I]

What is required for a complete knowledge of the metallic art; or, on the qualifications of the overseer of mines.

Before we enter more deeply into the inner sanctuary of our metallurgical art, we shall set forth in a few words what is required for a thorough knowledge of this art — with what endowments and natural gifts he must be furnished who has taken up the profession of this craft.

[Margin: The rules to be observed by the overseer of mines.] First. The metallurgist, or overseer of mines, should set divine worship before all else, mindful of the saying: *Seek first the Kingdom of God, and all these other things shall be added unto you* [recalling Matthew 6:33]; lest, while too anxiously searching out earthly and perishable treasures, he be swallowed up in the abyss of avarice and suffer the loss of his own soul. Therefore let there be joined to the fear of the Lord a constant diligence, by which everything is arranged according to the canons, rules, and precepts of the metallic art. This for the most part brings the great benefit that, for those who both know what ought to be done and take care that it be brought to completion, nearly everything turns out successfully and prosperously.

[Margin: Knowledge of minerals.] Secondly. In order that the metallurgist may fulfill all the parts of an upright and skilled man, it is necessary that he be most expert in his art — namely, that he know first which mountain, which hill, what valley-ground or open-field situation can be usefully dug, and which refuses digging. Next, that the veins, the fibers, and the joints of the rocks lie open to him; then that he have a thorough understanding of the manifold and various species of earths, juices, gems, stones, marbles, rocks, metals, and mixed bodies, and that

he likewise know every method of carrying out work underground. He should be acquainted with the materials to be tested and the things to be prepared by art for smelting [excoctio]; and since these are diverse, so too they require a different method in different metals. [Margin: The method of smelting metals.] For gold demands one method, silver another, and the other metals yet others — which I would have you understand applies also to the smelting of the concremented juices, salt, niter, alum, chalcantum [vitriol], sulphur, and bitumen, each to be carried out in its own way.

Thirdly. Before the metallurgist undertakes the *metallourgia* [Greek: μεταλλουργία (metallourgia, "metal-working")] — that is, the digging of veins — let him consider these seven things with himself. First, the kind of place; the disposition of it; the water; the access-road; the healthfulness; and the neighboring lordship. And in order to possess this knowledge, he must be furnished with an acquaintance with many arts and disciplines. [Margin: He must be instructed in various disciplines.] First, philosophy, so that he may understand the origin, causes, and natures of subterranean things. Second, medicine, so that he may provide for the diggers and the other workmen, lest they fall into the diseases to which they are exposed above others; and if they have fallen ill, he may either himself apply remedies, as physicians do, or take care to have them treated. Third, astronomy, so that he may recognize the regions of the sky and from them judge the extensions of the veins. Let him also be not unskilled in geometry, so that he may measure how deep the shaft must be dug — so that it may be reached by the gallery [cuniculus] driven all the way to it — and so that he may set fixed bounds and limits for each mine, especially in the depths, and measure them according to the established laws of geometry. Let him have a notable knowledge of numbers, or arithmetic, so that he may be able to bring to a reckoning the expenses incurred in constructing machines and in paying the diggers.

But nothing is so necessary to the overseer of metallurgy as statics [statica], by which he may know how to build the substructures of the mines and the hauling and hydraulic machines — either by himself, or by explaining to others the methods of constructing them. Moreover, this will teach him the weights of metals and the differences of one metal from another. And if to statics there be joined draftsmanship [pictura], then indeed he will be said to have attained a complete knowledge — if he can correctly lay out the branchings of the galleries according to the laws of ground-plan drawing [ichnographia], and correctly represent the prototypes of the required machines, as well as the site and position of the mountains and fields. Finally, since great disputes often arise

concerning the jurisdictions over properties, he must also be skilled in the laws, so that he may be able to form a correct judgment about the ownership of things.

On the various offices of those who are engaged in metallurgy.

[De variis officiis eorum, qui Metallurgiam curant.]

Under the overseer of the whole metallurgical enterprise, after the supreme lord and proprietor, there are the master of the workmen, the jurati (as they call them) [the sworn officials — mine assessors], the clerk of the mines, and the foremen of the galleries. [Margin: The office of the jurati.] The master of the workmen exercises command over all the diggers, except the mint-workers and the silver-refiner; he also punishes negligent workmen by fines; he settles disputes that arise concerning the mines; he grants and confirms mining-rights to those who request them; he measures out the mines and fixes their boundaries; he teaches and prescribes what is to be done in each mine. To him all the other foremen of the workmen render an account of the money spent in the preceding week, which the clerks enter in their register. This man must be a carpenter, so that he can build the shafts, set in place the props, and make the substructures that support the undermined mountain, lest the diggers be buried; and so that he can drive the galleries to channel off elsewhere the waters seeping from the veins and from the joints of the rocks. He must also know the veins and fibers, so that the shafts may be usefully dug, and must distinguish one excavated material from another — either by himself or through others already instructed in the usual rules. [Margin: Knowledge of mineral-deposits.] Besides, let him have knowledge of washing, purifying, and smelting the metals. Lastly, let him supply whatever is necessary to the diggers for their labors — iron for tools, leather for clothing, tallow for lamps, and so forth.

[Margin: The office of the jurati.] The jurati must be men of good faith and skilled in mining matters; their number, indeed, is set according to the multitude of the mines. Their office is to visit the mines, to inquire what is being done and what has been done, to take counsel concerning the machines, substructures, and new constructions to be made, and to deliberate about all the other things that concern the good of the mines: to settle, according to the laws of arithmetical proportion, the labors to be undertaken — in hard, rough, and rocky places, and likewise in soft, clayey, and similar ones — and likewise to punish the negligent, the fraudulent, or the thieving according to the gravity of the offense. Finally, when the jurati are absent, the overseer decides nothing of all this on his own authority.

[Margin: The office of the workmen.] As for the workmen, they carry out their labors in this manner. The span of the natural day is divided among them into three parts, in such a way that each span of time comprises seven hours. The first span of seven hours they begin at the fourth hour by astronomical reckoning, and it lasts until the eleventh. The second begins at the twelfth hour and lasts until the seventh in the afternoon; these are reckoned the day shifts. The third begins at the eighth hour and ends at the third hour after midnight. During this last, whether they are drawing water from the shafts or digging the vein, they keep continual watch by night-lamps; and lest they sleep from their watches or from weariness, they soften their hard labors with singing — neither altogether rough nor unpleasant — to which they are summoned for undertaking by the sound of a bell, at whose signal they gird themselves to their labors here and there, district by district. When the seven hours have been completed, then at a new signal — by the striking of clappers — the underground diggers, on perceiving it, give a sign by a mallet struck against the rocks to those laboring in the inner galleries of the mountains that the work is finished; though indeed the impending failure of the tallow in their lamps is for them a clear enough sign that the time is complete.

CAPUT II [CAPUT II]

On the diseases of miners.

[De Morbis Fossorum.]

Since the underground galleries are crammed with the malignant spirits of minerals, it cannot but be that the diggers are from time to time afflicted with unusual kinds of diseases. Hence, according to the diversity of the waters, the exhalations, and the air, different diseases must necessarily arise — of which some afflict the limbs, others injure the lungs, others the eyes, and others again, by a certain deadly and suffocating force, kill them outright. [Margin: The diseases of miners.] The colder water that tends to stagnate in the deepest shafts generally damages the legs and nerves; hence, unless they protect themselves with leggings made for this purpose, they must inevitably fall into well-nigh desperate infirmities. But in mines that are dry and devoid of moisture, a greater evil threatens them: for when they shake the earth with continual concussions and dig deeper to lay bare the matrices of the metallic clods so as to uncover the courses of the veins, the surrounding medium cannot but be infected with various effluvia of dust, which, drawn in together with the air and insinuated into the lungs, generate first asthma — that is, difficulty of breathing — and then

consumption [phthisis]. And if these effluvia further possess a corroding power, then, with the lungs ulcerated, they breed a dreadful wasting.

Moreover, there is a certain kind of cadmia [calamine / zinc-ore fume] which eats away the feet of the workmen when they are soaked with water, and likewise their hands, and injures the lungs and eyes. [Margin: By what means the diggers protect themselves against the harmful spirits.] Hence many protect not only their feet with leggings but also their hands with gloves, and their face with bladder-skins, lest the dust harm them. By this means, Pliny [Pliny the Elder] records, the makers of minium [red lead / vermilion] among the ancient Romans protected themselves against the mercurial spirits.

It sometimes happens that the diggers are forced to break and shatter the metallic rocks by applying fire; and while they do this, unless they withdraw in good time from the smoke, it can scarcely be told what monstrous kinds of diseases — which bring their death close upon them — they incur. For in these [Margin and main text continue on next folio.]

cases the air is poisoned in a remarkable way by a certain subtle and spirituous venom, which, squeezed out and diffused by the force of fire from the veins and joints of the metallic clods, exhales forth. If this clings to the vaults of the mines in the form of tutty, pompholyx, or soot, and afterwards in time falls down into the standing pools, it does great harm indeed to the diggers when the water is tainted with such death-bearing spirits. [Margin: How much harm poisonous soot causes.] For experience has taught that, if you stir up the pools of stagnant water even by the throwing of a stone, the venomous spirits that at once fly out from them kill, without any remedy, whomever they strike. The same smoke, while the fire is not yet extinguished, has been found to produce wholly outlandish symptoms. [Margin: The origin of the diseases of miners.] For the bodies of the diggers infected with this venom at once swell up so much that, robbed of all sense and motion, they perish without pain; while those who feel themselves infected, as they flee up the ladders to look to their safety, are meanwhile so swollen in hands and feet into a globular shape by the prevailing venom that, when they can no longer hold themselves on the rungs of the ladders, they fall from the ladders and exchange their life by an unhappy death. The diggers, therefore, made more cautious by the death of many, keep themselves from entering the mines for a full two days, with a fire built within the pits, until the death-bearing poison diffused through the air is gradually consumed by the fire.

[Margin: The malignancy of arsenic.] Again, wherever arsenic, orpiment [auripigmentum], sandarach [realgar], and similar matrices of poisonous

minerals are found, there the air presents itself so much more pernicious in proportion as it has been imbued with the more virulent exhalations of the said minerals, together with the exhalations of the mercurial veins. So Agricola [Georgius Agricola] reports that it happens in the caverns near the town of Plana [Planá, Bohemia], which at certain times of the year give off from the acid springs [acidulae — mineral springs] an exhalation that extinguishes lamps and, if anyone lingers there too long, kills him. Elsewhere, in deep-sunk pits, sulphurous and aluminous [exhalations] kill the well-diggers. [Margin: The deadly Charontian pits.] Such spirits exhale in the Neapolitan territory near the lake of Agnano [Lago d'Agnano], in a certain cave (they call it the *Canum* [the Dog's Grotto, Grotta del Cane]), which renders dogs detained there for a short while at once stupefied and as though lifeless, but, detained longer, suffocates them outright. Such chasms are found also in the territory of Tivoli [Ager Tyburtinus] and of Volterra [Volaterrae], as we have set forth in our [account of] Etruria [Hetruria] and Latium, which kill men and animals that approach too incautiously. See what we discuss more fully on these matters in the Fifth Book. Of such a death-bearing property, then, are those exhalations which from time to time meet the diggers from newly excavated galleries, with great slaughter among them.

CAPUT III [CAPUT III]

On the cure of the diseases of miners.

[De cura morborum metallicorum.]

Just as all the metallic diseases arise either from the virulent vapors of the metals or from the smoky exhalations that infect the air — these being diverse in nature and property — so too they bring about the most diverse diseases in the underground diggers. For some attack the lungs, others the stomach, some the brain, several the joints; nor are there lacking those that assail the liver, the kidneys, and the bladder. In these organs, then, through the continual insufflation of the infected air, or by the native heat within — no otherwise than by the force of fire within an alembic — they are now sublimated, now precipitated, now drawn off by distillation into one part and another, whence arise outlandish coagulations, corrosions, and putrefactions, from which the seed-beds of all the diseases take their origin. By what means, therefore, the diggers and the smelters of metals can fortify and preserve themselves against these, I have thought fit to show in a few words, so far as I have it from the physicians who, for hired pay, have the care of the workmen subject to metallic diseases.

[Margin: Remedies against metallic diseases.] The cure of a metallic disease can therefore be reduced to a threefold method: to the prophylactic, the dietetic, and the proper method of medicaments. The prophylactic is as follows. Let one who is not yet infected select that most excellent and specific medicament from the essence of Tartar, of which this is the composition. Let there be mixed together liquor of Tartar, laudanum of poppy, and oil drawn from colcothar. [Margin: The preparation of the medicaments.] Now colcothar is nothing other than vitriol calcined to redness; these, when distilled, will furnish a liquor which — taken in a dose of three grains every half-year — is said to render a man free and immune from all the poisonous vapors and exhalations of metals. But those who have already fallen into putrefaction from the corrosion of metallic exhalations are most commonly prescribed a balsam drawn either from vitriol, or from nettle, or from steel.

[Margin: Balsam of Vitriol.] They prepare the balsam of vitriol thus: they draw off from the vitriol its phlegm until it becomes sweet like honey and inclines to a purple color; the dose is one drop in water of speedwell [Veronica].

[Margin: Balsam of Nettle.] They prepare the balsam of nettle thus: let the salt extracted from nettle be rectified in its own aqueous portion, by a moderate fire of ashes, or of sand, or even of dew, until the greasiness of an oil is seen; this, separated from its dregs, is to be administered daily in a dose of three drops, in water of speedwell.

[Margin: Balsam of Magnet.] The balsam of magnet is prepared thus: let the magnet be reduced to alcohol — that is, to a most fine powder — upon which an equal weight of steel filings is placed, and let it be cooked in a glass vessel as well luted as possible, in an oiliness of the ashes of woad [Isatis]; afterwards they take the filings, or scrapings, of the magnet, which [are put] into rectified wine [as] much [as... — text continues on next folio]

until the wine turns red. Once the wine has been separated from this redness, the balsam of magnet is found at the bottom. Taken in the dose prescribed above, it allows no part of the body to putrefy.

For the diet to be observed, this cure prescribes the following for miners. Men engaged in metalworking and in the underground labors of the mines should, as far as possible, season their food with rock salt [sale petrae]. By the same principle, in place of spices they should use aluminous salt — the salt extracted from alum — which has no saltiness at all and yet seasons food excellently.

[Margin: A remedy against asthma.] Against the non-putrid asthma that metalworkers most often contract from mercurial vapors, they usually prescribe water of sowbread [aqua panis porcini, *Cyclamen*], the one remedy for diseases of the lungs. Its power is remarkably diaphoretic. For if the affected members — that is, the liver, stomach, and lungs — are kept in a state of perspiration [Greek: διαφορήσει (diaphorēsei, "sweating," diaphoresis)], the virulence of the mineral spirit will do them no harm; and if any damage has already been done to them, the diaphoretic power expels it — mucus, resin, or tartar — so that, with this diaphoretic or sweat-inducing power at work, neither stone nor gravel can settle in the bladder or kidneys. For sweat is the supreme safeguard in illnesses of this kind.

[Margin: Theriac.] There is no shortage of other household remedies, both for those who work underground in the tunnels extracting metals and for those who work at washing, purifying, and smelting them. Some make great use of theriac; others use metallic remedies compounded from salt, alum, saltpeter, salt-peter [salpetra], vitriol, and tartar. Miners admit that by the use of these they feel the greatest relief — which I judge happens for no other reason than a certain sympathetic affinity, whereby like substances taken into the body, having gathered together the little particles of the metallic effluvia where these have collected, then by the cleansing power of the salts draw them out together with the humors through the body's natural channels. For salts of whatever kind, once duly purified and reduced to their own purity, are a notable antidote [Alexipharmacum] against the malicious vapors of minerals. Everything malignant that lurks in salts comes from the heterogeneous clods of a malignant nature mixed and fused into them.

[Margin: Household remedies.] Again, against this kind of pestilential air of the underground pits, before the miners go in there are draughts of the best and finest wine, or servings of rich broths together with butter, onions, and walnuts. Some chew zedoary [Zeduarial] in the mouth, or some other root of a specific quality. Some even hold gold leaf in the mouth against mercurial spirits: for just as mercury, by a natural appetite, embraces gold in a remarkable way, so too the spirit, clinging to the gold leaf, goes no further. [Margin: Diseases of the lungs.] Against diseases of the lungs, balsam of sulphur itself, or the flowers, or what they call the "butter" of sulphur, have a wonderful power to purge the lungs, especially when these incline toward dropsy. [Margin: For peripneumonia.] Against peripneumonia it is most helpful if you dissolve into water, by distillation, half a pound of balm-water [aqua melissae] with one pound of tartar, together with red wine of better quality, mixing in juniper berries and chicory

flowers; take this daily in a dose of four drachms with a good strong wine. For the rest, see Paracelsus and Agricola [Georgius Agricola]. What I have written here was entrusted to me by the physicians in charge of the mines.

[Margin: Diet.]

CAPUT IV.

On the Remedies by which the malignant air in metallic tunnels is purged.

[Margin: By what means the air of the mine may be purged.] Nature has set two great obstacles in the way of men attaining the perfect happiness they desire from the longed-for treasures of the mountains — so that in this matter Nature seems to have shown herself not so much a Mother as a Stepmother. The first of these is the inexhaustible flood of standing waters, which, just as it obstructs the further working of the metallic veins, so too inflicts incredible damage on the mining enterprise. The second is the virulent and utterly deadly vapors or exhalations of the metallic veins, by which not only is the work hindered, but the workers or miners themselves are dealt — if not sudden death, then at least (as we showed in the preceding chapter) the inevitable kinds of exotic diseases — bringing great tragedy upon these wretched men. Of the first I will treat now, of that second discomfort of Nature later.

The question, then, is first this: By what art and industry can the virulent vapor and exhalation of the mines be purged, and the mine, together with the safety of the workers, be freed from so great a plague? [Margin: By what means the air of the mine may be purged.] There are those who think that this can first be done by a fire built of wholesome woods. But I judge that such a plan, far from supplying any remedy, would rather both smoke us out and, with the heat concentrated in such cramped quarters, open up greater dangers and a greater evil — indeed a nearer gate to death. They had perhaps read that Hippocrates freed whole cities from the plague by fires of wholesome woods set up through the streets and crossroads — which we too prescribed as possible in our *Treatise on the Plague* [Tractatus de Peste]; and so they thought the same could be done in the deepest places of the Earth. But it is one thing to use this method out in the great open sea of the external air, far and wide, and another within the closed-off bowels of the Earth, where it can in no way be done — as is plainly shown on two counts.

[Margin: Sealed vapors kill miners.] First: who does not know that fire in underground places, unless it is supplied with its own chimneys, cannot last? Or

that, if it is built near the door of a lower shaft-mouth, it fills everything with smoke, so that it brings the workers to the gates of death by suffocation by a far quicker route than even the most violent poisonous vapor? Fire cannot live without air; or, if it does not obtain sufficient air, it turns everything upside down with smoke, to the utter destruction of those laboring. Add to this that a pyre built in the hidden recesses of the Earth, so far from consuming the pestilential air, rather — by the violence of its heat — stirs up the exhalations and vapors that at first lay dormant within the receptacles of the matrices, and, rarefying them by sublimation, taints and infects the air throughout all the passages of the mines with its virulent power. Certain miners have experienced this evil to their own great harm: when, with their lamps lit, they drew near to places filled with sulphurous-bituminous vapors, the whole air present in the mines burst into flame and destroyed them, some suffocated, some burned up. The same has befallen some men who, while digging wells, were attacked by a similar vapor and in an instant were killed. So to build a pyre in the mines, so far is it from consuming the virulent air, that it rather increases it remarkably — driving out by the heat, from this metallic vein and that, still other and other exhalations.

[Margin: Bellows for purging underground air.] What remedy, then, is there against such great evils? I know that the air in mines is usually cleared by the aid of bellows. But unless this business is properly arranged, it will bring little improvement. For if external air is not drawn in from elsewhere, and the foul air is not driven out through some other unsealed opening, the same air must always remain, the air being now stagnant. I judge, therefore, that the air can be purged in two ways: either by means of bellows, or without any use of bellows at all. Before I show this, I would have the reader know that air is so constituted by Nature that, although air rushing from one place to another underground place can be admitted, nevertheless, unless this foul air has another place into which to withdraw, the other, external air can never be admitted — but if it has found such a place, then by withdrawing it at once yields room to the external air. This could be confirmed by countless experiments, if it were not commonly known to all. So that the air may be driven out, it is necessary that it have two openings: one through which fresh air is blown in from outside, the other through which it is blown out. This being so, you could arrange a machine of the following kind in the mines.

Diagram. A mine-ventilation machine built around a sealed wooden chest fitted with a large pair of bellows, driven by a water-wheel and worked by a man pulling on a lever. The chest sits on the ground; above it rise tall vertical posts that carry the bellows-frame and a pivoting beam. To the right, a large spoked

water-wheel turns a crank linked by jointed rods to the bellows. Below, a man braces himself and pulls down on a rope attached to the lever to work the apparatus. A curved spout (apparently a water-conduit feeding the wheel) is shown at upper right.

- N (top, left post): left upright supporting the bellows-frame
- I (top, right post): right upright supporting the bellows-frame [reading "I" / "Io"; the printed letter is set apart from the post]
- E (middle, on the bellows): the bellows themselves
- F (with E, bellows): the pair of bellows EF, sized to the chest
- A (lower left of the chest): one corner of the sealed wooden chest ABCD
- B (bottom left of the chest): lower corner of the chest
- C (right side, upper): point on the wheel-driven mechanism
- D (right side, lower): point on the wheel-driven mechanism

The accompanying text (printed beneath the figure) explains the construction:

Let a chest ABCD be made of the most solid wood, ample in proportion to the size of the bellows EF, so completely closed on every side that it admits not even the smallest particle of foul air. Into this chest let a tunnel, or channel N, be led, implanted into the chest at point G; then another channel from the side of the mountain at point V, which is likewise implanted into the wind-chest [cista Anemica] or bellows-box [ventosa] ABCD. Then let the bellows be raised by a man appointed to that duty, by the device the figure shows; and it will come about that, when either bellows is raised, the external air, through the channel —

[Margin: The mechanism by which the air of the mines is purged.] — N G — is drawn in and insinuates itself into the chest ABCD; but when either is pressed down, the air is expelled outward through the channel or tunnel EV. In this way the mine will always obtain fresh air, both for the cooling of the workers and for the dispersing of the malignant vapor. And if you wish to draw it off into other parts of the mine-workings as well, through their own air-holes, you can do so very easily by means of new channels directed from the chest to the various tunnels. This machine can also be driven by a tread-wheel [per totam], if there is a supply of falling water at hand.

Note here, however, that the bellows must be tightly joined at their base, so as to hold the air drawn in through the valves [affaria] — commonly called *ventilia* or *animellae*, which the Greeks call ἀνεμοτρόχλεις [Greek: ἀνεμοτρόχλεις (anemotrochleis, "wind-pulleys," air-valves)]. These are so set into the base of the bellows that, when one bellows is raised, the valve opens, and when the bellows

is pressed down, it closes. The chest, moreover, should be divided inside by a partition, so that the air drawn in by one bellows is not driven back by the other, but each one drives its air into a receptacle proper to it, from which it is then driven through the channel into the tunnel. But I leave these details to be put into execution by an ingenious craftsman.

[Margin: A second hydraulic machine.] The second method is this. If you find a stream in some mine, you can by its aid correct the malignity of the air in a better way, as follows:

In a chosen and suitably proportioned spot in the mine, let a chamber ABCD of whatever size be made, as appears in the second figure. Within —

Diagram. The second machine: a sealed vault-like chamber fed by a stream through an overhead channel, with the intrushing water striking a grated surface to drive air out through side conduits. A dome-shaped chamber (the "second figure") has, at its top, a channel through which a stream pours in; the water falls onto a slatted rock-surface inside the vault, throwing up spray. Tapering conduits (drawn like the necks of bellows) branch off to either side near the top.

- F (upper left): left side-conduit leading off from the chamber
- A (top center): apex of the chamber / inlet region, ABCD
- G (upper right): right side-conduit leading off from the chamber
- K (just below the inlet): the channel through which the stream is led in
- S (inside, lower left): point on the slatted rock-surface ST where the water strikes
- T (inside, lower right): point on the slatted rock-surface ST
- B (bottom left): lower corner of the chamber
- C (bottom right): lower corner of the chamber

— within this cavity, under a higher vault, let a stream be led down through the channel K (for we assume the stream flows from a higher place). The stream thus diverted through the channel K runs down to the rocky surface ST — from which it is distant by only two palms — and, plunging headlong with great force in the manner of a cataract, it likewise stirs up a mighty wind. This wind, unable to be contained, escapes through whatever door is open, through the channels EG, and fills the mine with fresh air; and it so disperses the virulent vapor that it can no longer do any harm. And this method is so much the more refined as it breathes out a greater supply of the most humid wind. There is this further advantage: that just as the stream is perpetual, so the wind too is perpetual, and the whole operation is carried on day and night without any man's labor. Yet, lest in time

the chamber be filled with water, let a stopcock [epistomium] C be placed in the side, through which as much water can pass out as comes in.

[Margin: Wind necessary for purging the air.] [Margin: The third method of purging the air.] The third method, without bellows or any other instruments, could be set up in this way, through the tunnels alone: namely, if on the western or eastern side, or some other place, caves AB are made, whose openings face out on the external surface of the mountain toward whatever wind the mountain is chiefly exposed to. For when the wind blows — let us say, for example, the east wind — the wind, entering opening A, will not —

Diagram. A cross-section of a mountain (drawn like a low mound or hill) pierced by a tunnel running through it, with a wind-opening at each end. Within the body of the mound, a winding passage connects the two openings; small trees are drawn on the crest of the mountain above. A pleated, bellows-like mouth is shown at each opening, A on the left and B on the right.

- A (left opening): the western (or windward) cave-mouth
- B (right opening): the eastern (or leeward) cave-mouth

— the wind, entering opening A, will not rest nor stop until it goes out through opening B on the opposite side, even one several miles distant. And in this way the mines would enjoy a perpetual wind of their own, by reason of the continuity of the tunnels from one opening to the other, to make the cleansing of the foul air. For the wind, once it finds an exit, will not rest, but will keep the air in continual motion by its blast; and once the air is set in motion, the venomous vapor, being thereby dispersed, cannot persist. Just as the Wind, among its chief offices, is for this very purpose appointed by Nature — to purge and disperse the air tainted with pestilential exhalations — so too in the innermost bowels of the Earth, if a wind can be admitted to ventilate the mines, the air must certainly be made better. Hence, in manifold ways and by various means, ventilation-shafts could be set up, which, set in motion by the wind through external openings — especially if it passes through narrow channels — could render the air thoroughly purified by cold. [Margin: In watery places where there are underground cataracts, the air is wonderfully purged.] For where it is cold, there the retracted vapors cannot find room for their own expansion. Hence, for the same reason, wherever cataracts of subterranean waters are found, there no one need fear noxious air. [Margin: Dry places are more dangerous.] In dry and hot mines, therefore, the greatest danger threatens the miners — though, if they are cooled by the methods described, they will then render it tolerable, to the great benefit and advantage of the miners.

CAPUT V.

On the manner of draining off the flood of waters that are a great hindrance to miners.

[Margin: A different method is suggested.] As the other curb that Nature seems to have set upon the avarice of mortals — so that they may not penetrate to the inmost treasure-houses of gold, silver, and the other minerals — there is the flood of standing waters in the underground mines; and this is the more destructive the greater the obstacles that arise in draining it. The first is the depth of the waters: if you have drained these with buckets [antleae] or leather sacks, you can scarcely see, without digging a new channel, where to divert it to. The second is the narrowness of the places, which hinders the whole arrangement of hydraulic machines; and since these are for the most part fitted out with iron, the acrimony of the mineral waters at once sets an obstacle to them — by which, in a short time, the iron tools are not only eaten away but pass into scoria, with the dissolution of the whole machine. Agricola, in *De re metallica*, Book 4, proposes various instruments and hydraulic machines; yet scarcely any of them are of use in those great cramped recesses of the mines, on account of the laborious nature of their construction. For just as they are built at enormous expense, so too — both on account of the iron chains, iron buckets, and iron poles by which they are worked, and on account of the acrimony of the mineral waters and the corrosiveness of the salts — they cannot last long. Add to this the narrowness of the places, which cannot be widened to make room for the machines without great expense; nor can the buckets, which they mostly use, last — for of whatever metal they are at last made, the mineral waters are always hostile to them, gnawing into them so long that they are consumed either by verdigris [aerugo] or by rust [rubigo].

[Margin: Instruments made of metal cannot last long.] Hence one would have to build them of pure wood, or of bricks baked of clay, so that, thus constructed, they might stand fast. Vitriolic waters, wherever they find iron, bronze, or copper, at once cling to it and do not cease to gnaw it by adhesion of corpuscles down to the very last bit of scoria. Nitrous waters, on the other hand, as soon as they come to rest, so coat the matrix and the cylinder of the buckets with a stone-forming juice [lapidifico succo] that they can scarcely be drawn out any longer.

[Margin: Various hindrances.] There is yet another hindrance: that after the water has been drained, either a new channel must be dug to divert it outside, or it must be drawn up through the shaft of the mine in leather buckets, as is

sometimes done — but not even so can any great benefit be expected, since the pits are usually filled from hidden springs, so that however much water you draw out, just as much new water flows into the pit from the springs. It also happens that the leather sacks or bags are mostly burst by the weight of the metallic waters. Wherever you turn, then, you always find one hindrance after another. Yet stubborn labor, as it conquers all things, so too — whether by blocking the veins, or by other means and methods — at last throws the reins upon reluctant Nature, so as to attain its purpose. In Hungary, as is written to me, it is carried out with buckets and leather sacks.

[Margin: A different method is suggested.] One thing remains, by which, in my own slender judgment, I think the matter cannot be better managed: namely, if the depth of the pits, together with the height of the shaft by which the descent into the mine is made, are first measured by the level [*ad libellam*], with regard to the external slope of the mountain. So, if the pit is higher, or deeper, or equal to some level field, then indeed you waste oil and labor in trying to divert the waters out of the pit elsewhere, and no other counsel remains but to draw it out through the mouth of the shaft. But if the level of the plain or valley is deeper, then you will have hope of drawing off the water by a channel deliberately made. As for those who think the business can be done by the suction or pull of hydraulic machines — they, relying only on speculations grounded in metaphysics, suppose the matter can be managed: but once they have drawn the water into some receptacle, where will they divert it to? The custom and habit introduced by long usage in the various metal-mines of Europe must therefore be abandoned; for since human ingenuity is sharpened daily, most of all toward inventing something to relieve necessities of this kind, yet so far nothing has been found that fully satisfies the wishes of metallurgists — apart from the instruments and machines we have mentioned. Certainly these are to be employed until God, the Best and Greatest, inspires something else, by which the matter may obtain the desired outcome.

[Margin: How the corrosion of the waters may be prevented.] And let this much be said about those waters which are collected in the bowels of the mines and, for the reasons stated, have no outlet. But if those waters could conveniently be diverted to the lower mouth of the shaft, then with greater convenience they could be led out by the instruments which Agricola prescribes in Book 4. But lest the chains and tools of the machines be consumed by the corrosiveness of the mineral waters, if they are well smeared with oil extracted from lead [*oleo ex plumbo extracto*], they could endure against all consumption. For there is nothing in the nature of things that keeps tools — even when submerged in

seawater — freer from all corrosion and rust than the said oil. But since a greater quantity of this oil is needed to coat so many chains and tools than the expense would bear, this too presents no small difficulty for getting the business done.

And these are the hindrances which [render] subterranean metallurgy, together with a notable and ir-[reparable]...

with notable and irreparable damage. These are: the dryness and the dampness of the mines and tunnels. [Margin: Drawbacks of mines.] Dryness, arising from heat and consequently from the most virulent exhalations, brings great ruin upon the miners. Dampness, by contrast, blocks the veins in the inaccessible parts of the mines, unless it is drained off by the usual industry with a crowded force of workmen. For where the dampness of the waters prevails, the workmen cannot remain there without harm. Cold, however, is in some measure beneficial: by it, just as by the stirring of the waters, all the malignancy of the mineral vapor is driven off — unless the waters, having stood motionless and stagnant for a long time, have drawn a film [cutis] over themselves from the poisonous exhalation. Even these, though, do little harm, provided that the waters, once driven off by that very agitation, have withdrawn elsewhere. For it sometimes happens in pits of this kind that a venomous vapor, stirred up even by the mere throwing of a stone, brings irremediable harm to those standing nearby.

CAPUT VI.

On the manifold courses of the mineral veins and fibers. [De multiplicibus Venarum fibrarumque mineralium ductibus.]

Now that I have set out the hindrances and obstacles by which the hoped-for profit and effort of the men who work the metals is frustrated, nothing remains but to insinuate ourselves more deeply still and to examine the recesses and wombs of the buried minerals, those chambers dedicated to their conception and birth — what Pliny [Plinius], Dioscorides [Dioscorides], Vitruvius [Vitruvius], Albertus [Albertus Magnus], and Agricola call "veins," following that line of Ovid [Ovidius]:

Now too, from the seed once received in the old days, the veins stiffen,
fields strong with their soaking clods.

[Margin: What mineral veins are, properly speaking.] The veins of minerals or metals are nothing other than certain vessels or receptacles of the matter that

they conceive for the formation of the minerals — like a mother's womb for the propagation of its offspring — the comparison being borrowed from the veins of living creatures. For just as those veins are distributed to the individual limbs, and through them the blood is spread from the liver into a man's whole body, so these mineral veins are dispersed both throughout the entire globe of the Earth, and especially through mountainous regions, by the waters flowing and streaming through them. [Margin: What the venules and fibers are.] Moreover, just as each individual vein has its own connected brood of smaller veins (which they call "capillaries"), so too the metallic vein has venules attached to it, sprung from the joints of the rocky mineral matter, which they also call "fibers" — although these supply the moisture in the contrary direction. The veins of the human body discharge the blood into the capillary venules; conversely, the metallic venules diffuse the moisture they have received into the larger veins. On this, see Seneca [Seneca], *Natural Questions* III.15, where he describes this analogy of the veins no less elegantly than learnedly. [Margin: They are compared to a branching tree.] If anyone considers more closely the fibers of the veins and venules, he will behold, within the joints of the rocks, an image not unlike that of a perfectly formed tree divided into its various branches.

Diagram. An engraved landscape plate showing, in cutaway cross-section, the interior of a large mountain (with a coastline, sailing ships at sea on the right, and scattered trees over the surrounding terrain), exposing the network of metallic veins running through the rock. A banner cartouche at the top center carries the title. Each vein is labeled with the type of vein it illustrates (corresponding to the categories discussed in the preceding and following chapters: deep, dilated, low, oblique, curved, transverse, etc.).

- Cartouche (top center): *TYPUS VENARUM Metallicarum in Fodinis* — "Type [Diagram] of the metallic veins in mines"
- Upper vertical vein (center): *Profunda* — "deep [vein]"
- Diagonal vein (upper left): *Vena obliqua* — "oblique vein"
- Vein near top right of the cutaway: *Vena curva* [?] — "curved vein"
- Horizontal vein (mid-level, left): *Intervenium* — "intervein" (the rock lying between two veins)
- Long horizontal vein across the middle: *Vena dilatata* — "dilated vein" (appears twice, left and right)
- Lower horizontal vein (left): *Vena humilis* — "low vein"
- Several short veins labeled simply *Vena* — "vein"

(Fol. 179 — recto)

others are dilated, others heaped up [cumulatae]. A "deep" vein descends from the topmost surface of the Earth into its lowest depth. A "dilated" vein is, as it were, a middle thing between the surface of the Earth and its hidden depth below ground, and it spreads itself out over much space. [Margin: What an intervein is?] One that occupies a large part of some place, drawn out in length and breadth, is called "heaped up" [cumulata]; and what lies in the middle between two veins is called an "intervein" [intervenium]. Again, among the deep veins some are one pace wide, others two cubits, some one cubit, others a foot — all of which the metallurgists call "wide," and which in some places sometimes extend even to twelve paces. Some, again, are only a palm wide, others three fingers, others two, which they call "narrow."

[Margin: Dilated vein.] The dilated veins differ among themselves in height: for some are one pace high, or two, or more; some a cubit, some a foot, some a half-foot [semissem] — all of which they call "high"; while those they call "low" are a palm, or three fingers, or two, or one, as appears in the figure. These in turn are variously divided, so that some are straight, others curved, some oblique and twisted, others transverse and circular. The differences of all these we display here in a diagram, to spare a longer description. [Margin: Vein shapes.] What the metallurgists call the "end," the "head," and the "tail" of the veins is, as is generally known, in no need of further explanation.

[Margin: Naming of veins from the regions of the world.] The differences of veins are taken, besides, from the situation of the parts of the world: thus some extend from East to West, some on the contrary from West to East, some from South to North, and on the contrary from North to South, while others, finally, keep to the intermediate quarters of the cardinal points — those that take their beginning from the joints of the rocks. So, for example, if veins slope toward the west into the depths, the vein is said to extend from East to West, and so on for the rest. Yet these differ greatly among themselves, since some descend from the very summit of the mountain down the slope into the valley, while others on the contrary ascend. See all of this treated more fully in Agricola.

CAPUT VII.

METALLOGNOMIA, OR On the signs of the hidden metal, and by what art the veins of the metals are recognized. [De signis metalli latentis, & qua arte Metallorum venae cognoscantur.]

As this is a matter of shrewd intellect to discuss, so too it must be handled with a correspondingly trained mind. [Margin: How the veins of mineral ores are recognized.] The treasures of the hidden metals, then, are discovered in various ways. I call them "treasures," because whatever pertains to the preservation of the human race — both to splendor and magnificence and to the use of necessities — derives its origin from the subterranean storehouses [gazophylacia], as I have pursued more fully elsewhere. But now let me take up the thread of my plan.

The subterranean veins of the metals become known in three ways: by a natural means, by an artificial means, and by chance. By a natural means: first, through metallic vapors and exhalations; second, through the disposition of mountains, plants, and trees upon them; third, through the uncovering of veins by the runoff of rains and torrents; fourth, through rivers, which most often carry along with them filings of metals scraped off the veins. By an artificial means: through the distillation — performed in the chemical manner — of mineral waters and of the mud of rivers and lakes; and second, through the divining rod [virgula divinatoria], of which a little later. By chance: through the uprooting of trees and the burning of forests; through the violence of a river falling and splitting the rocks; second, through the breaking up of plowland by the plow and its furrows; third, by the help of horses, pigs, and boars digging in the earth; fourth, through vine leaves, which the gold-bearing spirits tint to a golden color, as is very often found in Hungary.

These things now set out, let me continue my web. The signs, then, by which the metallic veins are detected are the following — drawn partly from Agricola and Cardano [Cardanus = Girolamo Cardano], partly known from my own experience.

I say first: the metallic veins are sometimes opened by some force (which you may prefer to call chance or fortune — it comes to the same thing), without human industry or labor, and in more than one way:

1. [Margin: Force of a torrent.] The rush of a torrent strips them bare, as once happened in the silver mines of Freiberg [Fribergi Argentariis — Freiberg in Saxony].
2. [Margin: Force of the winds.] The force of the winds, drawing up and uprooting trees that have grown above the veins.
3. [Margin: Breaking off of rock.] The breaking off of a rock from a mountain. This is caused either by long and heavy rain, or by an earthquake, or by a lightning-stroke, or by the violent rolling-down of snow, or by the rush of the winds. Virgil [Vergilius], *Aeneid* XII:

And as when a rock on a mountain top, headlong, is torn loose by the wind, or when a turbid rainstorm washes it down, or the creeping age of years undermines it.

4. [Margin: Plowshare.] The plow uncovers veins: for Diodorus Siculus [Diodorus Siculus] records that in Galicia [Galecia — Galicia in Spain] clods of gold were cut up by the plowshare. Hence Lucretius [Lucretius], *On the Nature of Things* V:

What is left — bronze and gold and iron were discovered, and also the weight of silver and the power of lead, when fire had consumed the vast forests with its blaze on the great mountains, whether sent down by a bolt of heaven...

5. [Margin: Burning of forests.] The burning of forests reveals the metals — which, as Diodorus Siculus writes, happened in the silver-bearing regions of Spain. (continued)

(Fol. 180 — verso)

...or because, waging savage war among themselves, they had brought it upon their enemies to inspire terror; or because, drawn on by the goodness of the soil, they wished to open up rich fields and turn the land into pasture; or to kill wild beasts and grow rich on the prey. For hunting by pit and fire arose earlier than fencing the glade with nets and rousing it with hounds. Whatever it was, from whatever cause the fiery blaze had felled the forests with a horrible roar down to their roots, and had scorched the earth with fire, the silver and gold flowed from the seething veins into hollows of the Earth, converging there, and a stream of bronze likewise, and of lead.

6. [Margin: Another force, that of a horse's hoof.] Finally, some other force lays a vein bare. For a horse (if this account is to be believed) opened up a lead vein at Goslar [Goselariae — Goslar in the Harz] with its hoof. By these means, then, fortune bestows the veins upon us.

I say secondly: the hidden veins of the minerals can be investigated by human art, in the ways that follow. [Margin: The veins of the minerals are investigated by human means.]

1. [Margin: From the welling of springs.] The bubbling springs are to be observed, which cannot lie far from the veins, since their water flows out of the veins themselves.
2. [Margin: From fragments of the veins.] The fragments of veins are to be examined which a torrent has dug up out of the earth — for the long passage of time again buries some part of them under the soil. But if such fragments have lain upon the surface, or are light, the veins are generally rather far from them, because the torrent has snatched the dislodged pieces far from the veins and, by driving them along, has made them light; whereas if they are fixed in the earth, or are rough, the proper veins are close at hand.
3. [Margin: Situation.] The situation is also to be considered; for it determines whether the veins are buried more or less deeply by the earth, and whether the fragments are pushed far or less far.
4. [Margin: Frosts.] The frosts are to be observed, by which all the plants turn white, except those that grow above the veins. For because the veins breathe out a dry and warm exhalation, they prevent the formation of frost; therefore, at any spot where the moist plants do not freeze into frost, there is a vein beneath. And if it breathes out something very hot, that ground bears low plants of a somewhat sickly color.
5. [Margin: Leaves of trees.] It is an indication of a hidden vein if in springtime the leaves of trees are livid or bluish; if the branches, especially the upper ones, are tinged with blackness or some other unnatural color; if the trunks are forked, if the branches are black or discolored. For the warm and dry exhalations of the veins produce these effects: they do not even spare the roots of the trees, but, scorching them, render them altogether feeble. For this reason the force of the winds more frequently brings down trees of this kind than the rest.

6. [Margin: Summit of the mountains.] Mountain peaks that face south, with their roots looking toward the north, give an argument of metal — and especially of silver, whose more productive mines tend to run straight from East to West.
7. [Margin: Color of the mountains and stones.] The color of the mountains and of the stones and earth teaches not only that metals are present there but also which kind they are: green comes from copper [aere]; black from silver and gold; purple from pyrite; livid from lead and iron; sallow [luridus] from chalcantite [calchanto — copper sulfate] and similar juices of that sort; ashen and dark from sulfur.
8. [Margin: Smell of the stones.] The smell, too, can be reckoned among the signs of the veins: for when you have rubbed together two stones of the same mountain, if metal lies beneath the mountain, they smell strongly of sulfur.
9. [Margin: Barrenness of the mountains.] All barren mountains are metalliferous: for the moisture is consumed within, so that plants cannot be generated; and the evil exhalations rob even already-grown plants of their life.
10. [Margin: Weight of the stones.] When stones or earth are heavier than reason would require, that is a sure argument of metallic matter.
11. [Margin: Splendor of the stones.] If, too, stones shine excessively in any part, or, being solid, are not wholly without luster, you may know for certain that the matter of metal lies beneath.
12. [Margin: Melting of the stones.] If you melt the stones in fire, you will detect at once both that metal is present, and its kind, and its quantity.
13. [Margin: Smell and color of the waters.] Flowing waters, too, afford some slight conjecture of this, for if they present a foreign smell or color, you will pronounce without doubt that there is metal in the mountain.
14. [Margin: Bottom of the riverbed.] You will also diligently explore the bottom of the riverbed; for there you will find a portion of metal. For it can scarcely happen, over a long progress of time, with each day adding something, that from the sinking of the heavier part no trace of metal should appear.

15. [Margin: Clefts of the mountains.] Besides, the clefts of the mountains indicate the sharp exhalations of the metals.
16. [Margin: Which plants delight in metals.] In addition, there are plants — rare ones, indeed, but the rarer they are, the more evident the testimony they give of the metals if they are present — that take pleasure in the company of metals. Generally such are these: those that bear no fruit, or little; low juniper, ivy, the wild fig, and the wild pine [pinaster] too, and most of the thorny kinds. There are also trees whose leaves are pale or deciduous, with slender trunks, and everything about them withers.
17. [Margin: Peaks of the mountains.] From the peaks of the mountains, where for the most part vapors tend to breathe out, there are indications of the hidden metals.

To these, finally, we add the divining rod [Virgula Divinatoria], which the metallurgists generally use in prospecting for metals. The divining rod is forked, made from various trees or fruits according to the nature of the metals to be sought out. For most of the more superstitious sort suppose that the effect cannot follow unless it has been cut on Easter Sunday, or on the day of the solstice, or has grown above a vein; nor will the business have any success unless the prospector was born on a Sunday. But just as Nature has no need of these superstitious circumstances in order to act, so too they show of their own accord that the Master of this art was none other than Sa... (continued)

(Fol. 181 — recto)

tan, who busies himself, with the ultimate ruin of souls, to draw into his nets the men who are greedy for gold and riches beyond what is right. [Margin: Vanity of the divining rod.] Hence some construct different rods, each suited to testing out particular kinds of metal. In this way they use a hazel rod [Columna Virgula] for silver, an ash rod [Fraxinea] for bronze, a spruce rod [Piceastri] for lead, a stalk of woad [Isatis caule] for iron, and so on. Some even use magic mirrors, with the addition of incantatory chants, in detecting metallic veins. Hence this vanity, introduced by whatever means, is everywhere rejected by skilled and God-fearing men as a kind of magical illusion. For no reason can be given why a forked rod, held firmly by both horns — even with every magical agency excluded — should nevertheless sustain such violence from the metallic vapors that they drag it downward.

[Margin: Experiment.] Indeed I myself, often making the experiment of this matter over the metallic bodies of gold and silver, was always cheated of my hope. And I clearly perceived that it is a manifest illusion not of a demon but of the one handling the rod — who, deceived by the force of his imagination, thinks that the rod inclines toward the metal of its own accord, when he himself is unwittingly twisting it. The same thing happens, by the way, in the case of those who suspend a ring by a thread and let it down with two fingers inside a glass cup, supposing that the ring, striking the cup as it runs this way and that, marks out the hour. A thoroughly bad deception, since that whole striking comes about from nothing but the pulse of the veins quivering in the fingertips: for if you press the thread firmly, the ring will be set in motion; if gently, it will rest without movement. I demonstrated this fallacy to many men by no means unskilled in physical matters, in a certain academy which a certain Prince had set up here at Rome to discuss the prodigious motion of the ring of this kind. That prince was of the opinion that the several metals, suspended in the said manner and grasped by the fingertips, are directed toward fixed quarters of the world by a kind of magnetic force — so that iron points to the North, gold to the East, silver to the West, bronze to the South, and the rest to the other quarters; and he thought the same happened with precious stones. But the experiment was greeted with universal laughter, when the metals fastened to a thread were let down from a motionless crossbar of wood, or were held lightly grasped by a steady hand: for then they took up an indifferent position according to the twist of the thread. And so this whole business was a mere mockery of the imagination, in that what the pulse of the vein had set in motion, the man ascribed to a property of some hidden motion.

That the same thing holds true, then, of the divining rod, is certain. The reason it cannot be that latent metals impress such a great and so sudden a force upon a rod that is not balanced, but violently twisted, that it is compelled to incline of its own accord all the way to the ground — anyone who has had experience of magnetic motions will testify. For how great a genius and industry are required so that the sympathetic actions of natural things may have their effect, and with how exact and precise a balancing the bodies must be arranged, can scarcely be told. Accordingly, all are to be laughed at who imagine that those forked rods, grasped in the hands, can be set in motion by so subtle a force of exhalations.

Lest, therefore, I should seem to have condemned the divining rod without any benefit, I shall here prescribe another method, which, as I have found certain by manifold experience, so too I trust that all who use it will in no way be cheated of their purpose.

EXPERIMENT I.

Let there be made, from a fragment of rock salt [sal fossile], a little blade [lanceola] one palm long. Join it to any piece of wood in such a way that the wooden part, attached to the salt blade, may move freely in equilibrium, fixed upon a pivot [obelus], or even suspended by a thread. Set this wood-and-salt blade over a pot beneath which a fire has been placed, with salt water or brine [muria] boiling in it, and you will find that the volatile spirits, passing off into vapors, cling to the salt blade by magnetic influence, as to a body like themselves; whereupon the blade, weighed down by the salt particles, will gradually incline downward toward the pot. The same thing, I judge, can happen if a like instrument were set over a vein of salt.

Diagram. A woodcut illustrating Experiment I. At the base, a round-bellied pot stands on a grated hearth or firebox, with flames rising up around and beneath it; a dense cloud of vapor billows up from the mouth of the pot. Above, a horizontal balance-bar rests on a small upright pivot-stand; from the bar's near end hangs the little blade (the salt-and-wood *lanceola*), suspended over the rising vapor so that it can tilt downward as it absorbs the salt particles. No labels or caption are engraved on the figure.

EXPERIMENT II.

Let a little blade be made from wood and a fine golden wire [aurea virga subtili], joined into equilibrium as we said in the preceding experiment. Set this over a pot in which pure quicksilver [argenteum vivum] has been placed; and if you cause it to fly off by applying a fire beneath, you will find that the whole of the mercury joins itself to the golden wire; whereupon the golden rod, weighed down by it, will incline deeply. The same thing, if a golden rod were exposed over a vein of mercury, would happen, as I... (continued)

[Liber X, Sectio II, Caput VII "Metallognomia" — conclusion]

is to be judged. In the same way, if you grind a lump of silver to powder, place it in a pot, and let it heat up by fire, then set above it a small blade [lanceola] made of wood and silver: the blade will draw the tiny silver particles into itself by a kind of magnetic attraction. Weighed down by this, it will necessarily incline toward the place from which the vapor breathes out. The very same thing will happen to a rod held above ore that contains brass [aes], whether the vapor and exhalation of the ore is raised by an internal Vulcan [internal subterranean heat] or by the external heat of the Sun.

Consectarium [Corollary]

From all this it is clear that the hidden matrix [matrix] of everything that flows together to itself by a kind of sympathetic attraction can be tracked down by rods of this sort — provided the sympathetic rod has been constructed, in the manner described above, with another substance endowed with the corresponding power. In this way, a rod made from those materials that have an affinity with simple elemental spring water — such as alder [alnus], water lily [nymphaea], water mint [mentastrum aquaticum], buttercup [ranunculus], and the like — will, when its root or stalk has been joined by a rod to another, non-sympathetic substance (be it wood or metal), and when it is then set down over a spot where you suspect a hidden vein of water lies beneath: in time, weighed down by the watery vapor, it will incline of its own accord. And it will do so without any superstition whatsoever — solely by the magnetism it possesses [magnetismo] — and so reveal the latent vein of water. I would not say this if I had not learned it for certain by an experiment of my own.

Indeed, certain trees standing over metallic veins have taught the very same lesson: their leaves and branches, weighed down by the vapor and as if clothed in a kind of film [cuticula], bent downward, so that they almost touched the earth. This is also plainly seen in trees growing on riverbanks, whose branches in time incline of their own accord toward the surface of the water.

Experimentum III

That there is a remarkable sympathy between iron and vitriol [vitriolum] is well established, since vitriol clings eagerly to iron alone — as if rejecting all the other metals.

So let a rod be made of wood and iron, properly joined together. If you place vitriol in a pot and let it exhale by the action of fire — wonderful to say — the iron at once changes to a rust-brown color, turning into a dusky verdigris [aerugo], as if transformed into brass [aes]. Pressed down by the weight, the whole rod bends and tips into the pot. And these are the things I thought worth setting before the reader concerning the divining rod [virgula divinatoria].

SECTIO III. DE FODINARUM METALLICARUM NATURA, Proprietate, variis accidentibus, varia ad Authorem Responsa.

[SECTION III. On the nature of metallic mines, their properties, their various accidents, and the various Responses addressed to the Author.]

Praefatio [Preface]

As I devoted the utmost care to this work, a great many difficulties arose, and I could scarcely extricate myself from their labyrinth. I therefore decided to consult the metallurgists of the Hungarian mines. (There are none more famous in Europe; and if anywhere on earth Nature lays out her riches and her playful industry above all, it is surely here.) So it seemed best to send off letters without delay, in which I gathered into nineteen propositions the various questions [dubia] occurring to me about metallic matters. But since none of the men in charge of the mines was known to me, I made use of the help of our Fathers at Neusohl [Neosolium; Banská Bystrica] and the neighboring Hungarian mining towns — above all the services of Father Andreas Schaffer. As he was no novice in the metallurgical art, so too he acted with incredible care, diligence, and solicitude in advancing the undertaking I had begun. Together with Father Georgius Weber, the Superior of the Residence at Neusohl, he warmly embraced it, sought out whatever he judged necessary for my purpose, and did so much with the directors of the mines (with whom he had long been on the closest terms) that they too promised to contribute their own share to advancing the work. To each of the directors of the Hungarian mines he handed over a copy of my questions, so that they might send their written replies here to Rome...

and so it was done. The names of those who replied to the nineteen points sent to them will be given below. But so that a later age may come to know the trustworthiness and diligence of these men, I have judged it right to present their Replies here in exactly the order in which they stand in the original manuscripts, with equal candor and sincerity, translated out of German into the Latin tongue.

RELATIO I.

De Fodinis Hungariae rebusque memorabilibus, quae in iis occurrunt.

[ACCOUNT I. On the mines of Hungary and the memorable things that occur in them.]

CAPUT I.

Responsio Schemniziana ad novendecim puncta ab Authore iis proposita.

[The Schemnitz [Schemnitz; Banská Štiavnica] Reply to the nineteen points proposed to them by the Author.]

Praefatiuncula [A Little Preface]

Whereas the Reverend Father Athanasius Kircher, Priest of the Society of Jesus, has — through the Reverend Father Andreas Schaffer of the same Society — earnestly requested that some information be given to him concerning nineteen points touching the condition of metals and minerals, as well as the constitution of the mines in these parts: We the undersigned — the prefects of metallic affairs, the sworn officials [Jurati], and the rest of the officers, administrators, and inspectors of the mountain mines — in obedience to his request, held a council at Schemnitz, a town of Lower Hungary, and deliberating upon the aforesaid points, now at last answer each of the doubts put to us, as follows.

To the First. *On the properties of mineral waters and certain metallic experiments.*

1. Reply 1. The waters that the miners [fossiores] meet at the start are for the most part tasteless, clear, odorless, light, and cold; but as one goes deeper they grow warmer, heavier, and more turbid, according as they are tinged or altered by the metallic juices. Some are white, some red, some green, some blue, some black; they have a certain definite odor, and while they are mineral-bearing they take on a sharp taste, so that fish cannot live in them.
2. When water stands motionless for a long time in the mines, there is generated on its surface a kind of mineral mist [nebula mineralis] resembling a film (in German, *Bergschwaden* [mine-damp]), which — if stirred up and drawn in by breathing — brings instant death. Waters of foul odor and taste are also found, which nonetheless do no harm. There is also a kind of water found there which degenerates into a shape not unlike sugar, namely into little white pebbles. As for the other intrinsic properties of the waters, the miners do not know them, and leave them to be investigated by the chemists and physicians. Experience does indeed teach that three miles [milliaribus] from Schemnitz a certain mineral water is found which gives goiters [strumae] to those who drink it, and that, on the contrary, six miles from here there is another water which, drunk, removes the goiters contracted from the said water.

[Margin: *Mira antipathia aquarum* — The remarkable antipathy of the waters.]

To the 2nd. *On the metallic efflorescences in little tree-like forms, and from which salts, vitriol, etc., they grow.*

Reply 1. Sometimes there are found in the mines crystals wound about with silver threads as fine as hairs, and other like things. In recent years a grain of pure, sheer silver was found (in German, *gediegen* [native]) inside a "foolish stone" [lapis fatuus] (in German, *Taubenstein*), in a kind of white chalk-like material called "stone marrow" [medulla lapidea], as if it had been deliberately hidden there; it weighed two pounds. There is another species of these growths, which in Latin sounds as *vestigium* [footprint] (in German, *Blackmahl* [?]). This clings to the foolish stones, pure and sheer, so that it can be cut with iron like lead. Such growths become volatile in a strong fire; and when such things are found in the mines, they take away from the miners the hope of brass [aes], because they hold it as an omen that, where they are found, they take away the brass where there is brass, but where there is no brass, they produce it there. From which salt or vitriol they are born, the mineral miners do not know.

To the 3rd. *Which mineral bodies above all are found in the mines of gold and silver, copper, tin, lead — and whether quicksilver and sulphur are everywhere found; how the sympathy and antipathy of metals is to be recognized?*

At Schemnitz [Schemnitz; Banská Štiavnica] there is most often found a vein of silver that contains a little gold. There are also found veins of silver containing copper or lead; ordinarily, the further north the silver veins run, the more lead they contain. In the valley of Hodritsch [Hodruša], in the deeper parts, gold and silver ore is found; but toward the summit, marcasite [marcasita] and iron without gold or silver. The vein of iron is twofold: one which...

serves for flux [fluxus] or fusion, similar in kind to the other, from which iron is smelted out. It is to be noted that some years ago a lodestone [lapis magnes] was found in the Ruda vein, from which several hundredweight [centonum centenaria] of iron were extracted. Again, the Schemnitz silver veins, mostly mixed with lead, contain no little antimony [antimonium], and also cinnabar [cinnabaris]; and sometimes there occurs a mineral cinnabar not unlike red lead [minium], containing silver. For this reason, since such minerals, when roasted and melted, give off a sulphurous or mercurial odor, it is altogether believed that there is [quicksilver and sulphur] there — even if quicksilver and sulphur are not present there in actuality, they are nonetheless present in potency, or have some analogy with those substances.

Likewise there is a certain mineral, which in German sounds as *Gleiss* [?], which promotes flux or fusion in the minerals, and in melting draws gold along with the silver. On the other hand, the vein of lead is rapacious and predatory. And there is another kind of marcasite [marcasita], frequent in the silver veins, which is sometimes empty of silver and sometimes mixed with silver. Where this is found, the miners reckon by augury that, where there are no brass ores, the same will be engendered there, but where they are, they will be corrupted. Green or yellow stones signify veins of gold and silver.

To the 4th. *By what machines do they drain off the subterranean water?* — On this Georgius Agricola [Georgius Agricola] answers in *De re metallica*, Book 6, etc.

To the 5th. *How do they resist the pestilent air [aura pestifera] produced by the metallic spirits?* — He replies: by air-shafts [spiracula] and bellows [folles], as above.

To the 6th. *Whether little demons [Daemunculi] or pygmies [pigmaei] appear underground?* — He replies in the affirmative, and recounts many examples.

To the 7th, 8th, 9th. *Whether they encounter certain animals which cannot be seen to live below the earth; and whether the miners experience storms, lightning-flashes [selaura? — read as fulgura], thunderclaps, lightning, earthquakes, and the like, just as with subterranean rivers and springs, etc.?* — He replies that at Schemnitz none of these things is found or experienced.

To the 10th. *Finally, that all the miracles of Nature should be noted.* — Reply: To describe the miracles of Nature briefly is impossible; we ought rather to marvel at the Creator's power and wisdom than to penetrate the nature of each single thing.

To the 11th. *On the heat and cold of the mines — in which parts they most prevail; whether the deeper they are, the hotter; and whether subterranean fires are seen?* — He replies that in those veins no excessive heat or cold is felt, unless the free passage of air is blocked; in which case the workings [fossae] are always hotter, until once again they enjoy free ventilation through the air-shafts.

To the 12th. *On the subterranean winds — whether their eruption takes place through the cracks of the workings; on the constitution of the subterranean air and its purification.* — He replies that winds are not felt in the mines, but rather foul vapors, which (as related above) are driven out by air-shafts and bellows.

To the 13th. *On subterranean earthquakes, etc.* — Reply: nothing of the kind has ever happened at Schemnitz.

To the 14th. *On the subterranean waters — whether they come upon subterranean streams and springs of sweet, nitrous, vitriolic waters, etc.* — He replies that in some places there is always found a very great flood-mass [colluvies] of waters.

To the 15th. *On the courses of the metallic veins — which part of the world they chiefly face, and whether the iron vein faces the north, etc.* — He replies that the courses of the metals never face one single direction, but now toward this one, then toward that, etc.

To the 16th. *On the sympathy and antipathy of metals and of the other minerals, etc.* — He replies that the miners do not know of these things.

To the 17th. *What is the method of separating the metals, etc.* — He replies: by handing them over to the separators [separatores], etc.

To the 18th. *What signs they have for recognizing veins of gold and silver, etc.* — Reply: it is impossible to describe the signs briefly, since each single metal has its own proper stone; this must be learned by long experience. The most certain assay, however, is the one performed by fire.

To the 19th. *Let the places be named in which, and from which, minerals are dug out. Likewise on the thermal baths [Thermae], the acidulous springs [acidulae], and how great is the depth of the mines.* — He replies: at Cremnitz [Cremnitium; Kremnica] there are veins of gold, and not far from there is a vein of quicksilver. At Schemnitz there are veins of silver, iron, lead, copper, etc. At Neusohl [Neosolium; Banská Bystrica] there is a vein of copper. At Püggantium [Pukanec? [?]] there is a vein of gold. At Königsberg [Regius mons; Nová Baňa] and Dülle [Dülle [?]] a vein of gold. At Libethen [Lubethan; Ľubietová] a vein of iron and copper. At Waze [Vaze [?]] and on the Angelic Mountain [mons Angelicus] there is a vein of gold.

There are two thermal springs near Schemnitz; where the water of these baths passes, it deposits a sediment which in time turns into a yellow stone. Near Cremnitz two thermal springs are found. Two miles from Schemnitz, beyond the river Gran [flumen Granum; Hron], near the village of Bukowina, two acidulous springs are found. Near Cremnitz too there are acidulous springs.

The greatest depth of the mines is 150 *Klafter* [fathoms] — that is, of ulnae [ulnarum; cubits].

Ita testantur [Thus they testify].

Ioannes Georgius Weiss, Prefect of the Mines. Iulius von Lansee, Sworn Officer of the Mine Accounts. Elias Angerman, Sworn Officer of Metallic Affairs. Ioannes Zuterig [Zuterig [?]], Scribe of the Mines. Andreas Ungedeu [?], Michael Reuter, Georgius Ulricus Kaiser, Ioannes Henricus, Martinus Sepp, Michael Korch — Inspectors of metallic affairs.

RELATIO II.

Responsio ad Quaestiones propositas, Joannis Schapelmanni, S. Caes. Regiaeque Majestatis, Minerarum cuprearum praefecti in Herrengrundt in Hungaria.

[ACCOUNT II. The Reply to the questions proposed, of Johann Schapelmann, prefect of the copper mines of His Sacred Imperial and Royal Majesty at Herrengrund [Herrengrundt; Špania Dolina] in Hungary.]

CAPUT II.

First Question. *On the properties of mineral waters, and on certain metallic experiments.*

Reply. Among us at Neusohl there is found a kind of vitriolated water [aqua vitriolata], in which iron is transmuted into copper. Each year they make 50 or 60 hundredweight [Centones] — that is, about five or six thousand pounds of copper. This vitriolated water is sharpened with the salt of vitriol [sal vitrioli]; and vitriol is nothing other than the white salt of the earth. This salt is dissolved by moisture; then, passing through the copper ores, it dissolves them and thereby acquires a green color. But if it passes through black copper ore that contains silver, then it is colored blue. All the other metals were placed in this water, but it touches none except iron, which it first turns into the finest powder and at last changes into the best copper — as if it had been deliberately melted in fire and cast into a definite shape.

There also bursts forth from the hardest rocks a certain mineral water which deposits a yellow sediment; but what its material may be, and of what virtue, has so far been unknown. There is also found a certain white water which turns into a hard stone. But if this water, before its coagulation, has passed through copper ore, then there is generated from it a stone called malachite [Malochites]. And when that water flows through copper ore containing silver, there is made from it a beautiful blue stone, like turquoise [Turcois]. This water, however, is nowhere

found more frequently than in mines abounding in flinty stones [lapides silicei] that contain copper together with silver.

2. On the metallic efflorescences in little tree-like forms, and from which salts, vitriol, and the like they draw their origin.

Reply. There are sometimes found in this ore copper efflorescences [efflorescentiae cupreae] of pure, sheer copper (in German, *gediegen* [native]), like the flowers, herbs, etc. mentioned above.

3. Which mineral bodies above all are found in the mines of gold and silver, copper, tin, lead; whether quicksilver and sulphur are everywhere found; how the sympathy and antipathy of metals is recognized.

For the most part there is found in the metallic mines, almost everywhere, marcasite [marcasita], in which sulphur is present. But quicksilver — sometimes in cinnabar [cinabria] — is found at least only in the mines of silver and gold; because quicksilver, or cinnabar, has its own proper ore. Among us at Herrengrund, quicksilver is not found in the copper mines.

4. By what machines do they drain off the subterranean water? — He answers: by suction-pumps [antliae], leather sacks, and the like.

5. How do they proceed against the pestilent air, and how do they remove it in the mines? — When the mines are deep, so that good air cannot be breathed in nor the foul air breathed out, then great bellows are fitted in such a way that good air is blown in and the foul air expelled. But if anyone has been harmed by the subterranean air, he uses no other remedy than to be brought at once into the open air.

6. Whether little demons [Daemunculi] or pygmies appear in the mines? — Reply: such have been seen and heard many times.

7. Whether animals are found in the mines? — He answers that no such thing is found, except certain little black worms that sometimes dwell in the pores of the stones.

8. Whether the miners experience lightning-flashes, storms, lightning, earthquakes, etc.? — Formerly at Herrengrund, before air-shafts [spiracula] were made in the mines, it was observed that vapors had collected in the mines, which were very easily set ablaze when a lit lamp was brought in, with a tremendous roar; and those touched by this fire were so badly burned that the skin could easily be

drawn off, as if they had been scalded by boiling water. For the rest, earthquakes do occur beneath the earth, just as above it.

9. *On subterranean rivers and springs — whether they are found?* — Subterranean waters are found in the mines, more or less according to the situation of the mine. From some mines they are led out by individual channels [ductus]; elsewhere they are drawn out by hydraulic instruments.

10. *Let all the miracles of Nature be made known.* — He answered: here there is nothing else new or wonderful, except a certain stone that represents various shapes.

11. *On the heat and cold of the mines — in which parts they most prevail; whether the deeper ones are hotter; and whether subterranean fires seem to appear.* — He answered: when the mines are dry, the deeper they are, the hotter, because it is impossible to make sufficient air-shafts for them on account of the depth; but when they hold water, they are not so hot, even if deep. But if they are deep, and dry, and have marcasitic veins, they are always hotter. Fiery storms [tempestates igneae] are not felt among us; but very often blue flames are seen at night in the mountains rich in metals.

LIBER DECIMUS — Metallurgia [Μεταλλουργικός]

Sectio III — De Fodinarum metallicarum natura (On the nature of metal mines)

RELATIO II (continued) — Johann Schapellmann, prefect of the copper mines at Herrengrund

(Source: PDF p. Fol. 187. The point-by-point reply continues from point 3.)

[Margin: Sulphur of purifying power.] ...At Kremnitz [Cremnitz] and at Königsberg, in the gold-bearing ores, there are sulphurous flows within the ores, where the sulphur keeps company with gold alone without harm — though much to the detriment of the other metals. And just as it purifies the gold, so from the others it strips away their splendor and beauty.

[Margin: Cinnabar.] [Margin: Pyrites.] In these silver-bearing ores zinabrium — that is, cinnabar — is likewise found, together with marcasite; and experience

teaches that cinnabar sometimes spoils the metal. Nonetheless it is a pleasure for the miners to see, in the foremost workings, fissures filled with the tincture of cinnabar.

In the copper ores at Schmolnitz [Schmöllnitz] and Herrengrund pyrites is found, so much so that I am led to believe that copper is generated from it — once the vitriolic humor mixed in with it is joined by internal heat and celestial influences. For experience shows that in mountains where copper ores are wanting, only a spurious pyrites is to be found as well.

[Margin: Silver readily associates with copper.] Silver associates amicably with copper and is the more advanced toward greater purity by it. But one must take care, during the smelting, that it does not lose everything through some malign quality mixed into the same — for it exerts its powers most strongly in the copper-shavings with which they are blended. In the same way silver associates with the other metals; indeed, in smelting it readily joins itself to copper.

4. By what instruments is water drawn out from the caverns of the minerals?

[Margin: Use of the pump [anthlea] in the mines.] First and above all, fixed cisterns built into the mountains are a great help. Into these the waters fall through fissures from the upper part of the mountain, and from there they are led off by certain conduits.

Whatever water falls below these cisterns is either extracted by a pump [anthlea], if the water is not abundant, or else by another hydraulic device — namely, by a larger channel of three fathoms [orgyae], which below the drum [tympanum] has a wheel above, and a chain passes through the channel, the wheel, and the drum. To this chain are fastened sacks of leather, which in the lower part of the channel scoop up the water and are drawn up through that channel. (See Figure V, set out at the end of this chapter.) There are more than seventeen such devices, one above another, and through each the water is conducted into a particular cistern, and from that one again into another, until it pours out into the common cistern mentioned above.

Another device is assembled from several pumps, in which the several pumps are set in motion by the movement of a single iron rod, and in this way the water is conducted off, as above.

5. How is pestilent air suppressed?

[Margin: Deadly air, to be purged in the mines.] This pestilent air is the lack of fresh air, by which vapors are normally dispersed. Now and then it settles, like a

fog, into pits; and with a certain sweet but malign odor, like that of new wine [mustum], it seizes those who disturb it, and quite often suffocates them. This malign air is dispersed by the introduction of fresher air through bellows that blow in good air, or else by continual agitation of the same pestilent air. But concerning these machines and their structures, see the end of this Section, Cap. 6.

6. Whether little demons [demunculi] appear in the mines?

[Margin: Little demons in the mines.] From times long past these have appeared, always as a good omen for the miners. Let the reader look in the preceding Book, on the subterranean demons, where he will find everything pertaining to this subject treated exactly.

7. Whether certain small animals are found in the mines, or storms?

Nothing has been observed by the miners, except earthquakes.

8. On subterranean rivers and springs.

[Margin: Water-springs in the innermost recesses of the mines.] Apart from what is said above, there are none; but from below, continual welling-up of waters is noted, so violent that they would burst out even through obstacles by force, were they not led off by another passage. Not far from Neusohl [Neosolium], in a village called Walascha, so powerful a stream bursts from the rock that it is fit to drive a mill.

9. All the marvels of Nature.

[Margin: Mixed metals are found.] This seems a rare thing: that in Upper Hungary the ores are so intermixed from copper, iron, and lead, that not infrequently in the uppermost part there is iron, in the middle copper, and in the depth lead-bearing material; and that elsewhere too there are copper veins infected with lead. In the silver-bearing stones it has been observed that they abound in lead, so that when such stones were cut open it was found that a hundredweight [centenarius] of such stone contained 20, 30, 40, even 50 pounds of lead — though such stones were not found in great quantity, for one soon came to other stones less rich in lead.

(Source: PDF p. Fol. 186. Relatio II resumes at point 12; points 10–11 fall outside this batch.)

12. On subterranean winds: whether their eruption is felt through the fissures of the mines? On the condition of the subterranean air — whether,

and by what means, it may be purged so that it does no harm, and by what instruments?

He replied: Subterranean winds are not perceived among us. Bad air is expelled from the mines by bellows and by air-shafts; or, if the mines are not very deep, by agitation of the air through suitable instruments.

13. On subterranean earthquakes: whether they so shake the earth as to crush those at work?

He replied that this does happen, and he relates that several instances have occurred.

14. On subterranean waters: whether they fall into subterranean streams, springs of fresh waters, of nitrous, vitriolated, or bituminous waters; and if they have no outlet, how they draw them off, and by what instruments?

He replied: There are found in the mines fresh waters fit for drinking, sometimes putrid and impure ones, likewise vitriolic waters which change iron into copper, as was related above. The streams are led off by aqueducts or by hydraulic instruments.

15. On the courses of the metallic veins: which quarter of the world they chiefly face; and whether the veins of iron in particular tend toward the North?

He replied: The courses of the metals — both of iron and of the others — run sometimes toward the South, sometimes toward the North, and sometimes the courses are cross-shaped [cruciform].

16. On the sympathy and antipathy of metals and minerals, and in what these consist?

He replied: Every ore has its own particular properties. Some produce only a single metal, others several at once. For the rest, the metallurgists are wholly ignorant of their sympathy and antipathy, nor do they inquire into them.

17. What is the method of separating the metals from their ores?

Each of the metals is separated in various ways. The general method, however, is this: the ore is first roasted in a gentle fire, so that the ♃ [Jupiter — i.e. the combustible sulphur] may evaporate — that is, the combustible sulphur; afterward it is washed until all the lighter earth, together with its corrosive quality, has departed. The heavier portion, which with each washing settles to the

bottom, is dried, and according to the condition of the metal is melted down and finally separated — as Agricola [Georgius Agricola] and Lazarus Erckerus [Lazarus Ercker] treat more fully.

18. What are the signs of ores, and by what means are the veins of gold and silver recognized?

The veins of ores are chiefly recognized by long experience and practice, since every vein has its own particular stones. A black, tenacious, clayey earth usually has the gold-ores around or beneath itself.

19. Let the places be named in which, and from which, minerals are dug in Hungary; likewise concerning the hot springs, the acidulous waters, and how great is the depth of the ores.

At Neusohl is dug an ore containing copper alone, and in the same place is dug another, black copper ore, containing copper and silver together. As to the depth of the mines, some are 147, others 137 [Fraktur: Klaffter — that is, fathoms (lit. "ulnae," ells)] deep.

At Kremnitz a vein of gold is found. At Schemnitz are found veins of silver and of lead. At Königsberg [Regiomonte] there is a vein of gold, likewise at Pukanz [Puganzii]. At Dilln [Dielen], as also at Holdritz [in Holdritz], veins of silver are found. There are hot springs: [Fraktur: Stubnerbadt; Bonißeibadt (?)]. And at Schemnitz there is a hot spring near the glassworks. Again, among us are found several acidulous springs, whose powers are unknown to me.

Thus far from the Relation of Johann Schapellmann, prefect of the copper mines at Herrengrund.

RELATIO III — Georg Schütz [Georgii Schutz], prefect of accounts in mineral affairs for His Sacred Imperial Majesty in the Schemnitz Chamber

(Source: PDF p. Fol. 186, lower portion.)

CAPUT III

1. On the property of mineral waters, and on certain metallurgical experiments.

In Upper Hungary at Schmölnitz [Schmolniz], as also at Neusohl in Herrengrund, there is found so powerful a vitriolic water that iron placed in it for some time degenerates into copper; and it is more powerful than that found at Schmölnitz.

This copper endures in the fire, but falls short in quality compared with the copper-stone if it cools; so it is added only to that. Here at Schemnitz, in the adjacent water, there was seen to adhere a certain solid scum, clinging to the timbers in the mineral water after the manner of a natural stone — which, however, has not yet been tested as to what mineral matter it contains within itself.

[Margin: Metallic efflorescences.] **2. On metallic efflorescences upon little shrubs, etc.**

In the silver-bearing ores there are often found silver efflorescences, where the most brilliant silver puts itself forth from the metallic stones in the form of a thread or a hair. Indeed, there are found shavings of pure silver of a finger's thickness — though somewhat blackish, and of a more or less leaden color. Not rarely there sprout forth crystalline parts as well, though not in such quantity as the silver; yet so pure that they surpass the well-worked Bohemian and Hungarian diamonds [adamantes].

3. What copper minerals in particular are found?

(Source: PDF p. Fol. 188. Relatio III, Caput III, mineral specimen items continue. These number the specimens Schütz sent; item 3 begins after the catchword "Cremb-" from Fol. 186.) ...That which has the splendor of gold is pure copper, which by the German mineralogical term they call [Fraktur: Gälff [?] — i.e. "gelb," yellow], to distinguish it from the mineral stones which, though they appear black, contain not only copper but also silver.

[Margin: Pyrites.] **3.** [Fraktur: Marchesidt bey m Khies] — that is, pyrites. This adulterine ore is found in the same place where the ore set down under number one is dug.

[Margin: Lead ore.] **4.** [Fraktur: Bley ärtzt] — that is, lead ore. This, under number four, contains a threefold reckoning of color: the first color is black and gleaming, and is the ore of pure lead; the second color has a white streak, and contains nothing, but is a kind of flint, which in the mines they call [Fraktur: Quartz], which is as it were the matrix of the ores; the third color is one which is nothing other than copper ore.

[Margin: Iron ore.] **5.** [Fraktur: Eysen ärtzt] — or Ruda — is iron ore, not far from Schemnitz, and is dug in the same place, where there are also hot springs; and there too, some years ago, magnets [lodestones] were dug out in great quantity, which in the smelting furnaces they worked up into iron.

6. There is iron ore, not at Schemnitz, but from another place of the mining towns of Hungary, called Roniz [Roniz], a place which lies toward Upper Hungary, 4 miles from Neusohl. This ore likewise contains iron, which is smelted there in fact for the uses of the Hungarian chambers. Concerning this ore it is to be noted that in this whole highland no steel [chalybs] is found, but only iron is smelted, and that not very well refined. In this same highland is found an iron ore in the form of balls, with which we attack the enemy by muskets.

[Margin: Silver marcasite.] 7. [Fraktur: Marchesidt mit Silber ärtzt vermengelt] — this is a silver ore which has gold mixed in with it; but what in this stone seems to have the gleam of gold is not gold, but is called marcasite.

8. [Fraktur: Ries [?]] — this ore is of no use, except to make the silver ores flow [Fraktur: in grossen Wercken] — that is, in large processes; therefore they call it here [Fraktur: einen Fluß] (a flux).

[Margin: Cinnabar ore.] 9. [Fraktur: Ärtzt mit Cinober] — or minium. The black color in this stone is silver ore, which has gold mixed in. The red color denotes cinnabar, in which quicksilver resides.

[Margin: Plumbago [graphite], ☉ & ☽ [gold and silver]-bearing.] 10. [Fraktur: Bleyglängig [Bleyglänzig] ärtzt] — it is an ore, containing silver and gold, having the splendor of a lead ore.

[Margin: Crystalline ore.] 11. I send here to Your Reverence a marcasitic ore, as it grows in the silver-bearing mountains of Schemnitz, from which Your Reverence will see how learnedly Nature produces crystals, which are both most lucid and sometimes grow into great quantity. I send specimens of both kinds under numbers 11 and 13. In this matter Nature's craftsmanship is marvelous, in that all the crystals growing here are six-angled by nature, polished, and pointed.

12. A crystal from the Schemnitz earth. [Margin partly truncated.]

[Margin: Crystal of prodigious size.] 13. This crystal was dug out in the copper-bearing mountains of the most excellent lord Franz Wesselényi [Francisci Wasselini], count of Hadad [Hadat], Palatine of the Kingdom of Hungary, where in the past year a crystal was found in such quantity that it weighed more than 100 pounds, that is, more than a hundredweight [centenarius]. So the most excellent lord Palatine was moved to inquire, through dispatched men, after a craftsman who might know how to carve and shape this crystal either into the form of a monstrance [monstrantia] or some such, and afterward, as he resolved, present it to His Sacred Imperial Majesty.

[Margin: Iron turned into true copper.] **14.** Here I send to Your Reverence copper which, in the Valley of the Lords (a place the Germans call [Fraktur: Herrengrundt]), was made from iron by the vitriolated water that flows within the mountain itself; and they call it [Fraktur: Zementkupffer], concerning which Your Reverence will find it inscribed under letter A, number one. And this is to be understood about this copper made from iron: first, that iron beaten into plates and cast into this water, in the quantity of several hundredweights, is turned into copper within these waters. Second, this copper has this peculiarity over other copper: that it need not pass through thirteen or fourteen fires, like copper smelted from ores, but can be worked up immediately into anything. Third, this copper made from iron is more apt for cups and similar more delicate works than that which the ores supply.

[Margin: Horseshoe turned into copper.] **15.** There is a horseshoe, in part turned into copper by the vitriolated water — that is, by [Fraktur: Zementwasser] — which would have passed wholly into copper, had it been left long enough in the said water.

[Margin: Lodestone.] **16.** I send here a piece of lodestone [magnes], which is dug at Schemnitz, and about four miles from Neusohl, and is found in several other places of Hungary. If Your Reverence should desire more, I will supply it.

[Margin: Copper and silver powders.] **17.** These powders are called at Neusohl by the German term [Fraktur: das Schwartz Fischeerck]. They are found in the Valley of the Lords, where copper is dug; through the water from the mountain these powders are washed out; they contain copper and silver.

18. Likewise there are powders from the same place, and they are called [Fraktur: Gälff Fischeerck], and they contain nothing but copper.

19. Here a color is called by the German term [Fraktur: Berchgrien [Berggrün]]; it is gathered at Herrengrund, where the water flowing down through the copper minerals in the mountain is led into certain chests prepared for this work, into which the water flows and leaves behind it this color settling on the bottom. It is to be noted — as I have it from those skilled in these matters — that this powder, or color, is so rich in copper that a hundredweight of this copper, committed to the fire, yields more than 54 pounds.

[Margin: Galactites [?], or milk-stone.] **20.** This stone is called by the common name [Fraktur: Steinhilch] by the miners; its origin is thus...

(Source: PDF p. Fol. 189. Relatio III, Caput III, items 21–35. Item 20 continues from Fol. 188's catchword "bet,") ...it flows through the veins of the yellow or black copper ores, and where it trickles drop by drop onto the beams by which the mountain is supported (set there to give the miners access at the entrance), it is turned into this stone.

[Margin: Sulphur ore.] **21.** There is a sulphur ore, which is dug in great quantity two miles above Neusohl. And although this ore is rich in quite good sulphur, and even somewhat productive of gold, nevertheless it is not in fact dug for any other use except to make the smelting of the silver-bearing and gold-bearing ores easier and more successful; hence it is called this sulphur ore. [Fraktur: zum Schmelzen Sluce [Fluss?] tauglich [?]] — fit for smelting.

[Margin: Coals [lithanthrax], harmful to the mines.] **22.** This stone is called [Fraktur: Steinkohlen]; it is a whole mountain between Neusohl and Kremnitz, two mining towns of Hungary, near the quicksilver mines, where it is dug together with cinnabar. No one here uses these coals for smelting ores, neither the smelters nor the blacksmiths for their forges, nor anyone else. I asked the reason, and received the answer that they stir up too violent a heat, so that it consumes the iron and destroys all the smelting.

[Margin: Copper ore.] **23.** There is a copper ore which they call [Fraktur: Gälff ärtzt]; it contains within itself no silver or gold, but only copper. The largest of these three was dug from the new pit which last year they found most happily, and with such great blessing that from this single pit it is thought His Sacred Imperial and Royal Majesty will have a yearly revenue of 50,000 imperials. The second of this kind is also dug at Herrengrund, and contains nothing but copper; the white stone found in the same place is called [Fraktur: Quartz]. The third sort is nothing but an ore of pure copper.

[Margin: Copper ore.] **24.** There is a copper ore which they here call [Fraktur: Schwartz ärtzt]; it contains copper and silver, of which they dig such a quantity at Herrengrund [Fraktur: Herzengrundt] that yearly, by separation, they extract about seven hundred silver marks — sometimes more, sometimes fewer.

25. This ore is of antimony [antimonium], which at the same time has somewhat of gold in it; it is dug in the mining towns in great abundance.

[Margin: Red sulphur.] **26.** This ore is called by some [Fraktur: Rothgulden ärtzt], by others [Fraktur: roter Schwefel]. They have indeed tested it by various experiments to find what it might contain, but discovered nothing native to it, except that it is a great poison.

27. There is a copper ore in pure gypsum, which ore is likewise dug here in the mining towns.

28. This ore, from the goods and lands of this college, near the mining towns, is so rich that — not only from the assay made by me, but also from the experience of many others expert in this matter, and of the sworn assayers of His Sacred Imperial Majesty made upon it — a hundredweight has been found to contain at least twelve lots, that is, 12 [Fraktur: loth], of silver (which, however, for the greater part is gold).

29. This powder, at the air-shafts of the furnaces, by which silver is separated from copper, is collected by means of Saturn [Saturnus — lead], and they call it [Fraktur: Bleyrauch]. [Margin: Soot of lead.] In the same workshop, just as the furnaces are double, so here a double powder is collected, dull yellow, and it is nothing else than arsenic. This powder the workmen dread as the greatest poison.

[Margin: Cinnabar still containing silver.] 30. There is cinnabar, which still contains silver; it is dug near Neusohl.

[Margin: Choice copper powder.] 31. This powder is the choicest copper; it is collected and made in this way. There is a furnace so prepared that into it are readily admitted 80, 100, or more hundredweights of copper not yet fully smelted. When this melts by the sheer flames which the bellows, drawn by waters, excite, the melted copper is cast out beyond the openings by the excessive blast of the bellows, and there is caught in a pan full of water. The material thus reduced to powder is so fine, and so purged, that the most noble water-clocks [clepsydrae] can be made from it.

[Margin: Iron turned into copper.] 32. This is water from the Valley of the Lords, or Herrengrund [Fraktur: Herrengrundt], near Neusohl, where there are copper mines, which they here call [Fraktur: Zementwasser], or simply [Fraktur: Zement]; it flows through the copper ores and is of itself vitriolated. Into this they throw plates of iron, and within three months a hundredweight and more of iron plates are turned into copper. At Schemnitz there is a place, about eight miles distant from Neusohl, where a similar water of greater efficacy and quantity is found.

33. There is a mineral sent to me from Schemnitz, whose force and virtue, since they have not yet communicated it to me by any information, I have now requested; and I expect it at the next opportunity, so that I may communicate it to Your Reverence as soon as possible.

34. I send here to Your Reverence an ore altogether precious — since at this time something like it is more rarely found — where Your Reverence will see pure silver efflorescing into its own filaments. The yellow that shines is purest gold; what is blackish is silver mixed with gold.

35. These green stones are likewise produced from water, as I wrote above under number 20, with this difference, however, that this green stone... [continues on a later page]

RELATIO IV — Father Andreas Schaffer, on the different minerals found in the Hungarian mines

(Source: PDF p. Fol. 187, lower portion.)

CAPUT IV

A specification of the minerals collected at Neusohl, Schemnitz, and in the other mining towns of Hungary, which the said Father — both for the adornment of the Museum and for the gaining of knowledge of minerals — sent to the Author, intent on his *Subterranean World* [*Mundus Subterraneus*], and they follow.

[Margin: Marcasite.] Number one. [Fraktur: Marchesidt von Silber, glett ohne tugendt] — that is, silver marcasite, which, though it may seem to contain something, yet in the fire leaves nothing but slag.

[Margin: Copper-bearing material.] 2. [Fraktur: Gälff bey m ärtzt] — that is, an ore containing copper, silver, and gold...

[Source PDF page order is non-linear. Reading order by running headers / page numbers: = printed 190]

(Continuation: RELATIO IV — Father Andreas Schaffer's specimen list)

[Printed p. 190, top of left column — continuation of the numbered specimen list begun in the prior pages.]

it is generated from water flowing through copper ores, just as that stone listed under number 20 is generated from water flowing through silver ores.

[Margin: A piece of alder-wood turned into stone.]

36. I am sending this stone, which I received on the most trustworthy authority from a most worthy man, who reported that an entire alder tree, branches

and all, was found in the water and had been turned into a similar stone. From that tree, thus turned to stone, he gave me this fragment out of a special favor.

37. This lead contains silver and gold within itself. I am sending it as a sample of one method of smelting silver from its ore. Moreover, I will give Your Reverence a special account of the method of extracting gold and silver from ores.

RELATIO V.

On the Tyrolean Ores [De Tyrolensibus Mineris], drawn up by the most noble and most distinguished gentleman, Lord Johann Gervick [Joannes Gervick], Counselor to His Serene Highness the Archduke.

CAPUT V.

Beyond the things common to other regions, it is reported that the glassy ores here [in Tyrol] contain silver and copper.

[Margin: The veins make themselves known by the sound of the ore.]

It is well known to the miners here that, where the mineral pits are worked, great rifts in the mountains are found, rifts separated internally by Nature herself from the adhering parts. The miners perceive this separation by a loud cracking sound, and it is a good omen to them — a sign of finding rich ores.

[Margin: Stones rich in copper.]

From the copper-bearing stones [lapides aerarii] found here at a place called Teuffers [?], an excellent vitriol [vitriolum] is made.

Likewise, from iron they make copper that is harder than the common kind, yet finer in color. The process goes as follows. First, a wooden vessel is filled with water however convenient; into this a fairly large quantity of marcasite [Marchesita] is placed. This water is made to boil with iron slag, called *Schlacken* [German: slag]. Second, the water is poured into another vessel, where again the same amount of marcasite is added and brought to a boil; this is done a third time as well, so that the water becomes as charged with vitriol as it can be.

[Margin: The method of smelting copper.]

The water is then left to settle quietly until the denser marcasite material sinks; the water is then poured off into copper cauldrons, into which iron plates are placed, and it is boiled so that the vitriolic water may attack the iron. As it boils, certain particles of the iron dissolve and sink to the bottom as a dense material. Once the vitriolic water is thus cooked, it cools and is poured into linen vessels — these vessels are wide at the top and narrow at the bottom. The water is left in them until the vitriol adheres to the sides. Whatever does not adhere is poured into a vessel of larchwood, into which several pieces of iron are placed, and it is left until it begins to boil of its own accord. When it stops, the water is poured back into the first little vessel, and that dense material is set aside; and this is repeated often, until several hundredweight of such dense material accumulates. Then this material is dried, and from it black copper is smelted out in a furnace, until at last, in another place called *Goltgrueben* [?], it is turned into fine copper.

§ VI.

On the Metallurgical Machines [De Machinis Metallurgicis].

[Note: the body running-head numbers this as § VI and the body heading reads "CAPUT VI." See QA report — both forms recorded.]

Although we made mention of the metallurgical machines in Section 2, Chapter 4 of this Book (*Mundus Subterraneus* X, sect. 2, cap. 4), since some matters were nonetheless omitted there which afterward came to my knowledge, I have judged it fitting to insert them here, as in their proper place. For they contribute in no small way to overcoming the difficulties that metallurgists encounter in the mines.

[Margin: The construction of the pneumatic machines.]

There are, then, various metallurgical machines, of which the chief place is held by the pneumatic [Anemicae] and the hydraulic [Hydraulicae]. The pneumatic, or air-machines [Ventosae], constantly supply fresh air to the foul air of the mines, and they are in turn divided into various kinds. The hydraulic machines are those by whose aid partly the waters stagnating within the mines are pumped out, partly the heaps of metallic and mineral clods are drawn out of the mines, and partly they also serve to lower and raise timber, men, and animals. Of these I shall treat briefly here, beginning with the pneumatic machines.

[Margin: The construction of the pneumatic machines.]

The pneumatic machines, or air-blowers [ventosae], are properly built by metallurgists to remedy, by a supply of fresh air, the air of malignant character lodged in the mines; and they are carried out in various ways: either by means of bellows — such as the machine placed in Section 2, Chapter 4 — or by little fans set in continuous circular motion; or finally, by certain drums [tympana] which carry the blasts of wind, taken in from outside, through channels to the innermost recesses of the mines. But since such is the nature of air that it can by no force be drawn into a channel unless the mine has within it another passage by which the wind let in may make itself an exit — for if it does not obtain this, it will indeed somewhat compress the putrid air within, yet the usual malignancy of the lodged air will always remain; whereas if it obtains an exit elsewhere, then the air, through an ever new and renewed admission of air, will be able to be perfectly purged, to the great relief of the miners.

[Printed p. 191, running header "DE FODINARUM NATURA." 191]

For the breeze in such underground places is sometimes so heavy that it not only makes breathing difficult and the work hard for those underground, but even extinguishes lamps and lanterns. Indeed, it sometimes even suffocates the miners themselves by cutting off their breath.

To remove these difficulties, then, they are accustomed to improve the air by various machines, as I shall describe.

Diagram. A full-page engraving titled *Figura I. Machina Anemica* (Pneumatic Machine). The scene shows a conical mountain in cross-section. At its summit rises a vertical shaft (axle) topped by a horizontal weather-vane device. On the left arm of the vane is a broad triangular sail or flag bearing the monogram **IHS** (the name of Jesus, the Jesuit emblem); on the right, a tapering tubular nozzle points toward a personified wind — a human face within clouds at upper right, blowing toward the device. The vane turns on a cylindrical drum-shaped housing at the top of the shaft. The shaft descends through a vertical air-channel into a chamber at the base of the mountain, where the air is delivered to the mine workings.

Readable labels:

- **IHS** (on the left sail): the Jesuit/Christogram monogram (decorative-symbolic, on the vane).

- A (right side of the drum housing): the nozzle/intake opening facing the wind.
- B (left side of the drum housing): the sail-arm side.
- G (top of the drum): the upper part of the cylindrical housing.
- D (below the housing): the lower fitting where the housing meets the shaft.
- C (upper right, at the wind-face): the personified wind blowing.
- S (left rim of the mountain summit opening): the mine-mouth / shaft opening.
- V (right rim of the summit opening): the opposite side of the opening.
- L (in the lower chamber, center top): the delivery point of the air-channel.
- N (lower chamber, left): left side of the underground chamber.
- M (lower chamber, right): right side of the underground chamber.

[Lower portion of p. 191 — explanatory text in two columns, beneath the figure:]

[Margin / sub-caption, italic: A machine for improving the air in mines.]

The channel **EL** [?], of whatever material, they first, in some regions, lower into the passage **VS** [?]; they make it firm with various timbers projecting from its sides. Onto this, outside the mouth of the passage, they set an instrument shaped like a cylindrical cask, as **GD** show — yet built with such craft that this cylindrical hollow vessel can turn freely in any direction. It has, moreover...

[Printed p. 192, verso running header "LIBER DECIMUS, Sect. III." 192]

a hole [was in the middle] large enough, marked with the letter **A**. At the bottom it also has a hole **E**, which corresponds to the mouth of the channel. To this, behind, directly opposite the hole **A**, let a vane **B** be attached — of the kind usually set on the tops of towers to indicate the quarters of the winds — and you will have the instrument complete. For since the cylindrical vessel is rotatable, it will come about that, with any wind blowing at last, the vane will always turn the hole **A** toward the wind; from which the wind, let in with the greatest force into the hollow of the vessel and packed in, is carried through the mouth of the channel into the innermost parts of the mine **MN**; and in this way, the squalor of the putrid air being dispersed, fresh air will always, day and night, fill the mine. We add a figure here, from which the reader will more truly grasp our meaning.

Diagram. A full-page engraving titled *Figura II. Machina Anemica* (Pneumatic Machine). It shows a mountain in cross-section with a vertical shaft running from the surface deep into the mine. At the top, above the surface, is a multi-bladed vaned wind-wheel (a windmill-like rotor of crossed sails). At upper right a

personified wind — a human face among clouds — blows a stream of air toward the rotor. The vertical shaft descends through the mine and carries, at two lower levels within the cavern, additional crossed-blade fans (paddle-wheels) mounted on the same axle, which stir and drive the air downward through the workings.

Readable labels:

- A (upper right blade of the top rotor): one sail of the surface wind-wheel.
- B (upper left blade): another sail.
- C (lower blade): another sail.
- D (right blade): another sail.
- E (center hub of the top rotor): the axle hub.
- (The face among clouds at upper right is the personified wind blowing toward the rotor; unlettered here.)
- (The two lower crossed-fan assemblies on the shaft within the cavern are shown but carry no legible letters.)

[Lower portion of p. 192 — explanatory text in two columns:]

Another method is carried out by means of little fans, of the kind shown in the following figure. Outside the mine they make a fan, as Agricola [Georgius Agricola] teaches, [mounted] on a long iron rod which [reaches] into the innermost part of the mine...

[Printed p. 193, recto running header "DE FODINARUM NATURA." 193]

[the iron rod] extends to the bottom of the mine, and there rests on a pointed spike in a hollow of thick glass. Below, on the iron rod **EF**, you may fasten as many blades as you wish, similar to the upper one. Thus, when the blade **ABCD** is moved by the wind **L**, it will turn the whole rod **EF** inserted into it along with itself, and along with it the blades fixed to it inside the hollow of the shaft; and in this way, by the multiplication of the blades, sufficient wind must necessarily be supplied to purge thoroughly the air lurking within. But if the depth were greater than the rod could reach, then the rods would have to be multiplied, and afterward set in motion by the manual labor of the miners. The blades, moreover, can be made larger or smaller for a greater or lesser wind, fitted not only with four vanes, but with six, eight, even twelve. It would be best if the outermost blade were covered over, leaving only a very large opening in the cover: for in this way the wind, rushing in through the opening with greater force, would turn the vane with a swifter motion.

On the Hydraulic Machines [De Machinis Hydraulicis].

Machine III.

Nothing is so necessary to mines as the hydraulic machines. For by these not only are the waters drawn out that stagnate within the mines, to the great hindrance of the miners, but also the mineral clods, and whatever furnishings pertain at last to the interior workings, are — together with the provisions assigned to the miners — both let down and again drawn up. They are, moreover, of various kinds.

Diagram. A full-page engraving titled *Figura III*. It depicts a windlass (the *peritrochium in axe* — wheel-and-axle) set over a mine shaft beneath a peaked timber-and-tile roof. Two miners stand on either side of a horizontal drum/axle: the one on the left (labels B, F) raises a crank-handle; the one on the right (labels A, C) turns the opposite handle. A rope is wound around the central cylindrical drum, from which a bucket or cask (labeled E) hangs down into the shaft. The frame rests on a timber base (labels H, I) and a lower crossbeam (label G).

Readable labels:

- A (right side of the drum/axle): one end of the axle / right crank.
- B (left side of the drum): the left side of the drum.
- C (far right, by the right miner's hand): the right crank-handle.
- D (implied as the left crank-handle, paired with C in the text "manubria C D"; on the figure the left handle area near the left miner).
- E (the bucket/cask hanging in the shaft): the vessel for raising water.
- F (center, on the drum): the cylinder/drum around which the rope is wound.
- G (lower center, below the drum): a fitting on the lower crossbeam.
- H (bottom left of the frame): the base timber, left.
- I (bottom right of the frame): the base timber, right.

[Lower portion of p. 193 — explanatory text in two columns:]

The most useful of all is the one that Figure III displays, which is nothing other than a wheel-and-axle [*peritrochium in axe*]. With a rope wound around the cylinder **AB**, water is conveniently drawn from the mine shafts by alternating hauls, by the aid of two miners turning the handles **CD**. But if the shaft is deeper, then several such [windlasses] can be set up within the channel of the shaft...

[Continuation of the description of Machine III, from folio 193:] ...[?] sent: and in this way the water is raised from one place to another. I have observed that this is done in some mines. But since the figure itself sufficiently makes my meaning clear, I refrain from describing it at greater length.

The Fourth Machine

Diagram. A hydraulic chain-of-buckets machine. Above is a large gear-wheel; from its axle descends a chain fitted at intervals with wooden balls (globes), running down into a vertical channel and through a fountain-like spout into a two-handled cauldron at the bottom. The wheel is turned by two crank-handles at left and right. Engraved labels:

- *Figura IV* (top): the figure title
- X (upper left): the left crank-handle
- R (upper left, below X): the left support post
- A (right of center, on the axle): the square axle [axis quadrata AB]
- Y (right): the right crank-handle
- D (center): a ball-link of the chain
- G (lower left): support frame at the basin
- T, H, M (lower left, stacked): the left-hand supports R T and S A and the vessel
- P (center, in the basin): the channel concavity into which the balls fit
- I (right): the well-shaft side
- Z (lower center): the discharge channel
- N (lower right): the discharge channel timber
- O (bottom, on the cauldron): the upper mouth of the vessel M O / the receiving vessel

Caption beneath: *Machina Hydraulica IV.* [Hydraulic Machine IV.]

A second machine is assigned to drawing off water, though it is a rarer type. It is constructed as follows. A wheel E D of conspicuous breadth — which they also call a drum [tympanum] — is fixed to a square axle A B, set upon the supports R T and S A, and is turned by two workmen by means of the crank-handles X and Y. The wheel has an iron chain wound around it, to which, every two or three palms, wooden balls are attached, sized in proportion to fill the concavity of the channel P. As the wheel turns, the chain is drawn down through the shaft I G H K all the way to the standing water; then, rising up again through the very middle of the channel sunk within the water, it draws the water up — water caught and

held between one ball and the next — and discharges it at the topmost mouth of the vessel M O into the channel Z O, as is shown in the present Figure IV.

The Fifth Machine

Diagram. A hydraulic bucket-chain machine driven by a large treadmill wheel. At right stands a great wheel (G...H) trodden by a man inside it; at left a vertical chain of leather buckets [haustra] rises and falls between rollers, drawing water up from a pool at the bottom and discharging it into a trough at the top. Engraved labels:

- *Figura V* (top center): the figure title
- G (top right): the treadwheel rim / its upper point
- A (upper left of center): the upper roller about which the bucket-chain passes [rota A B C D, upper part]
- N (left): the discharge trough / spout at the top
- F (left, below N): a frame point
- D (center): a bucket-link
- M (lower left): the receiving vessel / tub
- H (lower right): the lower point of the treadwheel
- [Several lower labels on the buckets and frame are present but not separately lettered legibly — the chain of leather buckets descends from A past D down to the water.]

Caption beneath: *Machina Hydraulica V.* [Hydraulic Machine V.]

The fifth machine is likewise hydraulic, and altogether similar to the previous one — except that, whereas the previous one accomplished the raising of water by its balls, the present machine does it by vessels: that is, by buckets, by pails, or by leather sacks fitted in one way or another to an iron chain. The wheel A B C D, like the previous one, is mounted on an axle to which another wheel G H is joined — a wheel that is trodden by beasts or men and so set turning (though it could equally be turned by crank-handles, as the wheel in Figure III was, or even by a stream of water flowing past). The trodden wheel turns the wheel A B C D together with the iron chain wound around it, a chain fitted with flexible links. Between these links, buckets are likewise hung, turning freely on their own handles. As the wheel revolves downward, the chain descends together with its buckets — empty and inverted; but once they reach the water of the well, they are submerged, take up water, and as they rise to the topmost curve of the wheel they are tipped over and discharge the drawn water into a channel set apart for

that purpose. I recall having seen this machine, to my great delight, in various places, for it brings up an incredible quantity of water.

The Sixth Machine

Diagram. A suction-pump (piston-pump) machine: a miner stands at left working a long handle that drives a piston-rod down into a tall cylindrical pump-barrel at center-right; water gushes from a spout on the barrel into a wooden bucket and from there down into a basin at the lower right. Engraved labels:

- *Fig. 6.* (top center): the figure number
- [The figure itself bears no further interior letter-labels; the parts (handle, fulcrum post, pump-barrel, spout, bucket, basin) are shown but unlettered.]

Heading above the figure: *Figura VI. Machina Anemica*. [Figure VI. The Wind/Air Machine — i.e. the suction-pump.] Caption beneath: *VI. Machina*. [The Sixth Machine.]

[Margin note in the heading reads *Machina Anemica* ("air machine"); the body text calls it *Machina Anthlea* (from Greek ἀντλία, "pump / bilge-pump"). The two names are used for the same suction-pump.]

The sixth machine is the suction-pump [*Machina Anthlea*, from Greek ἀντλία (antlia, "pump")], the most commonly used of all for drawing off water. Since nothing is more familiar or more widely used, I judged it not at all worth the trouble to describe it in many words. The machine you see here is employed in most mines. But since it is so arranged with pumps that they cannot easily raise water beyond 18 palms, they set up one pump after another at different points along the well-shaft, and in this way they discharge the water into certain pits — from one pit into another and another, hollowed out within the recesses of the shaft, all the way to the last and outermost one.

To these one might add the Archimedean screw [cochlea Archimedeae], which is everywhere used for drawing off water. But because in metal mines, owing to the narrowness of the space, it brings the greatest inconvenience, and because the shafts are deeper than such machines can reach, they judge that it should not be used. Yet if someone were to multiply them — as is done in the Augsburg water-machine [*Augustana machina aquaria*] — they might perhaps have a not inconvenient use in this way. Still, because vast expense would have to be laid out both in building and in maintaining them, we judge that they too should be set aside.

Countless other kinds of machines occurred to me here, but since I see that they can be of little use in the business of metal-mining, I indicate that only those should be kept which frequent use and long experience have by now introduced, and which it has found and approved — as the best and easiest, and not without profit.

Section IV

On the Particular Conditions of Mines

And on the Various Processes in Mining, Washing, Smelting, and Separating Metallic Ores One from Another.

Caput I

On the Purification of Metals.

[Margin: How metals are to be prepared for smelting.]

Concerning the nature of the veins, enough and more than enough has been said in the foregoing. But since Nature for the most part produces metals impure, mixed with earths, with concreted juices [sap-like mineral matter], and with stones, it is necessary that these fossil substances be separated, so far as possible, from the metallic veins before they are smelted. Therefore it remains to be told by what methods the veins are sorted out, broken up with hammers, pounded with stamps, scorched with fire, ground into powder, sifted, washed, and burned.

Skilled metallurgists, then, do not commit everything to smelting all mixed together — the pure with the impure, the useless with the useful. Rather, first the metallic clods must be pounded and broken up into tiny particles, whether they exist in earthy forms, in concreted juices, or finally in stones; then, by the manifold labor of the workmen, the pure must be separated from the impure and the worthless from the precious; then they must be washed and burned, and finally smelted, so that they may attain their goal.

[Margin: How the burning of metals is done.]

Now the metallic clods are burned for two reasons: either so that, made soft and friable from hard, they may be pounded more easily; or so that the greasy substances may be burned off — sulphur, bitumen, orpiment [Auripigmentum],

and sandarac [Sandaraca] — these being harmful to all metals except gold, and then most of all because they harm iron less than the rest. And since almost no gold is ever found to which some silver is not mixed, clods of this kind too must be burned in order to be smelted. For the sulphur and bitumen, which it usually has mixed in, in the most blazing fire dissolves the metal into ash and consumes the silver, as may be seen in bituminous cadmia [Cadmia bituminosa]. The method of burning, however, see in Agricola and in Ercker [Erkerum — Lazarus Ercker]. Upon the iron grate of the furnace A B they arrange the pieces in the form of a cone, then, fire being set beneath, they roast them; then they add the other metallic clods, and most especially pyrites — which, remarkably, when it is burned for the third time, the pieces placed on the very top sweat out something greenish, dry, rough, fine, and incombustible like asbestos [Asbestus] —

[Margin: Soot of pyrites burned a third time is incombustible.]

[the second column continues:]

which was also observed in the schist-stone [Schistus lapis] from which copper is extracted in Meissen [Misnia]. Water too is sprinkled now and then on the metallic vein, so that it may become softer and more friable; for when the force of the fire has dried out its moisture, water more easily dissolves it while it is hot, as happens with lime.

[Margin: The three torments that metals must undergo in their refining.]

Thus there are three torments [tormenta — "ordeals / treatments"] that the metallic clods must undergo before they reach the term of their perfection. The first is **crushing** [Contusio], and reduction into the finest particles, which is done in many ways and by many means. Harder materials are crushed by mills built for this purpose, whose pestles are raised by teeth set into the drums of a water-wheel and, by their fall and percussion against the teeth, are dashed against the rocks (just as is wont to be done in paper-mills and powder-mills) so as to reduce them to powder. Others grind them with millstones, no differently than grain. Softer material, however, they break up with iron hammers. When these things are done, they separate the metallic flour, and sift it through sieves pierced with holes variously the largest, smaller, and smallest. There are some too who use even sieves of bristle [setaceis cribris] to reduce the material to the finest flour.

The second torment is **scorching** [Aduftio], by which the mate-

[Continuation of Caput I, "De Purgatione Metallorum," from the prior page. The text resumes mid-sentence, completing "ma-/teria" — "the mate-/rial."]

the material to be refined, in order both to make the substance easier to crush and to better separate out the heterogeneous matter, is thoroughly scorched. This is done in various ways, which you may consult in Agricola.

[Margin: How the finest matter is crushed.]

The third torment is the actual smelting [coctura], by which the ores at last reach their goal — on which more below. Metallic matter that needs no fire is purified by washing alone, which itself is carried out in various ways. And so that I do not seem to have left the art of washing [lotura] aside, I will add here — besides the methods commonly used by others, and especially by Agricola in book 8 of his *De Re Metallica* — some further methods of my own. I do this above all at the request of certain princes who, having found gold-bearing sand in some rivers but so fine that it could scarcely be washed without the greater part of the tiny gold particles, on account of their subtlety, running off together with the mud during the washing, asked me to devise and suggest some easy and specific method for them — so that, just as iron filings are separated from heterogeneous matter by means of a magnet, there might likewise be some means of separating gold dust from the earthy portions of the other metals.

Now in the case of larger flakes of gold there is no difficulty in separating them from the rest, since gold, being the heaviest of metals, of its own accord during washing — while the other heterogeneous mixtures run off — settles and its flakes cling firmly to the bottom of the washing-channel. But this cannot be said of the smallest flakes, which generally, because of the tiny quantity of their inherent mass, run off together with the rest of the dross. So that I might not seem to refuse the princes their request, I suggested two highly effective means by which even imperceptible flakes of gold can be separated from the earthy refuse in which they lie. The first is by mercury; the second by crude antimony.

By mercury the procedure is as follows. The mud in which the gold dust lies is placed in a dish, and into it you pour whatever quantity of mercury you like; then with a spatula you thoroughly mix the mud together with the mercury. Since mercury by its natural appetite seeks out gold above all, and wherever it finds it flows together to it by a kind of magnetic union, you mix the mercury into the sand. Once this is done, and the earthy mixtures of the mud that float on the mercury are separated off, in this way the mercury alone remains, clothed in the gold flakes. You obtain the separation of these by making the mercury evaporate by fire. And so that you do not lose the mercury that has escaped — how you ought to recover it intact — will be explained below.

Diagram. A stamp-mill for crushing mineral ore [*Mola ad conterendam materiam mineralem* — "Mill for crushing mineral matter"], shown as a full standing apparatus on a four-legged wooden frame. At the right is a large vertical water-wheel turned by water (A B C); its axle carries a horizontal drum (tympanum) fitted with cams (teeth, A C D E), which raise and drop the vertical stamps (pestles) at the left; the stamps fall into a trough/mortar box (H K) where the metallic matter is pounded.

Labels, per the engraved caption:

- A B C: the water-driven wheel [*Rota aquâ versatilis*]
- A C D E: the drum fitted with its cams/teeth [*Tympanum dentibus suis instructum*]
- F M, G N: the pestles/stamps [*Pistilli*]
- H K: the concave mortar in which the metallic matter is pounded [*intra concava H K materia metallica contunditur*]

The other method is by molten antimony. If into it you pour the said mixture in which the gold flakes are contained, the gold flakes alone seek the bottom, while all the rest [continues below]...

whatever they finally are — the metallic and earthy portions that float on the antimony. And this is the means by which even the smallest speck of gold dust is separated from the impure mixtures.

Another method.

Sworn assayers of metals, in testing mineral ores in the mines, usually take first a small quantity of the ore of whatever metal, and investigate what it contains and how much, doing so by fire in this manner. From a heap of mineral stones that have first been crushed, they take, say, exactly one ounce, weighed as precisely as possible down to the thousandth, two-thousandth, or even three-thousandth part of a pound (which in German they call a *Probircenten* [assay-hundredweight]); this they then assay by fire. Having thus determined the weight, the arithmeticians proceed by the Golden Rule [Rule of Three] as follows. The thousandth part of the ore yields, say, the hundredth part — now, found by assay

[Margin: The way to extract metallic veins.]

[Margin (marginal calculation): 1000. / 999. / 100. / 999. / quid? 99.]

— of a pound of gold, silver, copper, or lead; therefore the other 999 parts will give just so much, and so much, of gold or silver — that is, 99. For example, one seventh-portion [*septenarius*] of ore contains within itself so much and so much of silver or gold; so, to process a full hundredweight [*centenarius*] of the said metals, how much expense must be laid out? And once the operation has been carried out precisely, both the weight of gold or silver and the expenses to be laid out [are known]; and when the expenses have been subtracted from the gold or silver, they straightaway yield the profit.

[Margin: How the assay of gold is set up.]

They make the assay in a small quantity, lest in large and very costly assays the master should incur a loss with no profit ascertained. They use scales so exact that they can easily weigh even hairs and any of the tiniest things. The vessels in which the assay is done are usually earthenware pots, or crucibles [*catini*], in which the metallic matter, first crushed and mixed with lead, is placed; these crucibles are then set in small furnaces for melting — the form of which we shall present below. For the differing condition of the metallic ore they have differing assays: for example, they make one assay on ore that contains gold, another on ore containing silver, copper, or another metal. With these preliminaries, then, they proceed to the processes that follow.

CAPUT II.

Another method of preparing metals, from Agricola.

The workmen, as Agricola reports, must first of all find wedges, plates, hammers, bars, poles, pivots [*verticula*], mattocks, and shovels: for these tools are most necessary for extracting metals from the mines. The mine must be situated in a mountainous place, and not far from some river, spring, or stream, so that the matter dug out can be conveniently washed before smelting. And since metal veins are enclosed within the crevices of the rocks, the diggers sometimes drive iron bars into the cracks and knock out the vein; but when the veins run along the sides of the rocks, they use hammers; and when such tools are applied in vain, then by the violence of fire they break apart the rocks and extract the veins.

But the metallurgists must first, once a vein has been found, make a test of whether it contains a small or a large quantity of metal: for when one works at a loss, the vein must be abandoned. The test is made by smelting a modest quantity; from this it is learned whether smelting a large quantity will bring loss or profit. Smelting, then, is seen to serve many purposes: not only to prepare metals for

use, but also to separate them from one another by the agency of fire — for they are usually mixed, and their defects are corrected by fire. In this way, then, they usually proceed in the German mines.

First the workmen throw the fragments of the veins into bins, so that they may be pounded by pestles tipped with iron heads, driven by a water-wheel; for they always procure great streams of water led down from the mountains, which by their rapid course turn the great wheels. The coarser stones with which the metals are mixed are first easily broken up with hammers; they are washed in pits and sifted again, until at last they are ground. By all these methods the metallic matter is first prepared before it is smelted in the furnaces. There are many furnaces in the metallurgical workshop, in which the veins are melted and the silver is separated from the copper, while huge bellows are raised by the force of the water-wheel and, by their constant blast and great motion, with a roar stir up the flame in the furnaces. Then the workmen throw the metals in from above, and others draw off with great ladles the molten metal, now separated from the crushed rocks, and pour it into molds.

But it is not only in this way that precious metal is separated from base, and in turn base from precious: for often two metals are found in one and the same vein, since naturally a certain portion of gold is found mixed with silver and copper; in black lead and in iron a small portion of silver; in silver some part of black lead; and finally some portion of iron in copper.

[Margin: How gold is separated from silver.]

Gold, however, is usually separated from silver by a strong water [aqua fortis, nitric acid] prepared from vitriol [*atramentum sutorium*, copperas/green vitriol], or from alum and saltpetre [*halinitrum*], which is exceedingly suited for separating silver from gold. The common composition of this water consists of one pound of [continues, "vitri-/ol..."] —

of vitriol, the same amount of salt, and three parts of spring water.

[Margin: The composition of the aqua fortis.]

It is also prepared another way, from four pounds of vitriol, two of saltpetre with half a pound of alum, and a pound and a half of spring water. Those who wish to induce softness in any metal sprinkle over it sublimate [corrosive sublimate], borax, and euphorbium reduced to powder. But if they want to reduce metals to a calx and a water, to draw a nobler metal into a baser, or to transmute them into

one another, they should read Wecker [*Vuecherius*, Johann Jacob Wecker] in his *Book on Secrets* [*De Secretis*], where he has disclosed many arcana of this kind.

CAPUT IV.

The gold mine and its conditions.

First, with the greatest care, one must observe the vein of gold — from what kind of stone it took its origin (since here we take "vein" not for the native vein of a place or mountain, but for the matter already dug out of the mountain). So, if you find a vein of gold in lapis lazuli, you will be blessed with a double benefit: partly from the gold extracted from it, and partly from the lapis lazuli, which — since among precious stones it holds no mean place — is most useful, partly to physicians for the cure of various ailments, and partly to painters for that ultramarine blue color than which none is held more precious or more costly.

[Margin: How gold is extracted from lapis lazuli.]

Gold is extracted from it in this way. First the lazuli vein is reduced to powder; then the powder, placed in a crucible, is thoroughly washed, and is worked with mercury up to the point of amalgamation. The flour of the stone will float on the mercury, while the golden offspring will seek the bottom. You then strain the mercury, still saturated with gold, through a leather bag; and the mercury will be separated from the rest of the gold, which remains within the leather bag together with the dross of the quicksilver. This, purified again by lye [*lomentum*], is found whole and pure. (See another method in book 12, near the end.)

Others do it thus, by the more usual earlier method. Over a slow fire they roast the gold-bearing vein in an open furnace until all moisture has evaporated; this is then reduced by means of a mill to a powder, and crushed in any other way, and must be smelted through a *cineritium* (which they call a cupel [*cupella*]), with lead added. In this way the gold will be separated from its vein and from the lead, as will be more fully explained below.

§ I.

The Generation of Gold.

Gold is generated, as we showed in the preceding sections, from a most purified sulphureous-mercurial vapor within a most pure matrix of suitably prepared saline earth, and over a long stretch of time is concocted by a gentle heat. And because this operation is accomplished only over a long span of time, it comes

about that the nature of gold acquires that brightness and preciousness. These verses make plain its like origin:

Soon, descending from there into the great womb of its mother, You will revisit, as a spectacle, her chambers — her offspring and her grandchildren. Believe me, in the blind darkness of Sulphur and quicksilver It is enough to have approached forces akin [to it]; This one thing you will accomplish, which hangs upon a twofold origin.

Moreover, there are many among the alchemists, as was unfolded above, who wrongly ascribe the generation of gold to art, on account of the many tales — not histories but fables — they have read about it.

[Margin: The fable about gold being made by a certain Moor.] [Margin (marginal symbols): ☿ ☽ ☼ — i.e. Mercury, Moon (silver), Sun (gold).]

Among others they bring forward a certain Moor who, in the region of Mauritania, at a smith's, used to add a certain citron-yellow powder to molten silver and instantly turn it into gold. They likewise report that there lived a man in Gaul who had a red oil with which he would transmute Luna — that is, silver — into the most shining Sol — that is, into the purest gold — albeit by imposture.

When Pico della Mirandola [*Picus Mirandulanus*] relates that in his own day gold was found in the stomachs of partridges, he says it is no wonder: for who does not know that hens, partridges, ducks, and similar birds crave nothing more than metallic bodies, as was said in the preceding sections?

[Margin: Gold in the stomach of partridges.]

So it is not at all unlikely that along the riverbanks they devoured the golden flakes scattered through the sand, which then by the heat of the stomach flowed together into a single mass — not, as he supposes, generated by some hidden power of the food, though I would not deny that Nature can impart this virtue to the surface of the earth. For they relate that in the chalk-mountains there were seen she-goats, called *Ibices* [ibexes], whose teeth were tinged with a golden color, in that part especially with which they cropped the grass — which no doubt happened from the tincture of gold-bearing spirits with which the grass was imbued.

[Margin: Why goats had teeth fitted with gold (i.e. gold-tinged teeth).]

Albertus [Albertus Magnus] reports that gold has sometimes been found in a human skull: if this is true, it comes about for no other reason than from the

vapors which, while the gold is being liquefied, rise up, and — just like quicksilver — coagulate in the brain.

[Margin: Gold found in a human skull.]

§ II.

The Nature and Properties of Gold.

The chemists strive in many ways to investigate the nature of gold, and to that end spare no labor — namely, by dissolving, weighing, tasting, subliming, and melting it, [continues, "in order that..."] —

so that from this they may search out all its affections; and in the end they establish it, in the second degree [of excess], as hot and moist. Galen, however, preferred to commend its coldness and dryness. But to grasp all the properties of gold better, it will not be amiss to examine all its qualities. And first, if we consider the active qualities of gold: gold, however long it is handled, never stains the hand of the one touching it — a prerogative that does not belong to the other metals; and so this is taken as the chief proof of its purity.

[Margin: Gold does not stain the hand.]

Next, gold when struck gives off a dull sound, and does not imprint lines of its own or of another color on any body unless it is rubbed on a touchstone, the Lydian stone [*coticula*, *Lydius lapis*]: for then it yields lines exactly like itself. All of which indicate the supreme perfection in gold.

[Margin: It has a dull sound.]

If the passive qualities of pure gold are considered: first, it suffers no harm in its substance from sharp juices; second, it is not brittle, although it is soft.

[Margin: It does not corrode.]

For when struck with a hammer it is so spread out that from single denarii fifty or more leaves of six fingers' length can be made — and this happens to gold beyond the other metals, on account of the most perfect matter of which it consists.

[Margin: Malleable into the thinnest leaf.]

Third, it is not attacked by rust unless it has been mixed with another metal; then it gives off a rust of the most delightful blue color, which painters call ultramarine blue. But if it is pure and unalloyed, even though it remains buried

in the earth for many ages, it contracts no rust; it is not fouled by salt; placed in a gold salt-cellar, it is not corroded, which does not hold for the rest.

[Margin: It does not rust.]

If the internal qualities of pure gold are weighed: first we shall observe, following Aristotle, that it is so melted by fire that it loses absolutely nothing of its substance — indeed, there it is purified and emerges more splendid, and loses none of its solidity.

[Margin: In fire it emerges purer.]

Next, gold placed in sharp waters [aquae acutae], which the goldsmiths prepare for separating gold from silver, is not at all dissolved into mud, as many wrongly suppose, but is divided into imperceptible particles, which, once the water is dried off, are reunited and restored to their former shape. We must note, however, that when it was said that gold is consumed neither by fire nor by use, this is to be understood in comparison with the other metals, since gold coins are worn away by the constant rubbing of fingers, and by long-continued fire gold gradually vanishes as its vapors evaporate.

[Margin: Gravity.]

Finally, among the external qualities of gold is reckoned a weight equal to black lead, and a warmth which is retained longer in glowing gold; and there is mentioned also its tawny color and gleaming brilliance, since gold is the first among metals to display color — color which shines out more in gold than in the other metals. Hence, by a certain analogy, the Interpreter of Pindar and the chemists assert that gold is dedicated to the Sun: for just as the Sun shines resplendent in the midst of the planets, so likewise gold gleams among the other metals.

Some add to the foregoing a bad quality of gold, on the grounds that, according to Pliny [*Plinius*], gold is poisonous. But it must be noted, first, that Pliny spoke of gold to which another metal had been mixed; whereas when it is purified by fire, then it sheds all the malignancy of any harmful quality — since, indeed, taken in medicines, it is so far from being harmful to a person that rather it wonderfully strengthens the vital faculty and refreshes all the spirits of the human body. As for what is told in the *Book on the Nature of Things* about gold growing cold at the approach of day, that must be set down among the fables, inasmuch as it is contradicted by daily experience.

[Margin: A fable about gold.]

§ III.

The Antipathy and Sympathy of Gold.

In a closely related and kindred order, the Antipathy and Sympathy of gold succeed to its properties. First, that sulphur and gold are at odds with each other, we gather from this: that gold, suffused with a sulphureous and foul vapor, instantly loses its pleasing color — although afterward, with that same sulphur boiled in water together with tartar and a little salt, its former splendor is restored to it.

[Margin: Gold is at odds with sulphur.] [Margin: How its color is restored.]

Likewise it takes grave offense from lead; for gold steeped in the fume of lead is reduced to the finest powder, and sometimes at the smell of lead it so stiffens that it cannot be spread by the hammer. For this reason the craftsmen are obliged to melt the gold again and pour a little nitre or sublimate over it, so that it may lay aside the bad quality received from the fume of lead.

[Margin: It is reduced to powder by the fume of lead.] [Margin: How the stiffness of gold is removed.]

Furthermore, lemon juice presents a stubborn enemy to gold, inasmuch as gold macerated in it is — according to Levinus Lemnius [*Levinus Lemnius*] — diminished in weight; but this too, by an experiment I performed, was found to be false.

[Margin: It is diminished by lemon juice.]

How great the sympathetic affection of mercury is toward gold has appeared from what precedes, since wherever mercury finds gold dissolved by fire, it straightaway seems to embrace the gold in a certain way. If, moreover, quicksilver is mixed into liquefied gold and the mixture is stirred until it cools, the gold will be reduced to a powder; for the quicksilver, penetrating, so couples itself to the golden matter that it allows it to retain no continuity, with no appearance of gold remaining at all.

[Margin: The friendship of gold with mercury.] [Margin: Mercury reduces gold to powder.]

This is not unknown to the Saracen craftsmen, as is found in the *Book on the Nature of Things*: travelers carry gold corrupted in this fashion with them, for afterward, placed at will in a small furnace, it rises again more beautiful and splendid.

[Margin: The trick of the Saracens.]

Those who separate gold from the impurities and earthy matter mixed with it in the gold-working shop declare that this is not a hatred between gold and mercury, but rather a kind of familiarity between them: for while they grind the mixed impurities on the mill and, carefully mixing mercury, add it to them, then whatever gold has been mixed in [continues, "the mercury..."] —

[Continued from the previous folio — the close of Caput IV, §. III, on gold's sympathy with mercury.]

mercury [hydrargyrum] takes it up, and afterward, when strained through leather, it leaves the gold behind in the bottom — as will become clear in what follows.

As for the report of Philostratus [Philostratus] that gold is uniquely craved by dragons [Margin: Dragons, δράκοντες], who does not see that this is a fiction of the poets, since they set up dragons as guardians of treasures? [Margin: Fables of the attractive power of gold.] Better known, then, is the love of the barnyard cock for gold, for I myself have seen one devour gold filings, gold coins, and copper coins with great greed. But the claim that the bones of this animal, when mixed with melting gold, consume it into themselves — and likewise, on the authority of Aelian [Aelian], that gold is drawn off by the leg-bones of a hawk, or even by the bone of the milvus-fish [milvus, the kite-fish] — we have found to be equally false. Again, what the *Liber de Natura Rerum* relates about the marvelous sympathy of the echinus-fish [echinus, the sea-urchin] with gold surpasses all the ravings of the poets: for it is dreamed that this creature, when preserved in salt, has such power that, brought near the mouth of a well, it draws out gold that has fallen down into it. And the claim that a fresh hazel rod plunged into molten gold reduces it to powder — because the moisture of the rod is drawn off by the gold and, in turn, the moisture of the gold by the rod — we have found false. Many assert the same thing of wine, on the grounds that wine rivals gold in color and in its other properties, and because, just as wine holds first place among vegetable things, so gold holds first among minerals.

Moreover, gold — like many other metals — embraces its fellows with a wonderful concord [Margin: How gold is bound with the other metals], when they are mingled by goldsmiths not unacquainted with this friendship; and this mixture they commonly call *lega* [alloy]. Lead and tin, then, embrace each other so amicably that, once joined, they form a mixture that cannot be told apart even by a skilled craftsman. Gold, however, can be bound closely only with silver and

copper. Finally, some imagine that there is even such a thing as a "golden magnet" [Margin: Whether a golden magnet exists], which would draw gold just as the magnet draws iron — such as Philostratus says the stone *Pantarbes* [pantarbes] is. This I judge to be a fiction, to be ranked among the dotings of old wives rather than placed in the nature of things; so that I cannot sufficiently wonder that such rank impostures and ridiculous absurdities have, by chains of linked errors, crept even into the schools down to this very day, since there is scarcely a book treating of the marvelous secrets of Nature that does not, among other things, make mention of this most fabulous *Pantarbes*.

§. IV.

The method of finding and preparing gold. [Inveniendi, & praeparandi Auri ratio.]

In his works Pliny [Pliny] handed down a threefold method of finding gold. The first is by observing the sands of rivers; the remaining methods of gathering it are described in the preceding chapters of this book, where I treated of the various techniques for prospecting metals. It remains only to speak of the art of preparation — for the gold of a river is worked up by one technique, and the inhabitants use various nets by which they extract nuggets of gold from the streams. This happens most of all at the river Zenus [?] [Margin: The river Zenus(?).], not far from the city to which the name of Carthage [Cartagena, in the New Kingdom of Granada] has been given, situated in the New Kingdom: for when, in certain months, heavy rains fall, the inhabitants fish up much gold-dust with nets, which needs no preparation. Likewise, near Mount Ctesias [?] in India there is said to be a spring that is filled each year with grains of gold, so that from it a hundred earthen jars full of gold are drawn off every single year [Margin: The fable of Ctesias about gold drawn from a certain spring]; for the vessels must be earthenware and brittle, since the gold congeals in them without preparation, and each jar equals a talent in weight. But let us leave such fabulous tales aside.

Gold is also extracted and prepared from other things besides streams and ores. First, by a certain mixture carefully prepared from gold dissolved in *aqua separationis* [the water of separation], together with lead or pitch and sand; under this mixture the gold is secretly carried off from region to region without suspicion... [?] [text partly broken; printer's lines interleaved] Pliny [reports] that Caligula Caesar [Margin: The covetousness of Gaius Caligula Caesar], most thirsty for gold, ordered a great quantity of orpiment [auripigmentum] — because of the resemblance it has to gold — [?] to be smelted, and that from it the purest gold did

indeed emerge, but of so slight a weight that the workmen felt a loss. From the stone *Cyaneus* [lapis lazuli], or *Lazuli* as the Arabs read it, and from red Hungarian copper, gold has been found to be separated by the power of quicksilver, of which a little earlier.

I have in my possession a Hebrew manuscript book [Margin: The fable of a certain Rabbi about the herb *boriza* turning into gold] which teaches that gold is produced and prepared from the juice of a certain herb; the herb it calls *boriza* [בוריזא? [?]], and it says it is a species of *Lunaria* [moonwort], born not in the fields and woods but in the brain of a stupid Rabbi. Its stalk is violet-colored, and it produces leaves like the leaves of marjoram, growing with the motion of the Moon, and the whole plant breathes the scent of saffron. The juice of this plant — oh, marvelous! — is so mingled with quicksilver that it becomes a kind of thickened mass, which, reduced to powder and sprinkled on copper, turns it into pure gold; and one ounce of this powder is said to suffice for tinting a hundred ounces of copper. Than which fiction nothing could be more stupid: for if it came anywhere near the truth, no doubt all metals would by now have been turned into gold. But back to our subject.

And so gold, once it has been cleansed of earth, washed, melted, and worked up, loses in these operations its yellow and splendid color [Margin: How its proper color is restored to gold]. For this reason the workmen sometimes steep it for the space of a natural day in *aqua tartari* [water of tartar], then wash it with fresh water and wipe it with a clean linen cloth; sometimes they boil it in vinegar with sal ammoniac, verdigris, and tartar; and sometimes...

with common salt, tartar, and sulphur, they keep it in water until it recovers its lost color [Margin: How a too-soft gold is made harder]. Indeed, when the gold is too soft, it is necessary to fix and condense it; and so, immediately after it has been extracted from the *chrysoplysis* [the gold-washing], they use *aqua regia* [aqua regia] prepared from verdigris, vitriol [calcanthum], alum, and calamine stone [lapis calaminaris].

All these things done and prepared, they cast the gold into bars [Margin: How alloy mixed in with gold is separated out]. To test whether these contain any silver or not, the workmen try them with the Lydian stone [lapis Lydius, the touchstone] and with assaying needles, which all craftsmen keep in their workshops. Hence, in order that the portion of metal mingled with the gold — which they call the *lega* [alloy] — may be wholly removed, some use a mixture of tartar and brick-powder: with this mixture they construct a small round furnace with brick walls, and they place the gold, coated with the same mixture, in a pot,

and they keep up a fire for one natural day. For in this way the foreign metal, or alloy, is consumed, and the gold is reduced to twenty-four *ceratia*, which are commonly called *carats* [carata].

CAPUT IV.

The silver-bearing mine, and its nature and properties. [Fodina Argentifera, ejusque natura & proprietas.]

Many, as is found in Agricola [Georgius Agricola], have supposed that a silver vein is not found pure by itself, but is mixed with a copper-bearing vein, or a lead-bearing vein, and with other metallic bodies. But this is contradicted both by experience and by history. For in the Potosí [Potosí] mountains of America, lumps of gold and silver are sometimes found so pure that they need no refining at all, but are handed over to goldsmiths just as they are born, to be worked up for the various necessary uses of household furnishings. Such things, they report, have likewise sometimes been found in the Hungarian mines — and not, I mean, within the hidden veins of the mountains, but even by the plow, in the furrows of the fields, and also among the roots of trees, or even in the springs that gush out from the gold- and silver-bearing mountains. Indeed, sometimes the very tendril of a vine and its leaves are seen tinged with a golden color. And in the innermost desert mountain-valleys of Monomotapa [Monomotapa], the annals of our Society relate, on the authority of the Abyssinians [Abyssini], that pure native gold is sometimes found like stones.

Agricola confirms these statements with the account of that silver tablet found within the Saxon silver-mines [Margin: A silver tablet from the Saxon mines, the natural work of pure silver], which Nature had brought to such purity and perfection that it seemed indeed to have been smelted by the goldsmith's skill and most excellently polished, and fashioned into a table — so that the Duke of Saxony [Dux Saxoniae] himself used to boast that not even to the Emperor would it have been granted to dine at so unusual, wondrous, and altogether magnificent a table, fashioned not by the hand of a craftsman but wrought by the incredible industry of Nature. This was a clear sign that silver has the very origins of its own birth within itself. To this is added that what is said of silver may be said of all the other metallic veins, since none is so pure and so cleansed of all heterogeneous matter that it does not always have some of the remaining metals mixed in with it [Margin: All metals are mixed with one another], according to the variety of the exhalations that tinge the veins now this color, now that — since particular veins are heightened, some into a blue color, some into green, others into a tawny and

dusky hue; nor are there lacking those that bloom out into an ashen and black color, and into other colors, according to their composition and combination with the first and proximate matter of the metals.

Silver, therefore, according to the proportion of this mixture, is found now in greater, now in lesser quantity, in keeping with the greater or lesser sulphureous-mercurial exhalation in the pure earth and the concoction proportioned to producing silver. For, as I have learned from the overseers of the mines, it usually grows in a stone of ashen or grayish color; and besides, in a certain hard stone not unlike Tiburtine stone, which they call *travertine* [travertinum]. The vein is heavy and weighty, furnished as it were with certain shining points — truly a clear indication of silver of better quality [Margin: In what kind of stone the silver vein is embedded]. But if it is found in a white and leaden-colored stone, then it is most sought after, because it is easily purged of its earthy quality.

Again, it is also very often found associated with marcasite [marcasita] or pyrites [pyrites], which, however, the more they pride themselves on a golden color, the less silver they promise; the more they approach a white color, the more fruitful a silver vein they pledge. The reason for this we give as follows: that the more gleaming color of the pyrites marks I know not what scorching, by which the silver is gradually consumed; whereas, on the contrary, the white color of the pyrites, as it indicates a more temperate heat, so too it pledges a richer supply of silver — especially if it has been associated with lead and copper. It sometimes happens that the silver is found joined with sulphur, arsenic, and not-yet-fixed mercury, and similar combustible substances; in that case there is no need of anything else but that, by a strong fire, the silver should be separated from the rest by evaporation. But just how this separation is done — by the practice they everywhere use in America — I will set out later.

The nature and properties of silver. [Argenti natura & proprietates.]

Albertus Magnus [Albertus Magnus] and others have declared that the matter of silver flows from the substance of sulphur and quicksilver [argentum vivum]. Brasavolus [Antonio Musa Brasavola] [?], however, holds that it is condensed quicksilver, comprehending sulphur by its power — since, from the frequent handling of silver, a smell of sulphur is perceived; but he asserts that under silver, and under gold, sulphur lurks in a different manner, inasmuch as he assigns to gold sulphur in act, and to silver sulphur in potency. But the true philosophers and...

diligent investigators of natural things affirm that silver arises from a substance more watery than fiery, and therefore set it in a cold and moist temperament [Margin: Other properties of the Moon, that is, of silver] — whatever others may have said about the cold and dry temperament of silver. Indeed, even Albertus himself reckons silver to be cold and dry, yet not without some moisture.

As for its other qualities, it must be considered that silver is malleable and resonant: for it communicates to the ears a not-unpleasant ringing; and though it be pure, it takes in a man's breath and at once dispels the cloud [it forms]. Moreover, if it is compared to gold, it is assuredly less perfect; and so the chemists are accustomed to say: as the Moon stands to the Sun, so stands silver to gold. But the Moon is of lesser light, and so silver too must be of lesser value and weight. Likewise, if we ponder the properties of each metal, we shall find the greatest difference between them. For, first, in extracting silver from the mines, it is not gathered so pure as gold, but is so mixed with earth and dross that its refining demands immense labor. Furthermore, refined silver is indeed spread out by the hammer, but less than gold, since it acquires greater hardness and thickness. Then it is lighter than gold and lead, since when melted it floats on top of them like oil; it is diminished by prolonged fire, and when hidden away in damp places it corrodes — afflictions by which gold, as we showed in the preceding chapter, is not at all troubled. And so authors ought not to be held in great wonder when silver, though it be most white, imprints black lines on bodies; this we judge to come from nothing other than the impurity of the metal. Finally, silver has this implanted in it by nature: that it shrinks from familiarity with sulphur, tin, and iron — just as all animals, and most of all the dog (on Pliny's testimony), abhor in a wonderful manner the smell that comes from silversmiths.

The method of finding and preparing silver. [Inveniendi Argenti, & praeparandi ratio.]

It has long been known to metallurgists that silver is generated in an ashen and dark soil, and is found where many pyrites are seen. Indeed, just as pyrites sprinkled with a golden color indicate gold veins, so whitish pyrites spotted with tiny grains usually indicate silver veins; therefore the place where the pyrites is observed to be whiter, rarer, and finer-grained will offer the greater hope of silver veins. Once the silver vein has been found and opened, the diggers go on extracting the silver until they reach an alum-ore; for when this concrete, lean juice is found, they pronounce the silver vein at an end.

These things laid down, we will proceed to the refining of the silver once dug out [Margin: The method of refining silver], which is smelted only with black lead, or

with the lead-ore called *galena* [galena], which is for the most part found near the lead-mines. Sometimes metallurgists draw out silver by the power of fire from bituminous *cadmia* [cadmia], which, however, contains but a small quantity of it in itself. Sometimes Pliny testifies that *minium* [minium, red lead], whose *vomica* [eruptive vein] is quicksilver, is smelted by metallurgists into silver [Margin: The transmutation of mercury into the Moon (silver)]. But when silver has been mixed with gold or copper, they are accustomed to employ many techniques for separating the metal, which Georgius Agricola pursues with diligent examination. Besides, some profess to extract pure silver from quicksilver — whether this be true can be tested only by experience. Pico della Mirandola [Pico della Mirandola] relates that in his own times it happened that quicksilver mixed with several other things for the medicine of a horse was transmuted into pure silver; and if this is true, I should readily believe that it was drawn out not so much from the quicksilver as from the things adjoined to it, with which it was mixed.

After the silver has been smelted and worked up with immense difficulty of labor, it lacks that whiteness which is desired in silver [Margin: How whiteness is induced in silver]; and so the craftsmen mix tartar with common salt in water over the fire, in which they heat the silver somewhat, and then draw it out most white. Furthermore, there are some who strive to tint the whiteness of silver with the yellow color of tutty [tutia] and turmeric [curcuma], so that by the prerogative of this color it may seem to rival gold. Others fatigue mind and body with labors to transform silver into gold; but concerning these operations see our opinion in the following book. But just how silver may be overlaid with gold, learn in a few words.

We have observed that this is done chiefly in a threefold way [Margin: The method of gilding silver]. The first is when, over a thin leaf of silver, another, similarly thin, of gold is laid, and beaten with the hammer until they cohere most firmly. The second is when, over a thick leaf of silver, a gold coin is placed and extended as broadly as possible with the hammer. The third method is when leaves of silver, mixed with gold by the aid of quicksilver and fire, are dissolved — a method I have described more fully elsewhere.

The use of silver in medicine. [Argenti in Medicina usus.]

In medical use silver is reported to have no common advantage, since the Dogmatic physicians use its filings and finest leaves, because this metal relieves the trembling and palpitation of the heart, strengthens the brain [Margin: The Moon (silver) cures afflictions of the head], gently eats away putrid flesh in ulcers, and finally brings much aid in mania and other melancholic afflictions.

Wherefore, since it is numbered among the cardiac medicines, it enters into the *Electuarium de gemmis* [Electuary of gems] ascribed to Galen [Galen], the *Aurea Alexandrina* [the Golden Alexandrine], and almost all the antidotes with which gold is mingled. Indeed, silver, by cooling, drying, and...

relieves the itch [Margin: Cures hemorrhoids] [Margin: Epilepsy] and pruritus, if it is applied mixed with oil of tartar, as Mylius [Mylius] notes. Likewise, others mix filings of silver with quicksilver, and wrongly extol this medicine to a wonderful degree for healing hemorrhoids. Finally, the medicines prescribed in a bolus are wrapped in leaves of silver.

The chemists prepare potable silver, then a calx, a saffron [crocus], a quintessence, an oil, and a salt — all of which preparations one may read in Libavius [Andreas Libavius] and the other professors of alchemy. They proclaim that the oil of silver, or of the Moon, will be of great use in diseases of the brain; therefore in healing epilepsy they give the patient three or four drops of it with water of flowers of betony, sage, and balm. They also publish abroad that the salt is by no means unprofitable not only in the aforesaid affliction but also in other diseases of the head, since it is said to consume all the superfluous moistures of the brain [Margin: Dropsy]. Indeed, they promise that from such a salt taken in a dose of four to five grains, with half a drachm of oil of juniper, the sufferer from dropsy will obtain very great benefit; and finally they assert that it is of much profit to a weakened stomach. Lastly, in the apothecaries' shops mortars of silver, with pestles likewise of silver, ought to be kept for grinding gems for the hyacinthine confection, lest the gems be altered by the powder of porphyry stone, which could be produced through the contact of the very hard angles of the gems. Nor does any other metal seem fit for performing this, since it could foul and alter the color and quality of the gems; but when they have been prepared in a silver mortar, this drawback is without doubt kept away from the gems.

CAPUT V.

The mixture of metals. [Metallorum Mistura.]

Nature, begetting metals within the womb of the Earth, sometimes mixes two or three or four of them, as we have explained elsewhere; hence men, taught by nature, on Agricola's testimony, reduced the method of metallic mixture to a use. Indeed, sometimes chance itself demonstrated the same thing, when — as Pliny relates — at the burning of Corinth gold and silver and copper flowed together into one [Margin: The mixture of Corinthian bronze], and so fortune in a manner assigned a tempering to the three kinds of Corinthian bronze: of these, one

gleamed white like silver, because that prevailed in the mixture; another shone with a tawny color, owing to the dominance of gold; the third was one in which an equal mixture of all was constituted. And so art and fraud imitate nature and fortune: while men, adding metals to metals, produce various mixtures, which the Greeks call κράματα [Greek: kramata, "blends, alloys"], the Latins *temperaturae* [temperings].

Craftsmen, therefore, can couple two, three, or more metals — whether simple or mixed; or a simple metal with a mixed one, and vice versa; or two simples with one mixture, and conversely; or, finally, pure simples with one mixture, or with two; and in these likewise a variation can be maintained. Likewise, a base metal is sometimes dissolved with a precious one, and contrariwise a precious one is added to a base one. First, silver is mixed with gold in manifold ways, and all these mixtures lack a name, as was made clear above; only the mixture of gold receiving a fifth part of silver is named *electrum* [electrum] [Margin: Of what electrum consists].

But when men, for the sake of gain, smelt a portion of a baser metal with a mass of a more precious one, they no doubt incur fraud — although some craftsmen persuade themselves that this can be done by the grant and favor of princes, so that gold coins are struck not pure, but with a moderate portion of silver. Today too, by the concession of the sovereign authority, men use a mixture of metals in striking coins, which the workmen and goldsmiths call *lega* [alloy]. Nevertheless, the Emperor Tacitus [the Emperor Tacitus], as Flavius Vopiscus [Flavius Vopiscus] reports in his Oration to the Senate, ordained [Margin: Tacitus forbade the mixing of one metal with gold] that no one, publicly or privately, should dare to mix copper with silver, nor silver with gold, nor lead with copper; otherwise he would incur capital judgment, with proscription of his goods. Although in former times, on Vopiscus's testimony, some had added lead to copper, so as to strike coins of the poorest quality, the silversmiths declare that it is permitted them by law to procure this mixture, when they take ten and a half ounces of silver and half an ounce of copper, and thus cast a one-pound mass of silver. Some of the chemists [Margin: The various frauds of the chemists in adulterating silver] add whitened copper to silver and sell it for genuine silver, although this fraud is forbidden under penalty of death. Today they mix a tenth part of black lead with tin, and from this mixture form basins, vessels, and many other works of this kind. Formerly, too, they mixed iron with copper, which was a fraud to many. By so many methods, then, are baser metals mingled with more precious ones. But conversely this is not to be set down in the category of crime, when more precious metals are added to base ones.

Lastly, there are certain mixtures of metals that take their name from the works resulting from them [Margin: The pot-metal mixture], such as the pot-metal mixture, which is made up of three or four pounds of plumber's lead [argentarium lead, lead-silver] [?] and a hundred of copper, and which goes into various kinds of vessels. Another mixture is called *bombardaria* [cannon-metal], from which engines of war are forged; and this is made when, to every twenty pounds of copper, one of white lead [tin] is added. A third mixture is made when, for the sake of the sound, to sixteen pounds of white lead half a pound of ashen lead is joined. A fourth...

[printed p. 206 — LIBER DECIMUS, Sect. IV]

CAPUT V (continued) — Metallorum Mistura [Metal Alloys]

[Margin: Various alloys for practical use.]

the mixture is composed when two parts of black lead [plumbum nigrum] and a third part of white [lead, i.e. tin] are joined together. The ancients called this "third-grade tin" [stannum tertiarium], and they used it for soldering pipes; common usage calls this mixture *Saldatura* [solder]. The fifth mixture is made when equal parts of each of the two leads are blended together. In Pliny's day [Pliny the Elder] this mixture was called "silver-tin" [stannum argentarium]; in our own times bowls and dishes are made from it. We should speak in the same way of the other mixtures, both simple and compound, since further ones may be added at any time.

CAPUT VI — Sympathia & Antipathia [Sympathy and Antipathy]

Metals agree with various stones, and especially with that kind of flint [silex] which Aristotle calls *pyrimachus* [fire-stone]. This is not unknown to the men who occupy themselves with the smelting of metals: they sprinkle this kind of stone over the molten metals so that the metals cannot fly off into vapor. Indeed, metals readily combine with that sort of pyrites distinguished by various colors; for this reason the workmen add this kind of pyrites to the metals in place of lead, so that in smelting the metals come out more fluid.

Furthermore, all metals have received quicksilver [argentum vivum, mercury] into their friendship, because it most willingly couples with all of them; and consequently they draw into their fellowship that species of hematite [haematitis] which is pregnant with quicksilver. [Margin: The friendship of gold with lead.] On this account this stone is said to draw metals to itself. Indeed, among the metals themselves both sympathy and antipathy are observed: lead is loved by gold and

silver, for when they are melted together they mix easily. By contrast, copper [aes] recoils from lead because of their contrary temperament. [Margin: The discord of lead with copper, and of tin with gold.] Likewise tin so disagrees with gold and silver that it almost consumes them. This is most evident in the furnaces, when the white lead [tin] is liquefied; it floats on top, and is easily drawn off with iron rods.

[Margin: An experiment.]

On the other side, metals and living creatures are at the greatest enmity, because they give off certain exhalations hostile to the animal spirit. For this reason one nowhere reads that any animal has been nourished on metals. [Margin: Metals are at antipathy with animals and plants.] Indeed, where metallic veins are found, neither do plants grow nor do animals dwell. And as confirmation of this we understand that in the metal mines the legs of the workmen are commonly afflicted, which are afterwards healed in the quarries of Assos [Assius], the stone of the sarcophagus. Moved by this same cause, physicians forbid the use of metals in the preparation of pearls [margaritae] or any other medicament of this kind, and prescribe only marble stones, because there is a danger that something metallic might cling to the medicaments being prepared which would be diametrically opposed to human nature, and from this grave symptoms could arise — as we taught in the Section *On Poisons* [in Sectione de Venenis]. Certainly, on Pliny's testimony, the odors emanating from the metal mines are unwelcome to all living creatures, but are most of all harmful to dogs, which exhale from the silver metal [?].

CAPUT VII — De Scoriis, & Excrementis Metallorum [On the Slags and By-products of Metals]

[Margin: The slags of metals.]

Excrements, or slags [Scoriae], are the metallic refuse [Metallica factitia] which are produced in the first and second furnaces while the veins of metals are smelted, while one metal is separated from another, or while molten copper is tinted. These are: Slag [Scoria], Diphryges, Cadmia, Pompholyx, Spodos, Litharge [Lithargyrium], Molybdena, and Scales [Squamae]. Some are produced outside the furnaces, such as verdigris [Aerugo], blue pigment [Caeruleum], white lead [Cerussa], and the like; of which separate mention was made in the Sixth Book [in Sexto Libro].

It must therefore be known that in the smelting of metals the slags are generated as certain by-products of the smelted veins, which the workmen call *Loppae*.

These float on top of the molten metal, and once cooled and congealed they become brittle like glass; and if they have retained any metallic moisture, they become heavy, and once this is separated off they pass into a pumice-like lightness. Thus the more earthy and dreggy part of the metal goes off into slag, which is the cleansing [purgamentum] of the vein cooked in the furnaces, as has been said — speaking, however, of the vein of gold, silver, copper, iron, and both kinds of lead. For the veins of quicksilver and lead do not produce ashen slags [cinereae scoriae], since they are not smelted. We do not, however, say that slag cannot come out of ashen lead [plumbum cinereum] when it is mixed with other metals and liquefied; this filth of the metal is rightly called by the Greeks σκωρία [skōria, "slag/dross"], since among them σκώρ [skōr] means "filth" [stercus]; by Celsus it is called the "refuse of metal" [metalli recrementum].

[Margin: What is silver slag?]

The slag, or refuse, of silver is obtained only when a vein of silver is purified in the furnace; but it cannot be pure, because the workmen add a little lead to it for purifying the silver. This silver slag is called *helcysma* [ἑλκυσμα], from ἔλκω [helkō, "I draw"], because this by-product is rendered so viscous that it is drawn out like birdlime [viscum]. [Margin: The slag of copper and iron.] The slag, however, which is collected from copper and iron is for the most part black, foul, and spongy or pumice-like.

[printed p. 207 — DE FODINARUM CONDITIONIBUS]

[Margin: Lead slag. — What Diphryges is. — Various species of Diphryges.]

[Caput VII continued.] Iron yields a larger quantity of slag than copper releases, since it is a more impure and more earthy metal — which indeed is obtained not only when iron is smelted in the furnace, but also when iron softens in the forge of the blacksmith [ustrina fabri ferrarii]. The slag of lead, however, differs most of all from the rest, because it is least stony, nor brittle like the others, but is observed to be quite pliant on account of the softness of the metal.

Among these slags of metals is reckoned **Diphryges**, and it is nothing other than the recrement of copper [aeris recrementum]; it is called διφρυγής [diphrygēs], as though "twice roasted," for among the Greeks φρύγω [phrygō] means "I roast." Four species of Diphryges are found. The first results from a certain mud of Cyprus, which first dries in the sun and is then burned with brushwood heaped around it; therefore it can with the best right be called "twice burned," first by the heat of the sun, then by the ardor of fire. Dioscorides wrote that this species is

produced only in Cyprus. The second species is nothing other than the sediment of copper roasted in the furnace, which Galen observed thrown away by the craftsmen in Cyprus. The third species is prepared from copper-bearing pyrites roasted until it has taken on the color of red ochre [Rubrica]. But it must be noted that burnt ochre [Ochrausta] takes on the same color, and is therefore similar to this third species of Diphryges, and is sometimes wrongly sold for Diphryges. The fourth species arises from any stones whatever found in the furnace after the metal vein has been smelted; and this species always has something of metal mixed in. A stone of this kind is first roasted, soon cooked in the furnace, then burned five times in another furnace, so that it can with just cause be called ἑπταφρυγῆς [eptaphrygēs, "seven-times roasted"].

[Margin: The preparation of Diphryges. — What is Cadmia? — Cadmia Botrytes.]

Today the workmen in the second furnaces prepare Diphryges thus, when they suspect that some gold or silver is present in the copper: they once again melt the copper with lead, because the lead washes it and carries off the gold or silver with itself. When this is done, in extracting the remnants of the lead they apply a moderate fire, so that the molten lead descends but the copper by no means does; for thus the copper is rendered like a spongy stone, which, once melted and thoroughly cooked, is changed into purified copper, whose slag is more purified than that which had come out of the first furnaces. The working men, calling this *Rasa* [?], sell it to the potters.

Further, while gold, silver, copper, and lead are being filtered, another by-product arises which is called **Cadmia**, which according to some is so named from "settling" [ab insidendo]. It is, however, an ancient name among the Greeks, and so the etymology of the name still lies hidden — unless we wish to assert that Cadmia was once observed while the copper-ore stone was being smelted, which some have designated Cadmia, perhaps because it was first found on Mount Cadmus. Galen left it in writing that Cadmia is sometimes made from pyrite stone, yet he commended the metallic kind, prepared from copper, above the rest. Four species of this are shown by Dioscorides.

The first is called **Botrytes** [βότρυς], as though "clustered," because βότρυς [botrys] is rendered "cluster of grapes." [Margin: Onychites.] The second is named **Onychites**, for it is ὄνυξ [onyx, "nail/claw"], since it has veins running across like a fingernail. [Margin: Placodes.] The third is surnamed **Placodes**, πλακώδης [plakōdēs, "crusty/plate-like"], since it is girded by segments as though by certain belts [zonae], for which reason it is also called *Zonitis*. [Margin: Ostracites.] The

fourth is called **Ostracites**, ὀστράκίτης [ostrakitēs, "potsherd-like/earthen"], which is rejected as the worst of all.

[Margin: Capnitis.]

Pliny, besides the four kinds described by Dioscorides, adds a fifth species, namely **Capnitis**, "smoky" [fumosa]: for καπνός [kapnos] among the Greeks means "smoke" [fumus]; but this is to be reduced rather to Pompholyx than to Cadmia. In our age Cadmia, resembling the bark of trees in the furnaces, is offered under the name of "Alexandrian Tutia" [Tutia Alexandrina]; which is a sign that it has adhered to iron rods [hastis ferreis]. [Margin: What is Tutia?] *Tutia* is an Arabic name, which however signifies not Cadmia but *Spodium*. [Margin: Spodium.] Here it is worth noting that the Tutia of the Portuguese [Lusitani] is not metallic; this is prepared in the Persian region of Quirmon [Kerman], neighboring Ormuz [Hormuz], from the ashes of a certain tree named *Goan*, for so the fruit of this tree is called; and this is by some called "Alexandrian Tutia," not because it is made at Alexandria, but because, carried from Quirmon to Ormuz, it is exported from there to Alexandria [hinc Alexandriam exportetur]. The authorities, however, commend in medicines not this but the metallic kind.

[Margin: What are Pompholyx and Spodium?]

From Cadmia, by reason of the fineness of their substance, **Pompholyx** and **Spodium** differ, since Cadmia, as has been explained, condenses into a certain solid material, but Pompholyx and Spodium cling to the walls of the furnaces like fine flour [pollen], although they take their origin from the same material, out of those furnaces in which copper is perfected, or in which Cadmia is burned. Pompholyx, however, is lighter, because flying up to the vaults it is glued together like bubbles, from which it drew its name; for πομφόλυξ [pompholyx] among the Greeks is "bubble" [bulla]. Spodium, in comparison with Cadmia, is heavier; therefore it falls upon the ground like ash, from which it received its name, for σποδός [spodos] means "little ash" [cinerula]. But true *antispodium* is prepared by art from myrtle alone, or from wild olive [oleaster] burned, which indeed performs the function of the cinerula of spodium. Avicenna writes the account of this metallic matter confusedly, when he asserts that Tutia is a sublimated smoke, and *Succudum* that which settles at the bottom; perhaps by Tutia he understood Pompholyx, and by *Succudum* Spodium.

[Margin: What is Litharge?]

To the slag of lead can be referred **Litharge** [Lithargyrium]; for it arises from lead too long cooked in the furnace, since it is the froth [spuma] which is collected

while silver is purified, and it congeals like a stone. It is called λιθάργυρος [lithargyros], having its name from "stone" [λίθος] and "silver" [ἄργυρος], as though "silver-stone" [lapis argenteus]; by the Arabs it is called *Martech*, and by the Latins "froth of silver" [spuma Argenti]. Dioscorides held that litharge can congeal without silver, while in the second furnaces silver...

[printed p. 208 — LIBER DECIMUS, Sect. IV]

[Margin: The use of litharge among potters.]

[Caput VII continued.] ...is purified mixed with lead; for then, in the boiling mixture, the lead, thinned by the violence of the fire and acquiring lightness, floats on top of the silver and becomes like a slag, which the craftsmen, gradually driving it to the sides, finally throw out and call *gesta* [?], which the potters are afterwards accustomed to use. Some wrongly think that the froth of silver made from gold is called *Chrysitis*, from silver *Argyritis*, from lead *Molybditis*; whereas litharge flows from lead alone, mixed with other metals — and especially with silver — for easier fusion or purification. And although it sometimes takes on the color of gold and sometimes of silver, this nevertheless comes from a greater or lesser roasting. For if, as soon as the burnt-off lead appears above the liquefied silver, it is removed from the crucible, then the litharge will gleam with a silver color; but if it remains there longer, it will acquire a golden color.

[Margin: Litharge natural and artificial.]

The workmen establish two kinds of litharge. One they call **Natural**, which comes from a silver vein mixed with a lead vein and liquefied in the furnaces; the other **Artificial**, which is prepared in the ways described above. Of this Dioscorides shows three kinds: the first kind from leaden sand [arena plumbaria] perfectly cooked in the furnaces; the second from the purification of silver; the third results from lead. [Margin: Various species.] Its yellow species is called *Chrysitis*; the white, *Argyritis*; the livid, *Molybditis*. The best froth of silver is prepared in Meissen [Misena] and Bohemia. Dioscorides, however, assigned first place to the Attic kind, which, since it was produced on Mount Laurium [Laurio], was called *Lauritis*; second place to the Spanish [Hispanica]; and third to the kind of Pozzuoli [Puteolana].

CAPUT VIII — Fodinarum Auri, & Argenti, quae in Peru, Novo Regno, & Nova Hispania in America reperiuntur, mira faecunditas, ex Relatione Patrum Societatis Jesu [The Wondrous Fertility of the Gold and Silver Mines Found in Peru, the New Kingdom, and New Spain in America, from the Account of the Fathers of the Society of Jesus]

In the whole Globe of the Earth no place has been found up to now that has furnished a greater abundance of gold and silver than that part of America which they call the **New Kingdom** [Novum Regnum, i.e. New Granada], **Peru**, and the **Potosí colony**. For, as Acosta [José de Acosta] relates (Book 4, ch. 4), the natives in Peru, not content even with vessels of gold — bowls, ladles, dishes, cups, flasks, glass vessels, and huge water-jars — had even chairs and entire vehicles made of gold, and made images of their idols out of pure and refined gold [obrizum aurum]. [Margin: The incredible abundance of gold in the Potosí region.] Pizarro [Pizzarrus], after he had overcome Atahualpa [Atalipa], is said to have found so much gold in the king's treasury that, amid the heap of golden plates arranged in a long row in piles, he could scarcely reach their height with his sword held out at full length; and the hooves of the beasts of burden were shod with golden, not iron, shoes.

And although that whole tract of America from the Tropic of Cancer to that of Capricorn is most fertile in gold and the other metals, yet to none does this most celebrated Potosí mining province seem to yield — the province of Los Charcas [Carcas] in the Kingdom of Peru, situated at 21° of southern latitude. [Margin: The Potosí region was once uninhabited because of cold.] And although this region lies under the torrid zone, it is so far from being scorched by the sun that rather, through the inclemency of cold, it was once almost deserted, and would doubtless have remained deserted, had not men, drawn by greed for immense treasures, not only come to the place but also there, by an incredible influx of men, built a vast city — necessary both for the abundance of essential goods and for luxury and delights.

[Margin: Description of the gold-bearing mountain.]

The mountain itself is exceedingly steep, more eminent than its neighbors by its slender and lofty summit. Its base obtains the breadth of a mile; from the highest peak to the base it measures 1,624 cubits, which the Spaniards call *Varas* or "rods" [Virgas], and these make a mile or one Spanish league. The gold-mine is said to have first been discovered by a certain Indian named *Cualpa*. He, when he had once come into the wastes of this mountain for the sake of hunting, and was

hindered from climbing by the roughness of the mountain, seized a certain shrub convenient for advancing his step; and as, with a rather violent pull, he tore it up together with its roots, he drew out a gold-bearing vein. [Margin: How and on what occasion the gold-bearing veins were discovered.] And since he was not unskilled in metallurgical matters, he found the vein, tested by fire, to bear the mark of better gold. So, concealing the matter, in time he came to such riches that he was an object of wonder to all, until others, the matter becoming known, finally — many more being selected — the whole mountain little by little began to be dug through, especially with the Spaniards coming upon the scene, who, greedier for gold than the natives, at length, not content with Mount Potosí, [Margin: The vastness of the veins.] discovered four other mines neighboring Potosí. And among other marvels, they hit upon a vein whose mass equaled the height of a spear, and afterwards upon another, almost in the shape of a comb, whose height was 300 and breadth 13 feet; extending into the depth to 50 or 60 fathoms [orgyae], it offered an inexhaustible treasure.

And as the records of the said places report, from the time of the Licentiate Polo [Licentiatus Polo], on Acosta's testimony, in place of the quint [quintarum loco, the royal fifth] there were registered 150,000 reales each week, sometimes 20,000 [recte: more likely 250,000 — see Numerical impossibles]; which sum each year constitutes at least one and a half million. Again, on Acosta's testimony, the records report that from the first arrival of the Spaniards in Peru, namely from the year 1545 to '74, seventy-six millions [Margin: 311 millions of gold expended for the royal treasury of Spain over 40 years.] accrued to the king's treasury...

[printed p. 209 — DE FODINARUM CONDITIONIBUS]

[Margin: 311 millions of gold expended over 40 years sent to Spain.]

[Caput VIII continued.] ...and from the year '76 to '85, thirty-three millions less; and so over a span of 40 years, 311 millions of *reales* were sent from the said silver into Spain — not counting those which were expended for the use of the governors and metallurgists and the administration of wars. The Potosí mountain is furnished with four principal veins, which are all situated on the eastern side of the mountain, laid out from south to north [from Auster to Boreas]. Where they are most diffuse they have a breadth of six feet; where narrowest, of one span [spithama]. [Margin: The multiplicity and depth of the veins.] Besides these, others too, diverse, are found sprung from them like the branches in a tree, through certain efflorescences. The individual veins are subject to the jurisdiction of certain lords, from whom they also take their names. Each vein has its own pits [fodinae]: the first, which they call "the Rich one" [Dives], numbers 78 pits, of a

depth now of 180, now of 200 fathoms [orgyael]; in some places, however, the pits have a depth of 60 or 70 fathoms.

The access or entry to the pits is as follows. In the side of the mountain they have pierced trenches or ditches crosswise, which reach as far as the seat of the ore. For since the veins which face south and north slope downward from above, it is necessary that their channels be followed as far as the roots of the mountain — which depth, as Acosta relates, is 1,200 fathoms. And although the depth of the pits is so great, yet a space six times greater must be gone around in the circuit before one reaches the very base of the mountain. The breadth of these ditches is for the most part eight feet, while the height obtains a little more than the measure of a standing man. And from these all the metals are brought out.

Diagram. Engraved plate captioned *Scalarum mira fabrica* ["The wondrous structure of the ladders"]. The image shows the steep, rocky exterior of the Potosí mountain (Cerro Rico), with a long, broad ladder-structure (a series of jointed rung-ladders lashed end to end, forming a single enormous stair) descending the rugged slope from the upper region toward the foot. Several small human figures of miners are shown climbing the ladders at intervals; one near the upper portion carries a torch or light. The rocky massif rises on either side with crags and outcrops framing the ladder run. The plate is uncaptioned apart from the heading; no internal point-labels are present.

[The remainder of the page:] As for how great the labors the diggers endure in bringing out the ore can scarcely be told; since, buried under the earth as though in perpetual darkness, they are compelled to accomplish their labors.

cannot even know what hour or day it is, nor when night is falling, since the Sun and Moon have no access to those innermost hiding-places of Nature. I say nothing of the diseases they contract in those pestilential caverns from the deadly mineral exhalations. Those who work in the mines use candles that burn continually, on a shift-system arranged so that they rest from their labors every twelve hours, the work-gangs relieving one another in turn.

[Margin: The miners' labors.]

The broken and pulverized ore-veins they load onto their backs and carry up by means of certain ladders, marvelously constructed, as the figure shows.

[Margin: The remarkable construction of the ladders.]

These ladders are made of three ropes twisted from oxhide, into which crosspieces are fitted in the manner of rungs, in such a way that two men

meeting on the ladder can conveniently make room for each other. Each ladder is ten fathoms long, with another fastened to its end. At the sides of the ladders, in various places, wooden benches have been built where the climbers can rest. The first man in the gang carries a lit wax candle to provide the light needed both for himself and for the companions following him. And since the depth is so dreadful that it strikes fear even into those who merely look down into it, these wretched miners — whether because their leather ladders break, or because the weight of the ore-veins loading them down overbalances them — broken and cast down by their toils, end their pitiable lives in a fearful death.

PROCESSUS I.

On the manner in which the gold called Virgin Gold, brought by Nature to its ultimate perfection in the island they call Hispaniola, is dug out and prepared.

[Margin: Pure gold is found everywhere in Hispaniola.]

If the bounty of Nature has enriched any kingdom of America, it has surely enriched the island of Hispaniola above all. For as is established both from the Account of our own Fathers and from the testimony of American writers, they report that there gold is found and dug out in vast quantity — not only within the innermost recesses of the mountains, but even on their outermost surface: among the fissures and clefts of the rocks, indeed even in the very valleys, plains, forests, fields, riverbanks, and riverbeds — and that this gold is not, as usual, fouled with the dross of heterogeneous particles, but is everywhere found pure and unalloyed.

[Margin: A mass of gold weighing 3,600 reales, found.]

For as Francisco d'Oviedo [Gonzalo Fernández de Oviedo] relates in his *History of the New Kingdom*, a mass of pure, unalloyed gold weighing 3,600 reales was found in Hispaniola.

[Margin: The manner of washing the gold.]

Since, then, gold is available even in the very fields, plains, forests, and river-mud without great expense, the Spaniards abandoned the mountain mines — seeing that gold could there be extracted, and once extracted separated, only at immense cost and with an enormous workforce — and instead extract and wash it out of the fields, plains, forests, and rivers in the manner that follows.

First, then, near some river, in places where the sand is rich in gold, they clear away the rocks, shrubs, and trees, and mark out a fixed extent of ground for the mine. Then they begin to dig up the soil to a depth of one foot, then another, and at once they wash this soil in the light and test it to see whether it is rich in gold. If not, they test another lot washed in the river. And if they have dug down six or seven feet, they abandon that spot and attack another part of the field, proceeding in this way until they strike upon a soil rich in gold. They then widen this mine in every direction, and the soil they have dug out is put into baskets and carried into the light, where it is handled by women appointed for this task: by washing it through fine sieves of horsehair, the mud is separated from the golden sands. And if any earthy and muddy material still remains, it is cleaned away by repeated washings, until, once all the dregs have been separated, only the golden grains and dust are left behind. This is gold so pure and of such excellence that it needs neither fire for refining nor lead or mercury for separation, but, melted down into ingots, passes straight into coinage.

Whether gold is actually fashioned by Nature in such level places — whether in the beds and banks of fields, plains, forests, or rivers — one might reasonably doubt.

[Margin: Whether gold is generated in level places, and how its origin is to be investigated.]

I say, then, that gold of this kind by no means took its origin in the said places, but was washed out into the plains by the down-flow of waters from the richest veins deep within the mountains. This could happen in various ways.

[Margin: This kind of gold was not generated in the plains, but brought down from the mountains by the rivers.]

First: the subterranean waters that pass through a vein of gold always abrade something from the compacted nuggets of gold and carry it off out of the mountain; this is why the mud of rivers teems with golden sands and grains — smallest, smaller, and largest — and when this mud is washed, the purest gold is at last collected.

Second: since an abundance of gold-bearing vapors is continually carried upward within the gorges of the mountains, the result is that, coagulating within the clefts of the mountains, they in time produce whole masses; and these masses, scoured away by the violence of torrents and rains — which prevail there especially in the months of December, January, and February — are carried down to the roots and level places of the mountains, where they are left behind, partly covered,

partly uncovered, by mud, clay, and rocks. And since each year a fresh supply of gold-bearing material is scoured from the surface of the mountains by the continuous rains of those three months and carried down onto the flat ground, the result is that the level places are forever covered over with new layers; and over many years the heaps of sand rise to an enormous height.

A clear proof of this is given by the same Francisco d'Oviedo cited above, who reports that in his own time, in the mines of the level ground, two skillfully wrought gold rings — of the kind the natives are accustomed to hang from their ears — were found, together with a quantity of charcoal so fresh that it seemed to have been extinguished not long before...

[Margin: The cause of this.]

as to colors. In a word, its colors are so varied that they seem to be tinted with a definite color out of their points and little veins. And this could not have come about by any other means than this: that long ago a bright fire was built there by the natives, and during the customary dances of that people rings were lost; then, by the violence of rains and torrents, the place was wrapped in sand and mud; and as fresh mud was brought down year after year in later times, the field grew to that very height which the later digging-out of the rings and the charcoal that was found demonstrated. And let this be enough concerning Virgin Gold dug out and washed in the American fashion.

PROCESSUS II.

On the separation and preparation of metals — chiefly gold and silver — as practiced in America.

The veins from which silver is extracted in the mountains of Potosí mostly run between two crags, which they call *Caja* [Spanish *caja*, the "box" or walls enclosing the lode], one of which is so hard that it can rival any flint, while the other is consistently softer and more brittle. Through the spaces between them the seat of the metallic veins extends — though not everywhere of the same bulk or running on an even course. For in some places the vein flows very thick and rich, most fertile in silver; in others, by contrast, it is more brittle. The one shows the color of amber, the other is blacker; one shows the appearance and color of a rose, another of ash. In a word, its colors are so varied that to those unskilled in such matters they might seem to be mere stones; but to the miners they are recognized by no other signs than the points and little veins of a definite color.

Whatever is dug out of the ore-mines is carried to the mills by Peruvian Sheep [llamas], which they use in place of horses and mules. They then proceed as follows in melting down the metallic ore.

[Margin: The method of purifying silver.]

They build furnaces, which they call *Guairas* [Quechua *huaira*, wind-furnaces], into which they first throw the mineral lumps, crushed by the mills. To make it dissolve more easily, they add a leaden metal, very easily reducible to a liquid, which they call *Soroche* [the lead-rich flux, *soroche*]. Once the froth has been stirred up by the smelting, it sinks down through the middle of the fire, while the lead, together with the silver, [settles to the bottom]; from one quintal of this kind of metal they sometimes draw 30 or 40 silver reales by smelting. Acosta also relates that a mass was once given to him from each quintal of which 200 or 250 reales were extracted. But the more barren veins yield at most only five or six reales each, and silver of this sort is for the most part very dry, and scarcely able to be smelted because of the scarcity of lead. For this reason it used to be heaped into piles and thrown away as useless refuse, until at length more skilled metallurgists discovered, through their ingenuity and industry, that by the power of quicksilver — at great and incredible cost — they could purify and refine the barren silver abundantly.

[Margin: From richer metals more is lost in the smelting of barren silver by means of quicksilver.]

It was likewise found that the better the metals are, the more of them is lost from the quicksilver mixture — quicksilver being apt to consume and devour metal in the fire, through the sublimation of the metallic particles it carries off with it. But to this too they applied a remedy: by tempering the degree of fire, no more is lost by that wastage. And this is done not at Potosí alone, but also in the Kingdom of Mexico, where they smelt by the aid of quicksilver. Hence, the art of fusion carried out through the little furnaces they call *Guairas* has been abandoned — of which in the circuit of the mountain of Potosí some 6,000 were once counted, all built for smelting silver; whereas today scarcely more than 2,000 survive, since quicksilver alone has claimed the chief place in the smelting of metals.

PROCESSUS III.

On the preparation of silver and gold by the aid of quicksilver, as practiced in the Kingdom of Peru.

Quicksilver is found in various substances, both earthy and stony. At Idria in Carniola it is for the most part extracted from moist earth, on which we treated at length in the foregoing pages. In America — as also in the other mines of Europe, chiefly in Spain — it is for the most part extracted from cinnabar and minium.

[Margin: The cinnabar mine of silver-quicksilver.]

In America, the power of the quicksilver embedded in the cinnabar was unknown before the arrival of the Spaniards on those coasts; the color of the cinnabar served the natives only for staining and tinting the faces of themselves and their idols — both for adornment, as they supposed, and to strike terror into their enemies. This continued until at last, through the efforts of the Licentiate Castro, Governor of Peru, its use was demonstrated, the quicksilver mines being first discovered in the year 1566; and chief among them is the richest mine of all, called *de los Santos*. This, as Acosta testifies, is nothing other than a rock — a most solid and hard cliff — soaked through and through with quicksilver, of such great size that in length it occupies 80 and in breadth 40 Spanish *virgae*, or rods. This rock, hewn through in a quadrilateral shape to a depth of 70 fathoms, is said to be of such great extent that at one time it can easily hold 300 men working together in it.

It now remains to tell how gold and silver are extracted by the power of quicksilver in America.

[Margin: The method of extracting quicksilver from its ores.]

We said above that huge heaps of silver-bearing ore had been piled up around the mountain of Potosí as useless. When Pero Fernández de Velasco, a man skilled in metallic matters, had examined these, he made use of the resource of quicksilver and drew from them a vast quantity of silver. The procedure for working both kinds of vein — the fertile as well as the barren — is as follows. The vein rich in quicksilver, well pounded, is thrown into a pot; the pot is then stopped up and committed to the fire. When this has been done, by the force of the fire the quick-

silver, as it were, makes a divorce from the silver and, separated and raised on high, when it meets a denser and more solid body and feels the cooler air, is at

once restored to its former nature, distills, and drops downward. When this is done, and the quicksilver thus protected, the pot — which has by now thoroughly cooled — is opened. Yet here the greatest care must be taken not to receive the fumes while the pot is still hot with quicksilver, for that is done at the gravest peril to life, or at the loss of one's teeth.

[Margin: A herb of the greatest power for the smelting of metals.]

Now since, for the dissolving of the metals, an infinite quantity of wood would be needed, a certain herb, a kind of broom-grass, was discovered, which grows most abundantly in the mountains of Peru and whose power is so wonderful that metals which cannot be melted even in the fiercest furnace-fires of burning wood and charcoal — this herb, gathered into bundles and thrown into the furnaces, immediately, to the great profit of the metallic trade, makes the veins flow. Once dissolved and smelted, the quicksilver is put into a leather sack, brought into the storehouse, and from there conveyed to Potosí, where, in the course of one whole year, 6,000 or 7,000 quintals of quicksilver are spent and consumed in preparing the metals — to say nothing of the amount that is gathered up daily, besides, from the dregs which form the matrix or sediment of the first washing of the metals.

[Margin: Quicksilver recovered from the dregs of the metals.]

These dregs, thus collected, are burned in furnaces, so that if any quicksilver has remained in them it may be drawn out and extracted. Now the yearly quantity of metals prepared at Potosí in these furnaces is reckoned, by the account of our own men and by the calculation of skilled persons, to amount to about 300,000 quintals. And from the dregs and from the remaining refuse of heterogeneous particles floating on top, [where] they find some silver...

from the matrix at least 2,900 quintals of quicksilver are recovered. Yet a remarkable property of the metals is observed in this operation too. Some metals indeed, with a slight expenditure of quicksilver, yield a great deal of silver; others give a large amount of silver at once but consume no less quicksilver; while others, by contrast, which give more sparingly, require less. And so, according to the condition of the metals, the metal-trade meets with good or bad fortune, with profit or loss. It is, however, commonly known that the richer the metals are, the greater the quantity of quicksilver they consume, and vice versa. But now to the practice.

[Margin: The method of separating the metals by quicksilver.]

The metals, then, are at the outset pounded as finely as possible in mortars with pestles prepared for this purpose, and are afterward strained through sieves and twisted copper wires; through which, if they have been skillfully and diligently worked, at least thirty quintals can be passed in the space of 24 hours. The metals thus refined through the strainer are thrown into a large, open vat, in such a way that for every 50 quintals of metal, fifty quintals of salt are added — the purpose being that the salt may consume and eat away the native greasiness of the ground metal; for in this way silver is more easily incorporated with the quicksilver, and combines with it.

[Margin: The method of procedure with quicksilver.]

This done, the quicksilver, put into leather or hempen cloth, is squeezed out in the form of dew or sweat onto the metals; these, first thoroughly worked over with stirring-rods for a better mixing of the particles, are then poured in. At length the mass, duly worked up into the form of cakes, is set out on hearths to be smelted by fire over the course of five or six days. If, then, the quicksilver, having properly done its office, has thoroughly combined with the silver, from...

water, they throw it in, and with a hand-mill, **B** or **C**, they grind down the metallic mass in roughly the manner in which mustard is usually ground and crushed, as the present figure shows. By this agitation, the clay and filth flow off from the metal together with the water itself through the channel **H** or **G**, while the silver, together with the quicksilver — because of its innate heaviness — sinks to the bottom of the vessel. And this, left surviving at the bottom of the vessel in the form of sand, is taken out and washed again to achieve the ultimate purity of the metal; once washed, it is pressed dry in a cloth or hide, so that whatever quicksilver had not been properly united with the silver runs off, while the rest remains within the leather bag as true silver — yet in such a way that only a sixth part of the mass is silver, the remaining five parts being quicksilver.

[Margin: How quicksilver is separated from silver.]

But they also proceed by another method, so that the quicksilver itself may likewise be separated from the silver. They put the compacted mass into vessel **A**, and, applying a strong fire, properly stop up the cover **V** of the vessel, as the figure shows. When the fire is kindled, then, the quicksilver dissolves into a vapor, which — escaping by the force of heat and lightness — if it strikes against those earthen pots, is at once driven together and thickens (not otherwise than as the vapors raised from boiling water condense into drops on the lid of the pot). Then, through the channel **I** assigned to this vessel, it flows down and distills, just

as through an alembic, into vessel **S**. Thus whatever quicksilver was expended on the smelting of the metals is recovered.

Diagram. A distillation apparatus for recovering quicksilver, set on a low brick hearth with a wood fire beneath.

- **V** (top): the cover/cap stopping the head of the still
- **A** (center, body of the still): the vessel holding the compacted metal-mass over the fire

- **S** (right, receiving pot): the receiver vessel into which the distilled quicksilver collects

it is tried out, fermented, and at last thoroughly smelted; then it is washed, dried, and rinsed again and again, cooked and recooked, subjected to the pestle, put through a sieve, and finally passed through furnaces, jars, and bucket-frames, and through fire and water itself — not without peril to the lives of the wretched metallurgists — so that it may serve human use and luxury.

PROCESSUS IV.

By what means silver-rich pure lead is smelted, and on its separation, as practiced in the Hungarian metal-works of Schemnitz [Banská Štiavnica].

After the metallic stones from the ores and the lumps of the veins have been brought to the appointed place:

First, a furnace for smelting is constructed out of pounded clay, into which fine charcoal-powder is mixed, together with a crucible made of the same material, into which the molten matter is discharged through a hole 1½ feet [wide]; the depth of the furnace itself is gradually enlarged by the smelting. Into this are successively thrown three or four hundredweight of fresh lead, five or six of litharge, and of hard lead — all of which are prepared in the pot with various smeltings and additives.

[Margin: The method of smelting the veins.]

First, then, into the furnace **A B C D**, through the hole **G**, is thrown ironstone of the cheaper sort, eight hundredweight together with two hundredweight of mixed marcasite with lead (which they call *Loh* [German *Lech*, the lead-copper

matte]); these are smelted within eight hours. Then there are added eight hundredweight of ironstone from the ironstone, two from the lumps or another stone (which they call *Schlich* in German), and six hundredweight of the material called *Loh*, which are smelted in twelve hours.

It being thus smelted in the furnace, in the forward part of the furnace, above that pot or crucible...

Diagram. A domed smelting-furnace of the Hungarian (Schemnitz) type, with a fire-chamber at the base and a collecting pot beside it.

- G (at the apex / charging vent): the hole through which the charge is thrown in
- A (left side of the furnace body): one corner-point of the furnace **A B C D**
- B (right side of the furnace body): another corner-point of the furnace

- L, M (the pot at right): the receiving pot or crucible (*catinum*) set before the furnace mouth, with a stirring-rod

pure and simple silver, yet diminished by a fifth of itself, is left remaining. From each pair of these cakes, one is made weighing about sixty-five pounds; these are then carried off to the appointed places to be assayed, given their fifth-mark, and stamped. And the silver is of such great purity and excellence that it is sometimes finer than 2,380 *Alloys*. Silver is forced to undergo all these tortures and hardships until it comes out tested, pure, and clean. For even when it is examined more closely as pure, the mass — or rather the paste — is still crude, the mass out of which the silver is ground, sifted, pounded, fermented, and at last smelted, then washed, dried, and rinsed again and again...

Fol. 214 — continuation of the Schemnitz lead-silver smelting ...a broad opening of one palm's width is made, so that the melted material may flow into that pot. In this opening the less pure mass, called *Schlüg* [Schlick/slag] in German, is separated from the other, called *Loh* [Lech/matte] in German. The first flows off into another, special pit; the other remains in the pot, and is successively rolled out from there, until the silver is drawn off from the lead. With this *Loh*-mass set aside, there remains lead rich in silver, which once skimmed off is set aside.

Afterward the remaining material — called in German *Floß-Schlüg* — is again worked in the furnace for about eight hours, and is again let down into the pot LM, until it is well processed.

This done, fresh lead — about three hundredweight — and an equal three hundredweight of litharge [lythargyrium] are again thrown into the pot and melted down. The more impure mass, called *Schlaken* [slag], which melts out first in the furnace, is let down into the pot and pressed free of all the silver still clinging to it. This melting-out of the mass — which in German is called *Schlaken* once it has flowed out — is repeated twice or three times, in such a way that at one time twenty, indeed thirty-six hundredweight of this mass and of the other, which they call in German *Offenbruch* and *Waschwerk*, six hundredweight, eight hundredweight of lead, and six hundredweight of the purer mass rich in marcasite, called *Loh*, are all taken together. All of this is melted for eight hours, until that more impure mass, called *Schlaken*, is entirely smelted out. When this is done, the lead rich in silver is again taken up from the pot.

Once the lead is removed, about thirty hundredweight of marcasite [marchesita] and eight hundredweight of fresh ironstone [lapis ferrarius] are produced and melted down, so that the mass called *Loh* may come out within about eight hours. And when from it about fifteen hundredweight of the material called *Loh* have flowed out, the work in this furnace is finished.

Now another furnace is prepared for further purifying that lead — called in German *der Treibherd* [the refining-hearth] — prepared from the ash of oak-bark and sand. This is heated for two days and nights before the work. Then at last, within two hours, three hundredweight are processed (the mass thrown into this

furnace for purifying they call in German *blütß*). If this mass, called *blütß*, begins to take on color, it is stirred about by a bystander with a hazel rod, that is, a stick of hazel-nut wood; and when this mass seems sufficiently smelted, they quench it first with lukewarm, then with cold water, and purify it with a nearby instrument from the adjacent dross of hard lead. This mass is then transferred to another hearth, called in German *Brengaden*, where it again becomes incandescent and is first restored to its own purity. From there it is at last carried to the place where the silver is finally separated, called *Scheidgarten*; and from twelve hundredweight of rich lead there remain nine hundredweight of litharge, one and a half of hard lead; the rest is pure silver, which is finally separated in the manner we described in the preceding sections.

PROCESSUS V. CHYMICUS.

Used in Hungary, for separating gold from silver.

Silver containing gold is first purified of all metals by cupellation [Cineritium], or *fulmen*, according to the art, with lead. Afterward this silver is granulated, or rolled into sheets as one pleases, and one ounce of it is placed into three ounces of purified aqua fortis [aqua fortis purgata] in a separating glass — as will be seen below — in warm ashes, or upon a tripod, with a little fire. The silver at once dissolves, the gold being left behind in the form of a black calx [calx nigra], into which the dissolved silver is to be poured off by tilting. The black calx is then to be washed so many times with common water until all the sharpness of the aqua fortis has departed; afterward it is to be dried, ignited in a crucible, and finally melted — and one will have all the gold that was contained in the silver.

[Margin: How gold is separated from the other metals.]

This method of separating gold from silver is called *quartatio* or *inquartatio*, for this reason: that when you wish to carry out this separation, there must always be three parts of silver and one part of gold, which is the fourth part [quarta pars]. For gold mixed with an equal part, or with double the silver, is not dissolved by aqua fortis, nor by *Chrysulca* [aqua regia]; but if you wish to make the separation of the said metals by means of *Chrysulca*, the gold must exceed the silver threefold — then the *Chrysulca* dissolves the gold, leaving the silver behind.

Now it must be seen by what method the silver is to be separated from the aqua fortis, which is done in two ways: one is by precipitation [subsidio] of the aqua fortis, in the usual way for such purposes; the other in the way we shall shortly explain. [Margin: Another method here.] The first is this: that the aqua fortis full of silver is placed in a retort, and with a receiver fitted, it is distilled, first with a

slow, finally with a stronger fire of ignition, until all the aqua fortis has gone out from the silver — this being kept for similar uses. The silver left at the bottom is then to be ignited a little more in a crucible, and finally melted into silver, as is the custom.

The other method is this: let the silver dissolved in aqua fortis be mixed with four parts of common water; into this mixture let a copper sheet [lamina cuprea] be placed, and let it be left for 24 hours — and you will find all the silver fallen to the bottom. From this the water is to be poured off, and the silver washed so many times until all the sharpness has departed, then finally dried and reduced with a fusing powder [pulvis liquefactivus].

[Margin: The various separations of metals from gold.]

Now it should be noted that the aqua fortis, from which silver has been separated by means of copper, contains copper in itself — because, from that water, by placing in it an iron sheet, since the nature of aqua fortis is always to take in what is easily soluble and to let go what is difficult — by this experiment it is clear that the said transmutation of iron into copper by means of vitriolic water [aqua vitriolaris] is not true, but rather a precipitation of the copper from the water by means of the iron; and in this

Fol. 215

step [passu] many ash-mongers [ciniflones] — alchemists — can impose upon those ignorant of metallurgical matters, feigning a transmutation of copper into silver, as I myself have once seen.

There is also another separation of silver from aqua fortis by means of water in which common salt has been dissolved. Then the silver falls to the bottom in the form of a white powder, which must be sweetened by many repeated washings, dried, and finally reduced with some fusing powder. These are the chief, the more usual, and the safer methods of separating gold from silver.

[Margin: The properties of aqua fortis.]

Now, concerning aqua fortis, which is of two kinds — one called *Virginea* [virgin], the other *Separatoria* [separating]. The *Virginea* is that which is simply distilled from niter and alum, or from niter and vitriol. This water has many dregs, and for that reason is not called *Separatoria*. It is cleared of dregs by adding to each pound half an ounce of silver: thus the silver will be dissolved, and the water will send its white dregs down to the bottom, which are to be separated by pouring

off. For if these dregs were not separated from the water, then, in the dividing of gold from silver, they would be mixed with the gold and would foul it. Others, however, purify the water in this manner: they dissolve silver in it, then distill, and the silver remains at the bottom together with the dregs of the aqua fortis; and this method is better than the former.

PROCESSUS VI.

From the account of Father Andreas Schaffer.

It must be noted that silver is extracted from ores of two kinds. One has no admixture of gold, or scarcely any worth mentioning, so that it is not worth the trouble to separate that little gold — such is the silver, almost the only kind in the mining towns of Hungary, which is extracted from copper. The other, which is gathered from silver ores (such as is all that is extracted from the Schemnitz pits), has much gold mixed with it.

[Margin: How gold is separated from the other metals.]

Now, how this gold is separated from the silver is a fine thing to see, and I shall send it to the Reverend Father in writing very shortly. There are two methods. One is *im grossen Werck* [in the large works], the process of which Your Reverence will receive under the letter K. The other is *klein Werck, im probiren* [the small works, in assaying], which method I have here put into practice as follows.

First I took some *Goldhältigen Silberkorn* [gold-bearing silver-grain], which I draw out upon an anvil with a hammer into a very thin sheet. This sheet, cut into the smallest particles, I throw into *ein klein gläsern Schaidkolben* [a small glass separating-flask], pouring on aqua fortis, and I hold the glass over the coals so that it warms — not too much, however, lest the glass break. In this boiling water the gold is dissolved from the silver and sinks to the bottom of the glass in the manner of a black powder; the silver mixes with the water, so clearly that it cannot be distinguished from spring water. But if the aqua fortis is not strong enough, or sufficient to dissolve the gold completely, I pour on fresh, until the whole water becomes clear and pure. This done, when the water labors no more, I pour off that aqua fortis little by little

little by little [paulatim] into a prepared earthen pot full of well-warmed common water, yet in such a way that the black powder resting at the bottom does not pass out of the glass. When I have poured off all the aqua fortis, I pour fresh common water into the glass and wash those black powders; and when they have

settled, I pour off the water, and pour the well-washed golden powders out into some dish, and dry them over the coals — thus I have pure and virgin gold alone.

[Margin: How silver is extracted from the water.]

It now remains to extract the silver from the water, which is done in this way. I took a copper sheet (and what I greatly wonder at, they say that no other — neither of iron nor of steel — is of use, but only one of copper). This, suspended by some thread, I put into the middle of the pot over the burning coals, into which that aqua fortis has been thrown — and behold, the silver clings to the sheet, which must be held suspended in the middle of the pot. I draw out the sheet, and with some little stick wipe off the clinging silver in the manner of an ashen mud into some little vessel, and I have pure and virgin silver.

It must, however, be observed that the aqua fortis ought to be separated in a great quantity from the sweet water in the pot; otherwise the copper sheet will be eaten away and dissolved, and the silver adulterated. This I learned by experience. It is also worth knowing and noting, and may serve as a point worthy of consideration.

Fourthly. [Margin: A wonderful property of the silver powder.] If from the said aqua fortis in which the silver is, or from the very white silver powder collected in this way, any part of a person is touched, it so blackens the hand or face that the blackness can be removed only with the greatest labor. And those ignorant of this often deceive and vex these craftsmen. Yet this blackness is more quickly removed — as I learned by experience — with oil of tartar [oleum tartari] than, as they say, with fresh butter. Recently, while someone wanted rather curiously to examine the things I sent on the 7th [gev. 7. = *den 7ten?*, the 7th], I marked a cross on his hand with this water; he could not remove this cross in the space of more than one month, nor by any washing or rubbing, until he washed himself with oil of tartar. Salt of ashes [sal cinerum] also removes this stain. I add, with regard to the silver, that it should be noted that much silver, which is not extracted as a residue on the sheet, settles at the bottom of the pot.

Fifthly, it is also marvelous — what has been grasped by experience and is wont to serve for the vexation of the untrained and beginners, *welche eerst anfangen zu probiren* [who first begin to assay]. From the writing under the letter L, and another under letter G, no. 4, at the end, the Reverend Father will find *wie man das Silber von Bley schaiden, und in Probir-Ofen auf der Capelle abtreiben soll* [how one is to separate the silver from lead, and refine it off on the cupel in the assay-furnace]. So when they wish to do this, *und der Korn-Silber schon auf der Capeln*

ist [and the grain-silver is already on the cupel], if even a small particle of tin [stannum] is added, *so läßt sich das Silber nit abtreiben* [then the silver cannot be driven off / refined], and there is virtually no way of separating the silver from the lead, which the admixed tin causes — or at least it can be done only with the greatest difficulty and immense labor; such troubles does the tin cause, if it is mixed in. Without tin, *kann man's abtreiben* [one can refine it off]...

[Margin: A wonderful...]

Fol. 216

at most within two hours [ad summum intra duas horas], especially if hand-bellows are used. But if tin has been thrown in, such an assayer will need even ten hours; the more skilled assayers have indeed another method, of which in what follows.

As to what the Reverend Father writes in the second letter sent to me — namely, that I should explain to him how the iron must be prepared, so that it is turned into copper by vitriolic water — I inform Your Reverence that they are accustomed, both *in Herrengrund* near Neosolium [Neusohl / Banská Bystrica], and at Schemnitz near *Sepusium* [Margin: The method of transmuting iron into copper], that all old iron and broken iron implements, which can no longer be of any use — such as old iron shovels, broken rakes, axes, etc. — are forged at the smith's by fire into round, oblong, oval-shaped sheets, etc.; and the thinner they are forged, the more quickly they are turned into copper. This is the practice.

But the Reverend Father should know that that vitriolic water is found deepest inside the mountain, because there, on account of the copper ores dug out, there are great pits and excavated places. To that depth where the said water is found, there will be — if I remember well — a hundred fathoms [orgyiae], if not more; for certain I cannot say, I forgot to inquire. There a small stream of vitriolic water flows out from the mountain; and there they have troughs — they call them *Kasten* [chests/boxes] — made of wood, into which they channel that water. These troughs are always full of that water. Into these troughs they throw the iron sheets, and there (*in Herrengrund*, where the water is not so strong as at Schemnitz) they let them lie for three months. Then that iron is already fully turned into copper, and it lies in the water like gold; if it is taken out, the material is as soft as mud, or like a mass of bread — *wie ein Taig* [like a dough]. But afterward, when it is carried out from the mountain, it hardens.

[Margin annotation, left side, in manuscript hand: *Vid[e] supr[a] l. 6 [?] Sect[io] 2 Cap. 2 [?] proem [?] §. 1 [?] pag. 524 [?]* — a cross-reference to an earlier passage; reading uncertain.]

CAPUT IX.

On the Mines of Copper [Aes], or Cuprum.

Copper [Aes] is properly generated by a sulphureo-mercurial exhalation, in earth that is atramentous [terra atramentosa, vitriol-bearing], impure, and variously contaminated. Indeed, by its very color it at once shows that a metal of this kind has been violently scorched, since it shines with so intensely red a color. And just as the vein is of various color, so too it is generated in diverse kinds of stones. And although some call it weak, leafy [foliosum], and earthy, yet, since it is easily extended by the hammer, it thereby openly shows that it possesses an inner richness [pinguedo intrinseca], by which the parts are not easily dissolved from the parts, as was said in the preceding.

[Margin: Signs of latent copper.]

The chief sign, then, of a copper vein lying hidden somewhere is the fissuring of rocks of a yellow and blue color, and an abundance of cracks. And the reason is that Mercury, raised too high by excessive heat, dries out the stone in its inner moisture, whence it must of necessity be that fissures and cracks arise, as it were, by the dissolution of the bond of continuity. Whenever, therefore, you find such rocks of a blue color within a rock of grey color, shaded with little veins of green color, let that be for you a sure sign of an excellent and rich vein. If again you see rocks of the mountains glittering in the manner of talc — which are indeed nothing other than the leafy brood of pyrites [foliata pyritis foetura] — you will obtain a near sign of a hidden vein. Moreover, vitriolic water from the mountains, of a greenish color and metallic smell, which coats the bed of the river with a certain putrid, thin, and slimy green matter, as if with a kind of skin, will indicate a mountain pregnant with copper. The reason for this is none other than that the river abrades from the coppery veins certain vitriolic corpuscles, which, then cast down within the river, while they cling to the stones, with time, by the natural richness of sulphur in which they abound, form this green skin I have spoken of.

And as copper has great use in human needs, so too Nature willed it to be most abundant, and most easily worked on account of its flexible nature — for it is easily tinged into orichalcum [aurichalcum, brass] by the aid of calamine earth [terra Gelaminae / lapis calaminaris]; with the powder of sulphur it is easily

reduced to a calx; with salt it is changed from red to white; with tin, or with arsenic, it readily renders itself fusible — of which more fully in what follows. Nor are there lacking those who, by frequent cementation [cementatio], extract from it some quantity of gold as well. The secret method of proceeding will be declared below in the chapter on Iron. But how copper is changed into orichalcum, I explain in a few words.

The Method by which Copper is Transmuted into Orichalcum.

[Margin: The first method.]

Take fragments of the best copper and of calamine [Cadmia], and place them by turns into oblong pots, which, filled with copper and calamine, are let down into furnaces excavated below, and the fire is kindled in certain channels, as it were. So when they have been melted together, the copper, tinged with the color of gold, is changed into orichalcum. This is the common method.

[Margin: Another method.]

But others throw thin plates of copper, about a finger's breadth wide, into the pot in which silver is usually melted, and they smear its outer part with clay, which when mixed becomes iron-scale [ferri squama]; the inner part, however, with the purest honey. Likewise they smear each of the copper plates, and sprinkle on them the finest powder, which is made from fossil calamine [Cadmia fossilis], lees of wine [faeces vini], which they call tartar, and charcoal of linden-wood [carbones tiliae] in equal portions. The pot, moreover, is covered with an earthenware lid [operculum fictile], which has a hole into which a stylus is inserted, by which the melted copper is stirred. But the lid...

Fol. 217

the lid [culum] too, on the part where it joins the pot, is smeared over with superimposed clay. The pot, fitted out in this way, is placed in the furnace. And so, when calamine [Cadmia] is mixed with the copper, there first comes out red smoke, then blue, and finally yellow — which signifies that the mixing has been accomplished and the orichalcum perfected.

[Margin: Signs of the operation completed.]

Another Method by which Copper is Colored.

When copper has been diligently purified and separated from the other metals, the craftsmen strive to color it in manifold ways. For sometimes they add

calamine [Cadmia] to it when molten, and the copper takes on a golden color. Sometimes they add magnet [Magnes], or talc [Talcum], and then it presents the appearance of silver — since from white talc, by chemical instruments, a water is extracted which is most excellent for whitening copper. Other methods besides are reported by which we can counterfeit silver out of copper. [Margin: Various ways of coloring copper.] Some attempt to achieve a metamorphosis of copper into silver by grinding equal portions of orpiment [Auripigmentum] and saltpeter [halinitrum] in a glass vessel over coals, and adding half an ounce of this powder to each pound of copper, mixing until it is transmuted into a true silver form. But this can in no way be called a transmutation into silver, but only an accidental tincture of silver.

But if we consider the mixture, this is wont to be of two kinds: for copper is mixed either with other metals, or with other fossils [minerals]. Of the latter mixture we treated a little before, when with magnet it acquires a silver color, and with the calamine-stone [lapis calaminaris], called *Cadmia*, a golden color. For by this last method, copper being melted, the prepared orichalcum [Aurichalcum] is so called.

[Margin: The mixture or alloy [Liga] of copper.]

And so, before copper is melted together with other metals, its fusion — whether slow or quick — must be weighed. Mizaldus [Antoine Mizauld], to accelerate the fusion of copper, mixes in horses' hooves during the melting. As, therefore, the other metals have their own mixture, which the craftsmen call *Lega* [alloy], so too copper is not exempt from this — not that the mass of the copper be increased, as was related of gold and silver, but that a certain viscosity be removed from it, which prevents it from being rightly cast for various works. It is therefore mixed with tin and with orichalcum; yet the proper and best mixture, or alloy, by which it is perfected, is said to be tin, so that works may be made without [other] metal — for in works requiring the hammer and dilatation, the purest and most perfect copper is grievous [unsuitable], since copper mixed with brass is broken by the hammer.

[Margin: The various mixtures of copper for making various things.]

This mixture must be varied according to the variety of works: for statues require one, cannon another, bells another, and finally mortars and cauldrons another. Inasmuch as a hundred pounds of copper with twelve of tin make the metal for the larger artillery pieces [tormenta bellica], but a hundred pounds of copper with twenty of tin constitute the metal for bells. This mixture is sometimes called

by the craftsmen *metallum* [bell-metal], sometimes commonly *bronzum* [bronze], according to the greater or lesser quantity of tin it receives. Some, with less expense, mix orichalcum or lead with the copper, and likewise what they call *bronze* they strive to cast for various works.

[Margin: In the fusion of copper three things are worthy of consideration.]

Three things are especially worthy of consideration in molten copper. First, this is innate to it by nature, as Pliny relates, that when great cold comes on, it melts better and more quickly — although it does not endure the vehement assay of flames, for it is wholly burnt up. From this it is to be concluded that there is much combustible exhalation in it, besides that, in comparison with the other metals, it gives off a sulphurous and fetid smell.

[Margin: Why copper is better burnt in cold weather.]

Next, if a pebble, or mud, or wood, or a wet coal — as Agricola attests — falls into the copper still molten in the pot, then the pot, roaring like thunder, casts out all the copper it contains, and damages and sets fire to whatever it touches.

[Margin: Copper's thunderbolt.]

Again, if one considers the copper once made: it is to be noted that copper, often wiped, contracts rust [*verdigris*] more quickly than copper neglected; and immune from this blemish, as Pliny attests, it is preserved with liquid pitch. But smeared with oil, or moistened with salt and vinegar, it is straightway vexed with *verdigris* [*aerugo*] — though afterward it is not consumed by it. For which reason works of copper are said to attain almost eternity; indeed, copper is easily tinged into the appearance of silver.

Finally, the investigators of natural things have reported that that water is the best which, long held in a copper vessel, has not stained it. [Margin: A wonderful property of copper.] Likewise, they relate that water kept in copper vessels has been observed to rise with a notable increase when the clouds are condensed into rain; and they conjecture that this arises from the fact that Venus rules over the sea and over copper. But these things, as they are repugnant to experience, so are they to be reckoned mere fancies and sportings of the imagination.

The Uses of Copper in Medicine.

In many afflictions by which the human body is troubled, copper can be applied as a most effective remedy. And that it is most useful in medicine we gather from this, that those wounded by copper are cured more quickly than those struck by

iron; and although thermal waters infected with verdigris promote vomiting, nevertheless they are of no small help to the mouth, glands, uvula, and eyes.

[Margin: The effects of copper in medicine.]

Hence Dioscorides employs copper vessels for eye-medicines. For which reason Macrobius wrote with the best of right that workmen engaged in copper mines are always strong in the health of their eyes, and that others suffering in the eyes, coming to the copper-works, recover their former health. For this reason, in the apothecaries' shops, burnt copper [aes crematum], flower of copper [flos aeris], verdigris [aerugo], and scale of copper [squama aeris] are kept, since, according to the mind of Dioscorides, they are endowed with a drying and astringent virtue. Flower of copper, according to the same author, not only astringes but represses flesh growing over ulcers, and confers clarity to the eyes. Scale of copper is held to be best in Cyprus, which likewise, mixed with ophthalmic medicaments, checks the flux of the eyes and removes the roughness of the eyelids.

[Continuation of] Caput IX — De Fodinis Aeris, seu Cupri [On the Mines of Copper] (*copper, continued*)

(Fol. 218 verso)

Verdigris [aerugo] imparts a sharp quality to the taste, and according to Galen it shares in a digestive faculty. For that reason, when mixed with wax and oil, it brings wounds to a scar. Today in the apothecaries' shops verdigris is used in place of flower of copper [flos aeris]; its virtues are celebrated by Jodocus [Jodocus Willich?] in these verses:

It binds, it thins, it draws forth tears, it heals ulcers, It overcomes calluses
and the hardness of a place. It dries out the filth of the ear; but when it
grows up inside the nostrils, the diseased flesh must from there be
pressed away.

Finally, burnt copper [aes ustum] is called by the barbarians *Calceumenon*, though properly it ought to be called *Chalcos cecaumenos* [Greek: χαλκὸς κεκαυμένος (chalkos kekaumenos, "burnt copper")]. According to the opinion of Dioscorides it strongly astringes, dries out, and easily heals ulcers thoroughly; for this reason it enters into various external medicines. Burnt copper [aes crematum] is placed in the Apostolic plaster of Nicolaus Alexandrinus [Nicholas of Alexandria]. Verdigris [aerugo] goes into the *emplastrum divinum* of Nicolaus Praepositus [Nicholas of Salerno], into the Apostles' ointment [unguentum Apostolorum] of Avicenna, and into the Egyptian ointment [unguentum

Aegyptiacum] of Mesue [Mesue the Younger] — all of which medicines, since they share in a sharp quality, cleanse most thoroughly though not without some biting, and nevertheless contribute in no small measure to the cure of a putrid ulcer. The professors of alchemy, by various artifices, prepare from copper — or "Venus," as they themselves call it — a powder, a lime [calx], a saffron [crocus], a quintessence, a tincture, an oil, a vitriol, and a flower; the preparations of all of which see in what follows.

[Margin: χάλκωμα — what it is.]

Orichalci praeparandi ratio, et Modus [The Method and Manner of Preparing Brass]

Many men, professors of the metallic art, beat common copper [aes] into thin sheets; to half a pound of these they take an ounce of tutty [tutia, zinc oxide] together with garlic, figs, honey, and mouse-dung, and by melting all these together at once they turn it into brass [orichalcum]. We do not approve of this method, since we have other, easier methods in Agricola [Georgius Agricola].

[Margin: The method of tingeing copper into brass.]

Today at Milan copper is tinged into brass in the following way. A quantity of beaten copper is taken and cut into pieces; the melting-vessel must be large enough to hold them, yet is not filled all the way to the top, so that there may be added to it a certain heavy mineral earth of a yellow color, called *Gislamina* in the vernacular, perhaps on account of its color. Over these is laid a powder of glass, and the whole mass is melted, and the copper of a red color acquires a golden color. Indeed — to the great profit of the workmen — that earth is so joined to the metal that the mass is increased to a remarkable degree. Others, finally, think they can give brass a silver color; among them is reckoned Falloppius [Gabriele Falloppio], who brings to a boil in vinegar equal parts of sublimate of quicksilver [mercury] and sal ammoniac, and then quenches in it the heated brass. But of these things at greater length in what follows.

[Margin: The method of tingeing copper into a silver color.]

Natura et differentiae Orichalci [The Nature and Varieties of Brass]

Utrum Orichalcum nativum sit, an tantum factitium [Whether Brass is Native, or Only Artificial]

Nature so contrived this metal that, by reason of its color, it approaches gold; for this reason many report brass [orichalcum] to be a certain metallic material

which of old was held more precious than copper — although Caelius Rhodiginus [Lodovico Ricchieri] wrote that brass appears to be a coppery metal, namely *Chalcoma* [Greek: χάλκωμα (chalkōma, "copper-ware, bronze")]. Nevertheless, by comparison with copper, nature endowed the former with this: that it should possess a greater hardness, in keeping with that verse:

With woven roughness of gold and hard brass.

Berinautins [Beringuccio? — i.e. Vannoccio Biringuccio] [?], departing from the opinion of many, judged that brass lacks veins of its own, and reproached Pliny, who, while sometimes mentioning brass among the metals, did not assign it a natural locality; and he further adds that a vein of brass could be dug up even today if one had once been found — indeed, establishing his opinion more and more firmly, he declared that, just as steel is reduced to iron, so brass is reduced to copper. We, however, in refuting this opinion, say that brass is nothing other than copper tinged by the subterranean power of Vulcan with fossil cadmia [cadmia fossilis, calamine] — and that, while it is to be found both artificial and afterwards native, nevertheless it is not the artificial kind that is prepared with so great a difficulty of labor and at the expense of so much work. Brass is therefore twofold: Natural and Artificial. We call native that which is dug out from mines of its own — drawn from this ore [?], which Pliny most highly commended for its outstanding excellence; this kind later ceased, for the said reason; and a certain species of natural brass, which is dug between Mexico and Darien [the Isthmus of Darién, Panama], and which nonetheless can be melted by no violence of flames, demonstrates this fully and more than fully.

[Margin: Whether brass is native and artificial.]

Minera Plumbi, ejusque conditiones [The Ore of Lead, and its Properties]

Although lead [plumbum] is for the most part held by metallurgists, on account of its extreme impurity and its abundance of earthy refuse, to be an imperfect, leprous, and scarcely fixed metal, nevertheless, if we examine its admirable qualities a little more deeply, it ought by no means undeservedly to be esteemed most highly — since without it neither the separation of gold from silver, nor of silver from the rest of the metals, can be obtained, nor can the native splendor of a precious stone and a gem be achieved except by its help. For where heaps of veins of gold mixed with silver are dug up, the metals are better separated from them by no other means than by lead, as we saw a little earlier; and so gold and

silver come to their due perfection only by the aid of lead alone. But of the usefulness of this metal more fully below.

[Margin: The uses of lead.]

It is found chiefly in various rocks and earthy clods, almost always with some admixture of gold and silver: first in a certain spongy, white, and hard rock, which they call *Columbinum* [columbine, lead-colored], whose mark is given by certain black spots and grains scattered here and there over the surface of the stone. Then too it is found in a stone of a red or rusty color,

[Margin: What is the matrix of lead?]

(*Fol. 219 recto*)

and then in certain earthy clods of an ash-gray color, of the kind reported to be found in Andalusia in Spain. And just as it is separated from its veins with easy effort, so too it is refined without difficult labor, and melted with a small fire — sometimes by itself, sometimes mixed with other metals which, associated with lead, flow more easily in the fire. And — what is remarkable — it preserves the other metals from being burnt up by the arsenic even in a powerful fire, and from flying off with the mercury. But why lead alone is endowed with this separative power, and is therefore found heavier and weightier than the other metals, and especially when joined to silver: of this matter there is no other reason than that lead, through calcination — all its pores being closed and its airy and watery spirits evaporated — is rendered much denser than in its prior natural state; and the denser and more compacted a body is, the heavier too it is made to be, as experience teaches.

[Margin: Lead, the friend of silver.] [Margin: Why calcined lead is heavier.]

There is also another property in lead: that when calcined by a most powerful fire of reverberation, so far is it from losing anything of its bulk and weight, that it is rather reduced to a lime [calx]. This is plain in corpses, which are much heavier when life had departed from them than while life was in them — because the living body, full of air and spirits, is to some degree lightened, whereas the dead body, all its spirits expelled and its channels closed, is rendered more compact.

[Margin: Why the dead body is heavier than the living.]

The cause of this is that lead, of itself and by its own nature, being little fixed, and excelling the rest in wateriness — whereas silver and copper are dry metals — it

follows that that wateriness of the lead, joined to dryness, by its watery viscosity fattens up the dry, and consequently [makes it flow more easily when incorporated with it]. [Note: the text recombines here with the column begun above ("...so that, incorporated with them, it makes them flow more easily").]

Caput X. — DE FERRI FODINIS [On the Mines of Iron]

Ferri Natura, et proprietates [The Nature and Properties of Iron]

Although Pliny explained the nature and affections of this metal in many words, we shall here adduce whatever experience has established for us concerning the nature, properties, and preparation of iron. Iron [ferrum], an impure and earthy metal, is composed of burnt sulphur coupled with a slight watery moisture not well mixed with an earthy exhalation; for that reason, in the fire, beyond the other metals, it scatters a most foul-smelling smoke. On this account it is called a base and ignoble metal, and this is made plain by its livid color. Hence too Albertus [Albertus Magnus] reported that iron likewise results from a mixture of impure quicksilver and from unclean and earthy sulphur. It is therefore no cause for wonder if iron, struck by iron, sparks, since everyone knows that this proceeds from the substance of sulphur.

[Margin: The genesis of iron.] [Margin: An experiment.]

Iron has, besides, another material congenial to it, which can in no way be burnt up; for there are observed, in the furnaces in which iron is composed into masses, certain vapors exhaling from the iron-material, which turn into a down [lanugo] clinging to the walls and roofs of the workshop, to which nature has assigned so great a force that it cannot be consumed by the greatest vehemence of fire. These things being so, some, weighing the temperament of iron, place it in heat and dryness — so that the astrologers accordingly placed iron under the dominion of Mars, a hot and dry planet. Besides that experience declares the temperament of iron to be hot, in that the superfluous moistures of the stomach are consumed by it and stubborn obstructions are opened up. On the other hand, Galen seems to reduce iron to coldness and dryness, when he compares it to a stony substance, which on account of cold and dryness is stable. Many authors afterwards in Medicine — and no ordinary ones — followed this opinion. For the Conciliator [Pietro d'Abano] pronounces iron to be cold; Jacobus de Partibus [Jacques Despars], in his commentaries on Avicenna, declared iron to be cold and dry; Manardus [Giovanni Manardo] established that chalybeate water [aqua chalybeata] is cold and dry; indeed many others seem to confirm this opinion with one voice. Therefore, to reconcile such great men, who have written

variously about the temperament of this metal, it must be asserted that — according to the dominion of the primary qualities — iron cools and dries; and since certain sulphurous portions are possessed by it, by these the stomach is strengthened, the excrements contained within it are consumed, and obstructed vessels are opened in a wonderful manner.

[Margin: The quality of iron.]

Since, then, everyone knows that this metal proceeds from a substance of earthy, coarse, and burnt sulphur, it strongly resists fire, and at last softens, and is melted only by a vehement blaze of flames. And although nature has engendered so great a hardness in this metal, nevertheless that same nature has produced a water which erodes iron without difficulty — such as is the well-water in Cepusium [the Zips/Spiš region] at Smolnitium [Smolník, Slovakia], and of the same condition is the river Styx around the Thessalian Tempe; since water of this kind cannot long be held in iron vessels without their being eroded and its flowing out. Indeed — what is worthy of greater wonder — the experience is that living creatures are harmful to this metal. For Theophrastus relates that on the island of Syaros [Syros], when the inhabitants had been driven out, the iron was eroded by mice; and some, on the report of Mizaldus [Antoine Mizauld], have declared that among the Chalybes the mice made great havoc in the iron-workshops. From this it is to be gathered that the hardness of this metal is not so very remarkable that iron cannot be twisted by the hands.

[Margin: Whence the hardness of iron.] [Margin: An observation regarding the temperament of iron.] [Margin: Iron eroded by mice.]

(Fol. 220 verso)

We have seen some men breaking an iron nail with remarkable ease. For they would take two bands three ells in length, woven partly of coarser and partly of finer thread, with which they so wrapped the iron that the finer part embraced the nail; and then, by a simple twisting of the hands, they divided the nail into two parts.

[Margin: A rare experiment.]

Again, iron undergoes other affections. First, when glowing-hot and struck by the hammer, it emits sparks, which are called *strictura* by Nonius [Marcus Nonius? / Nonnius]; and in smelting it yields a refuse, namely slag [scoria] or *loppa* [dross], which is thrown away by the smelter and by the blacksmiths. This, however, is that very material from which the chemists [Chymici] asserted the Philosophers'

Stone [lapis Philosophorum] to consist. Lastly, it undergoes rust [rubigo], and in the course of time is entirely consumed by water, according to that verse:

Rust gnaws iron, and the wood-worm gnaws timber.

[Margin: Rust consumes iron.]

But when it is fouled by human blood, according to Pliny, it is more quickly spoiled by rust; and this defect is, in Pliny's view, kept off from the iron by gypsum, white lead [cerussa], and liquid pitch. Likewise every kind of ironwork does not feel rust if it is smeared over with deer-marrow, the fat of a cat, or white lead mixed with oil of roses. Tin [stannum] too, poured over iron, prevents it from rusting; but when mixed with iron, in the opinion of Albertus, it renders it brittle and scarcely ductile.

[Margin: A remedy against rust.]

§. I. — Sympathia et Antipathia [Sympathy and Antipathy]

We find that iron is by no means at variance with the nature of animals, herbs, and stones. In the first place, it is in no way adverse to human nature, since iron has lurked hidden in wounds for a long time without harm to the patient. For Zacutus Lusitanus [Abraham Zacuto Lusitano] relates that a deep wound was inflicted on a certain woman through the crown of the head with a sharp knife; she lay sluggish and drowsy for several days, and at length, the scar having closed over, complained not at all of any impairment of animal function, and again went about her household business. But when, after a space of eight years had passed, she died oppressed by a malignant fever, the curious surgeons, opening the skull, found between the dura mater [meninx] and the skull the middle part of the knife with which she had once been wounded, all rusty. Among the brute animals there is none that delights so greatly in iron as the ostrich [struthiocamelus]; for this bird, when an iron nail or key is thrown to it — as I myself more than once tested in Malta — at once meets it, and no otherwise than as a dog at the sight of a piece of bread, greedily swallows down the iron it has seized, the cause of which we have explained elsewhere.

[Margin: An observation of iron lying hidden within the human body for a long time.] [Margin: Why the ostrich delights in iron.]

This indeed is not far from the truth: namely, that bedbugs [cimices] are most greatly delighted by the smell of iron; for when iron is fixed in a place where they nest, a little afterwards they all, as if in concord, embrace it. Moreover, there is no lack of vegetables that love the friendship of iron, and which on this account very

often grow up over ores. Among these plants are reckoned chiefly wild woad [Isatis sylvestris] and madder [Erythrodanum, Rubia], since, being marked by a certain ferruginous quality, they not only serve to preserve the magnet — as we showed in the *Ars Magnetica* — but [also], when reduced to ash and placed in glass furnaces, they leave behind in the bottom of the crucible a certain ferruginous sediment. On the other hand, there are other plants which are utterly adverse to the iron-nature; and this Gaudentius Merula pronounced concerning basil [ocymum]. Likewise iron is joined by no bond of friendship to Mercury, Gold, and Silver, since it is coupled with them only with the greatest difficulty; and therefore the workmen of the mint have never observed anything of the said metals to have stuck to the iron pans of the workshop.

[Margin: Bedbugs delighted by iron.] [Margin: The friendship of iron with plants.] [Margin: The disagreement of gold with iron.]

§. II. — Ferri praeparandi et temperandi ratio [The Method of Preparing and Tempering Iron]

Pliny relates that in Cappadocia men exert themselves with no great labor to have an abundance of iron, since they flood the ground with a certain river, and from that earth iron is produced as though it came forth from furnaces. Likewise those dwelling above Amarcantum [?], a city of Ireland [Hibernia], fix a wooden spear in a certain pool, and after some months find that the part of the spear wrapped round with mud has degenerated into the finest iron; the part submerged in the water turns into whetstone [cos], and the part that remained above the water keeps the proper nature of wood. So too in the island of Ireland, likewise near a certain town, a stone is found which by a simple burning is turned into iron. Aristotle assigns such a preparation of iron, saying that by the vehement power of fire iron is melted in the manner of the other metals, and much slag is separated, and thus iron is rendered purer and harder; and by repeated operation iron is converted into steel [chalybs]. For the rest, before the vein of iron is smelted, it must be carefully examined, whether it can be rich or poor in iron. Therefore an ore of iron of some known weight is taken, which, reduced to a very fine powder, is placed upon a fine bronze plate,

[Margin: Earth and stones are changed into iron.] [Margin: An observation in the smelting of iron.] [Margin: The quantity of iron is determined by the magnet.]

(Fol. 221 recto)

with a piece of magnet placed beneath; and while this is gradually moved, the grains of iron, following the motion of the magnet, are separated from the earth,

and in this easy way the quantity of iron contained in the vein is known. Today in Germany iron is prepared in two ways: first, it is drawn out from certain stones; secondly, it is smelted out from a red earth, as it were damaged by ferruginous rust — which work is carried out in Silesia. Besides, there are some in Germany who draw out the best iron from the magnet [magnes]. It must be noted, however, that those who chiefly smelt iron of good quality exert themselves with various labors and fatigue the body with diverse exertions — those who busy themselves about the iron-vein, which is worked with difficulty and is coppery [aerosa]; which methods are to be read in Agricola. If now we turn our mind to the temperaments of iron, recooked iron, carefully separated from the slag, acquires no common hardness.

The craftsmen in the workshops, however, first observe the color of the glowing iron, and then choose the liquid according to their intention, so that the iron quenched in it may obtain hardness or softness. When, therefore, the violence of the fire has brought the iron to the ultimate mark of whiteness, they call it "silver," and then they do not quench it, because it would be consumed; but if it is tinged with a saffron or red color, the iron is called "rosy" or "golden," and then, plunged into liquids, it is made harder. Today in the workshops a fourfold tempering [tinctura] of iron is observed: the first is of a white color, which is too hard; the second is yellow, by which bones and stones are cut; the third is mixed of purple and blue, suitable for cutting wood; the fourth is black, which is reported to be too soft. On the other hand, the liquids in which the white-hot iron is to be quenched, according to the varied temperament, must be weighed. Many rivers are celebrated as suited to the tempering of iron: for this reason iron, in the writings of the ancients, was commended in Noricum; of this condition are the Bilbilis, the Tarassus [Tarazona/Queiles?], the Salo [Jalón], the Chalybs (so called by Justin), and (by others) the Iberus [Ebro] — whence Iberian breastplates are read of in Horace as the strongest. Of the river Salo, Martial sang thus:

[Margin: The temperaments of iron varied with various instruments.]

The Salo, temperer of arms, girds it about with a thin but restless current.

Likewise in Italy the river Comum [Como], flowing between, and the Lambrus [Lambro], flowing through Milan, are reported to enjoy this same prerogative; wherefore of this last river it is sung thus:

I wanted no breastplate but one hardened by the Lambro.

Virgil too, speaking of the sword of Turnus, excellently tempered in the Stygian river, sang in this manner:

The sword which the fire-mighty God himself had made for Daunus, his father, and had dipped, glowing, in the Stygian wave.

Since, then, in iron sometimes softness, and at other times hardness, is desired, there will be methods to be assigned by which we may easily achieve either. That Glaucus of Samos [Glaucus of Chios], who invented the art of soldering [ferruminatio] — according to Suidas [the *Suda*] — quenched in oil the iron he wished to be soft, and in water that which he wished hard. Some, to communicate hardness to iron, place lead in a cavity of the iron and heat the whole until the lead goes off in smoke; and they repeat this work so often that the iron softens like wax. Moreover, iron repeatedly made white-hot and cooled by itself softens in a wonderful manner; experience teaches this in iron wires, which, when ignited and cooled by themselves, come out soft and ductile. Others, in the juice of mallow or of beans, quench glowing iron, and then draw it out soft. Others smear the iron with oil of bitter almonds, and cover it over with wax mixed with asafoetida [Assa foetida] and a little of the salt Alkali, and wrap the whole in niter and in clay made of horse-dung, and leave it in a fire of coals overnight; and thereupon they have iron tractable and soft.

[Margin: Various experiments.] [Margin: The method of tempering iron, and various experiments with the juices.] [Margin: The tempering of the sword.]

Moreover, iron carefully wrought can be tempered softer or harder according to the intention of the worker, since swords require one temperament, files another, and arms prepared for defense another. Albertus handed down that iron is made sharper by a tempering of the juice of radish and of the water of earthworms — which Porta [Giambattista della Porta] denied to answer to experiment. Swords, therefore, require such a tempering that they be endowed with a sinewy thinness, lest, while they strike with the point, they break; likewise they demand a sharp edge, so that, striking with the cut, they may sever; wherefore the body of the sword is tempered with oil and butter, but the edge is quenched with sharp liquids, so that in cutting it may acquire strength. And this work — as Porta advises — the workmen accomplish either with wooden channels or with wet woolen cloths. The chisel [scalprum], again, according to the same Porta, for cutting iron, is to be made red-hot in the forge, and when the ruddy color of the rose appears in it, it is to be quenched in water; then a second color, tawny, is to be awaited, and again it is to be plunged into water. Likewise, for carving marble, iron prepared from the best steel and ignited is to be wetted with water when a rosy or red color appears, and soon after, when removed and a golden color appears, again to be plunged into water. A file is to be tempered in such a way

that it can conveniently file other iron: take, then, soot from the tips of horn or from the hooves of an ox, a portion of ground glass, and common salt, and let all be mixed with vinegar; then the file, soaked with this mixture, is to be made white-hot by fire, and afterwards quenched at once in vinegar, or in urine, or in cold water.

[Margin: Other temperings of iron.] [Margin: The tempering of the sword.]
[Margin: The tempering of the file.]

A fishhook requires a similar tempering, so that it may not be bent in the least by the bites of fish; conversely, iron for phlebotomy [bloodletting] requires a soft tempering, lest in the operation it be either bent or broken. Likewise grass-scythes [falces herbariae], because they are thin, do not require a strong tempering.

[Margin: The tempering of the fishhook.] [Margin: Phlebotomy.] [Margin: The scythe.]

After various instruments or arms have been fabricated from purged and carefully tempered iron, they are accustomed to be marked with certain images or characters; therefore, to carry out this work, iron pyrites [pyrites] of a golden color, reduced to powder, is macerated for one natural day in vinegar, and the vessel being brought near the fire so that it boils, another vinegar is added on top; and when this has been dried off, the material is distilled through glass instruments into a liquid, with which images or letters are designed upon any iron instrument; these at first sight will appear black, but when dried and rubbed with a linen cloth they will be seen golden. Many, on the occasion of the quenching of iron in various liquids and of its tempering, suppose that iron can be ripened into copper [cuprum], both by nature and by artifice. But it must be noted that iron is not so cooked off by nature that it comes out [as copper], as Scaliger [Julius Caesar Scaliger] most excellently proved in his *Exercitationes* [Exercitationes]. Moreover, iron immersed in vitriolated waters, both natural and those prepared by art, is dissolved; and since

[Margin: How letters are cut into steel.] " complete the catchword of the prior folio.]

since waters of this kind, sharing in vitriol — and also containing copper — once the iron substance has been dissolved, the copper is found at the bottom of these waters. This copper is not generated from the iron, but rather is precipitated out by the agency of the iron.

[Margin: Chemists' water for dissolving iron.]

For dissolving iron, chemists use a strong red water, which is made up of a quarter [part] of white vitriol, seven ounces of Hungarian vitriol, a third [part] of salt, and half an ounce of alum. But Pandulphus Anglus [Pandulf of England], who wrote on minerals [*De Fossilibus*], reported that iron is better liquefied when quenched in honey. Finally, iron can also be mixed with copper and with tin, but it is thereby made coarser and more brittle.

Let these things, gathered from various authors, suffice. Anyone who wants further techniques — by which iron may be purified, and also coated with gold and silver — should consult the last Book [of this work], which will recite a long series of these secrets.

§. III.

On the iron-mines of Ilva, commonly Elba, an island of the Tuscan Sea.

[Margin: The excellence of the iron of the island of Ilva [Elba].]

Just as no metal is so necessary for human use as iron, so too there is none that is produced in greater abundance almost everywhere; so much so that scarcely any region of the world is found where it is not at hand. Thus provident nature willed it to be available everywhere and for this purpose, since in the human economy nothing can be made without iron. Hence Italy, Germany, France, Belgium, Spain, Poland, Asia, Africa, and America — as the geographical accounts teach — are full of iron-mines. I therefore consider it superfluous to append here a fuller catalogue of the world's iron-mines. I will say only that on the island of Ilva [Elba] there is such an abundance of iron ores that the whole island could be called nothing but iron — and not of the lowest grade, but the noblest and most excellent of all. And since I personally surveyed the island some years ago, and observed with the utmost diligence the manner of extracting, preparing, and converting it into steel, I have thought it worthwhile to set out here the method and procedure just as I saw and observed it.

I say, then, that iron — like the other metals — is not always found at the same degree of perfection. For there is a "sweet" iron, as on the island of Ilva [Elba], of such perfection that even the raw lumps of ore can be smelted, by the simple and ordinary fire of smiths, into a noble and workable iron fit for every use. The reason for this is the supreme purity of the iron. In other places, however, the iron is not of this quality, but raw, uncooked, rough, and so corrupted by earthy

matter, by the odors of other metals, and by impurities, that it can scarcely be brought to a better condition except by the immense violence of furnaces and fires — and that with great expenditure of labor and cost. There are also other ores which, more or less, contain copper, and are therefore [continued below]...

[Bottom-of-column note carries to the right column:]...subject to such mixtures of impurities. How the pure can be separated from the impure, I will explain, taught by ocular experience. For the most part the procedure is as follows.

[Margin: Cooking [smelting] of the iron.]

First. There is need of a man skilled in iron ores, who knows how to separate the pure ore-lumps from the impure. Let him set these selected lumps aside, broken into pieces, by their respective grades.

Second. Above all, great care must be taken with the charcoal. Here in Italy they generally use charcoal of mastic [lentiscus], holm-oak [ilex], elm, ash, and similar trees, inasmuch as these kindle the most powerful and effective fire.

Third. The pieces of iron ore-lumps are cast into an open furnace and cooked; once cooked, they are drawn out again and exposed to rain and to the heat of the sun. For in this way the iron matter is, as it were, ripened and digested toward attaining its proper perfection.

Fourth. This done, the pieces, impregnated by sun and rain, are again broken into parts, with careful observation whether they give off the odor of another metal. If you find such, let them again be cooked in the manner described, until — the odor having been deposited — they yield the simple odor of iron. And so at last the smelted iron will give a sweet and malleable [iron]. Yet it sometimes happens that an iron of this kind is so obstinate in its hardness that it refuses all cooking. In that case it will be destined for [conversion into] steel, by the method we will set out a little later. So that you may have the signs of pure or impure iron, note that there are four species of iron ore.

[Margin: The various species of iron ore.]

The **first** species is a heavy, compact mineral lump, separated from the company of earth, rock, and the other metallic bodies, of a brown color; and this is the perfect [one], and the one uniquely desired.

The **second** has a certain indefinable adjoined luster together with a granular substance, which is easily crumbled into powder between the fingers; and it is everywhere rejected as a vein of bad character.

The **third** is a mineral lump packed with coarser grains of a black color, which — as it always smells of copper — is likewise everywhere neglected.

The **fourth** species, finally, consists of finer grains, and according to the condition of its matrix is found now better, now worse.

There are besides other lumps which indeed are easily smelted into iron, on account of the admixture of the other meltable metals, but which sustain the hammer only with difficulty, owing to the weak cohesion of their parts. And contrariwise, there are those which sustain the hammer, but have a difficult liquefaction. The former generally have no other use than for casting cannon [*tormentis bellicis*]; the latter can be reduced into iron of better grade.

You will ask: What are the signs of pure or impure iron, and how are they recognized?

[Margin: Signs of the purity of iron.]

I say that, even if iron is found in earthy substances, that iron is nevertheless held to be the best which is dug from those mountains from which cold waters, not unpleasant to the taste, flow forth — especially if the place is set in a more salubrious air, [continued]...

let this be established. Very often, too, [iron] is generated in a certain white rock, not unlike a flint; and if you smelt it together with the rock, a hard iron will for the most part be obtained — but it turns out otherwise if you separate too little of the ore from the rock and melt it once put into the forge.

[Margin: Matrices of iron.]

Sometimes too the iron ore is found in red and yellow earth, easily dissolvable into sand by rubbing, or even soft like mortar [malta]. In gathering lumps of this kind I would not have you waste your time, since nothing good comes of it.

Now, so that you may recognize the purity and goodness of the iron, proceed thus.

[Margin: Test for the goodness of iron.]

First. Let some specimen of the ore be put into a strong lye [lixivium], and then, after some time, drawn out, and set over the fire; with the bellows applied, blow up the fire gradually. If you observe diligently the little bubbles and the vapors of various color, this is itself a sign of various commerce of metals [i.e., a mixture]. If

[it is] without color and without little bubbles, you will judge the iron to be of the best and most compact kind.

Second. A sign of good iron is a bole — a dusky, soft, and unctuous earth — which, when seized by the teeth, raises no grating sound.

On the transmutation of iron into steel [chalybs].

I will describe, with all the brevity and clarity I can, how steel is made from iron, the whole process.

Since steel is nothing other than iron reduced to the last state of its perfection and purity — which is of two kinds, natural and artificial — and since natural [steel] is found in few places, the metal-smelters, supplying the defect of nature, convert any iron whatever into steel by that ingenuity and skill which I shall now subjoin.

[Margin: The cooking of iron, and its conversion into steel.]

First. They take iron — already, as was said above, thoroughly cooked [smelted] in the furnace — of such a quantity as suffices for their purpose, and break it into the smallest pieces.

Second. In Vulcan's hearth [i.e., the forge] they set up a round receptacle for making the steel, larger or smaller according to the quantity [desired], [made] of clay, of which one third part is potter's clay [argilla], and two thirds are charcoal reduced to powder, well mixed with water and compacted into an amalgam. In the center of it let there be made a hole, through which the bellows can discharge their blast to fan the coals.

Third. Let this receptacle — both to reflect back the fiery heat, and to hold more firmly the heaped mass of the iron fragments and the charcoal to be put in — be fortified, by setting stones around it, like a kind of wall.

Fourth. Let this whole receptacle be filled to the top with coals; and when, by the urging of the bellows, these have blazed up into the highest heat, they then proceed as follows.

Fifth. From the iron that is to be converted into steel, broken up into small bits, they throw the particles, little by little, mixed with the powder of ground marble and of other fusible flints, scattered among the heaped-up coals now kindled. And in this way the iron sustains an easy fusion within the receptacle.

[Margin: How the steel is made.]

Sixth. This done, from the same iron, [now] beaten by the force of the hammer into rods, placed into the molten matter of this receptacle, they leave [them] for four or five hours, continually urging the fire and the coals with the blast of the bellows, and also moving and stirring the material with a longer iron rod, until the pores of the iron rods are filled out, in their substance, by the subtle molten matter now within the receptacle. When the workmen observe this, at once — with tongs, one after another snatched out and stretched a little upon the anvil by hammers — they quench [them] in a separately prepared bath of cold water. And if they find that these have not yet reached the due perfection, they cast them again into the bath while still glowing from the molten matter, and repeat this as many times as needed, until [the iron] attains its ultimate perfection.

By this industry it is so purified and perfected that, in hardness, compactness, color, lightness, and luster, it seems to have taken on a difference specifically distinguishing it from iron. I am not unaware that others, too, quench iron tools of this kind, when made white-hot, in certain juices of herbs, with truly remarkable success, as we made clear in the preceding [pages].

On the transmutation of iron into copper [aes].

There is a great disagreement among the chemists and metallurgists concerning the transmutation of iron into copper, which must be decided, with all possible diligence, in a fitting way.

[Margin: The transmutation of iron into copper is not proper [i.e., not a true transmutation].]

Paracelsus and his followers affirm the perfect transmutation of one metal into another — perhaps with this aim and intention: that they not give up as lost that great art concerning that ridiculous philosophers' stone, so much bandied about, which they also say undergoes a perfect transmutation. But even the very overseers of the metal-mines, men instructed by a marvelous skill in extracting, washing, and cooking metals, and by a knowledge of other arcane matters — these, I will not say deny this, but rather laugh at it.

Certainly, as Father Joannes Schafferus [Johannes Schaffer] writes to me, in the mines of Hungary which they call Herrengrund [Špania Dolina / Herrengrund], copper of the best grade is made from iron — with truly great annual revenue to the Emperor. But as to how they proceed in this metal-metamorphosis: although I showed the method in the Eighth Book, yet it has seemed good to repeat it here in a few words.

They take rusty and useless iron — such as the stock of various old tools — and, putting it into the furnace and reducing it on the anvil, they extend it into the thinnest plates. This done, they lay these plates at the bottom of a vitriolated stream, which flows in the deepest galleries of the mines, and leave them there, once laid down, for several months. Thus established [continued]...

[Fol. 224 — running header "LIBER DECIMUS, Sect. IV." The text continues: "...when in time they approach the stream..."]

so, when in time they approach the stream, they find that the plates have, as it were, passed over into a yellowish [color], like an amalgam. Once these are exposed to the air and the winds, they harden into [copper] of the best grade. And thus the procedure is carried out at Neusohl [Banská Bystrica / Neusohl] in Hungary.

It is asked, then: can this be called a true transmutation of iron into copper? I say that there can in no way be a true transmutation here, since not the whole iron is changed into the substance of copper, but only by accident. Let me explain.

[Margin: The reckoning and manner of the transmutation of iron into copper.]

For since within vitriol there exist innumerable coppery [aerata] corpuscles, and since these have the greatest sympathy with iron, it happens that they at once flow together toward the iron, and insinuate themselves intimately into its pores. And since they are endowed with spirits of great acrimony, hence, once insinuated within the iron, they soon begin to gnaw it, until — all the fatness of the iron being consumed and the ferrous substance dissolved — it passes into a scurf, that is, a rusty powder. The vitriolated corpuscles, however, substituting themselves in the place of the consumed iron, are glued together — by the native fatness both of the iron and their own — into a single mass; and this, soft at first within the water, yet exposed to freer air, to the winds, and to the sun's rays, hardens into perfect copper. And in this way the same [quantity] comes to be that was there before: before, indeed, through the dispersion of those corpuscles into the water; now, through the union of the same, drawn out of [the water] by the iron.

[Margin: An experiment.]

For if a true transmutation took place here, no iron at all would be left over. But experience teaches that just as much iron-rust remains as the previously iron mass weighed before. And, in order that I might take the proof of this matter more exactly, the aforementioned overseers of the Hungarian mines, through the

above-mentioned Father Schaffer, sent me — out of their goodwill toward me — a vial of the said vitriolated water, together with a horseshoe half of which was copper and the other half iron.

[Margin: An experiment taken from the author [i.e., performed by Kircher himself].]

Into this vial, then, I put an iron thread, which within three days was wholly consumed; the pulp [pulte] remaining at the bottom, separated from the dross, yielded pure copper, while the dross came nearly to the weight of the iron thread — so that henceforth no one can doubt about this matter.

[Margin: The difference between artificial and native copper.]

This too is most worthy of admiration, which Father Schaffer writes concerning a certain physician very familiar to him, a great chemist — his name is Morlandus [Morland?] — who, taught by frequent experience, found a great difference between the copper made from iron by means of vitriolated water and that which is dug from ores. For from a hundredweight [centenario] of copper made by art, by vitriolated water from iron, he reports that he extracted 25 *lotones* of gold...

[Margin: An experiment.]

whereas from a hundredweight of copper from ores he could not draw out even six *lotones*; and he asks of my slender capacity the reason for this matter. I replied that this is no wonder. For since vitriolated water flows not only with atramentous [inky/coppery] corpuscles, but also with golden ones — abraded together with the vitriol from its own veins — hence it happens that these [golden corpuscles], attracted by the vitriolated corpuscles out of natural sympathy, flow together into one within the pores of the iron; and, the iron being consumed, they settle at the bottom into a single meal-like mass, from which afterward — hardened by the dryness of the surrounding air — that gold is separated by liquation. And the richer the gold-vein through which the vitriolated water has flowed, the greater the abundance of gold there will be in the coppery corpuscles. This, however, I would think can in no way happen, unless the vitriolated water passes through a golden vein. And the reason why, further, not so great an abundance of gold is dug out of mineral copper, is that it is generally wrapped in earthy filth, and so offers but a scanty abundance of the gold existing within it. But if the golden vein were joined to copper, I do not see why the same abundance of gold could not be drawn from it as from vitriolated copper. The solution therefore depends on this: that that chemist performed his experiment

on a copper-substance poor in gold, but on a vitriolated copper rich in gold — so that nothing in this is worthy of admiration.

But as to how, from silver — from which all the gold has already, as he writes, been extracted — he nevertheless drew out still as much gold as was worth eight *grossi*: he communicates the secret to me in these words.

[Margin: A chemical secret for extracting gold from silver.]

"Take of antimony, of tartar, and of saltpeter [salis nitri] one ounce of each; let them be mixed together, and dissolved in cold spring waters [salia frigida fontana]. If from these you separate one ounce of silver through the cupel, it will yield one ounce of gold equivalent to eight *grossi*. But if you should do this experiment a second time with the same silver, you will extract nothing, the silver remaining sterile."

He marvels, however, how, from silver from which all gold has [supposedly] been extracted, gold can nevertheless still be drawn out by the aid of the said ingredients. I say, then, that it is false that all gold has been extracted from the silver; since silver cannot be so purified but that some particles still exist within it, which, afterward augmented by the antimony — in which all chemists confess that there is always something of gold — exalt that gold to the value of eight *grossi*.

CAPUT XI.

On salt-mines, and on the preparation of salt.

Although in the Sixth Book we treated abundantly of salt, yet since meanwhile, from various quarters, various accounts of salt-mines have been transmitted [to me], which are not without great profit, I have judged that they should be set down here.

The first salt-mine occurs in Upper Austria, at Traunkirchen; the second, in the county of Tyrol; [the third]...

[Fol. 225 — running header "DE FODINARUM CONDITIONIBUS." The text continues: "...the third, in the County of Burgundy."]

the third, in the County of Burgundy [Franche-Comté]. And first, indeed, in the mines of Upper Austria, as Father Joannes Eissert [Johannes Eissert] writes to me from the Traunkirchen Residence of our Society [the Jesuits]: the water, already imbued with various salt from the salt-mines, is drawn out — first it is raised

from the pits by a wheel fitted with wooden buckets and dippers, and poured into channels, [going] to the pans [*sartagines*] and the vaulted receptacles, in which it is always kept ready, against arising need, for the cooking [boiling].

[Margin: The manner of extracting the saline water from the pits.]

They also use pulleys without a wheel, or [with] an axle in a windlass [*peritrochium*], as the experts in mechanics [the *Statici*] call it — that is, an axle fitted with a wheel or with levers [handspikes], which is turned by the diggers, by one or more, with a rope wound around the axle, just like a roasting-spit [*veru*]. The rope has, on each side, a bucket-vessel attached, so that, when one vessel full of salt-water ascends, the other empty one descends, as appears in the Figure.

Diagram. A woodcut of a well-and-windlass apparatus for raising brine from a salt-mine shaft. The figure shows an upright wooden frame (two posts joined at the top by a cross-piece) supporting a horizontal winding axle. A rope passes over the axle with a bucket-vessel suspended at each end of the rope, so that one bucket rises as the other descends into the shaft below. The wooden curb/housing of the shaft (here drawn as a tub-like or barrel-staved enclosure) sits at the base. The figure is uncaptioned and carries no lettered labels. It illustrates the windlass-and-paired-bucket mechanism described in the adjacent text.

They also use suction-pumps [*Anthliae*], which pour the salt-water into a vessel shaped like a wine-cask [*dolium*]; and from these, the taps being afterward opened, the water is led through channels into the destined places. This water, however, is at first sweet [fresh] on the outside, and by deliberate design it is diverted into the vaulted receptacles of the salt-mines (as they are called), which they call *Stantiae*. There, by the dilution of the saline ore, it is wholly converted into salt-water; and when it has now been sufficiently imbued with salt, by means of the said instruments it is drawn out to the cooking [boiling]. But if, somewhere outside, any want of fresh water occurs, then they carry the saline lump out, broken into pieces in leathern sacks; and afterward, carried to a place where fresh water is available, they cast it into that [water] to impregnate it with salt, and keep it for the cooking. But where fresh water passes through the underground salt-mine — as at Salzburg — there, with greater saving, they lead it, already extracted and prepared, through channels to the salt-kitchen to be boiled; there the salt-water sometimes has a depth of many fathoms [*orgyae*].

Baronius [Cesare Baronio] reports, in his *Annals*, that in underground pools of saline waters of this kind, in the year 1260 (if I am not mistaken), an entire human body was found, which had suffered no corruption whatever, [being] of

such fresh and snow-white flesh, and with the [visual] keenness of the eyes so lively, that it seemed to counterfeit life.

[Margin: A human body found in salt-waters.]

And so it was offered, on account of the extraordinary rarity of the thing, to the Duke at Munich [Monachium]; and he, delighted by a spectacle of this kind, when he placed it within his treasury [Gazophylacium], it is then said that — as though unaccustomed to the air — the body at once dissolved into a saline liquor, its flesh flowing away.

But now [back] to the point. There are in Upper Austria, near Ischl [Ischlen], Hallstatt [Halstad], and Traunkirchen, very lofty mountains, within whose belly are lakes and pools, both of every kind of mineral waters, and most of all of the most crowded salt-mines. These, diverted in the manner mentioned above into fresh waters, degenerate into a salty liquid, which is then led through channels into the salt-boiling pans.

[Margin: The vastness of the cauldrons [pans].]

The above-cited Father writes that, from the mountain which they call Hallberg [Halsberg / Hallberg], this salty water is led for four German miles, as far as the pan situated beside the lake, to a place which they call Langwath [Langwies?], through 24,000 channels mortised one into another, each of which is ten geometrical feet long. The pan, he says, is of an oval shape, the largest in breadth out of three others — thirty paces in breadth, sixty paces in length, but with a depth of only one foot and a half.

[Margin: Annual revenues from salt.]

From these salt-works the Austrian princes, the Archdukes, are said to have in annual revenues 800,000 Rhenish florins, the expenses reckoned in together, which revenues run up to 1,100,000 florins. In the said mountains of Hallstatt a double kind of salt is found.

[Margin: Salt.]

The first is solid, pure, and gleaming like crystal; this is indeed called rock-salt [*sal gemmae*], because, brought by nature's fire to such perfection and maturity, it is so fixed that, of six ounces, after solution in the filter, almost nothing remains except half an ounce, which adhered to the instruments — that is, almost nothing is lost. The other is variously colored, and is found now reddish, now violet, now

of a dark color; but since it is viscous and gives off a sulphurous odor, it is everywhere left behind.

[Margin: The balsamic spirit of salt.]

From the salt of the first kind, the overseer of the mines reports that he extracted a balsamic spirit and oil, most excellent in extracting [medicinal] substances and in the cure of diseases.

[Margin: The mines are filled with new salt each year.]

It was also observed by the diggers that, after a certain course of years, the mines are refilled with new salt — a fact of whose truth no one ought to doubt, just as we have shown elsewhere in this work. For if the mines of any metals whatever, and of stones, once exhausted, are in the course of time refilled with a new birth, how much more the salt-mines? For since saline exhalations breathe out continually from the inmost bowels of the earth, hence, wherever they find a body alike and homogeneous [to themselves], there the little bodies [corpuscles], condensed by the cold, are soon united by a certain magnetic action, whence in time a new increment of salt emerges.

In the Austrian salt-works, so that they may know when the fresh water, diluted with salt, is sufficiently salty and fit for the cooking, they use the following test: [continued]...

adapt it on a lathe, so that it takes the form of a pear, as shown in figure A. Into its lower belly they pour a small quantity of lead at O —

Diagram. A pyriform (pear-shaped) wooden float partly submerged in a cylindrical vessel of brine, seen from above and slightly to the side. The vessel is the salt-tester. The float is weighted with lead so that it rides at a fixed depth in adequately saline water.

- V (top, the stem/neck of the float projecting above the surface): the upper tip whose emergence indicates saturation
- A (center, on the body of the float): the pear-shaped float itself
- O (lower belly of the float): the lead weight poured into the float's base

just enough, that is, for it to sink in the brine up to the little stem V. If the stem floats with half its length above the water, it shows that the brine is rich enough and holds sufficient salt for boiling. If it sinks more, or less, the brine is reckoned insufficient.

But since this procedure carries certain imperfections with it, I think the matter can be settled by a far better and more exact test, which I have decided to share here with the salt-makers [Empyristae].

[Margin: An instrument for testing whether the brine holds sufficient salt for boiling.]

Proceed as follows. First weigh the water — in whatever quantity — that experience has already shown to be sufficient for boiling. Once you have done this, have the glassblowers make you a phial A–B with a long neck swelling out into a belly at C, the length of which, A–D, comes to a quarter of a span [palmus]. Make it exactly in the shape and size you see here.

Diagram. A tall graduated glass phial — a hydrometer — drawn upright. The long narrow neck runs from A at the top down to D, and is marked off in ten numbered divisions (the scale 10, 9, 8, 7, 6, 5, 4, 3, 2, 1 reading top to bottom along the neck). Below the neck the glass swells into a rounded belly C, tapering to a point at the foot B. A drawn hand at the side points to the fifth graduation. Inside the belly is the figure for the quicksilver charge.

- A (top of the neck): upper end of the graduated stem
- B (foot): pointed base of the belly
- C (the swelling belly): the bulb of the phial
- D (junction of neck and belly): lower end of the graduated section A–D
- Scale 1–10 (along the neck, numbered): the ten graduations
- 8 (within the belly C): the charge of quicksilver placed inside [reading uncertain — appears to mark the quantity of mercury; the text says fill to the fifth graduation]

Mark the neck with as many graduations as you like — say, ten. Once this is done, pour quicksilver into the phial; then set the phial, charged in this way, into the water and observe which graduation it registers. You will do best if you put in only so much quicksilver that, when the phial is set in the water, it sinks to the fifth graduation. Then seal the mouth of the phial as tightly as you can, either with a hermetic seal or with wax at A, and you will have an infallible instrument — useful not only for testing whether boiling will be adequate, but also wonderfully apt for testing all sorts of waters to find how much salt they contain.

For when this vessel is set into salt water and filled, if it sinks precisely to the fifth graduation you may be certain the water is fit for boiling; if it sinks below the fifth, that is a sign the water holds more salt; if it sinks above the fifth, then — in

proportion as it is submerged more or less — it is a sign the water holds a smaller portion of salt.

The reason is plainly clear: the more salt the water holds, the less the weight sinks in it; and the less salt the water has, the deeper a heavy body sinks in it. This is so certain that no one can or should doubt it. You see it in ships, which sink deeper in the Tiber than when they are committed to the sea: there [at sea] they ride three or four spans higher because of the density that the salt gives the seawater. You will also find that if you put this instrument into pure fresh water, you will see it almost wholly covered — for since fresh water is utterly pure and very thin, the weight of the phial drives almost to the bottom of the vessel in which the water stands, meeting no resistance. But I treated this more fully in the first volume.

Here the salt-workers [Halurgi] put no small problem to me: why is it that water fit for boiling keeps to a kind of mean, so that it is neither too salty nor too little salty? For, as the above-cited Father Joannes Eissert writes to me, experience shows that if you throw a solid lump of salt, however large, into fresh water, the water nevertheless draws no more from it than is needed for boiling. Once the water is steeped with enough saltiness, it grows as it were nauseated and stops drawing in any further, so that the lump you put in remains whole.

[Margin: A remarkable property of salt.]

To resolve this, I say there is no other reason than that the water craves neither more nor less salt than is required for the original, native saltiness of the mine — a saltiness which Nature has tempered, for human use, to just such a proportion. Once the water has reached that, it seems to need nothing further. Experience confirms this in fish: living perpetually in the briny sea, they nevertheless draw from the brine only as much as Nature requires for their sustenance, neither more nor less.

[Margin: Confirmed by experiment.]

The same happens with artificial salt. For if, as they report, the salt-workers boil and stew fresh fish in the salt-pan, the fish are seasoned by the salt no more than is needed to make them fit to eat — even though they boil wholly immersed in the salt water of the pan.

Another marvel, he says, occurs in these places: the salt water that adheres to the pan in which it is boiled freezes in a nearby cold spot — the place where fresh water for the salt-workers' use is drawn. There it takes on various and most

beautiful shapes and forms, so transparent that they can scarcely be told from crystal; and, just like rock-salt, they are never round but are always fashioned by nature in a square figure.

[Margin: Another thing worth wondering at.]

As for why they form in that cold place, the only cause is this: while the salt is boiling in the nearby pan, the saline vapor and exhalations rise, and when they strike that cold spot they condense there and degenerate into the shapes we have described. For just as fire by its force purges every earthly dross away through sublimation, so too...

these [vapors], joined and united by the cold of the place, must of necessity congeal into a crystalline transparency.

[Margin: The origin of the sugar-like [bodies] out of salt.]

He adds that in the same place there are found white bodies, so worked by Nature that they cannot be distinguished from sugar confections. The reason for this is none other than that the vapor, still infected with earthy and nitrous refuse, condenses in the cold spot and degenerates not into a transparent but into an opaque white substance.

[Margin: Hydria, rich in quicksilver.]

Not far from these salt-works lies Hydria [Idrija], a quicksilver mine. Although I treated this at length in the chapter on quicksilver, still — since the Father cited above informed me of many things about a mine of this kind that are not so commonly met with, things observed there — I thought them worth inserting here.

"At Hydria," he says, "eight miles distant from Labacum [Ljubljana], a mine most rich in quicksilver and most productive of revenue, subject to the Archdukes' jurisdiction, is to be seen. About it they report something worth recording: that little mountain demons [daemunculi montani] are very frequently sighted there, and the miners count themselves fortunate if they hear them."

[Margin: Subterranean demons.]

The common opinion is that such little demons appear only where rich veins of ore lie; they are often heard working with a hammer, but are themselves invisible. They will not tolerate blasphemers, swearers, whistlers, or wretches of any kind. Hence the superstitious miners are accustomed to set out for them, in a fixed spot, a little pot full of food each day, and once a year to bring them — as a

gift — a little red coat the length of a boy, bought at a fixed season. If they fail to do this, they find the little fellows harsh and offended; but if they satisfy them, they find them well-disposed: for these dig out and hammer loose such a quantity of metal as the miners themselves could scarcely manage in many days with all their toil. Thus does Satan, the enemy of the human race, make sport of superstitious men.

[Margin: An arsenic mine.]

Not far from Hydria, on the borders of Upper Carinthia, eight miles above the town of Villach, in the valley of Ratschach [Raščach (?)], there is found yellow and white arsenic [orpiment] of the better sort. The yellow, being of the better grade, is what Venetian merchants put to various uses, and they even sell it to the Egyptians — who use this arsenic, scattered over their fields, to kill off the swarming serpents that every year, after the Nile's flooding, are born from the mud in great abundance. They say that near a mine of this kind no venomous animal or worm has ever been seen.

Against the virulence of the arsenic the miners mostly use certain cooling salves, and theriac, and they also shield their faces with a glass or bladder mask. And since this ore contains within itself gold, silver, and copper, human greed — despite so great a peril to life — is accustomed to dig it out in the following way. First the vein is explored and detected by the striking of hammers: if a struck rock throws off a spark, that is a sure sign of a rich arsenical vein...

of the better sort. Then in many places they bore into the veins with great augers, and once the holes are made they thrust in larch tubes filled with their gunpowder, and add a very long fuse; this, lit from outside, the moment it reaches the powder bursts the whole arsenical vein into pieces in an instant. So that afterward, once the fire is out and the mine has cooled, they may gather up the fragments of arsenic without danger. This, once boiled, after the silver has been separated, they reduce into white flowers and into a glassy consistency.

The miners in this mine work in boots and gloves, by night and by day, only twelve hours at a stretch. A hundredweight [centenarius] of the raw ore is got out for 16 kreuzer, that is, 6 bajocchi; refined, the hundredweight costs 15 florins. Out of a hundred hundredweight of this ore there are twenty hundredweight of pure yellow arsenic. So much for the Austrian mines.

[Margin: The Tyrolean salt-works.]

Of the Tyrolean salt-works, since I have made ample mention elsewhere, I thought it needless to repeat here — since in exactly the same way fresh water collected within the salt-bearing mountains, having drawn in enough saltiness, is then led through channels to the pans of the salt-works for boiling. I add only this: there is scarcely a place in Europe where Nature sports with a greater variety of things. For it is not only most full of gold, silver, iron, copper, and lead, as in Swabia [Suevia], but also of precious stones. Of these things both the Most Serene Archduke and his Most Serene Consort — a most zealous investigator of such matters — wished to inform me, through Father Michael Staudacker [Michaël Staudacker], chaplain to them both. And the said Father writes to me thus:

[Margin: Marvels in the Duchy of Tyrol.]

"I set forth, at the command of the Princely Archdukes, some things worthy of wonder which Nature contrives in the county of Tyrol. The Princes devote themselves singularly to the knowledge of metals; and — what is remarkable in a woman — the Most Serene Lady is no stranger to this science, but applies herself in person to this labor and work. She has even undertaken to search out and sort the stones which formerly were not even named and were held in neglect, though they are in truth precious and might deservedly be reckoned among gems. For when worked and polished they turn out most beautiful, charming the eye with a clear and remarkable color; and they not only give the eyes pleasure and wonder but are altogether worthy to be valued at a high price as well.

[Margin: A marvel in the Tyrolean Duchy.]

I could wish that Your Reverence might see some specimen of them: you would surely praise, and marvel at, riches of our homeland hitherto unrecognized. A great store of such stones has now been gathered, among which have been found jaspers, agates, chalcedonies, and rubies — not, indeed, so fiery and blood-red as the Oriental ones, but of a paler purple, which is nevertheless truly most lovely, so that perhaps before some eyes — at least for their rarity — they might carry off the palm from the others. Our stones would truly deserve — and I will say it without lying — to be called gems, so that some mention of them, with praise of the Most Serene Lady, might find a place in the *Mundus Subterraneus*. I had brought these letters thus far when, conversing soon after with the Most Serene Lady, I learned from her..."

[Note: Between the two text leaves the source carries a full fold-out engraved plate (the salt-works apparatus), oriented sideways; only the right edge of the

engraving is visible on the verso shown here, the bulk of the figure being on the recto fold. The visible portion shows part of a timber-framed mining/hoisting structure with shafts and beams. The engraver's signature is legible at the foot.]

Diagram (Source: PDF p. [fold-out plate]). A large fold-out engraved plate of a salt-works / mining apparatus, printed sideways. On the verso leaf shown here only the right margin of the engraving is reproduced; it shows part of a vertical timber-framed structure — heavy posts, cross-beams, and what appear to be hoisting shafts or channels (deeply hatched walls). The full figure lies on the fold's recto and is not present in this opening. Signed at lower right: "H. Bonzon delineavit." ["H. Bonzon drew it."]. No interior point-letters are legible on the visible fragment. — Plate fragment only; full plate is a if the recto fold is needed.

[Margin: The origin of gems.]

"...I learned that among the gems hitherto found among us there are also numbered amethysts, emeralds, cornelians, turquoises, garnets, malachites, and diamonds — small ones, indeed, but of such hardness that they scratch other diamonds while themselves admitting no scratch. The Most Serene Lady says our chalcedonies surpass the Oriental ones. Diamonds, she says, are born where crystal is generated: this is six-sided [hexagonal]; amethysts have four angles; garnets about twelve or ten.

Further, she says she has found by experience that the beginning, or matter, of all gems is a liquid, or water, drawn off through the metallic veins; flowing down drop by drop, it first congeals into talc, then into gems. According to the color of the talc, the gems too are tinted; and these finally harden thoroughly while, rolled down from the mountains, they are washed by the waters of the river Oenus [Inn]. But those that are dug out in their very native soil — that is, in the caverns of the mountains — have not yet taken on so great a hardness. Also in the river called the Sill [Sill], which mingles with the Oenus [Inn] not far from Oenipontum [Innsbruck], flints are little by little, in the course of time, tinged a yellow color. This stream once was, and perhaps still is, gold-bearing." So much for the rarities of the county of Tyrol; let this suffice.

On the Salt-works of Burgundy [De Salinis Burgundiae]

When, after my usual fashion everywhere, I had set up a correspondence with learned men about the secrets of natural things, in aid of the *Mundus Subterraneus*, and among others had consulted that truly distinguished and most learned man Johann Menecard [Joannes Menecard], canon and succentor of Saint

Maurice, concerning the Burgundian salt-works — he showed himself most ready to render every kind of service, and left nothing undone to give me exact and accurate information about the salt-works to be seen in Burgundy, famous for their renowned name, with a drawing of the things added. And since his letters are full of salt [i.e., wit], I have decided to set them down here as a testimony for posterity. He writes thus:

"Your Reverend Paternity directs that some things be transcribed about our subterranean treasures. This task laid upon me I undertake with the greatest eagerness — provided only that the plainness of my style detract nothing from the majesty of the subject, or from the truth.

At our Salinae [Salins], then, by a happy sport of Nature, salt springs leap up — springs which, sunk so deep as it were from the very bowels of the earth, against nature gush forth and of their own accord well up on high. Now Salinae [Salins] is a most ancient town, the chief place of Sequanian Burgundy [Sequanica Burgundia], or capital of the County of Burgundy [Franche-Comté], situated in the Valley of Scodinga [the Valley of Scodinga], open to the Roman road of kings and consuls — indeed passable even in the days of Julius Caesar [Julius Caesar] (which can be shown by many proofs). The whole valley, wooded at first, was set about as if planted with castles on the surrounding hills, until herds and flocks, all day long, became the greediest indication of this hidden and not yet sufficiently recognized benefit. It was ruled by various princes; but now it...

claims the titles and dominions of the most invincible Philip, King of Spain [Philip, King of Spain]. One of the two castles overhangs the city gates and — by its customs, and by the birth there of Saint Claude [Divus Claudius] — is exceedingly famous among the most holy Princes of Salins; they call it Bracon. The rest, along the ridges of the mountains that look down on the city's borders, serve at a distance as fortifications, hostile to enemies. Between two opposed mountains, very steep and sheer to the east and west, the meridian of the city runs down through the roots of those mountains, with walls running parallel on either side; the remaining mountains rise very high to the south and north, and are separated from the city itself by a mile and more. In the midst of all these, as it were at the fountainhead, the salt springs bubble up.

[Margin: Salt springs.]

Of these therefore we send you the faithful drawing, together with the wonderful and varied intensity of their qualities — for within a space of eight, or at most ten, feet of difference the springs of differing sources boil up in differing quality

and leap up in differing quantity. Of these in turn we here append the indications, marked with letters, most exactly.

A. designates the best of the springs, which through fine sands, between two rocks and living stone, bubbles up most copiously from the bottom as if out of a pot; and even when the others fail it yields fresh increase of both water and salt (as is shown by the daily experience of the noble Pierre Chaudes [Petrus Chaudes], who almost from boyhood has presided over this stewardship by hereditary title); nor does it ever grow turbid, or fail, except that when the North Wind blows it is somewhat diminished in quality and quantity. For the rest, a hundred and twenty-five pounds [librae] of this water yield the whitest and best salt, by means of fire set under the cauldrons, which are about four ten-foot rods [decempedae] in diametric breadth and three feet in height. This water is so salty that — unless the water itself is tempered for boiling with other, weaker waters — the salt itself congeals and coagulates in the form of sea salt.

[Margin: A thing worth noting.]

It is further much to be noted that the brine [muria] which is left over after the boiling, if it is mixed with the other waters when they are applied to the fire, increases both the dose and the quantity of the salt, and improves its quality, so that a hundred pounds of water yield twenty-eight, and sometimes more, pounds of the best salt.

[Margin: Salt-spring 2.]

B. The neighbor of the first, only four fingers' breadth away, and called the spring of the lead channel: *Source du canal de plomb* [French: "Spring of the lead channel"]. It draws salt from the living rock, and with it scruples [tiny grains], or little sands like cinnabar or scarlet in color. It is somewhat unequal to the first, whether in quantity or quality; and for a hundred pounds of water it yields only twenty-four pounds of the most refined salt of pleasant pungency. In summer each loses one pound of salt — the former yields only 24, this one 23. The waters of both are mixed together for the best use, and are sent into a common reservoir for use. There is nothing in this one different from the first as regards weather or winds, and the rest.

[Margin: Salt-spring 3, the new one.]

C. A new or more recent spring, *la nouvelle Source* [French: "the new spring"]: scarcely unlike the foregoing, except that it flows out only about an ounce, and if twenty...

Diagram. Large fold-out engraved plate depicting the Salins salt-works (Franche-Comté), drawn from life. The plate spans two PDF pages (a single physical fold-out). It shows, in section and plan, the underground salt-springs, the brine-channels, the lifting-machinery (geared water-wheels and bucket-chains), the great vaulted brine-reservoirs, and the boiling-houses, all keyed by letters that the facing text explains spring by spring and machine by machine. A workman's hand and arm are shown at lower left holding a tool [L]. The plate is signed at the engraving's foot: "H. Bonzon delineavit." ("H. Bonzon drew it."). A printed locator at the upper corner of the second sheet reads "Tomus 2. ad Fol. 228." [Volume 2, to Fol. 228].

Readable labels on the plate (positions approximate, as the fold-out is rotated):

- A: a spring / brine-vessel at lower left (the best spring of the facing description)
- B: a ladle or vessel adjacent to A
- C: a ladle / scoop at center-left
- D: a spring outlet at lower center
- E: a vaulted recess at upper right
- E, F: paired labels near a grated channel at center (the wheel F = the iron wheel-indicator)
- F: small water-wheel at center
- G: a channel-mouth at center
- H: the great central vaulted reservoir (the grande cuve)
- K: framework / steps at lower center [K]
- L: tool held in the workman's hand, lower left
- M: a small water-wheel at center-right
- O: outlet at center-right [?]
- P: vertical shaft / post at center of the second sheet
- Q: a hatch or sluice with handle at lower area of the second sheet

[The lettered description of the Salins salt-works continues from the preceding page. Running header, recto: "DE FODINARUM CONDITIONIBUS." — "On the conditions of the mines." Fol. 229.]

coagulates as much as three pounds of salt — yet it is usefully mixed with the rest, since it suffers something of the same effect, as regards winds, storms, and rains.

[Margin: The fourth spring.]

D. The fourth spring, called *le Durillon*, set off from the others by an interval of just six feet. It yields one pound and more from its very source, perennial entirely like the rest, and never in the least turbid. It bubbles up, leaping high out of the middle of the sand. Now because it mingles with itself a certain amount of fresh water, it produces only seven pounds of salt per hundred of water.

[Margin: A remarkable effect of this spring.]

Yet I have come to know something extraordinary in this regard from experience: for whereas during the dog-days [per canicula] the earlier springs decline, this one increases by its native goodness, so that for a hundred of water it returns about fifteen or sixteen pounds of salt, and it flows out always with the same purity and quantity. Accordingly it is at that season usefully mixed with the others, and is drawn off into the common reservoir (which they call *Cuppa, la Cuve*).

[Margin: The fifth spring.]

E. It flows down about a span [palmus] higher than the rest — *la vieil puisoir*, as you might say, the old draw-well — and is separated from the others by a space of three perches [perticae]. It is the meanest of all the foregoing, since it coagulates only six pounds of salt per hundred. But because from the upper workhouses, in which the salt is boiled and shaped into set molds, the salt that falls off trickles down through hidden passages into the source of this spring, it is therefore salted abundantly, mixed with the others, and usefully boiled — nearly the equal of the preceding one. It suffers the favorable or unfavorable effects of seasons, weather, winds, or rains in like manner, with equal increases and decreases.

[Margin: Description of the draw-up machinery.]

F. An iron wheel, which catches in the trough of the common reservoir the waters flowing down from the channels, and by their fall turns round, until — the reservoir being full — the wheel, blocked by the surface of the overflowing water, stops itself; and by means of a small rope tied to its axle, it is rendered useless. When the wheel is at rest, the little bell, which performs the duty of an overseer, signaling by the overflowing of the brine, is silenced; and then, without delay, the man set in charge of raising the waters hitches mules or horses to the transverse axle of another, upper wheel. So it comes about that the wheel, geared to the wheel by oblique spokes — with little fir-wood buckets attached to a rope — raises the brine from the common reservoir into the upper trough. From there it is afterward distributed, finger by finger, through leaden conduits [euripi] and channels to the various boiling-houses where the salt is cooked — houses they

call *Bernae* — by a truly admirable artifice, which can be understood well enough almost from the figure.

G. A small basin, which carries the useful brine together into the common reservoir.

H. The common or great reservoir: *la Grande cuve*.

I. A channel or small trough which carries the waters of the fourth spring — the one they call *Durillon* — to be cast, together with the waters of the fresher spring, into the river through the lower passages.

K. Steps, by which one descends from above to the lowest springs.

L. The wellspring of fresher and quite drinkable water, set off about eight feet from the leaden channel. It nonetheless tastes somewhat of saltiness, so that even per pound of water it would yield two — or somewhat less — if well boiled. This, however, is scarcely perceptible to the taste, and so it is rejected as useless. By the same artifice with which the brine is raised — through similar instruments and a little bell — it is so managed, lest the fresh water, breaking out from the very reservoir or *cuppa* (in French *Cuve*), be mixed with the brine; and it is regulated with no less care. For the rest, this fresh spring is at no time increased or diminished, nor does it become turbid with any wind blowing, whether from the south or the north [sive Austro, sive Borea], nor does it grow more abundant or fall short, but it always presents itself with uniform output.

M. A shorter iron wheel, one foot and a half in diameter, which catches the waters of the fresh spring as they flow down, so as to indicate how full the larger reservoir is — just as we said of the brine.

N. The reservoir or *cuppa* of the fresher water.

O. The channel of the same water, which is carried off into the river.

P. The other channel, by which the brine is led down into the upper salt-works.

Q. Another little basin, which catches the brine spurting up through just as many little buckets, and conveys it to the neighboring conduits and crossbars, which they call *Tourets*.

The rest of the features, which are explained more fully in the figure, belong to the huge vaults sunk more than sixty feet below the common pavement. All of these, when men look closely within, they proclaim — not absurdly — to be the eighth wonder of the world [octavum Orbis miraculum]. But those who presume

to reason about these things more wisely and exactly, in the manner of the philosophers, cannot but marvel that we are separated from the sea by about eight hundred thousand paces [octingentis circiter millibus passuum]. To this must be added the situation of the city, as described above, ringed on every side by very high mountains. For the slopes of the mountains — both those that face the west and those that face the north, and those that lie between north and east — nourish, plentifully enough and chiefly in the boggy parts of their fields, the Thracian stone [lapidem Thracium], which the people of Liège [Leodienses] call *Houille* [coal] — otherwise most fit for the boiling of salt, except that it is most unpleasant by its reek, while its sharpness suits the brine somewhat.

[Margin: A field rich in coal [lithanthrax].]

To this must be added that the rest of the mountains — chiefly those that slope toward the south, set off by another mile from the city, and some of them on the north almost adjoining the city — hold gypsum of every kind: white, whiter, and whitest. And gypsum agrees well with brine, and the two mixed together coagulate the more tenaciously; so that one may readily suspect the gypsum-works to be the wombs of the brine-water. However that may be, it is an arduous thing in matters so abstruse to know everything, or to define it — something that befits His most Reverend Paternity alone.

[Margin: Gypsum.]

I shall add here for all this what I myself have more than once experienced. In those larger reservoirs that are appointed for the keeping of brine, the brine sometimes rests unmoved for twenty, or even thirty, years — until the springs, over a longer summer, are somewhat diminished and are not equal to the distribution of salt; then there [it congeals]...

[Margin: The effect of salt turned into crystal.]

it congeals into crystal. I myself was given a piece of it, a foot and a half long and half a palm high. I broke off a small fragment the size of a nut and threw it onto burning coals. Almost as soon as it had taken in the heat, it burst apart like a lightning-flash from the middle of the hearth, and with a great crash shattered itself across the empty room. The fragment, as it split into pieces, kept up a continuous crackling; and had any of the pieces struck me in the face, they would surely have inflicted a wound. From that dangerous experiment I learned what the thing is that the chemists call rock-salt [Sal gemma] and "decrepitated salt" [Sal decrepitum]. If there is anything further to be conveyed to Your Reverend Paternity, at the slightest nod, at the least sign, Your Reverence has approved—

Always Your most devoted and most obedient Jean Menecard, Canon and
Succentor of Saint-Maurice de Salins.

MUNDI SUBTERRANEI LIBER UNDECIMUS — CHYMIOTECHNICUS

In which the universal apparatus of the Chemical World, together with the marvelous operations performed within it, is set forth—arranged in accordance with the archetype of Nature by means of a skillful technique of chemistry—and false alchemy [Pseudo-chymia] is exploded from its very roots.

PRAEFATIO

There lies in the human mind, set within it from heaven, I know not what little spark of the knowledge of truth. Once kindled and stirred, it seems unable to enjoy any rest until at last it reaches that toward which it is borne by so great a longing. If anyone has ever felt this spark, surely I feel it in myself, as I contemplate ever more deeply the wondrous majesty of the divine wisdom in this theater of Nature, and search out the inner sanctuaries—the very mysteries, I mean—of GOD and of his handmaid Nature, shining out in each particular thing. These mysteries are beheld both in the threefold Kingdom of the Universe and, above all, in the chemical workshops of the Geocosm. Driven onward by them, I set out with the greatest zeal to investigate whether we too might, by imitating Nature through metallurgical Art, produce something similar—just as goldsmiths, whom they call Alchemists, have at every period boasted that they can do.
[Margin: The author's study concerning alchemy.]

For this reason, in my various travels I made it my single aim to meet men renowned for the fame of their name, whether chemists or men distinguished by their reputation in the metallurgical profession, and—whether face to face or through frequent correspondence by letters—to confer with them about the secrets of the Great Gold-making Art, as they call it: so that I might find out at last what is to be believed about that most celebrated stone, the "wand of Midas," that worker of such great marvels, and learn what may be hoped for. But by a fruitless labor I rolled and rolled again not so much that philosophical stone as the stone and boulder of Sisyphus, since I found no one who could satisfy my questions—or even satisfy the very experiments not infrequently performed in my presence. So I betook myself to the original springs of the ancient writers: first the Hebrews, then the Arabs, afterward the Egyptians, who are believed to have

contributed something in this matter, and I examined their records (of which I have no small number, written partly in Hebrew, partly in Arabic). [Margin: Arabs who wrote about alchemy.]

Among the rest there are: works of the *Zohar* [Greek: Ζωάρ], unknown—or rather spurious—on the perfection of the Sun, on the marriage of the Sun and the Moon, by the author Zadith son of Hamuel; the works of Hermes [Hermes Trismegistus] as well, in whose Life it is said that he was Enoch [Enoch], and that he handed down the gold-making art to his descendants before the Flood—they relate that he gave it to another Hermes after the Flood, the one whom their own people call أدريس [Arabic: *Adrīs* / Idris], "Adris." There is also in my possession an Arabic book on the mass of the Sun and of the Moon; the *King Haled on the Stone of the Philosophers*; and several other treatises besides, so many and so overgrown with a dreadful barbarity, so wrapped up in such inelegant—not to say ridiculous—metaphors, riddles, and allegories, that not even the authors themselves seem to have understood what they meant. So much so that it has come into my mind that nothing is easier than to write such things, since whatever first comes into one's head can, under fantasies of this ridiculous human kind,

be set down in word-games and verbal mockeries for the vexation of clever minds. [Margin: The dreadful jumble of useless matter in the Arabs' records.] And since I could find nothing to my taste, I took up Lull [Raymond Lull / Ramon Llull], Villanova [Arnald of Villanova], Rupiscissa [John of Rupecissa], Isaac Hollandus [Isaac Hollandus], Trevisanus [Bernard of Treviso], Bacon [Roger Bacon], Paracelsus, Basil Valentine [Basilius Valentinus]—the authors of the Great Art—and countless others besides, in order to draw out from these men themselves the prodigious method and rationale of producing the stone. [Margin: Latin and Arab authors who follow them.] Therefore, weighing their sayings and deeds on the inflexible balance of truth, I made trial of whether they could sustain the Lydian touchstone of true philosophy. But in all of it I saw nothing but that pronouncement of the Wise Man, worthy of all praise (*Ecclesiastes* 8, last verse): "I understood that of all the works of GOD man can find no explanation of the things that are done under the Sun; and the more he labors in seeking, the less he finds; even if the wise man says that he knows, he cannot discover it." [Margin: The emptiness of the alchemical authors.] "I found one man upright"—and he entangled himself in endless questions, all of them the more difficult the more abstruse and impenetrable is the subject they treat. For whoever has carefully compared all the sayings of the said authors with one another will find opinions about the Great Art of the stone so divergent, so perplexed and intricate, that one might more easily clean out the stable of Augeas than the workshop of

these mutually dissenting Artists. What I think, therefore, about Alchemy, what I think about Chemistry, I have resolved to make plain in this book, bending myself to this one task: to separate the true from the false, the lawful from the unlawful, the just from the fraudulent, the dissonant from the harmonious; and to show, by demonstration [Greek: κατ' ἀπόδειξιν (kat' apodeixin, "by proof")], what Nature can do and what it cannot—relying on the hope that men distinguished by wisdom, and by their command of Medicine and Philosophy, once they have seen the weight of the arguments and experiments, will without difficulty distinguish truth from falsehood together with me. May GOD, Best and Greatest, the Father of lights, favor this undertaking.

SECTIO I — DE ORIGINE ALCHYMIAE (On the Origin of Alchemy)

CAPUT I — De Nomine, Definitione, & Divisione Alchymiae (On the Name, Definition, and Division of Alchemy)

The name "Alchemy" [Alchymia] is a mixed barbarous word, drawn from the Arabic article ال [al], which is customarily prefixed to all Arabic nouns, and from the Greek χύειν [Greek: χύειν (chyein, "to pour, to fuse")]. It has been made the common property of all peoples and nations, just as the name *Almagest* [Almagestum]—from the Arabic *al* and Greek μέγιστος [Greek: μέγιστος (megistos, "greatest")]¹—amply shows, being the great work of Ptolemy's construction [Construction of Ptolemy]. Those who would have it a purely Arabic word are clearly deceived, since by the Arabic name الكيمياء [Arabic: *al-kīmiyā*], which is most frequent in the books of the Arabs, the term was itself borrowed from the Greeks—like countless other words that occur everywhere. [Margin: The etymology of Chemistry from Cham (Ham).] But those who derive it from the Egyptian word *Cham* suppose that it was first set down in writing by Cham [Ham], the first king of the Egyptians, son of Noah; that it was preserved in the Ark and carried over into Egypt; and that posterity ever afterward cultivated it, handed down by Mesraim [Mizraim], son of Cham, and by Hermes his counselor.

But since we have discussed all these things most fully in the *Obeliscus Pamphilius* and in the *Oedipus Syntagma*—on the hieroglyphic alchemy of the Egyptians—we refer the reader to that work, where we teach in full light that the Egyptians by no means understood the transmutatory Alchemy, or (what is the same thing) the great mystery of the Elixir or of the Philosophers' Stone. [Margin: The transmutatory art was not known to the Egyptians.] Rather, they understood that art which they call Spagyric [Greek: σπαγυρικήν (spagyrikēn, "spagyric")] or

the metallic art, which consists chiefly in the separation, purification, washing, and decoction of metals; and which is not inaptly called ἄλχυμιά [Greek: ἄλχυμιά (halychymia)]—that is, from the perpetual intervention of salt, the "pouring of salt" [salis fusio]—which we have also set out at length in the preceding passages. [Margin: Metallurgy alone was known from the origin of the world.] And that the Alchemy of the Egyptians must be understood in this way, no one should have any doubt.

It existed too among the first men of the world before the Flood, while Adam was still living—rightly cultivated by Tubal-cain [Tubalcain], son of Lamech by Sella [Zillah], as is recorded in *Genesis* chapter 4: "Sella too bore Tubal-cain, who was a hammerer and a smith in every work of bronze and iron." [Margin: The first metallic art.] And no one should doubt that bronze and iron, drawn out from the mines not pure and unalloyed but worked by the metallic art (which Adam the First-formed [Adamus Protoplastus], divinely inspired, had taught his sons as something indispensable for the conduct of human life), were thus drawn forth and worked. And the descendants of Adam—that is, Noah and his sons—received it by ancestral tradition and, after the Flood, propagated it into all the parts of the world. From this the manifold

species of Alchemy emanated. Of these the first and most ancient of all is the one we call Metallurgy, or the Metallic Art, which we describe as follows. [Margin: Metallurgy the most ancient of all.] **Metallurgical Alchemy is nothing other than the art of preparing, washing, smelting, dissolving, coagulating, and separating the pure from the impure in metals, for the necessary uses of mankind**—and this we properly call Chemistry. [Margin: Definition of Metallurgy.]

The second species is transmutatory Alchemy, which is also called χρυσοποιΐα [Greek: χρυσοποιΐα (chrysopoia, "gold-making")], by which the Alchemists have imagined to themselves that any imperfect metals can be transmuted into the purest gold and silver. This we define in the following way. [Margin: Definition of Alchemy.] **Alchemy is the science that teaches how to make and generate a certain medicine, which they call the Elixir; which, when it is cast upon metals, perfects and completes them in the moment of projection, and transforms them—not only from imperfect into perfect, but also into gold and silver, according to the proportion of the medicine cast.** Whether this definition can stand, and whether the effect answers to the definition, will be taught in what follows.

The third species may rightly be called Spagyric or analytic Chemistry, in which the bodies not only of minerals but also of vegetables and animals are resolved into their elements. [Margin: Definition of Spagyric Chemistry.] This is also called Chymiatría, or medical chemistry, and it is occupied chiefly with the skillful extraction of oils, salts, and spirits—or quintessences—from minerals, metals, plants, and animals for the use of Medicine. It is a study worthy of all praise; for, drawn and brought forth from the inmost springs of natural Philosophy, then refined by the zeal first of Kings and afterward of many princes, deservedly and rightly enrolled in the number of the liberal sciences, it has come at last into the most sacred embrace of Medicine. [Margin: The praise of Spagyric Chemistry, or of the Spagyric Art.] The immense benefits flowing from it into the human race cannot be sufficiently celebrated with fitting praises, since it is truly the spring of a deeper Philosophy, the key, the marrow, and the soul of human wisdom—both of the Physical and of the Pharmaceutical faculties—the root of Medicine and its one single goal, toward which wise men in every age have aimed. For it has laid open to us so many stupendous works of GOD, Best and Greatest; it unfolds so many of Nature's sacraments; it brings forth so many preparations of medicaments, and at last the hidden uses of herbs, animals, minerals, and of almost all bodies, stored away in the inmost bosom of Nature—so that those among physicians who neglect it, or who would have it buried, may deservedly seem ungrateful toward the human race. And since, concerning the first Alchemy, which we call Metallurgy, we have treated most fully in the preceding Book, it remains for us to spread the sails of our reasoning toward the two latter kinds.

CAPUT II — De Alchymia, quam Chrysopaeiam vocant (On the Alchemy They Call Chrysopoeia)

In the whole of natural Philosophy I find no subject so controverted, so exposed to so many great struggles of combatants, so teeming with monstrous differing opinions, as this one which is openly bandied about concerning the making of gold. [Margin: The intricate study of alchemy.] So I would judge it superfluous to set pen in motion over the decision of such great controversies and disputes; and we have thought it more prudent to suppress the matter than to touch this apple of Eris [Eridis pomum / apple of Discord]. Yet because my judgment on this subject has been demanded by many—and I have been most urgently begged to say what I think of it—I will, with all the exactness [Greek: ἀκριβεία (akribēia, "exactness, precision")] that is possible, lay open my opinion.

There are four matters about which, among Philosophers and Mathematicians, there has been moved at every period an inextricable controversy, undecided to

this very day. [Margin: 4. Things which are talked of and discussed, and not found out.] The first of these demands the squaring of the circle [Quadratura circuli]. [Margin: 1. The squaring of the circle.] The second the Statical faculty claims for itself, and it is perpetual motion [motus perpetuus], which some wrongly think can be set up by a certain skillful mechanical contrivance. [Margin: 2. Perpetual motion.] The third Physics arrogates to itself, and it is the construction of a lamp [lampas] that should burn with a perennial and eternal fire. [Margin: 3.] The fourth is Alchemy, by which they imagine that imperfect metals can be converted into the purest and noblest gold by the power of the Philosophers' Stone, endowed (as they themselves say) with a divine efficacy. [Margin: 4. Concerning the Alchemy they call Chrysopoeia.]

There are, and have been, innumerable Mathematicians who, with stubborn zeal and incredible labor, have striven to move "squares with rounds"—so as to reach that which has been so greatly desired and sought for now nearly two thousand years, namely the squaring of the circle. [Margin: The true and real squaring of the circle is needed by geometers, and not yet found.] And yet to this day no one has been found who could boast that he had discovered the true and real Squaring sought by the Mathematicians [Greek: τετραγωνισμός (tetragōnismos, "quadrature, squaring")]—the squaring that consists in the unequal [recte: inadequate; *inadaequata*] proportion of the diameter to the circumference. Although some have believed so firmly that they had detected it that by no words, by no arguments, would they let themselves be torn away from it—until at last, convicted by the detection of their fallacies and, as it were, deluded by some doubtful light, they have subsided, their peacock's tail folded up.

The same thing has happened to the explorers of artificial perpetual motion. [Margin: Artificial perpetual motion.] Carried sideways by a perverse imagination and by desire for the thing they are attempting, after vast sums have been spent in fruitless labor, they convince themselves too confidently that they have accomplished the thing. But then, once the experiment is made, having gained—in place of perpetual motion—a fixed establishment of perpetual rest, and finding themselves deluded in a pitiable way, they have bewailed their state to the point of despair. In the year 1661, ten inventions of perpetual motion were sent to me from various regions to be examined, which their authors [Margin: Concerning perpetual motion.]

they yielded, claiming they would produce the long-desired effect; but when tested against the Lydian touchstone [ad Lydium Staticae lapidem], every one of them was found, without exception, to be riddled with gross fallacies

[paralogisms]. This so worked upon the minds of their inventors that they abandoned any further inquiry into the matter — gave it up as a lost cause, as it were — and turned to more useful studies. Nor do I recall ever once seeing any real effect produced by such a contrivance, whether one circulated in manuscript or published in print, even though everyone everywhere proclaims that perpetual motion has been discovered by this man or that, in this city or that. Indeed, a good many authors have not been ashamed to grace printed books with showy titles of this kind:

The Machine of Perpetual Motion, So Long Sought Through So Many Ages, Vainly Pursued by the Industry of So Many Mathematicians' Genius, at Last Brought to Full Perfection and Demonstrated.

There you have it — with titles like this, contrived to lend some credit to a thing never actually accomplished, certain men are not embarrassed to celebrate the triumph before the victory. All of which I would say of perpetual motion that is *purely artificial*. That a perpetually moving machine can be made from Art and Nature combined, with Nature lending her aid underneath, I do not deny — the sort of thing we exhibited in our *Magnetic Art* [in Arte nostra Magnetica]; yet such machines are generally found to be devoid of any practical benefit. The same is to be understood of the perpetual light or fire [de lumine seu igne perpetuo], all of which we refuted at length in the preceding Book, in the chapter on asbestos [capite de Asbesto], and to which we refer the reader.

But let us now return to the goal we set ourselves. What has been said of the arts just mentioned holds true above all of alchemy. For you will scarcely find an alchemist of any reputation who does not either boast of possessing knowledge of that Stone, or claim to have seen, in the hands of someone else, the working of the Great Art — though if you examine the truth of their claims more closely by Cleanthes' lamp [ad Cleanthis lucernam], you will find nothing but rotten and worm-eaten wares; or, at most, an operation dressed up by some singular trick; or simply the separation of gold from the other metals, which is the metallurgist's proper business, accomplished with no transmutation at all. And so I am firmly convinced that difficulties of this kind will never, at any time, be exhausted, and consequently will endure until the coming — to speak as the Hebrews do — of **Elijah** [Eliae], that is, until the consummation of the age. For just as these matters subsist in the individual case, so too they demand a greater exertion of human ingenuity to penetrate such a mystery — an access granted only to angelic minds. For Nature is so jealous of her own rights that in matters of this sort she never

permits herself to be mastered by human industry, having reserved the secret mode of her working to herself alone.

[Margin: Alchemy's pursuit is futile.]

From these premises I conclude, finally, that although mysteries of this kind are in themselves and by their own nature knowable, they nonetheless lie so deeply convoluted in the innermost recess and very center of Nature that no human ingenuity can draw them out. I say, therefore, that alchemy — which we call transmutatory chrysopoeia — does indeed have an object knowable in itself and by its own nature, yet one that perhaps only an angelic or a demonic intellect can reach. But because alchemists, fighting tooth and nail [*pro aris et focus*] for it, insist that it has been cultivated from the very beginnings of the world, nothing further remains but to examine whether the things they boast of are true, and whether that philosophical Stone — perhaps known to no one ever — possesses the powers, as great as they claim, that they ascribe to it.

[Margin: Alchemy is knowable, yet is still not known.]

CAPUT III.

De Antiquitate Alchymiae. (*On the Antiquity of Alchemy.*)

That alchemists are said to practice the transmutatory or projective art [*Arte Transmutatoria seu projectoria*] of no such great antiquity as they persuade themselves is plain even from this: that before Christ no writer whatsoever makes any mention of it. The pseudo-alchemists, to win greater credit for their Stone, derive it from Adam himself — indeed, that they might leave no presumption or rashness unattempted, they assert (not so much impiously as foolishly) that it was prefigured by God Almighty through the tree of good and evil in Paradise, and that Adam afterward learned this art from it. They claim that Adam handed it down to his descendants — to Enoch [*Enoch*] and his sons — and that it was propagated to Noah [*Noë*], who then through his children disseminated it into all parts of the world; that its chief cultivator was Ham [*Cham*], and that he passed it on to posterity through his son Mizraim [*Misraim*] and through Hermes. All this they attempt to demonstrate from authors wrenched into shape in the most extraordinary way — as though we ought to believe that in those first beginnings of the world the human race devoted itself, before all else, to no other art than that which consists in the confection of the Stone. Let them say whatever they will: no one of sound judgment will ever be persuaded of it.

[Margin: On alchemy propagated to posterity — the foolish opinions of Adam.]

From Sacred Scripture, too, we know that Adam and his descendants tilled the soil not with gold but with iron; and again they try, by I know not what flimsy arguments, to show that **Belus** [Belum], **Ninus** [Ninum], and **Semiramis** also practiced this art. They assert that among the Egyptians the whole art was described in hieroglyphic letters by Hermes — of which, however, I find not the slightest trace in those letters. They report that **Pythagoras** [Pythagoram] too was skilled in it, and that he indicated the art by the golden thigh [per aureum femur]. They hold that **Moses** [Moysen], instructed in all the wisdom of the Egyptians, cultivated it; and they attribute it to **Hippocrates** [Hippocrati], **Aristotle** [Aristoteli], the divine Thomas [Divo Thomae, i.e. Thomas Aquinas], **Apollonius of Tyana** [Apollonio Thyaneo], **Albertus** [Alberto, i.e. Albertus Magnus], and the rest of the philosophers of great name — for no other reason than to win some authority for a most trifling art. So I cannot marvel enough that the human mind...

[Margin: It is false that the hieroglyphic alchemy was handed down by Hermes.]

should have occupied itself with so many trifles, when, with so many fables and so many ill-conceived assertions, those men are so far from having advanced the credit of the Art that they have rather destroyed all its credibility entirely, made it vanish, and rendered it hateful to all. They show, moreover, that **Solomon** [Salomonem] too was versed in it, from a Magical Book composed by him which they call the *Clavicula Salomonis* [Key of Solomon]; but since the *Clavicula* is stuffed with horrid and altogether abominable matters, I judge that it issued, more truly, from the devil's workshop than from Solomon. For who does not here see the imposture of the pseudo-chemists? If Solomon had been skilled in this gold-bearing Art, he certainly would never have had gold brought from **Ophir**, the farthest shores of the Indies, at truly enormous expense and at peril of life, by a three-year voyage.

[Margin: Solomon an alchemist.]

The pseudo-chemists do not stop here. Whatever fables superstitious antiquity ever devised, they assert were practiced for no other end than to express, beneath those occult mythological wrappings, the wondrous mysteries of the philosophical Stone lying hidden there. They say this art was set forth: through the twelve labors of Hercules [Herculis]; through the golden fleece [vellus aureum] won in Colchis by the Argonauts; by the Greeks through the πολυθεϊαν [Greek: polytheïan, "multiplicity of gods" — the war of the gods]; by the Egyptians

through the history of Osiris, Isis, Horus, and Typhon. But lest I waste time on the most frivolous of matters, let whoever wishes read **Pierre Jean Fabre's** [Petri Fabri] *Hercules Chymicus*, **Michael Maier's** [Michaëlis Mayeri] *Arcanorum Arcanissima*, and **Georg Herwart's** [Georgii Hervortii] interpretation of the *Tabula Bemina* [the Bembine Tablet] — in which they attempt to interpret, ineptly (not to say ridiculously), that nothing else was signified by the Egyptians than the rationale and method of the Great Art.

[Margin: Fables of the ancients signify nothing other than alchemy.]

But whoever has worked through our *Oedipus* [Oedipum, i.e. Kircher's *Oedipus Aegyptiacus*] will plainly see that the intention of the Egyptians was quite other than to signify by these things the mysteries of the philosophical Stone, which they never knew. I would pursue all of this here at greater length, had I not described it most fully in the *Alchemy of the Egyptians* [Alchimia Aegyptiorum] inserted in the second volume of the *Oedipus* — where I demonstrate that the Egyptians, by certain symbols, signified by no means the art of the Stone, but rather the metallic art, by which from certain earthy materials they extracted a vast quantity of gold; and that by their *Elixir* they signified not a Stone, but a liquor extracted from precious stones, herbs, plants, and aromatics, suitable for the prolongation of life.

[Margin: What the Egyptians understood by the philosophical Stone.]

Nor do the alchemists stop even here, but are not ashamed to show — foolishly, impiously, and in words full of blasphemy — that the mysteries of their Stone were signified by Solomon in the *Song of Songs* [Canticis Canticorum], as in a kind of epithalamium of the Sun and the Moon. We, however, applying ourselves so far as we could to the antiquity of this lost art, find that no mention of it is made by any writer before Christ. **Caligula** [Caius Caligula] Caesar was the first of the emperors who, on Pliny's testimony [Plinio teste], is said to have cooked gold out of orpiment [auripigmento]; but since the gain did not answer to the expense, they say he gave up the work. Yet to separate gold from orpiment belongs not to transmutatory but to spagyric chemistry, by which the gold that is naturally present in arsenic or orpiment is separated, by the force of fire and by decoction, from the earthy dregs to which it is bound — which is the metallurgist's proper business.

[Margin: Caligula the first metallurgist among the Caesars.]

Nor did **Pliny** [Plinius], most curious of mortals, have any knowledge of this transmutatory art, or of the Stone or Great Mastery [magni Magisterii]: this is

sharply evident from his treatise *On Metals* [de Metallis]; for had he possessed it, he would beyond doubt have made the most ample mention of it, as of a subject most curious of all. And as for the claim that **Julius Firmicus** [Julium Firmicum] made mention of the word *Alchimia* — this does not occur in the manuscripts of the Vatican Library, but it is likely that the word *Chimia* was added, either by some trick or by the printers, to lend the word *Alchimia* a certain show of antiquity.

[Margin: Pliny did not know the version of alchemy.]

I add, moreover, that if the mastery of the Stone had been known only to the most curious writers — to **Aelian** [Aeliano], **Solinus** [Solino], and the rest of the philosophers and orators — they would doubtless never have ceased to extol it to the skies with great titles of praise. For what subject could there be more noble, more excellent, and more worthy of admiration than that by the sole efficacy of the philosophical Stone all things should be turned into gold? **Suidas** [Suidas] relates of **Diocletian** that, when in his reign the Egyptians, grown powerful in gold and riches, were plotting revolution through the murder of many distinguished men, the rebellion that had been stirred up was at once quelled in its very beginning; and that, lest in future the Egyptians, relying on the resources of gold and riches, should cause the Romans much trouble with fresh tumults of rebellion and sedition, all the writings of the ancients on the smelting of silver and gold were everywhere, by Caesar's command, consigned to the flames.

[Margin: Roman writers never made mention of alchemy.]

The Egyptians, then, were indeed skilled in the gold-bearing art — not, however, in that fabulous art of the Great Stone (otherwise it would not have been held in the place of a great secret), but in the art by which, through separation from earthy clods by smelting, it is done: that is, the metallurgy common to all. Some years later followed **Zosimus** [Zosimus], a Greek writer, whose books *On the Sacred Art* and *On Chrysopoeia* are said to be still preserved in manuscript in the Royal Library at Paris [Bibliotheca regia Parisiis] — concerning which, however, since it is not clear to me what they contain, I have thought it best not to interpose my judgment. Following him, **Nicephorus Blemmydas** [Nicephorus Blemmidas] wrote on the same matter [?]; but, as is plain from a Vatican manuscript, he makes no mention of the Stone, being wholly intent on spagyric alone.

These were succeeded by the **Arabs** [Arabes], who, the first authors of this Stone, filled the world with countless fables and superstitions. Enticed by the spurious

writings of Hermes [Hermetis] and the rest of the ancient Egyptians, stuffed with mystery, and eager to publish something new, they thrust upon the world this vegetable Stone, prevailing in divine virtues, as the treasure of treasures; and, to win some authority for their offspring, they strove not so much to *prove* their art from the most ancient monuments of Hermes as to *authenticate* it. There is in my possession a vast supply of these Arab writers...

[Margin: The Arabs propagated alchemy.]

in the production of marvelous effects, that I may pass over in silence the variety arising from the bridal combination [paranympha combinatione] of things. Whence, even from this consideration, if not the impossibility of alchemy, at least its inevitable, inextricable difficulty may be proved. Add to this that neither I, least of all men, nor anyone else among the most sublimely gifted writers, whether of the ancients or the moderns, has down to this very day demonstrated the true and evident μεταλλογένεσεως [Greek: metallogeneseōs, "of the generation of metals"] rationale — since this matter is of so abstruse an investigation that the more anyone thinks he has advanced in such abstruse operations of Nature, the more difficulties always seem to remain for him to overcome and to resolve, out of the perplexity of a wavering mind.

[Margin: The generation of metals is inaccessible to the human intellect.]

So I cannot marvel enough that certain pseudo-chemists, with such confidence, dare to attempt — with unwashed hands, so to speak [illotis manibus], instructed in no knowledge of natural philosophy — that greatest of all the masteries of Nature, that argument, I say, which the wisest have long since judged a lost cause, inasmuch as Nature seems to have reserved to herself alone the things of metals, with every approach to the intimate and arcane inner chambers of her workshops [ergasteriorum] shut off.

[Margin: The folly of certain idiots who set themselves up as chemists.]

If, then, anyone perfectly knew the exact rule [amussim] of Nature — by which she sublimates, precipitates, dissolves, and coagulates the heterogeneous humid, fixes and hardens it with the appropriate clods — and if he also knew the rationale of the subterranean furnaces, he could doubtless accomplish something in the artificial production of gold, silver, and the other metals. But since it is scarcely granted to human ingenuity to approach this Corinth [hanc adire Corinthum], certainly nothing remains but that from the effects we may attain, by certain conjectures only, the distilling vessels of the Subterranean Archeus [Archei Subterranei vasa]. For my part, having long and much speculated about

this pyrotechny [pyrotechniam] of Nature, I have at last, led by reasoning from various experiments, judged that earthen vessels and furnaces [vasa terrae, fornacesque] can be constructed in the manner that follows — on whose model the artificial vessels of the chemists may afterward be built.

Diagram. A landscape engraving showing a mountain massif cut away in cross-section to reveal the interior, captioned by a banderole (scroll) at the top: *Matrices Metallicae Geocosmi* ("The Metallic Matrices of the Geocosm"). Beyond and above the cutaway, ranges of distant hills with scattered trees recede toward the horizon. At the base of the mountain's interior is a central fire-chamber: an oval reservoir wreathed in flames, inscribed *Hydrophylacium* (water-reservoir) on its body and *Pyrophylacium* (fire-reservoir) in the flames below it. From the head of this chamber rises a trunk that branches upward and outward into a root- or tree-like network of metallic veins (the "matrices"), ending in swollen nodes distributed through the body of the mountain. The labels mark stations along these veins.

- Banner (top center): *Matrices Metallicae Geocosmi* — "The Metallic Matrices of the Geocosm"
- A (within the oval chamber): *Hydrophylacium* — the central water-reservoir
- (in the flames beneath A): *Pyrophylacium* — the fire-reservoir
- B (just above the chamber, at the base of the trunk): the spring-head from which the veins issue
- C (upper right node): vein-terminal node
- D (upper center node): vein-terminal node
- E (upper left node): vein-terminal node
- F (left, mid-height node): vein-terminal node
- G (left, lower node): vein-terminal node
- D, E, F, G (along the lower right horizontal vein-band): successive vein-terminal nodes

in great abundance; in which, however, I have found nothing but some non-essential — indeed, purely accidental — transmutations of metals and tinctures, such as coagulations of mercury and separations of gold from silver, of this from copper and lead, tested by me with no unhappy success, of which more in what follows. But where they treat of their Stone, I do not think any fables or fictions more absurd could be devised by human ingenuity than those which they themselves describe under monstrous wrappings of parables and allegories, and

set forth with such obscurity of words that not even Oedipus himself would seem able to suffice for the exposition of their mysteries. Since we have displayed all this in our *Hieroglyphic Alchemy* [Alchimia nostra Hieroglyphica], with the citation of a great body of Arabic texts, I have thought it superfluous to recite it again in this place.

[Margin: The Arabs' horrid fables about the Stone.]

These traditions of the Arabs were first followed by several men of great name among the Latins: **Arnold of Villanova** [Arnoldus Villanovanus], **Raymond** [Raymundus], **Lull** [Lullus], **John** [Ioannes], **Azoth** [Azotus], and last of all **Paracelsus** [Paracelsus] — whom countless others followed, who, gaping after gold and either not understanding the Arabs' meaning or interpreting it wrongly, drew (as it were) a golden chain let down from heaven [aurea catena caelitus deducta] — that is, a new Hermetic philosophy — and by it, at first, drew on, as if by golden chains, the minds of kings and princes greedy for the promises of such great things. Their favor, and a mind inclined toward the pursuit of gold, kindled so great an appetite [orexin] that they gave themselves over wholly to it, not without damage to public affairs.

[Margin: The Latin chemical writers. / Why alchemy was so cultivated.]

Hence it came about that scarcely any actor, soldier, mountebank, barber, surgeon, bath-keeper, mechanic, merchant, or physician was to be found who did not soon, in a single night, sprout up into an alchemist like mushrooms; hence there came forth — as if from a certain Trojan horse — so much *κατάρρευμα* [Greek: katarrheuma, "scum/refuse/dregs"] of disgraceful men, so many deceivers and impostors of princes, so many leeches of human blood, so many emptiers of purses. So much so that even Paracelsus himself is forced to confess that chemistry is the field [ager] of all those who wish to feed themselves dishonestly, and that there is no pig that does not dare to root with its snout in the vineyard of chemistry — most of whom were deserters of their own profession.

[Margin: Paracelsus on alchemy.]

[Margin: Description of the pseudo-chemical deceivers.]

These were: officious busybodies [ministri πολυπράγμονες], apostates of the law, druggists reduced to ruin [ad incitas redacti], lazy artisans, brass-smiths, crafty mountebanks [Agyrtæ versipelles], goldsmiths who hate gold [Aurifabri φιλάργυροι (philargyroi, "money-loving") — ironically], rash strollers, drunken tailors, stupid fullers, tooth-breakers [dentifragi], chattering barbers, and

decoctors of their tenfold chemistry [decem Chymicorum decoctores], and others of this bran — vain, rude, and unskilled little men who, when they have squandered their goods, are carried about nearly everywhere on earth like flies, trumpeting great things about that blessed Stone, the Son of the Sun and Moon, perpetually dreaming of golden mountains, the very poorest of mortals promising the riches of **Croesus** [Crassi (recte: Croesi)]; in a word, with their brains drained dry by their circulations [circulationes], they leave behind them color for a tincture, a stone for the Philosophical Stone, charcoal for treasure, and ashes. And from this it has come about that chemistry, an otherwise noble faculty, has incurred marks so foul that today nothing is held cheaper than an alchemist, nothing more deceitful and fraudulent. But now, setting these things aside, let us return to our purpose.

CAPUT IV.

De Pyrotechnia sive ad Chimicas operationes requisitis vasis, & instrumentis. (*On Pyrotechny, or the Vessels and Instruments Required for Chemical Operations.*)

It cannot be that the chemists should rightly construct anything, unless — having grasped Ariadne's thread [filo Ariadnae] in this labyrinth of mineral Nature — they proceed according to the rules and operations of Nature, with the **Archeus** as their guide [Archeo Duce]. In all the arts and sciences a natural prototype is needed; and this is clear from the art of painting. For just as the painter and sculptor, in painting and fashioning the likenesses of things, need a prototype to produce anything worthy — and if he lacks one, let him be assured that he will bring forth nothing but a monstrous birth — so the **Geocosm** ought to be the archetype for alchemists, if only it were permitted to enter it. For here it teaches the perfection of the art exactly, while in its inner womb, furnished with countless furnaces or alembics, by a certain marvelous mastery of fire that is incomprehensible to the eye...

[Margin: The imitation of nature is difficult.]

[Margin: Nature's hidden paths in producing gold.]

[Margin: With occult instruments.]

working upon the humid, it now exalts it into vapors, now dissolves it; now calcines, coagulates, and hardens it; and so long does it putrefy and ferment, until at last in the appropriate subterranean matrices it produces the metal intended

by Nature. In which work it proceeds by ways so occult, along paths so occult, in those inaccessible workshops [ergasteriis] of Nature, that in attaining and comprehending them it seems to elude every grasp of human ingenuity — since neither the combination of graduated heat with the appropriate marriages [conjugiis] of the earthy clods, nor the proportion of disparate things to be knit into one, is suited to us.

Yet unless the alchemists observe this order of Nature most precisely in the confection of the Stone, let them be assured that they will certainly never arrive at what they intend and aim at.

[Margin: The proportion of things unknown to us in the production of metals.]

But who is endowed with a wit so subtle that he may penetrate the rationale of the furnaces, the alembics, and the siphons in the hidden lap [in abdito sinu (recte: suscipi[?])] and kingdom of the Archeus? Who may conceive the manifold variety of the masteries and tinctures, and the mode by which it operates? So that meanwhile — to admire the wondrous variety of the salts, minerals, and the rest...

[The following continues Liber XI, Sectio I. Reading order reconstructed from page numbers and running headers: p. 238 → p. 239 → p. 240 → the full-page plate "Tom. II. 241". PDF page order is non-linear.]

[Margin: Subterranean furnaces and hearths.]

It is certain — as we showed in the first volume — that hidden deep within the bowels of the Earth there lies a manifold arrangement of fire-chambers [pyrophylacia]. These act as so many hearths, diffusing their fiery heat through all the pathways of the Geocosm and along the Earth's tubular channels. First of all, Nature has arranged within those inner recesses of the Earth a multitude of cavities, which serve as a kind of cucurbit [glass distilling-flask]. Just as these are packed with a diversity of minerals, so too the moist matter within these cucurbits is resolved into vapors by the force of the fire set beneath. The vapors pass through the blind channels of the Earth's fibers, escaping wherever an opening offers itself, into various hollows of differing nature; and wherever they encounter earthy clods, there — drawn by a kind of magnetic force — they form a metal proportioned to the nature both of the earth and of the vapor. But all this is better shown by a figure than by manifold verbal reasoning.

[Margin: An account of the manner Nature employs.]

Let there be, then, a subterranean fire-chamber X — a cauldron, or one filled with a mineral water, or a Mercurial-sulphureous womb [matrix] which through its various tubes distributes its fire-exalted vapors into the various ore-matrices of the mountains, C D E F. Suppose, then, that first the matrix A — a kind of cucurbit packed with sulphur, mercury, and salt — gives rise, by the service of the fire set beneath, to a spermatic vapor, mercurial-saline-sulphureous. This vapor slips out through the channel B C; and if at C it strikes a matrix holding a vein of the purest sulphur, it is enclosed there on every side as if in an alembic, condensed by the coldness of the place into a water. This water, drawn up higher and imbibed by the purest sulphur of a red color in that place, and digested by a moderate warmth through the channel B C, in time — once the moist element has been consumed — is converted into gold. But if the vapor strikes through channel B D into matrix D, which is filled with a white sulphur not so pure or fully concocted, then it will at last generate silver there. And if the vapor from A, passing through channel B E into matrix E, strikes one filled with impure sulphur variously contaminated, then there it produces copper [aes]; but in matrix F, filled with sulphur that has been burnt, impure, and contaminated with earthy refuse, it produces iron. In this way, in matrix G, filled with magnesia, plumbago, and bismuth, it engenders lead and tin. You see, then, the procedure of Nature in producing metals — and how one and the same vapor, according to the diversity of the matrices, by means of sublimation, distillation, coagulation, and the fermentation carried out within the matrices, at last produces diverse metals.

[Margin: Chemical vessels constituted on the model of Nature.]

From this operation of Nature the philosophers, gradually coming to a certain knowledge of metallic transmutation [μεταλλολογήσεως — Greek: metallologēseōs, "metal-working / the study of metals"], devised vessels, furnaces, alembics, cucurbits, and the like, constituted on the model of Nature — so that, looking perpetually toward these as toward the prototype of Nature, they believed they would at last accomplish by art, in the highest degree, what Nature labors over for a long time. But since in the chrysopoeia [gold-making] this can in no way be carried out without those aids — without which the art

cannot be brought to completion — and since we may seem able to proceed, and may not be reckoned "untried and inexperienced" [ἄπειροι καὶ ἄπρακτοι — Greek: apeiroi kai apraktoi, "without experience and without practice"] in the things necessary for either refuting or establishing this art in any way whatever, I shall here first set down the whole construction of the vessels suited to chemical

operations, so that it may shine forth most clearly from the individual examples appended what use each one serves in pyrotechny.

Nevertheless, in order that what we have set forth at perhaps greater length than was proper in the preceding pages concerning the hidden constitution of the Subterranean World might be turned to some use necessary for human life, I have decided in this Book — which we also call the *Geocosm Applied* — to set out, by a certain easy, clear, and ready method, a kind of demonstration [ἰχνογραφίαν — Greek: ichnographian, "a ground-plan / outline drawing"] of the marvels of chemical art [Chymotechnia], so that what Nature, by the efficacy and industry implanted in her, brings to birth in the fertile womb of the Geocosm, we may likewise be able both to bring to birth and to produce — by a certain manual technique of art [Encheiromatico] adapted to imitating Nature in her every form [pantamorpham]. And so that this may be done with all possible diligence and method, I shall first set forth certain paradigmatic canons of the universal chemical operations to be carried out in chemistry, so that the kindly reader may learn how one must proceed in the preparation, calcination, coagulation, and fixation of metals, and in the other matters to be treated fully a little later. Once these are done, we shall take up the alchemical operations, so that what that Stone of the Philosophers may be — known to the blear-eyed and to barbers alike [lippis et tonsoribus notus, i.e. proverbially known to everyone] — and whether, by a true and real mastery, and from what materials it can be made, and whether it possesses such great powers as the alchemists boast it has, may become known to the curious reader more clearly than the midday light.

Chemistry [Chymia] is so called, as we have said elsewhere, from χυμός [Greek: chymos, "juice"] — or rather from χέειν [Greek: cheein, "to pour"] — which means the same as "to fuse, to liquefy, or to reduce some mixed body into a liquid or juice." And just as χυμός means "juice," so chemistry is the art that makes juice, that is, that resolves solid things into juice. We define it thus:

[Margin: Definition of the spagyric art.]

Chemistry is the art of separating the pure from the impure, and thence making medicine for the healing of bodies, and apt for bringing metallic bodies to metallic perfection. This definition holds good by its genus, its specific form, and its proper end. The genus is "natural art" [Ars Physica]. It is an art, because it is a habit productive in accordance with reason, and that in natural things. Its form is the separation of the pure from the impure, proper to this art. I said "the pure," because it claims for itself the resolution into their elements not only of metals, but also of the mixed bodies of herbs, plants, and animals. This separation is

carried out in various ways, as will afterward be clear from the chemical operations.

In chemical art [Chymiotectnia], therefore, two things are to be considered: both the things that serve the operation, and the operation itself. The former are the place and the cause, the auxiliaries.

[Margin: The place fit for chemical operations.]

The place of chemistry is the subject containing the matter to be elaborated — namely, the furnace and the vessel. A furnace is a place in which fire is skillfully and suitably adapted for preparing matter in the chemical way.

CAPUT V.

On Furnaces, Vessels, the Degrees of Heat, and the Other Chemical Operations.

[This Caput-V heading and its subhead appear on p. 239. Note: the prior chapter was Caput IV; the running header throughout this opening reads "DE ORIGINE ALCHYMIAE."]

[Margin: The structures of the small furnaces and their rationales.]

One kind of furnace is open, another closed. The latter is so called because it is open at the upper part, and is either a *Probatorius* [testing furnace] or a *Ventusus* [draft furnace]. The *Probatorius*, or assay furnace [docimasticus], is an open furnace in which metals are purged, examined, or sublimed; it is generally made of clay or of iron plates, as is shown in the first Figure of the following Diagram, where by the *conisterium* we understand the place of the ashes, and by the *pyriterium* the seat of the fire.

Diagram. A full-width engraved plate titled **FABRICA FURNORUM** ("The Construction of Furnaces"), showing six numbered furnace types in cutaway and exterior view. Each furnace is captioned with its name above it and a figure-number. Labels read:

- **Fig. 1 — *Furnus apertus probatorius*** (open assay furnace), upper right: a domed furnace shown in cutaway.
- C (top opening): the upper mouth
- D (upper chamber): the assay chamber
- F, F (mid-level side holes): draft/regulator holes
- C (mid-chamber, lower): the fire-seat

- A, B (lower arched chamber): the ash-pit / base
- E (right side): air-draught hole
- **Fig. 2 — *Furnus ventosus*** (draft furnace), top center: a tall furnace shown in cutaway, with bellows-fed fire.
- F (top): the crucible/upper opening
- D (mid, with flames): the crucible in which metals are melted
- C (left mid): mouth
- E (right side): bellows-nozzle hole
- *Pyriterium supra craticulam* (labeled mid-body): the fire-chamber above the grate
- A — *Conisterium* (base): the ash-place
- (to the right, an undraped curved object on a wooden stand — apparently an associated part, unlabeled)
- **Fig. 3 — *Furnus cæmentatitius*** (cementation furnace), upper left: a tall chimney-furnace in exterior view.
- D (top, with flame-vent): the upper turret through which charcoal is thrown in
- C (mid, with flame-vent): a spiracle
- H (right side): a side feature [the air-hole H of the text]
- A (lower body): the body of the furnace
- H, B (base, ash-door): the ash-removal mouth
- *Pyxis seu tegula cæmentatoria* (labeled below, with a small box/tile object): the cementation box or tile
- **Fig. 5 — *Athanor, Furnus Philosophicus*** (the Athanor, or Philosophical Furnace), center: shown in cutaway with nested vaults.
- E, H (upper left turret): the turret-top features
- D (left turret): the turret through which charcoal is fed
- Q (top of vault): the dome/cover
- P, P (upper vault): the spiracles
- M (mid-vault): the hearth on which the matter is placed
- L (vault): vault interior
- K (lower vault, with grate): the lower fire-vault
- G (lower left): the regulator-hole
- B, C (base left): the ash-mouth features
- F (base center): the fire-channel from the hearth
- A (base): the foundation

- **Fig. 4 — *Furnus Reverberatorius*** (reverberatory furnace), lower right: shown in cutaway as a tiered cabinet.
- I (top): the crown
- *Reverberatorium* (upper shelf, labeled): the reverberation chamber
- K (top right): regulator-holes
- G, F (mid): the openings
- D — *Pyriterium* (middle shelf, labeled): the fire-chamber
- H (right side): a side mouth
- C (with grate): the transverse grate
- B (lower right): the ash-mouth
- A — *Conisterium* (base, labeled): the ash-place
- **Fig. 6 — *Furnus Acediæ*** (the "Furnace of Sloth" / labor-saving furnace), lower left: three connected cylindrical furnaces.
- D (top, shared turret): the turret through which charcoal is thrown
- On each of the three cylinders, top to bottom: C (smoke-vent / spiracle), B (fire-chamber / pyriterium), A (ash-place / conisterium)

Explanations of the Furnaces.

FIG. I. The *Probatorius* or assay furnace is open, one in which the more perfect metals are purged, examined, and — to speak in chemical terms — "fulminated" (refined). Its foundation is marked by the letter **A**. **B** denotes the open mouth of the furnace, or the place of the ashes. **C** is the intermediate part between the lower and upper mouth. **D** is the mouth of the furnace, in which the metallic material to be assayed is placed upon the grate. **E** is the hole serving for moving the coals with an iron. **F, F** are the holes appointed for moderating the fire, fitted with their registers [sliding dampers] for any degree of heat. **G E** is the hole necessary for drawing in air.

FIG. II. The *Furnus ventosus* or draft furnace is open, one in which minerals, stirred up by the force of the fire by means of bellows, are melted and fused. **A** is the place appointed for the ashes of the ash-pit. **B** is the mouth of the ash-pit, fit for drawing in air. **C, C** is the grate sustaining the coals and a vessel set beneath them. **D** is the crucible in which the metals are melted. **E** is the hole fit for inserting the bellows-nozzle. **F** is the hole that serves for emitting smoke.

FIG. III. The *Furnus cæmentatitius* [cementation furnace] is one in which fire is skillfully accommodated for cementing things. **A** is the ash-pit [conisterium]. **B** is the mouth of the hearth, with its iron grate, fit for placing upon it the vaulted tile or the cementation box. **C** are the holes or air-vents in the four sides. **D** is the

small turret through which charcoal is thrown in over the tile or box. **E** are the small mouths fitted with their registers for extracting the ashes and for drawing in air, as is also the hole **H**, which is always open.

FIG. IV. The *Furnus reverberatorius* or calcining furnace, one in which the matter placed in it is calcined by a reverberating flame. **A** is the ash-pit. **B** is the mouth through which the ashes are removed. **C** is the transverse grate. **H D** is the space of the forward hearth. **E** is the mouth through which the logs are placed on the grate. **F** is the floor on which the matter to be calcined is placed. **G** is the opening of the floor, through which the flame, passing through and reverberating, calcines the matter set above the floor. **H** is the mouth through which the matter can be placed on the floor. **I** is the vault or covering for the smoke. **K** are the holes or registers appointed for moderating the heat.

FIG. V. The *Athanor*, which is also called the philosophical or secret furnace, serving especially — as the alchemists suppose — for making the Stone. **A** is the empty foundation of the furnace. **B** is the little mouth of the ash-pit. **C** is the mouth of the tower **C E**, within which the grate is placed. **D** is the tower through which charcoal is thrown in over the grate. **C E** is the iron cover of the tower. **F G** is the mouth through which heat can pass from the hearth **C** into the furnace **K**, fitted with its register **G**. **H** is the spiracle of the tower appointed for drawing in air. **I K L** is the furnace, having its hole **I**, through which the heat enters within the vault **M N**. **O** is the hole through which the heat can enter from furnace **M** into **P**. **P** is the hearth above which the matter to be elaborated is placed. **P, P** are the spiracles together with their registers. **Q** is the completion or covering of the furnace.

FIG. VI. The *Furnus Acediæ* [Furnace of Sloth], in which, with one fire and little labor, diverse furnaces are kept warm, and which can easily be accommodated to any tasks whatever. **A** are the ash-pits [conisteria]. **B** are the fire-chambers [pyritaria], separated from the ash-pits by grates. **C** are the smoke-vents or spiracles. **D** is the small turret through which the charcoal is thrown in.

And let this much, said concerning furnaces, suffice for accomplishing the labors of the alchemists. The remaining kinds of furnaces, see most amply described in *Book XII, Section [?], On the Art of Distillation*, where you will find whatever can be desired concerning the hidden structure of furnaces. [Margin: l. 390.]

[Margin: The various kinds of furnaces suited to various operations.]

The *Furnus ventosus* is likewise an open furnace, in which, by the benefit of wind and bellows, the force of the fire being increased, minerals are melted and fused;

its figure is shown by the second figure of the Diagram. There are besides furnaces which they call *Tecti* [covered/roofed], some of which are simple, others compound. A simple one is that which needs no aid from another, and it is again twofold: calcinatory and cementatory. The former serves for calcinations, the latter for cementations — and the latter is also called *reverberatorius*; the figures of both are expressed in the third and fourth figures of the Diagram. Again, the artificers have certain furnaces which they call distillatory. The *Furnus dissolutorius* [dissolving furnace] is simple, by whose aid, by transmitting the subtle through the gross, things are dissolved; and it is either *Ascensorius* or *Descensorius*. The former serves for distillation by ascent, the latter for distillation by descent, and concerns dry and moist dissolution. It is a dry dissolving furnace when the vessel set in the furnace is touched immediately by the fire. See the figures of each in the fifth and sixth figure of the Diagram.

[Margin: The water-bath. / The bath of Mary (*Balneum Maricæ*).]

There is also a *Furnus balnei* [bath-furnace], in which things are dissolved in hot water held in a copper vessel [ahena], and it is commonly called the bath of Mary [*balneum maris* / *Maricæ*, i.e. *balneum Maricæ*, the water-bath]. But the *Balneum roris* [vapor-bath, "bath of dew"] dissolves them only by the vapor of warm water. — Again it is called *descensorius*, because by its aid, driving the moisture downward, things are dissolved. See the figure in the Diagram.

Having set out the simple furnaces, let us now proceed to the compound ones, where with one fire several furnaces are kept warm — such as those they call *Athanor* and *Acedia*. *Athanor* in Arabic — التنور [Hebrew/Arabic script: al-tannūr] — is the same as "furnace," called by the chemists ἀτὴν ἐχλῶ [Greek: a-tēn-echlō (?)] [?]; so called because it serves the more secret operations in chemistry, and hence it earned the name of the Philosophical furnace. There is a varied manner of building it among various authors. We have selected the one which the eighth figure shows in the Diagram as the better, and more suited to the subterranean furnaces of Nature. [Margin: The Acedia furnace.] It is called the *Acedia* furnace because by one fire and with little labor diverse furnaces are kept warm; see its figure in the Diagram.

[Note: the text refers to an "eighth figure" of the Diagram, but the plate as printed shows only six numbered figures (the Athanor being Fig. V). This is the author's or compositor's figure-numbering discrepancy, transcribed as printed.]

§. I.

The Account of Vessels.

One kind of vessel is brought to the fire, another is not. Some are of glass, some of earthenware, some of metal. Of glass are all those vessels commonly called *phialae* [phials], *vesicae* [bladders/flasks], and *urinaria* [urinals/receivers], which are frequently used in solutions and coagulations.

[Margin: Circulatory vessels.]

Of glass too are mostly made the vessels they call *circulatoria* [circulatory vessels], because the liquor poured into them is agitated, as it were in a circle, by ascent and descent; their use in chemistry, for subtilizing liquors, is great. They are of various shapes. The more usual ones are those they call the *Pelican*, the *Dyota*, and the *Caecum* [the Blind]. See the figures.

[Margin: The Philosophical Egg.]

There is also a vessel they call the *Ovum Philosophorum* [the Philosophers' Egg], whose uses will be taught in what follows; it is either of earthenware or of metal,

[Full-page engraved plate — "Tom. II. 241"]

Diagram. A full-page engraved plate (uncaptioned) depicting a solar burning-apparatus used for distillation. At upper right, the Sun (with a face) emits a dense fan of rays. These rays strike a large spherical lens or burning-globe mounted on a tall pedestal stand at the left, which concentrates and re-emits the rays downward to the right onto a distilling apparatus standing on a table. Readable labels:

- **F** (upper right): the radiant Sun
- **E** (large globe/lens on the stand): the burning-globe (water-filled sphere / lens)
- **H** (below the globe, on the pedestal): the neck/socket holding the globe
- **B** (mid-stand, with a horizontal rod): the adjustable arm/axis of the stand
- **i** (small upper bulb of the apparatus, right): the alembic head / receiver-bulb
- **A** (the body of the cucurbit/flask below i): the distilling-flask
- **C** (the furnace base beneath A): the furnace / heating-base supporting the flask
- **K** (a separate flask set on a box at far right): the receiving vessel

No labels flagged [?]; all eight readable.

just as the copper cauldron is. The **bladder-vessel** [vesica] is a metal vessel made of copper in the form of a bladder, or of an egg, as is clear in the figure. Its use is in distilling vegetable substances.

The vessels that serve for melting are the **funnel** [infundibulum] and the **pyramid** [pyramis]; the **ash-pan crucible** [catinus cinereus] and the **crucible** [crucibulum], as appears in the figure.

[Margin: The ash-pan crucible, from what materials it is made.]

The **ash-pan crucible** [catillus cineritius] is a melting-vessel made from the ash of light oak wood, thoroughly cleansed of all charcoal and other impurities of the residue. It is made from two parts of this, together with one part of the best-pulverized ash of bones that lack marrow (excepting pig-bones), moistened and properly blended in its own mortar. The crucible [crucibulum], being a vessel commonly known, needs no explanation.

Among the non-melting vessels there is the **cementing box** [pyxis caementatoria], that is, an iron vessel formed of clay obstinate against fire, in the manner of a box, fitted neatly with its own lid; see the figure.

[Margin: Alembic.]

What the **alembic** [alembicus] is, is commonly known. It is set upon a vessel, which is called the **gourd** [cucurbita], and the **retort** [retorta]. The figure of all these you may see in the engraving [in Schematismo]. The remaining vessels, together with the instruments — so that nothing be lacking for this work — consider in the engraving.

§. II.

Caloris adhibendi ratio.

[The method of applying heat]

Heat, to be applied in chemical operations, is the assisting cause by which the substances to be treated are hastened and fostered; and it is either natural or artificial.

Natural heat is when the rays of the Sun either by themselves bake the material set before them, or — gathered in a concave mirror — are brought to bear upon the thing.

[Margin: The reflected rays of the Sun by means of a mirror.]

The use of this heat is immense in dissolving and calcining metals; and in the northern regions indeed that anacampitic [reflected] heat can have its place, but not so in the southern. For, as is wont to happen in Egypt, things are dissolved most powerfully not by the reflection of the Sun's rays, but by the heat of the burning Libyan sand alone, when the vessels are set into it.

[Margin: The deception of chemists concerning the Sun's reflection by a mirror onto a chemical vessel.]

This too is most worthy of observation in concave mirrors: that unless someone perpetually attends the work, who continually applies the deflected ray to the glass bladder, they can produce no effect — since the Solar radiation [actinobolismus Solaris] is not perpetual, as many of the chemists, ignorant of the anacampitic faculty [anacampitica facultas], persuade themselves, namely that it remains fixed upon the gourd, but rather changes its position together with the Sun's motion. Since I have pursued all these matters at length in the *Ars Magna Lucis et Umbrae*, I refer the reader there. From which, in order to dissolve things ingeniously, I judged that this machine could be made.

Let the vessel A be a glass gourd set upon a tripod with the alembic I; let a rounded peg be soldered to it below at the place D, and let an iron arm D G, capable of being turned, be inserted into it, so that it may rotate as if about an axis D. To this arm, at the place G, let there be raised perpendicularly

another arm G H, which holds a concave mirror; let the mirror be E.

[Margin: A new machine for dissolving things by the Sun's reflected rays.]

Therefore let the mirror E be so applied to the Sun's rays that, reflected, they strike the gourd A; and as the Sun recedes, let the mirror, together with its arm, be turned around until the rays again strike the gourd. In this way the reflection of the rays affects the gourd with a constant heat. But since, according to the altitude or depression of the Sun, the reflected rays also receive a different position, we have for this reason added to the gourd a smooth peg, so that by its help the gourd — now raised, now lowered — may more easily, according to the Sun's position, receive its reflected rays. Unless this be done, you will accomplish the chemical work only with the greatest difficulty by the Sun's reflected rays, since the actinobolism [actinobolismus], or solar radiation reflected from the mirror, continually changes, and scarcely for as long as one might finish reciting the *Miserere* psalm by reading does it rest upon the gourd. But this whole

procedure [encheiria] you will carry out more easily with a glass globe filled with water, and likewise with the happiest success — the rays being refracted and aimed at the gourd in a direct vibration. But now let us return to heat.

Artificial heat is that which can be kindled, directed, and administered at the artisan's will.

[Margin: What artificial heat is.]

It is twofold: **Digesting** [Digerens] or **Separating** [Separans]. Digesting heat is that by which the material to be dissolved is digested; and digestion is for the most part accomplished in the Athanor or in a furnace. It is done in the Athanor when, the tower of the Athanor having been filled to the very top with charcoal, we kindle the fire in the hearth, and with an iron spatula or register we open or close the little door at our discretion (so that in this way the heat may be transferred to the Athanor). And in this way the digesting heat can be distributed, as it were, into certain grades, so that at the beginning the material tends toward whiteness, in the second grade toward yellowness, in the third toward redness.

[Margin: Heat of dung.]

Heat of dung [calor fimi] is when, the vessel having been placed in dung, digestion takes place; and it serves very greatly for digesting and putrefying things. Sometimes horse-dung is used, in which the vessel is buried; sometimes sand, or an iron pit, and the like, concerning which more in what follows. (*L. XII, Sect. 3, de arte distillatoria* [Book XII, Section 3, On the distilling art].)

[Margin: Separating heat.]

Separating heat is that called by whose help the subtle is separated from the gross; and for a gentle heat indeed they use the bladder-vessel [vesica], or the ash-hearth.

[Margin: Heat of the bladder-vessel.]

The heat of the bladder-vessel is a gentle heat, by which, the alembic being applied, the moist substance is drawn out from the material placed in the bladder-vessel.

[Margin: Heat of ashes.]

The heat of ashes is when the moist parts are drawn out through ashes.

[Margin: Strong heat. / Free heat.]

Strong heat [fortis calor] is when things are separated by a more intense or sharper fire. **Free heat** [calor liber] is that which touches things immediately; **impeded** [impeditus], that which does so by means of something else.

[Margin: Heat of charcoal.]

Heat of charcoal [calor carbonum] is when the heat of the coals touches things immediately; its use is in cementation, assaying, calcination, and dissolution.

[Margin: Heat of flames.]

Heat of flames [calor flammorum] is when, wood being laid on,

[the wood being laid on,] the heat passes into flames; and its use is in reverberating and calcining all the bodies of the metals.

[Margin: Heat of the bath.]

Heat of the bath [calor balnei] is when things are distilled either by boiling water, or by the vapor of it as an intermediary.

But all these things we have judged should be set before you, reader, in the following resolute Table, presented to the eye in a single synopsis.

Diagram. A full-page synoptic bracket-table (the *Tabula Chymio-Technica*, "Chemico-Technical Table"), a branching dichotomous outline classifying the whole subject matter of chemical technique. The classification is reconstructed below from the nested brace-brackets.

The two grand divisions, on the far left, are:

- **Things serving the operation, which are** [Operationi servientia, quae sunt] — apparatus
- **The operation itself, which is** [Operationem ipsam, quae est] — the processes

I. Things serving the operation divide into:

A. Place [Locus] — i.e. the furnace and the vessels:

- **Furnace** [Furnus]:
- **Open** [Apertus]: Assay-furnace [Probatorius]; Draught-furnace [Ventosus].
- **Closed** [Tectus]:

- **Simple** [Simplex]:
- **Calcining** [Calcinatorius]: Cementing [Caementatorius]; Reverberatory [Reverberatorius]. — also: of the bladder-vessel [Vesicae].
- **Dissolving** [Dissolutorius]: Ascending [Ascensorius] — Dry [Siccus]: ash-pan crucibles [Catini arenarii]; Descending [Descensorius] — Moist [Humidus]: bath [balneum].
- **Compound** [Compositus]: Athanor [Athannor]; Acediae [furnaces].
- **Vessels** [Vasa], the other component pertaining to fire:
- **Made of a definite material** [Ex certa materia factum]:
- **Glass** [Vitreum]: Phials [Phialae]; **Circulatory** [Circulatorium]: Pelican [Pelecanus]; Dyota; Egg of the Philosophers [Ovum Philosoph.].
- **Metal** [Metallicum]:
- Serving **subtilization** [Subtiliationi]: the bladder-vessel [Vesica]; the copper cauldron [Ahenum].
- Serving **melting** [Fusioni]: Funnel [Infundibulum]; Pyramid [Pyramis].
- **Mineral / earthen** [Minerale / Terrenum]:
- **Receiving the material** [Materiam capiens]:
- **Melting** [Fusoria]: Ash-pan crucible [Catillus cinereus]; Crucible [Crucibulum].
- **Non-melting** [Non fusoria]: Cementing box [Pyxis caementatoria].
- **Another vessel** [Aliud vas]: Sand-pan crucible [Catinus arenarius]; Vaulted tile [Tegula fornicata].
- **Vessels for the operation, at the artisan's discretion** [Operationi inservientia, pro artificum arbitrio]:
- **Upper** [Superiora]: the cooking-vessel [Coctus]; Alembic [Alembicus]; Beaked [Rostratus].
- **Lower** [Inferiora]: Gourd [Cucurbita]; Retort [Retorta].
- **Not moved** [Non admovetur]:

- **Containing** [Continens]: Receiver [Receptaculum]; Shell-dish [Concha].
- **Transmitting** [Transmittens]: Funnel-tube [Tritorium]; Separator [Separatorium].

B. The assisting cause [Causa adjuvans]:

- **Hand-instrument for the fire** [Instrumentum manuarium igni]:
- **To be applied** [Admovendum]:
- **Always** [Semper]:
- **Slender** [Gracile]: Grating [Craticula]; Iron rod [Baculus ferreus].
- **Broad** [Latum]: Spatula; Forceps [Forfex].
- **At discretion** [Ad arbitrium]: Fire-shovel [Rutabulum]; Spoon [Cochleare]; Ring [Circulus].
- **Not to be applied** [Non admovendum]:
- **Wooden** [Ligneum]: the dioptra [dyoptra].
- **Metal** [Metallicum]: Iron plate [Tabula ferrea]; Little mortar [Mortariolum].
- **Heat** [Calor]:
- **Natural** [Naturalis]: the Sun's rays [radii solares].
- **Artificial** [Artificialis]:
- **Simple** [Simplex]:
- **Digesting** [Digerens]: Athanor [Athannor]; Dung [Fimus].
- **Separating** [Separans]: of dung [Senis (recte: Fimi?)] — of the bladder-vessel [Vesicae]; of ashes [Cinerum]; of sand [Arenae]; of iron filings [Scobis ferri]. **Impeded** [Impeditus]. **Strong** [Fortis] — **Free** [Liber]: of charcoal [Carbonum]; of flame [Flammae].
- **Mixed** [Mistus].
- **Bath** [Balneum]: of the sea [Maris]; of dew [Roris].

II. The operation itself [Operatio ipsa] divides into:

- **Calcination** [Calcinatio]:
- **Corrosion** [Corrosio]: Vaporous [Vaporosa]; Immersive [Immersiva] — Moist [Humida]: Amalgamation [Amalgamatio]; Precipitation [Praecipitatio]. Dry [Sicca]: Cementing [Caementum]; Commixture [Commixtio].
- **Ignition** [Ignitio]: Combustion [Combustio] — Vitrification [Vitrificatio]; Reverberation [Reverberatio] — Incineration [Incineratio].
- **Solution / Dissolution** [Solutio / Dissolutio]:
- **Elevation** [Elevatio]: Dry sublimation [Sicca sublimatio]; [Greek: μετεωρισμός (meteōrismos, "raising up / elevation")].
- **Subtilization** [Subtiliatio]:
- **Descent** [Descensio]: Hot [Calida]; Cold [Frigida] —
- **Direct** [Directa]: by the Alembic [Alembici]; by the bladder-vessel [Vesicae].
- **Oblique** [Obliqua]: by the Retort [Retortam]; by the side [Latus].
- **Moist** [Humida]: Circulation [Circulatio]; Deliquescence [Deliquium]; Washing [Ablutio]; Filtration [Filtratio]; Imbibition [Imbibitio]; by leather [Corio].
- **Exaltation** [Exaltatio]; [Greek: μετεωρισμός (meteōrismos)]; Putrefaction [Putrefactio]; Digestion [Digestio]; Extraction [Extractio]; Cohobation [Cohobatio].
- **Liquefaction** [Liquefactio]:
- **Simple** [Simplex].
- **Assaying** [Probatoria], by means of: the ash-cupel [Cineritium]; Antimony [Antimonium].
- **Coagulation** [Coagulatio]: Cold [Frigida]; Hot [Calida].

CAPUT VI.

Canones Methodici & Paradigmatici, queis operationes Chymicae per experimenta, & varia Exempla singulis operationibus propria ostenduntur, & comprobantur.

[Methodical and Paradigmatic Canons, by which the chemical operations are demonstrated and proven through experiments and through various examples proper to each operation]

So that the reader might perfectly understand what is meant by so many and so manifold chemical operations, and what those operations accomplish in the chemical pyrotechnics, and what use they have, in this chapter I have decided to set forth not only the [Greek: κατὰ τὴν θεωρίαν (kata tēn theōrian, "according to theory")], but also the [Greek: κατὰ τὸ ἐγχείρημα (kata to encheirēma, "according to the operation / undertaking")] — that is, the practical and manual operation — through various examples and experiments proper to each operation, for the sake of the curious reader. And first indeed we shall begin with calcination, and the manner of calcining each individual thing.

Paradigma Experimentale I.

[Experimental Paradigm I]

De Modo calcinandi res.

[On the manner of calcining things]

[Margin: What "calx" means among chemists.]

We said above that calcination is nothing other than the dissolution of coagulated things. Now **calx** [calx], in the chemical signification, is any powder comminuted into the finest and almost impalpable parts by the removal of superfluous moisture; and it is produced either by **corrosion** [corrosio] or by **ignition** [ignitio].

[Margin: How things are calcined by smoke.]

The former resolves coagulated things into calx by means of corroding spirits, either by vapor or by immersion. Things are resolved by smoke or vapor when metallic bodies, reduced to thin sheets, are calcined by an acrid, corroding smoke. And this can be done either when the laminated bodies are suspended over strong waters [aquae fortes], or over vinegar, or over the residue of pressed

grapes (which they call *Vinaccia* [grape-marc]). Sometimes too the nobler metals especially are rendered brittle by the breath of molten lead, or of quicksilver. Through calcination, therefore, all metals become, as it were, charcoal and ash by the power of the windy fire alone — by which all tenacious, soft, and greasy earth turns to stone, and stones indeed are reduced to lime, as may be seen in the potters' kiln for lime and bricks.

EXEMPLUM I.

[Example I]

Quomodo Crocus Martis ex Chalybe per vaporosam corrosionem calcinetur.

[How the Saffron of Mars (crocus Martis) is calcined from steel by vaporous corrosion]

First you will prepare a strong water [aqua fortis] from equal parts of saltpeter [sal petrae] and vitriol [vitriolum] calcined to whiteness, and you will pour it into a glass gourd. Then in the upper part of the gourd you will suspend sheets of steel [chalybs], and — the mouth of the vessel having been sealed with lute [lutum], so that the spirits of the strong water cannot in any way exhale — you will allow it to evaporate in warm sand for the space of 24 hours. Then, the vessel being opened, you will take out the sheets, to which you will find a saffron [crocus] adhering in the form of a most subtle powder, which you will wipe off with a hare's foot or some other instrument. And in this way, always repeating the same operation, you will proceed until no further saffron extracted by the spirits appears on the sheets.

CONSECTARIUM.

[Corollary]

[Margin: How lead is calcined.]

In exactly the same way you will calcine lead into ceruse [cerussa], namely if you suspend it over vinegar within a gourd.

[Margin: How copper [is calcined].]

And copper sheets suspended within the vessel over the residue of pressed grapes are calcined by the corrosion of the vapors.

EXEMPLUM II.

[Example II]

Quomodo immersiva corrosione res calcinentur.

[How things are calcined by immersive corrosion]

This operation is accomplished either by **precipitation** [praecipitatio] or by **amalgamation** [amalgamatio].

[Margin: What precipitation is.]

Now precipitation is when bodies, eaten away by corroding waters and dissolved into water, are beaten back into calx by the withdrawal of the corroding water, or by any other means. In this way silver dissolved in strong water is said to be precipitated by throwing in copper, common salt, or sal ammoniac [sal ammoniacum].

[Margin: Precipitation of silver.]

[Margin: How gold [is calcined].]

So too gold dissolved in aqua regia [aqua regia] is beaten back by adding a small portion of quicksilver; and if a little sulphur be mixed with it, and it be set to the fire in a closed vessel, then — the quicksilver and sulphur having evaporated — a most subtle calx is left at the bottom. And the more the bodies are dissolved, the more, and the more subtly, are they calcined.

[Margin: What amalgamation is.]

Amalgamation, since it is nothing other than the calcination of a metal by means of quicksilver [hydrargyrum], is the means by which you will calcine bodies in this manner: let the metal, drawn out into thin foils or sheets, be mixed with six, nine, or twelve parts of quicksilver, and be united, so that a mass everywhere uniform with itself is made. And in this way you will obtain the metal discontinuous and calcined; for, the quicksilver having been raised by evaporation over a gentle fire, the metal is left in the form of a thin calx.

PARADIGMA I.

[Paradigm I]

Praecipitationis Mercurii per solutionem, seu calcinationem. Ita autem procedunt Artifices.

[Of the precipitation of Mercury by solution, or calcination. The artisans proceed as follows]

They take half an ounce of the best-purified gold, and reduce it into thin little plates, and dissolve it in aqua regia made from common salt and not from sal armeniac [sal armeniacum] (because the latter renders the mercury volatile),

Liber XI — *Chymiotectnicus*, Sectio I

Caput VI — *Canones Methodici & Paradigmatici* (continued)

[Fol. 244 — Paradigma I, continued]

[Margin: Ἐκπάνωσις [Greek: ekpanōsis, "expansion/development" (?) — the term as printed is corrupt; apparently meant as a label for "the operation"], or operation.]

[the solution] made; afterwards they take half an ounce of the best glass of antimony [vitrum antimonii], and dissolve it in the same way in aqua regia. They also dissolve three ounces of quicksilver, well washed and purified, in aqua fortis — so that the three liquids are clear and transparent, with nothing appearing in them that is not dissolved. They combine these solutions and repeatedly separate off the liquids from the precipitate, always drawing off the liquid and pouring on fresh aqua regia, until the mercury, placed on a red-hot iron plate, no longer gives off any smoke. Finally, once the spirits of the aqua regia have been thoroughly driven off, they pour on spirit of wine to the height of three fingers, and distil it six times from the precipitate over a strong fire, until the mercury is fixed and gives off no smoke from itself. You will then calcine it under a vaulted tile [tegula fornicata], properly heated to red according to the art.

[Margin: Calcination is the mortification of metals.]

You see, therefore, that calcination is nothing else to the chemists than the mortification of minerals and metals, as Paracelsus puts it. Gold, for example, is mortified by calcination so that it may be reduced into a tincture, a quintessence,

a resin, a saffron [crocus], a vitriol, and a sulphur. The method and the assaying of each of these you will find in what follows, and especially in the final book.

Paradigma II

How a metallic body may be calcined by corroding and desiccating salts, through cementation.

[Margin: What cementation is.]

Cement, or cementation [cæmentatio], is nothing else than a dry corrosion, by which metallic bodies — stratified with the aid of corrosive liquids — are broken apart and calcined. We give you an example of this in the preparation of crocus Martis, or saffron of steel, by cementation. The procedure of the craftsmen is as follows.

[Margin: The method of cementing.]

The body to be cemented is reduced into thin plates and cut into small pieces with shears. The corroding substances [species corrodentes], for their part, are pulverized and moistened with vinegar, urine, or aqua fortis, so that they form a kind of paste — though some use them dry. Then some portion of this paste, or powder, is put into a cementing box [pyxis cæmentatoria], and a plate is laid over it; over that plate another portion of powder is sprinkled (this is called *stratification*, and "making layer upon layer"); another plate follows this, and so on, until the box is filled, or until no plate remains. [recte continues on Fol. 245-equivalent text — but here the column continues directly; see next.]

and finally it is closed off with powder laid on top, and stopped up, the joints of the box being secured with another tenacious lute [clay sealant]; and it is set upon the fire, or (what is better) in its own furnace, and is cemented by degrees for four, six, eight, twelve, or twenty-four hours — indeed, even for several days, as the case requires, it is kept in there. At last, once the box has cooled, it is taken out, and the plates are separated from the powder; they are found wholly broken apart and calcined.

For example: the intention is to prepare crocus Martis, or saffron of steel, and that by cementation. Then I take as much fresh quicklime [calx viva] as is needed, and moisten it with urine until it becomes like a porridge. Afterwards I coat the bottom of the cementing box with this pulp to the thickness of a broad finger, and add plates of steel on top of it, and fill the vessel as was said, and seal it firmly with lute. Everything duly prepared,

[Margin: Crocus Martis.]

I place the box in our cementing furnace, and apply a continuous fire of the third grade rising to the fourth for twenty-four hours. At last, the vessel being removed, I thoroughly pound the material contained in it in a mortar, and pass it through a sieve, so that it becomes a very fine powder; here I wash away with hot [water] all the lime from the steel, and take the residue — a most excellent crocus Martis. In the same way crocus Veneris [saffron of copper] is also made, which can serve for many operations.

Paradigma III

The method and procedure for calcining antimony by the species of calcination they call commixtion, with the aid of sulphur, saltpetre, and common salt.

I take of stibium [antimony ore], saltpetre, and common salt equal parts — that is, equal amounts — and, ground very fine and mixed together, I place them in a crucible well secured with lute, but in such a way that some small hole is left in the middle of the surface, through which the arsenical and poisonous spirits may exhale. I set it in a wind-furnace [furnus venti] and kindle a melting fire; and if I wish, I also employ the service of the bellows, so that they may flow sufficiently in the crucible.

[Margin: The method of calcining antimony.]

Here, however, one must carefully note how long the smoke ascends through that hole left in the surface: for as long as it is still evaporating, it indicates that the material is not yet sufficiently calcined. But when all such fuming spirits have vanished, I increase the fire nearly to its full strength for a quarter of an hour; and at last I remove the crucible, and once it has cooled I open it and extract the material, where I find the antimony in the bottom separated from the soot, just as the regulus is from the slag. This antimony I knock off from the salts with a hammer, and grind it into a powder, which is as red as cinnabar, and most suitable in medicine for compounding certain very excellent remedies. And as this is the best method of calcining antimony, so it is also the most celebrated — both because it can be carried out within the space of half an hour [continues on Fol. 245]...

[Fol. 245 — running header "DE ORIGINE ALCHYMIÆ."]

and because it retains no salt with itself, but expels it from itself.

It remains now to say how metallic bodies are reduced to a calx [lime/oxide] by the violence of fire, through combustion and reverberation — of which the former occurs by incineration, the latter by vitrification.

Paradigma IV

How metals, by vitrification, may be converted out of combustion into a transparent glass.

[Margin: What incineration is.]

[Margin: What vitrification is.]

Incineration will be treated more fully in connection with vegetable and animal substances; therefore in this place we shall speak only of minerals, which are reduced to a calx alone, and not into ashes. So then, take this experiment of how quicksilver, or hydrargyrum, is vitrified.

[Margin: The procedure.]

They take red oil of vitriol [oleum vitrioli rubeum], made according to the art and rectified; in this they dissolve quicksilver — washed and purified by sublimation, or by salt and vinegar — and they keep it warming continuously in heat for so long, until no mercury at all, neither living nor precipitated, appears any longer, but the whole lies hidden in the oil in liquid form. This done, they pour this oil containing the mercury into a glass retort suited to the quantity of the material, and place it in a sand-bath [catus arenarius]; and with the fire kindled, they drive the oil off from the mercury into an adjoining receiving vessel. And thus the mercury will have been reduced to a calx by precipitation. Of this precipitate I take two ounces, and of lime, silver, and sal ammoniac one ounce each [ana unciam unam]; these, ground and mixed together and placed in a phial, they prepare for sublimation, where the sal ammoniac ascends, and the mercury together with the Moon [Luna = silver] — the weight being likewise preserved — remain in the bottom in the manner of the purest gold. Afterwards, in a strong glass, or in a crucible coated with glass [crucibulum devitreatum], they set it in a wind-furnace to flow; and with the fire increased, it passes into a fixed and transparent glass, which seems to have descended from a golden colour to a paler one.

[Margin: Lunar glass.]

This glass is of infinite virtues, as they suppose — to recount each of which in this place is neither part of our plan nor of fairness; rather, having demonstrated the

manner of making it, we commit it to the skilful investigator of chemical medicine [chymiatría].

Paradigma V

How gold may be vitrified into a transparent substance, according to the mind of Libavius.

[Margin: Gold vitrified.]

Take half an ounce of the purest gold, and eight ounces of Hungarian antimony [Antimonium Ungaricum]: place them in a melting-pot over the fire, so that they melt together; and once it is melted, pour it out — but take care that it does not turn into a regulus. Pound this mixture well and thoroughly, so that it becomes a most subtle powder, which is to be calcined in the same way that they calcine antimony when they wish to make glass, until it no longer fumes. So then, when you have the powder thus fixed, set the melting-pot on the fire so that it glows fully, so that it turns into glass; afterwards little by little pour the powder into the glass in the same manner, so that it flows just so long, until this glass becomes red and transparent — which you can test with some iron rod; and you will find the gold in the bottom of the crucible diminished by half. Pour the glass into a basin, and you will have transparent gold, mixed with glass of antimony in equal weight.

Paradigma VI

How sulphur may be worked into a glass by ignition.

Take a great quantity of common sulphur, and place it in a crucible, or in a [earthen] dish — three *lotones* [a unit; $\sim\frac{1}{2}$ ounce] at a time — under an ignited vaulted tile, so that it burns. When that sulphur is burned, put another three *lotones* in the dish, so that this too is burned; which you will do until one pound has been burned in the dish, and you will see some ash of a grey colour. But of this pound of sulphur you will take no more than two drachms of ashes; of the second [pound], and the rest, you will take a whole *loto*. Burn in the aforesaid manner ten pounds of sulphur, and that ash, which was previously grey, will become red like blood, and in the following manner will pass into a ruddy glass.

[Margin: How to vitrify sulphur.]

Take of this red ash, very well ground, half an ounce, and of borax one drachm, and melt with a most intense fire; and there will be made a certain transparent glass, endowed (as they say) with remarkable virtues.

Paradigma VII

How a tincture of antimony may be extracted by reverberation, according to the mind of the chemists.

[Margin: Reverberation, or ignition.]

To ignition belongs reverberation [reverberatio], by which stibium and other bodies are reduced into a subtle calx by a reverberating and reperiussing fire, through closed or open reverberation.

[Margin: The procedure for preparing a tincture of antimony.]

Equal parts of antimony and sal ammoniac are taken, and placed in a retort, and driven by a strong fire; there all the antimony passes over, and nothing remains in the body of the retort but a turbid dregs. This antimony, thus dissolved through the retort — the sal ammoniac being separated by frequent washing, so that it is left sweet, tainted by no saltiness — I dry and grind most finely, and convert into an alcohol [a fine powder], and place it in our reverberatory [furnace]; and with the fire of the flames kindled, I open just one flue [fumarium] for a while, until our antimony, which was red, is turned into whiteness. When it has become white, I open the second flue, until the increased fire strips off the whiteness from it and adorns it with a yellowness. As yet more yellowness appears [continues on Fol. 246]...

[Fol. 246 — running header "LIBER UNDECIMUS, Sect. I"]

with the third flue opened, I advance it to a citron colour, and with the fourth I bring it to a perfect redness. Onto this red antimony I pour rectified spirit made from wine, and I extract the essence, or tincture, in a closed vessel. When the spirit of wine is no longer tinged with colour, I draw it off from the tincture. This is the true preparation (as they say) of the tincture of antimony, of which Theophrastus [Paracelsus] makes mention.

Paradigma VIII

How, by subtiliation, the more subtle dry parts may be raised together with the adherent [substances] of their vessel, and may be sublimed in a long or a short time.

[Margin: What subtiliation is.]

[Margin: Twofold.]

Subtiliation [subtiliatio] is a dissolution by which the more subtle parts are raised from the gross, the spiritual from the corporeal, the volatile from the fixed, in the manner of smoke, by the force of fire, and are condensed at the top of the head [capitellum] of [the vessel]. Sublimation comprises under itself exaltation, elevation, and fixation, and accomplishes a wonderful change in things; for in it the pure is separated from the impure and fixed, in such a way that it remains unaltered in the fire. For if that which has been sublimed is again ground with its dregs and mixed, and sublimed again as before — which will be done so many times until it no longer sublimes, but all remains together in the bottom and is fixed — from these there is afterwards made a stone and an oil, when and as often as you wish. Namely, if you set the cooled [matter] in the air, or in glass, there it is at once dissolved into an oil; and if this is again committed to the fire, it will once more be hardened into a stone of great virtue.

[Margin: The wonderful power of sal ammoniac.]

We shall in due time tell how, by the working of this, many corrosives are turned into sweet things, and sweet into bitter. It is also a marvel that any metal whatsoever, sublimed by means of sal ammoniac, is turned by cold into an oil, and by fire into a stone — which the alchemists reckon one of the greatest mysteries of Nature, to transmute a metal into a stone. But what this has to do with the [Philosophers'] Stone which generates gold, I do not see, since to transmute that [stone] back into a metal is impossible, because it is essentially distinct from a metal; and therefore it ought to be called only accidental. For it seems a stone, which in reality, of itself and by its own nature, is not a stone. Paracelsus greatly triumphs in this experiment, in support of the truth of the great Art.

[Margin: [Handwritten marginal annotation, partly legible:] [?] in praxi [?] / Petrus [?] / Reg. 1 [?]]

But let us give an example of how flowers of sulphur [flores sulphuris] may be made by this art. Proceed thus:

[Margin: The method of making flowers of sulphur.]

Take some material to be sublimed, and — either alone, or mixed with other materials — enclose it in some glass or earthen vessel, broad or deep below, so that with two parts empty, the third is filled. Onto this vessel, or cucurbit, set a blind alembic [alembicus cæcus] pierced at the top with a small hole, with lute laid over it, so that the spirits or sublimed parts cannot exhale; secure it firmly.

Then place it in a sand-bath, three fingers from the bottom and walls, with sand intervening, or set it in a free fire, and increase the heat by degrees.

[Margin: Another procedure.]

By first placing some smooth iron plate in the glass, you will easily test it. For when any moisture is still left, it adheres to that plate; but when all the moisture has departed, dry spirits ascend, and then close the hole of the alembic, fortified with some glass laid over and with good lute, so that the spirits do not escape; and at last keep up the fire for a while, until all the material to be sublimed has been elevated. Some, in place of the cucurbit, use a little dish [scutella] or some iron shell containing the material, with a glass cone duly fitted to the walls of the lower vessel.

For example: I take of well-purged citrine [yellow] sulphur two pounds, of common salt and of slightly calcined Hungarian vitriol half a pound each, each pulverized and mixed together; I place them in a cucurbit, and with a blind alembic perforated at the apex set on, kindling a fire of the first grade until the moisture has vanished, then with the opening closed proceeding by degrees, until all the finer sulphur ascends. This sulphur — called by the chemists flowers of sulphur — once taken out of the alembic, I rectify, a second or even a third time always adding a fourth part of salt and vitriol replenished by sublimation; and I obtain the most beautiful flowers of sulphur, resistant to very many affections [influences].

Consectarium [Corollary]

In this way you will likewise accomplish the sublimation of sal ammoniac. Take as much common salt as you wish, and fill a pot with it, and cover it, so that no coals or ashes fall into it; place the pot in the ground, and cover it with extinguished coals; then, the coals being kindled to the glowing of the pot, and these in turn reduced to ashes, you will find, in the cooled pot, the salt prepared — which may be called calcined salt.

[Margin: The sublimation of sal ammoniac.]

Then take one pound of ground sal ammoniac, and an equal quantity of added iron filings; sublime the mixture, grind this sublimate again, and sublime it, and when the salt has glowed white, you will have completed the sublimation. Of this sal ammoniac thus prepared take as much as you find, and of calcined salt 12 [parts/ounces — figure as printed]; grind them together, and with it sublimed

seven times, adding the prepared salt each time, and you will have what was sought.

[Margin: Sublimation of moist things, twofold: straight and oblique.]

Sublimation — which is also called moist elevation — is nothing else than the distillation of parts attenuated into vapours, by which the subtle parts are separated from the gross; and it is either straight or oblique. The straight is when the moist, more subtle parts, raised upward and adhering to the vault of the cold alembic, are condensed into a moisture, and through its beak [rostrum] distil drop by drop into its receptacle and fall back. The moist oblique elevation is when, with the vessel lying obliquely, the moisture is raised; and it occurs either through the side or through a retort. Through-the-side elevation is accomplished when, with the vessel inclined obliquely and to the side, the moisture [continues on Fol. 247]...

[Margin: Oblique sublimation, what it is.]

[Fol. 247 — running header "DE ORIGINE ALCHYMIÆ."]

slips forward, as is plain from the apparatus of the schematism [vasis Schematismi]; in which way the best red flowers of antimony are usually prepared. Elevation through a retort is when the moisture is driven from the retort. Each of these two methods has its use in things that are endowed with more tenacious spirits.

For example: if you wish to make by this operation the no-common oil of the Philosophers [oleum Philosophorum], proceed thus:

[Margin: How the oil of the Philosophers is to be prepared.]

Take of the purest wax 15 ounces, of turpentine 18, of benzoin 1, of rectified spirit of wine 30, of common ash 6; mix them, and distil according to the art through a retort, and there will come forth phlegm, water, and oil, which you will separate from one another and keep each apart. The water will be of use against the plague, and the suffusion of the eyes [cataract], for the healing of all wounds, and for obstruction of the urine; against the pricking of the sides, or pleurisy, the oil is wonderfully helpful. But of these things [we shall treat] more fully in their place hereafter; for the vessels, see in the following book, in the section on the distilling Art.

From what has been said you have how moisture is raised by sublimation. It now remains for us also to give examples of the operation by Descent, hot or cold.

Now hot Descent [Descensio calida] is the distillation of a liquor from dissolved bodies, with the vessel inverted. For since certain bodies — such as bones, woods, and the like — whose moisture cannot, on account of its weight, ascend upward, [exist], so by descent we must obtain the effect of sublimation. Consult the vessels in the following book.

Paradigma IX

How distillation by Descent of heavier things is to be accomplished.

Take an earthen cucurbit, and put into it the fragments of the things to be dissolved; and, lest they fall out when the cucurbit is inverted, cover them with some larger fragments, or with little rods laid crosswise next to them. This done, apply another cucurbit, in which there is a little water, to this inverted one, so that the upper exactly meets the lower at the orifice. But between the two it is proper that some iron plate, strong enough, concave like the pan of a balance and perforated, be placed, which may hold back the falling fragments lest they slip down into the vessel set beneath. Finally, dry the closures made fast with the best lute, and set the vessel in its furnace, and place the receiving vessel in sand or in ashes, so that, being safe from the violence of the fire, it may the more easily receive the moisture forced down [into it].

Now how cold distillation by descent — which they call *deliquium* [deliquescence], or filtration — is to be carried out, take [the following]:

[Margin: What *deliquium* is.]

Deliquium is a cold descent, when coagulated bodies, exposed to a cellar, to the air, to a well, or to some other cold and moist place, upon marble, a glass slab, or what they call a *permanica* of Hippocrates [a conical filtering bag/sleeve], by the benefit of external humidity — which is joined to the dissolving bodies — are dissolved into a moisture, and flow down into the vessel placed beneath. They are dissolved especially in the cold: powders that have been calcined, salts, and other bodies of this kind, which savour of the nature of salt, which are dissolved in the cold and again coagulated in the heat.

[Margin: What filtration is.]

Filtration is a cold descent, which lets the watery humours pass down through a filter — a woollen cloth, linen, silk, or absorbent paper rolled up, or folded in the manner of a funnel — leaving the dregs in the filter.

Exaltation, or subtiliation, has besides two other species annexed to it: exaltation, and

[Margin: Digestion.]

digestion [digestio], by which things, dissolved over a short time, gradually degenerate [pass over] into a purer and greater grade of their virtue. But those that require more time are called Circulation and Ablution.

[Margin: Circulation.]

Circulation is the exaltation of vapours revolved around in a circulatory vessel, which — the impurities being cast off, which otherwise could not be separated — establishes [the thing] in a more excellent grade. Take this experiment of it:

Paradigma X

How wine, for example, ought to be sublimed by the benefit of Circulation into a most mobile essence.

Take the thing to be exalted, and put it in a circulatory vessel, and close it Hermetically, and place it in sand, or in a bath; and keep it in there so long, until it has attained its goal. For example: much labour and study is expended in the true extraction of spirit of wine, so that it may be had without any phlegm; for whenever it has been raised, it always draws some phlegm with it. Therefore by the manner of circulation

[Margin: Preparation of the quintessence.]

the most generous wine that can be is taken, and it is poured into a capacious circulatory vessel, and with the orifice sealed it is set in a bath of [boiling] water [balneum maris] for fourteen days, so that the water boils continuously; afterwards it is taken out, and poured into a phial; and warm, it is set in winter into cold snow-water placed beside [it] and agglutinated [sealed] with an alembic and receptacle; but in summer into a cellar, set onto a vessel containing glacial shells [conchae glaciales, i.e. ice]. And the pure spirit, free from all phlegm, will rise above the alembic and slip down into the receptacle. When nothing more ascends, the receptacle is removed, and the phial is taken out with the wine — which contains no true spirit, but only burnt wine [vinum adustum]. This spirit of wine, still set in the circulatory, is rotated so long, until it can no longer [pass] from glass to glass, but must be advanced by distillation, or moist elevation; and when the material on which it must act is set into the receptacle, it readily

embraces it, and abandons its flight. This method, as they say, is to be noted with a white stone [i.e. marked as excellent].

[Margin: The various species of the chemical operations.]

There now follow the remaining species of the chemical operation, which are: Ablution, Imbibition, Cohobation, Digestion, Ceration, Putrefaction, Extraction.

[Margin: Ablution.]

Ablution is an exaltation by frequent infusions.

washing away impure matters and restoring them to purity.

[Margin: Imbibition.]

Imbibition [imbibitio] is a washing in which a liquid added to a body sinks back into the body. It washes by repeated moistenings until, once coagulated together with that first body, it can rise no higher but remains entirely fixed — an operation than which there is nothing more secret in alchemy.

[Margin: Cohobation.]

Cohobation [cohobatio] is the repeated drawing-off of a liquid that has often been poured back onto its body. The verb *cohobare*, "to cohobate," — that is, "to pour off through cohob" — is borrowed from a word of the Arabs and signifies nothing other than "to repeat."

[Margin: Ceration.]

Ceration [ceratio] is the softening of a hard substance, or the preparation of a non-fusible juice for liquefaction. It is called ceration because it makes a chemical medicine, brought to the fire like wax, readily flowing. The alchemists are wholly absorbed in converting quicksilver into gold and silver by ceration; for this medicine, by being joined to the Sun [gold] or the Moon [silver] through the medicine, they wish to be united — so that once the moisture has been consumed by the fire, the thickening and fixation of the work takes place; of which in its proper place.

[Margin: Digestion.]

Digestion [digestio] is a subtiliation in which crude substances are dissolved over a long time by a digestive heat. It has two species: putrefaction and extraction.

[Margin: Putrefaction.]

Putrefaction [putrefactio] is a digestion in which the substance of a thing is dissolved, through the retention of vapors and the access of an external heat, so as to generate a nobler being. Its proper effect is to consume the old nature of things and to introduce a new form, whereby afterward — and for the most part — the fruit of another generation is produced. [Margin: The wonderful power of putrefaction.] For corrosive spirits are sweetened by it and rendered milder; colors are changed in it; the pure is separated from the impure, the impure settling to the bottom. Putrefaction is carried out when the material, placed in a vessel, is set in dung, and the heat of the dung is maintained for a fixed time; or it is also done when the vessel is set in a dew-bath.

[Margin: Extraction.]

Extraction [extractio] is a digestion in which, the bodily concretion being broken up, the subtler and purer parts — seized by some solvent [menstruum] poured over them — are dissolved out, the dregs being left behind. I shall add an example of this.

PARADIGMA XI.

How an Extract of Rhubarb is made.

Take as much rhubarb as you wish, and once it is powdered, pour on enough spirit of wine [spiritus vini] to stand four fingers above it. With the vessel closed, set it in a bath for four days to digest. Then, opening the vessel, separate by decanting the colored spirit from the root, and pouring on fresh spirit, set the closed vessel again to digest. Repeat this until the spirit takes on no further color — for then the whole tincture and essence has been extracted from the rhubarb. Then, all the extractions being combined, draw off the spirit in a water-bath [balneum Maris], and keep the remaining essence in a glass vessel for use; it cannot be evaporated [?] and is of great efficacy in many other afflictions.

PARADIGMA XII.

How the great secret mystery of Vitriol is made — from the secrets of the Roman College [ex secretis Coll. Rom.].

Take twelve pounds of Roman or Hungarian vitriol; dissolve it in ordinary distilled water, then set it in warm ashes so that the water evaporates until it forms a kind of crust. Then place it in a cold spot for two or three days, and the vitriol — once some dregs have been set aside — will turn to little stones. Take this vitriol, which passes into a powder first white, then yellow. Then dissolve it

again in common distilled water, and let it stand in warm ashes for 24 hours, and you will find a great deal of dregs at the bottom of the vessel. Decant what is pure, coagulate it, set it aside in a shell-dish, and again dissolve it — for as long as it takes until it deposits no more dregs and tends toward sweetness. Note well, marking it with a white stone, that its greenness is to be carefully preserved; otherwise the oil and the labor would be lost. Then put this purified vitriol into a phial, which you will close well with a hermetic seal, and set it in a philosophical furnace [furnus Philosophicus], where you will raise the fire by degrees from ten days to ten days, until the vitriol approaches redness, until at last it becomes red like a ruby.

Take out this red vitriol and put it into a glass cucurbit; pour on a good quantity of corrected and pure spirit of wine, and keep it well closed in a gentle warmth for four or five days. Then decant the spirit and pour on fresh, until you have extracted from the vitriol all its power and efficacy. Put these extractions into a cucurbit, and in a water-bath separate the spirit; pour spirit on, separate again to a third time, always removing the dregs. Finally pour distilled rainwater onto the extract, wash it, and set it in ashes for four or five days, so that it may extract as much as it can. Decant what is dissolved, and apply other distilled water, keeping it in warm ashes for the same number of days; repeat this three times. Pour together these extractions, and in a water-bath separate the water. Then take this extract, put it in a medium cucurbit, with an alembic and receiver fitted on and luted, and distill — first with a gentle fire, then with a stronger one — and there will rise the blood of the green lion [sanguis Leonis viridis], red like a ruby, which (as the chemists say) in the dead and dark of night gleams like a carbuncle, and whose odor surpasses all other fragrant things. This marvel, however, I have not yet been permitted to see; and so I take that hyperbole of the chemists on trust.

[Margin: Another method of preparing Vitriol.]

Extraction of vitriol, sweet both to taste and to smell.

Take Roman vitriol calcined to a red color; then over each pound pour two quarts of perfectly rectified water [aqua, i.e. aqua vitae], and set it to digest in a water-bath [balneum maris] for five days; then let your vessel cool. Pour off the spirit [aqua vitae] as clearly and as purely as you can from all the earthy dregs — or, if it seems good to you, filter it — and afterward keep it; it will be better if you keep it in a bath, and this liquor will be of a yellow color. This done, take the dregs that remain and pour them out into a new earthen open dish; but if they have clung too stubbornly to the bottom of the vessel, pour cold water on and stir until you have drawn off all the dregs. Evaporate the water by boiling; calcine the dregs,

and when calcined grind them into a very fine powder; then, as before, pour fresh spirit over them and extract as before, and you will see your spirit tinged with a green color. Therefore do not cease from drying and pouring on until you have all the green color that lies hidden in it; this place in a bath for five days, for a use to be shown shortly.

Now let us return to that yellow, tawny tincture which we earlier left well stopped in the bath. Place it in a cucurbit with an alembic very well luted on, in well-purged ashes, and distill at the same time an oil red like blood [oleum sanguinis], and the spirit [aqua vitae]. Afterward separate the spirit from the oil in a gentle bath, and you will have this oil — as they call it, "blessed" [benedictum] — left at the bottom of the vessel. But if there remain in the cucurbit of the first distillation black or white dregs, keep them as the earth of this Stone. Now let us return to that green water, in which white earth and salt are contained. Evaporate, then, the spirit from it, and whatever remains is earth, from which a most white salt is to be extracted in the following way.

[Margin: Crystalline salt.]

Take this earth and put it in a pot, and calcine it for the space of three days in a reverberatory furnace; afterward take it out of the fire, and with spirit [aqua vitae] extract the crystalline salt; and in this way you have that precious salt, and the oil of vitriol, whose properties I leave to the skilled physician.

[Margin: Another method of preparing Vitriol.]

There follows now the *Assaying Liquefaction* [Liquefactio probatoria], which is done either by cineritium [percineritium, the ash-cupel method] or by antimony. The former is done when a metal is fulminated by lead and assayed — of which take this experiment.

PARADIGMA XIII.

How a Metal is fulminated by lead.

[Margin: Fulmination.]

Take, then, an ash-cupel [catillus cinereus], and set it under a vaulted tile in an assaying furnace. When this has been filled to the top with coals, it is kindled with some live embers at the head of the fire, and the fire is maintained. And so that the cupel may grow white-hot the more quickly (for the metal is not to be put in beforehand), let the mouth-openings and air-holes be open. Then, after an hour or two have passed and it has glowed thoroughly, let there be put in a portion of

lead proportioned to the amount of material to be assayed, and that gradually; once it is melted the metal is put in, and as the case requires, all the openings are closed and the fire is skillfully governed. This regimen must be demonstrated to the eye by an experienced hand, for it varies according to the nature of the material.

[Margin: The metals are burned up by the lead.] [Margin (later hand): Plumbum non abit in fumum, sed incorporatur catillo... absorbe[tur] [?] — "The lead does not go off in smoke, but is incorporated into the cupel... [it is] absorbed."] [Margin (later hand): NB.]

Thus at last it comes about that, together with the lead, the perfect metals are burned away [?] [recte: the imperfect metals — see the parallel statement "metallis perfectis solis in medio catilli," only the perfect metals remaining] and pass off into smoke, and drive the slag [scoria] to the edges, the perfect metals alone being left in the middle of the cupel. But if perhaps it should happen that the lead hardens together with the metal being assayed and cannot be moved to flow by the fire, a little antimony is added on a spoon, and in a moment it will return to its former state. This secret the assaying craftsmen [Artifices docimastici] hold as a great secret. At last, the cupel being lifted out with tongs, the metal, while still hot, is separated off with a knife.

PARADIGMA XIV.

How, by means of Antimony, Gold is separated from Silver and the other metals.

Take gold mixed with other metals, and mix in with it three parts of powdered antimony; and in a crucible put it in a wind-furnace [furnus ventosus] over a stubborn fire. Then, with the help of bellows if you please, when it is thoroughly melted pour it into a warmed and tallow-smeared cone-mold [pyramis]; there, the lips being struck with a hammer, a regulus [regulus] containing the gold will settle at the apex, which strike off with a hammer. The antimony left over, moreover, put again into a melting-pot over the fire even a third time, and proceed in the aforesaid manner, so that all the gold may be driven out of the antimony. At last put these reguli into an earthen cupel near the bellows, and with coals heaped on in the manner of a furnace kindle the fire, and keep playing the flame over them until, all the antimony being evaporated, pure and refined gold settles, which is at once coagulated.

To these we append **coagulation** [coagulatio], by which we reduce liquid and soft substances to a solid mass through the removal of moisture — of which in its proper place. It is accomplished either in cold or in heat. Coagulation is hot when

dissolved substances are coagulated by a suitable heat; it is cold when substances that have been dissolved in heat are coagulated in cold. And under it are contained **fixation** and **fermentation**.

[Margin: Fixation.]

Fixation [fixatio] is the habituation, by fire, of a thing that flees the fire, so that it may remain — whether this be done by sharp agents [acies], or by a slow and long decoction, or by frequent sublimation, or by solution and coagulation often repeated, or finally accomplished by the addition of a fixed substance.

[Margin: Fermentation.]

Fermentation [fermentatio], inasmuch as it requires a more exact exposition, we have judged ought to be described in a chapter of its own.

And these are the things concerning chemical operations which I judged ought to be communicated to the reader — without foreknowledge of which let no one hope to attain a perfect knowledge of chemistry; so that, before the beginner [Tyro] proceeds to what follows, these things are most necessary to be known. Thus whoever has duly grasped these canons will find no difficulty in the terms of chemistry or in the reading of books. Nothing, then, now remains but that we turn our pen to that great mystery of the chemists concerning the Philosophers' Stone, so that the lovers of truth may learn what can — and what cannot — be done in this most intricate business by human ingenuity and the industry of art.

SECTIO II.

DE LAPIDE PHILOSOPHORUM.

[On the Philosophers' Stone.]

CAPUT I.

What the Philosophers' Stone is, what the Elixir or philosophical Tincture is, and whether by its means true and natural gold can be produced by art.

[Margin: The difficulty of this argument.]

Scarcely any argument in natural philosophy [Physiologia] have I found so very curious as this theme of gold-making [Chrysopoeia] — one stirred by so many, so great, and so sharp skirmishings of authors, and torn apart by so great a variety of opinions (by which, with the suit still pending to this very day, they strive to

drag one another, by the entangled rope of objections, now to this side, now to that). For my part, weighing more deeply the reasons of each side, this way and that, I shall openly declare what I think, with all the candor that is due. And while I do this, let the reader persuade himself that my business is not with raw, unlettered pseudo-chemicasters, but with philosophers.

[Margin: Four opinions concerning Chrysopoeia.]

I find four principal opinions concerning the gold-bearing art. The **first** is of those who hold the art of gold-making [Chrysopoeia] to be impossible [Greek: ἀδύνατον (adynaton, "impossible")]. The **second** is of those who separate, by art, gold and silver from lumps of minerals and metals — which we call metallurgy [Metallurgia], and which we treated in the preceding Section in many and various processes; and about this there is no difficulty at all, since gold and silver of this kind deservedly hold a place at the outset in the commerce of human dealings.

[Margin: Sophistical Chrysopoeia.]

The **third** opinion the theologians chiefly maintain, who assert that gold can indeed be produced as though true, which nevertheless may not be sold for true at the same price at which true gold is sold, nor is it lawful to use it in medicines — which we shall hereafter call "Sophistical" [Sophisticum]. It comes about when to gold and silver some other suitable metal is joined, whence by art a third thing results, and is sold under the name of gold; and money-changers [Collybistae] for the most part use it, and they call it *legam* [?].

[Margin: The Chrysopoeia properly so called, which alchemy promises.]

The **fourth** opinion, proper to the alchemists, is of those who assert that chemical gold can be produced not only as true and genuine, but even far nobler, more excellent, and purer than natural — according to that saying of Augurellus [Aurellius]:

When but a thin part of itself is cast upon the waves of the sea — were the sea then quicksilver — the whole, the vast sea entire, could be turned into gold.

So say Isaac Hollandus [Isaac of Holland], Paracelsus, and Villanovanus [Arnald of Villanova] — men who, it can scarcely be said how greatly, have exposed themselves to the mockery and jeers of right-thinking philosophers. That this is a mere fiction I shall most fully establish in what follows; so that not inappropriately — as is plain from the definition — they have called the Stone

"mystical" [mysticum]; since in truth it can be called wholly mystical, both in sense and in meaning. The ancient philosophers understood by a stone of this kind, by the Elixir and the Tincture, something altogether other than what the modern alchemists imagine to themselves.

[Margin: The Philosophers' Stone is mystical and fictitious.]

It is wonderful, too, that this is described by the likeness of almost all things. For they call it Heaven [Coelum], chrysosperma [the gold-seed], the seed of gold, the blessed earth, living water, water of life, dry water, the wood of life, the seal of Solomon, the fire of Nature, the Virgin's Milk [Lac Virginis], the Mercury of the Philosophers, the Dragon, the Eagle, the Raven, Laton [Latten], the Elixir, the medicine of all diseases — of which "whoever drinks does not die" — and the like, partly ridiculous, partly irreligious.

[Margin: The various nomenclature of the Stone.]

All of which — that I may not dwell any longer on so many trifles — see in the fabulous Hermes Trismegistus, in Trevisanus [Bernard of Treviso], Isaac, the fictitious Morienus [Morienus], Lullus [Ramon Llull (pseudo-)], Paracelsus, and the rest of the Arabs in the *Turba Philosophorum*. But so that the disputes of the chemists concerning the Philosophers' Stone, here brought forward, may be more clearly understood, let us speak first of the matter of the truly mysterious Stone, then of the manner of making it — from which, no doubt, the truth of the proposed dissertation shines forth.

[Margin: The labor of Nature in producing things.]

We said in what preceded that Nature generates three principles from the four elements — Salt, Sulphur, and Mercury — and that from these, joined together in due proportion, it generates metals, produces trees, begets animals; and when it has reached its own term, then — as though the final end is now attained — it ceases. For whatever is contained beneath the circle of the Moon is distributed into three kinds, no more and no fewer, divided into the threefold Kingdom of Minerals, Vegetables, and Animals. In these three Nature claims its own dominion for itself, and in them it acts, moves, and works; so that if you seek anything else outside them, you may rather be reckoned to seek it in Utopia than in the realm of Nature. To the pattern of Nature, then, as to a prototype, the alchemists ought to attend, in order to attain their end. For as we said in what preceded, unless they take up a matter common to all metals, they will never rise to the accomplishment of the great work of the Art.

It is asked, then: What is that wonderful matter of the chemists, from which they hunt such great treasures of gold and silver? In determining this matter, it can scarcely be explained how greatly the authors disagree among themselves, both in substance and in name; so that from this very head they sufficiently and more than sufficiently show the uncertainty of the Art. For either one alone attains the truth, or all together; but just as the former is uncertain, so in the latter case the truth, wrapped in so many contradictions, can have no place.

[Margin: The conflict of the alchemists among themselves.]

Villanovanus assails Lullus; Paracelsus attacks both; Libavius [Andreas Libavius] entitles this last "the foulest impostor of all two-footed and four-footed creatures"; while all the rest, rising up against Libavius, call him a sycophant, full of spite, savage in satiric bite, and entitle each and every one of the others fools and ignorant of things. And since they cannot agree about the matter, they rage against one another like dogs, with countless taunts and reproachful names; so that, in place of investigating the truth, you hear nothing but taunts, jeers, calumnies, and the reproaches of an idle and ill-tempered crowd.

No less is the disagreement over the naming of the matter. Some name the slag of iron; some salt, or alum; some Magnesia, Cadmia, Calcanthum [chalcantite, copper-vitriol]. Nor were there lacking those who so firmly persuaded themselves that "blessed Arsenic" [Arsenicum benedictum] is this matter, that they wish it to have been indicated about this by the Sibyl; and let us indeed recite the verses — for thus the Sibyl says:

[Greek verse — Sibylline acrostic riddle:]

Ἐννεα γράμματ' ἔχω· τετρασύλλαβός εἰμι· νόει με· αἱ τρεῖς αἱ πρῶται δύο
γράμματ' ἔχουσιν ἐκάστη· ἡ λοιπὴ δὲ τὰ λοιπά, καὶ εἰσιν ἄφωνα τὰ πέντε·
τοῦ παντὸς δ' ἀριθμοῦ ἑκατοντάδες εἰσὶ δις ὀκτώ, καὶ τρεῖς τρις δεκάδες
σὺν γ' ἑπτὰ· γνούς δὲ τὰ ἐμὰ οὐκ ἀμύητος ἔσῃ θεῖης παρ' ἐμοίγε σοφίης.

[Greek: an acrostic riddle: "I have nine letters; I am four-syllabled; understand me. The first three [syllables] have two letters each; the remaining one has the rest; and five [of the letters] are voiceless [consonants]. Of the whole number there are twice eight hundreds, and three times-three tens together with seven; and once you know my parts, you will not be uninitiated in my divine wisdom."]

Which I interpret thus:

I have nine elements [letters], and I am four-syllabled; Perceive me — the first three syllables are formed Of two elements each, the rest remain In

the remaining [syllable], five of which are non-vowels [consonants]: Of the whole number there are twice eight hundreds, And three times-three tens with seven — if you will have known me, The wisdom that is mine, O Goddess, will not lie hidden from you.

By these verses, Cardanus [Girolamo Cardano], Romonetus [?], and Paracelsus assert that the prime matter of the Stone was indicated, by a kind of divine revelation, through the Sibyl, and that it is none other than Arsenic — the reason being that *Arsenicum* is four-syllabled [in Greek, ἀρσενικόν] and consists of nine letters. But that this is a frivolous conjecture is plain from this: that the Sibyl spoke in this place not of the matter of the Stone, but of the mystical name of GOD — as is plain from the context of the prophecy. Hence, with the meaning of the oracle more deeply unfolded, I find that the Sibyl there, under an allegorical and enigmatic reckoning of numbers — which the Greeks call ἰσοψηφίαν [isopsēphia, the equating of numerical values of letters, gematria] — indicated the name of CHRIST: namely, the name ὁ Ἄνθρωπος Θεός [ho Anthrōpos Theos] — MAN-GOD, or GOD-MAN.

The numerical reckoning [isopsēphia]:

Greek letter	Value
α	1
ρ	100
σ	200
ε	5
ν	50
ι	10
κ	20
ο	70
ψ	50
Total	506

[Margin: The true interpretation of the Sibylline riddle.]

Now let us see whether it is so. First [the Sibyl] says: "There are nine elements [letters]...

nine letters belong to me, and just as many letters are found in ὁ ἄνθρωπος Θεός [the Man-God]. This same name also has four syllables: three syllables are formed

from pairs of elements — AN, ΘΡΩ, ΠΙΟ — and the rest remain in what is left over, that is, ΘΕΟΣ. Now of these, five are non-vowels: namely, in the name ἄνθρωπος [anthrōpos, "man"] as assumed, there are five consonants, ν, θ, ρ, π, ς. And the number that results from this is "twice the hundreds, eight times," that is, 1600, "and thrice three tens," that is, 90, "together with 7" — so that the total number is 1697. If, then, ὁ ἄνθρωπος Θεός be resolved into numbers, you will obtain nearly the same number of which the Sibyl speaks, as appears in the margin: 1674. But ἀρσενικόν, when resolved, contains no more than 506 — a number assigned to the oracle ἀντισόφηφος [counted by equal numerical value]. Who does not see how greatly this differs from the words of the oracle? But these things are said only in passing [παρέργως].

The gematria of ὁ ἄνθρωπος Θεός, letter by letter:

Letter	Value
ο	70
α	1
ν	50
θ	9
ρ	100
ω	800
π	90
ο	70
ς	200
θ	9
ε	5
ο	70
ς	200
Total	1674

There are others who, for the matter of the Stone, take toads, hairs, eggshells, and — so that no kind of filthiness be missing — menstrual discharge, human blood, and the embalming-matter of mummies. [Margin: Various opinions about the matter of the Stone.] Some, finally, hold that the search must be conducted in earth, water, and air, in stables and latrines. And although the wiser sort think that all these things ought to be understood, under a kind of allegory, as referring to the salt found everywhere, many nonetheless — like Bacon [Roger Bacon] —

take them in a real sense, as is clear from his operations. Those who seem to come closer to the truth are the ones who assert that sulfur and quicksilver [hydrargyron] are the proper matter of the Stone. But not even these agree among themselves: some mean mineral sulfur and quicksilver, while others mean what they call the sulfur and quicksilver "of the Philosophers" — and on this point most of the more celebrated Philosophers concur. What the sulfur and Mercury of the Philosophers actually are will become clear a little later.

Those who believe the Stone can be made from common sulfur and Mercury are utterly deluded. For although they try to imitate nature directly, they remain ignorant of nature's hidden motions, processes, and incomprehensible pathways, and so remain in perpetual darkness — just as was said in the preceding chapter about the furnaces of the subterranean workshops. [Margin: Sulfur and Mercury are tamed only with difficulty.]

Finally, those who, on hearing that quicksilver and sulfur are the prime matter of metals, then go and boil them down, rightly waste both their oil and their labor. For the quicksilver and sulfur out of which gold and silver are generated are not, in the mind of the Chemists, the common kind, since those two have already attained their own degrees of perfection. Quicksilver, indeed, if you bring it even to the smallest fire, flees and vanishes into thin air, and the compound is also separated out, so that it can be held back by no barriers or bolts. Sulfur, too, when set to the fire, is turned into one form after another — even though the conjunction of both, carried through to the end of the digestion, is necessary in the generation of metals.

Likewise mistaken are all those who seek that Stone in marcasites, tutty [tutia, zinc oxide], antimony, arsenic, and orpiment [auripigmentum]. For in these the sulfur is wholly inseparable — and unless they resolve and separate it completely, they will accomplish nothing, so that once it has been separated from the said species of minerals, the remainder must necessarily crumble into powder. Those who seek the Stone in vegetable nature must be expelled outright from the school of the Chemists, since each individual species of things is brought to perfection by generation within its own proper grade of nature: man produces man, ox produces ox, a plant produces a plant of its own species. In vain, therefore, do those labor who think the Stone can be made from wine, as Lullus [Ramon Llull] does; and in vain those who would make it from human blood, or urine, or eggshells, like Rogerius Baconus [Roger Bacon]. [Margin: The matter is not found in vegetable nature.] For it is foolish to seek in nature what is not in it: grapes cannot be gathered from thorns, nor figs from thistles. By the whole

breadth of heaven, then, and against the dictates of nature, do certain idle Alchemists err, who seek the Stone outside the bounds of their own purpose, in I-know-not-what incongruous, dissimilar, and heterogeneous things.

The matter out of which the Stone is made must be a mineral of nature. Now, some minerals are lesser, others greater. [Margin: Division of minerals.] The lesser are those that are produced without the addition of quicksilver, such as stones, salts, and purely sulfurous bodies. The greater are those that consist of quicksilver, of which some withstand the hammer — like gold, silver, copper, iron, lead, tin — while others do not, like antimony, magnesia, marcasite, and the various species of pyrites; for although these are imbued with mercury, it is so poorly tempered with the said bodies that it can in no way be fixed, and consequently they cannot be the matter of the Stone. Nor do the lesser minerals contribute anything to the fabrication of the Stone — such as salts, niter, alum, salt of feathers [sal plumae], and so on — first, because their production differs in form, nature, and composition from the generation of quicksilver; and second, because there is one nature and one property of seed for a single species, out of which it is produced. There is the further point that they are found to be plainly contrary, as to their nature, to metallic bodies. [Margin: Salt bodies are not the matter of the Stone.] For salt bodies corrupt, erode, and destroy metals; and according as they are fixed or non-fixed, pure or impure, they reduce them all to nothing; and the subtler they are, the more they render metals alien to their own nature, and burn up their innate moisture, in which the secret of the Stone lies hidden. Hence whoever tries, by aqua fortis and sharp and corrosive waters, to recall metals to their prime matter, rightly rolls the stone of Sisyphus. [Margin: Aqua fortis is not the matter of the Stone.] For these are of a wholly heterogeneous nature from the things out of which the chemists contrive the fabrication of the Stone. Nor do sulfurous bodies do anything to the purpose, since they always taint and corrupt. Since, then, they are contrary to metals, I do not see how they could furnish a medicine wholesome to metals. And yet...

[so far is it from promoting] the perfection of metals that it rather, by its scorching quality and by its own bulk, hinders it to a remarkable degree. The pure innate seed, by contrast, if it has been entrusted to a pure matrix, will there generate, in that same place, a pure metal as well — without nature's long labor, by a certain marvelous magnetism of nature — attaining its own goal while it does that for which the seed had been ordained. [Margin: How the generation of metals occurs.] But if, on the other hand, this seed should fall into impure matrices, contaminated with the various refuse of earthly clods, then, according to the degree of greater or lesser impurity, it will produce a metal — or also a

mineral — now more perfect, now more imperfect, as we have set forth at length in its proper place. If, however, in the genesis an earthly and combustible dross has mixed itself in, then, in proportion to the quantity it has with it, it will beget antimony, marcasite, pyrite, and other non-ductile minerals; and these, because they partake of mercury, can indeed be liquefied, but are not thought to be advanced by nature toward perfection. But if a small amount of sulfurous and blackish dregs has mingled itself in, and the mercury has not been sufficiently concocted, the common quicksilver of the rabble will result. And if the dregs are bad, of bad savor and foul, and also of weaker virtue, they will infect the Mercury and render it brittle, heavy, and muddy — which, since it is not well coagulated, likewise degenerates into lead. But if the sulfur is bad and not well miscible with the Mercury, tin is generated. And if those sulfurous dregs are stony, unclean, and earthy, they will produce iron; and if such sulfur is reddish and burnt, copper will be begotten.

And from all this it is plain — perhaps more fully than is fitting — clearly enough what the Alchemists must do, in order to extract from the things mentioned that intended metallic seed. Yet, although we cannot deny that it is present in those things, the method of drawing it out is all the more uncertain the more the manner of nature — which uses that seed in the generation of metals — is unknown to us; indeed, it is scarcely investigable by human ingenuity. [Margin: The difficulty in making the Stone.] Nor, as yet, has any method been found by the artificers that would satisfy the intended making of the Stone. I am not unaware that such a spermatic sulfur lies most pure in gold and silver alone; but to separate this from the incorruptible and indestructible substance of gold — here is Rhodes, here is the leap. [I.e., "here is the real challenge."]

But what that prime matter is — whether the Mercury of the Philosophers, or the spermatic sulfur, or that metal-generating vapor — is difficult to know through experience, since it is most remote from all the ministry of the senses. The Alchemists say it is a certain third nature, common and altered out of the diverse mixing and digestion of sulfur and quicksilver [hydrargyrum], in which there inheres a mineral power for generating the compound. [Margin: The matter of the Stone according to the Alchemists.] These two act and are acted upon, the one on the other, perpetually, until they are carried over from the form of the imperfect bodies first generated into another form, and at length, through continued digestions and purifications, arrive at that last and perfect...

form, which is the form of gold, in which is the final terminus of motion — where also the agent, that is, the sulfur, is wholly separated from its matter. As even the

Alchemists themselves confess, many indeed seek this, but very few find it; or if they have found it, they are nonetheless ignorant of the preparations — that is, of the proper proportion to be used in making the Stone. And yet all confess that, by art, the medicine is to be drawn out from these alone, in which perfection will dwell potentially through nature — wherein lies the perfection of the pure matter — and in which, accordingly, all metals are found.

From this it is gathered that they suppose that which is uncertain, and which still lies hidden, concealed, in the inaccessible treasury of nature: a subject, I say, still entangled in infinite difficulties and contradictions, perplexed and intricate. [Margin: A circle is committed by the Alchemists in determining the matter.] But, to return to the matter just described: I ask, what is that "common nature"? They answer that it is a matter altered out of the diverse complexion and digestion of Sulfur and Mercury. I ask: is that mixing a mixing of common sulfur and mercury, or of the philosophical sort? If the former, they now plainly contradict themselves, since they hold that this should by no means be taken up into the work of the Stone. If the latter: I ask, what then is that philosophical sulfur and mercury? They say it is the prime origin of metals — and so they plainly commit a circle, defining the known by the unknown. I ask again: how are these separated? They answer: from the form of the imperfect bodies, which are now constituted in their own state, into another form, which is that of gold. I ask, how can it be transmuted into the form of gold, since the form of imperfect bodies is not gold and cannot give what it does not have? Or, if they say this is done by a seed, how is that seed not utterly destroyed through so many digestions and torments of fire? They answer that this form is drawn out of the potency of the matter into another form, that of gold, through the various operations by which the matter is worked. But it must now be examined how, with what zeal, and with what stubbornness of labor, they strive to prepare a matter not yet even known to them, so that at length that marvelous offspring may emerge from it. They proceed as follows.

[Margin: Calcination of things.]

The process used by the Philosophers in making the Stone.

The artificers, therefore — after they have found the prime matter of which we spoke in what precedes (if indeed they have found it) — first judge that it must be calcined and purged of all its impurities, by restoring its heat and conserving its innate moisture. For in chemical calcination, as they say, no diminution of the body should occur, but rather a multiplication. Then, attenuating the thickness of the calcined matter into a certain liquid substance, they reduce it (if it please the

gods) into its prime matter, which they call mineral water — water that does not wet the hands. And then there comes to be one thing in genus, though not in number; whose sun they call the father, the moon the mother, and Mercury the mediator, according to the Tablet of Hermes [the Emerald Tablet]. And the body is altered — not stripped of its own form, but a new form is induced upon it immediately, since nothing in the nature of things is found wholly stripped of form.

In this way they now separate, from the substance thus dissolved, the four elements, and divide them into two parts: into the ascending or spiritual, and the lower or earthly. [Margin: Separation of the four elements.] These two parts are nonetheless of one nature; for the lower is the ferment that fixes it, and the upper is the soul that vivifies the whole. Yet the division of these is necessary, so that they may the more easily, in the end, all be transmuted into one another — the earthy part, by passing into water, growing black; the water then, by passing into air, being whitened; and the air being converted into fire, the cycle [pericyclōsis] being completed.

Once the separation of the elements has been accomplished, they make a conjunction of water and air with earth and fire, so that each of the elements may be dispersed within another, the proportion being preserved. [Margin: Conjunction.] By this ratio they assign to the sea three parts of its water, but to the female nine; and then like applauds its like, and equal rejoices with equal, on account chiefly of the concupiscence of material adherence, and of the sulfurous form.

These things, thus conjoined, they putrefy — but with a moist heat, lest, the fire being kindled, the Mercury be separated, or carried aloft on account of its spiritual nature — so that by this corruption the matter may be altered, the elements be naturally divided, and regeneration may follow. [Margin: Putrefaction.] For nothing is born, or grows — not even an inanimate thing — except once putrefaction has occurred.

After Putrefaction they proceed to coagulation, and, with the same most temperate heat altering the matter of the Stone, they operate both internally and externally, until the matter whitens and takes on the likeness of pearls, and there comes to be the fixing-together of the volatile spirits with the bodies, and a true coagulation. [Margin: Coagulation.] This white thing they call the "spine," and white incombustible sulfur, which never recedes from the fire.

Finally they betake themselves to "feeding" [cibatio] — namely, to the ingrossing of the subtle and the subtilizing of the thick — by mingling their water with ash, and their milk with foliated earth, moderately indeed, so that thus the whiteness and redness, goodness, quantity, and virtue of it may grow and be increased, and so that, by cooking, the matter may be nourished. [Margin: Feeding.]

Then they sublime the matter, with a sublimation not of the common kind — though what sort it is cannot be conceived — and thus they purge it of all impurities by elevating the body and rendering the spiritual thing itself, and the spirit corporeal and fixed, and by diminishing the sulfurous saltiness, so that the whole may be whitened and may be liquefied most quickly. [Margin: Sublimation.]

Once the sublimation is completed, they ferment the matter, joining the spirit with its whitened earth and lime as with its ferment, or incorporating the soul with the body. [Margin: Fermentation.] For they cannot display their permanent virtues — spiritual accidents — unless they are joined with fixed bodies as with a ferment, which reduces what is set before it to its own nature, color, and savor, by this mutual and common impression of body and spirit, without which the work cannot be perfected — just as dough cannot be leavened without leaven.

Moreover, for the greater nobility of the matter, they judge that it must be exalted: by augmenting the spirit, subliming and subtilizing the earth through natural rectification, through the circulation of all the elements, and through their true graduation, until they are brought back to a perfect embrace. [Margin: Circulation.] Then, by repeated solutions and coagulations, they increase their "Salamander" in virtue, and with a new ferment increase it in virtue and quantity — and that to infinity.

Lastly they make the projection upon the imperfect [metals], of one weight upon many, according to the perfection of the medicine. [Margin: Projection.] For the more it is subtilized and made tinging, the more abundantly it operates; and thus, by imitating nature, they perfect the imperfect metals and convert them into Luna [silver] and Sol [gold]. From its own purified matter, refined by art and subtilized, then fixed by decoction and digestion until it comes forth into a white and at last a red color, made volatile again and again fixed, until it has ingress and tinges perfectly — from this they make their medicine and their powder, which they call the Philosophical Stone. [Margin: Calcination of metals.] And this they do by various operations, with diverse things, many vessels, and many furnaces — as the uninstructed in art might perhaps gather from what has been said — whereas for the true philosopher, in this whole great work, there is but a

single operation, a single life, one thing, one vessel, one fire alone, and one furnace alone, as they all confess with one voice.

But, leaving words aside, let us approach the thing itself. For who does not see that, from these words — cast as it were into the air — nothing has yet been specified? Whether, however, we may draw any light from the Alchemists themselves in that great fabrication of the Stone now remains to be seen; for from these things it will appear, clearer than light, what is to be hoped and what despaired of. Let us therefore show, from the Alchemists' own practice [ἐγχείρησις], how the prime matter of metals is to be drawn out and prepared.

Paracelsus prepares the primal matter of metals by this procedure [ἐγχείρησις]. "It must be known," he says, "that the resuscitation of metals is twofold: one which reduces calcined metals, by reduction, back into their first metallic body; the other which reduces metals into their prime matter — that is, into quicksilver. And it is by the latter, indeed, that one proceeds. Calcine metals by means of common Mercury; place this lime, and just as much quicksilver, in a sublimatory vessel, and let them stand for a while, until both coagulate into an amalgam. [Margin: How the prime matter of the Stone is prepared.] Afterward, elevate the mercury from the lime by sublimation; grind the elevated portion again with the metallic lime, and sublime, as before. Do this so often until the metallic lime at last liquefies over a candle, like wax or ice — then it is rightly done. Let this metal be placed in digestion for its due time, and the whole will be changed into living Mercury, that is, into its own prime matter — which is indeed called the Mercury of metals and of the Philosophers, which very many Alchemists have sought, but few have found. Thus is living Mercury now prepared out of all the metals — namely, the mercury of ☉, ☿, ♂, ♀, and so on." The words are clear; but if they are rightly weighed, they do not answer to practice. [Margin: Refutation of the practice. / Refutation of the practice of Paracelsus.]

For, first, he calcines the given metal by means of common Mercury, which all artificers reject as unfit for the work; then he sublimes the lime until it coagulates into an amalgam — which without doubt is nothing other than a compound of lime and mercury. Then he orders this to be ground again, and performs this operation so often until it liquefies over the candle-fire like wax; then he subjects it to digestion or putrefaction for a fixed time — say a philosophical month — that the whole may be converted into Mercury, which he calls "of the Philosophers." But I say that, in this operation, no other mercury is exhibited to us than the one with which he first calcined the metal; and although, by sublimation and putrefaction, it has been very well purged of all the earthy dregs mixed with it, it

does not follow from this that this "philosophical" Mercury is distinguished from indestructible common Mercury, since it differs by nothing but degrees of purity — as may be seen in all sublimes. [Margin: Mercury is indestructible.] And as for his saying that this whole lime is converted into Mercury, that conflicts with natural principles. For since in metallic lime the sulfur has its own part, to say that the sulfurous part of the lime — specifically distinct — is converted into Mercury can neither be said nor ought to be; for no thing in the nature of things can be so purified that it does not leave behind it something of those earthy parts of which it consists. There is the further point that even common Mercury is, of itself and by its own nature, incorruptible and indestructible; for it cannot be so mastered by fire that, when it has vanished into thin air, it does not at once, on meeting cold, revert to its pristine — that is, fluid — nature, with not even the least part consumed, as we have now often proved by experiment. False, therefore, is what Paracelsus promises in this place.

Joannes Azoth prepares and makes ready the prime matter of metals, with a view to the Stone, in another way. [Margin: The pragmatism [πραγματεία] of Joannes Azoth.] "Mercury," he says, "is the prime matter of our work, and afterward becomes the dissolving menstruum of bodies, the virgin's milk, and the nourishment of the black earth, and likewise the azoth of ablution. From our Mercury alone is drawn out every virtue of the art. There is in Mercury whatever...

(...how the wise men seek it.) But how that Mercury is prepared by Joannes Azoth — who copied most of his material from Raymond Lull [Ramon Llull] — take note.

CAPUT II.

Whether any true and real transmutation of one metal into another exists.

This is the chief foundation of those who profess the gold-making art, by which they believe they can demonstrate the art to be true and real. And I would gladly subscribe to their view — if not as to the practice, then at least as to the theory — provided that the hidden paths of Nature, the secret skills Nature employs in her operations as she works in the generation of things, and the precise and absolute proportion of the things to be combined were not unknown to me. But since, by the testimony of Ecclesiasticus, all things are difficult, and no one can explain them in words, there arises that perplexity of mind in those who investigate Nature's hidden recesses [Margin: The hidden recesses of Nature are inscrutable

to the human mind.], that stupor of intellect by which a man, stricken, sees that the further he has advanced into the inmost part of things, the further off he still finds himself from the threshold of truth. As a result, it is to angels and demons alone that the inmost kernel of Nature lies open — the nest of her hidden warmth, the mode, principle, and most absolute proportion by which her passible things are fitted to active ones. Were this marvelous knowledge of things communicated to the human intellect, it could doubtless at last reach that goal which countless philosophers have sought as their one object, with such intense and stubborn study, over the span of many years, longed for through fruitless labor. Truly fortunate, then, and thrice and four times blessed, is the man whom, in his probing of Nature, some blessed error by lucky chance has led to the inner shrine of some great discovery.

Yet despite these difficulties, some defend the certainty of the art with such constancy and such stubbornness that — to win belief from those ignorant of these matters — they appear to claim outright that they can demonstrate the art's infallible truth not, I will say, under any doubt, but even by geometric proof. For my part, just as I will not readily assert that the art ought to be approved, so too I firmly maintain that as to its theory it is only probable, and that for men it is scarcely possible — moved to this above all by the consideration that among so many theorists there is not one who has shown the actual practice of this matter, except perhaps with the devil as his teacher, or by the usual deceptive tricks of imposture; of which more fully in what follows. For that the devil can do many things in the transmutation of natural things out of true knowledge — knowledge that we cannot grasp even with our utmost effort of mind — is established [Margin: The devil's knowledge in natural things.]. For who but the devil could fashion, by human skill, a body of airy substance not unlike a human body, or like any animal whatsoever? Who could, by human skill, disturb the elements, stir up storms, swell the sea? Who could suddenly produce insects and imperfect animals of every kind? Surely no one but an angel or a demon — endowed as they are with a power superior to the human — can accomplish this; who does not see it? And yet, when they perform such great things, they do so not miraculously but by a power and efficacy of Nature hidden from us; among which I judge that the gold-making art too is to be counted, which they know perfectly according to Nature's pattern.

Having set these things out beforehand, let us now examine what that metamorphosis, or transmutation, really is, by which the gold-makers [Chrysopoeoi] boast they can work such great wonders; and from this it will become plain what can and cannot be done.

The metamorphosis, or transmutation, of one metal into another can be considered in two ways: first, in itself, properly and immediately; second, by accident, improperly, and by the mediation of something else [Margin: What transmutation properly is according to the mind of the alchemists.]. Those things are transmuted properly, in themselves, and immediately, in which there is an aptitude and capacity for change, and which possess some common subject capable of receiving the change, and which, finally, in any way receive into themselves the action that effects the alteration. And in this manner it is impossible for the *species* to be changed, but only the individuals of that species. This is the opinion of Roger Bacon [Rogerius Baconis], who means by it nothing other than that the species of things cannot be altered in the abstract, but only in the concrete — that is, the individuals of the species. But a metamorphosis is called improper, or taken by accident and by mediation, when there is in the subject no aptitude for change, nor any common changeable subject, nor any immediate subject of the altering action itself, but all these follow from some [other] subject. In this way species and accidents can be transmuted. For example: silverness [argenteitas], which is the species of silver taken in the abstract, cannot be transmuted into the species of gold, which is goldness [aureitas], nor is it possible for silverness to become goldness; for taken in this sense species cannot be changed, since they are not in themselves subject to sensible increments, nor do they have in themselves a divided or contrary composition that would be the cause of change or the subject of it. But by accident, improperly, and by the mediation — for example — of fire, they are transformed, by the alteration of the particular and divisible things; for as these are corruptible and composite, and exposed (or subjected) to sensible increments, so too, through various purifications, digestions, and sublimations — whose subject is transformed into another — this silver or gold becomes the subject of a different species, which something else has completed.

(...which something else has) completed the purification or digestion. From this definition it is plain that Bachonius [Roger Bacon] understood by such a definition nothing other than a certain metallic transmutation, by which, through various digestions and putrefactions, gold becomes the subject of another species — something no philosopher has hitherto doubted. And experience plainly teaches that in minerals and metallic bodies, whose underlying matter is of one species, just as it naturally proceeds into one mineral after another of differing species, so too it effects various transmutations, as we showed at length earlier in the discussion of the generation of metals, and as is evident from the great variety of species among stones, gems, and other minerals.

Hence I conclude that gold, silver, copper [aes], lead, and so on, though they differ in species, nevertheless — because they have a single underlying matter, which we earlier called the sulphureo-saline-mercurial exhalation [halitus] or vapor — differ from one another indeed in species, but not in matter [Margin: How the transmutation of metals is to be understood in the generation of metals.]. For this kind of exhalation, created together by God out of the elements, is not gold, silver, or lead, but as it were a certain seed, which, poured out within the differing wombs [matrices] of the Earth, produces — according to the difference of the wombs — different minerals and various metals: by solution, I say, by digestion, by circulation, and finally by coagulation. These things we demonstrated by countless examples in the Eighth Book, concerning the marvelous power of the petrifying juice [succus lapidificus] to turn anything whatever into stone. As for the wondrous power of vegetable nature, by which not only is one herb transmuted into another, but also from the rotting juice of herbs and the putrefaction of animals, animals of a different species are produced, we shall discuss this metamorphosis with a great array of experiments in another Book of this work. Who denies the transmutation of nourishment — both of men and of animals — into flesh and blood? What can fire not do? By its agency all things, mineral, vegetable, and animal alike, are turned into ash, and from ash into glass. From all this it is plainly evident that it is not the alchemical *species* but only the *subjects* of the species that can be transformed.

And that these laws of Nature, working by herself, are immutable, no one ought to doubt; so much so that in her operations — depending as they do immediately on the Archetype of the Divine intellect — she cannot err. But whether anyone, by the skill of human art, can reach the summit of a similar transmutation — this is the very question raised here; for this is what gives us our quarrel with the alchemists.

Paracelsus says that transmutation is nothing other than when a thing loses its own form, and is so altered that it is in no way like its former substance and its own form, but takes on another form, another essence, another color, another power, another nature and property [Margin: Transmutation according to the mind of Paracelsus.] — as when a metal becomes glass or stone; when wood becomes charcoal, clay becomes stone and brick, hide becomes glue, linen becomes paper, a horse becomes a god, or a he-goat, grain becomes a man. Yet this transmutation, in the alchemical enterprise, he judged impossible to perform without the Philosophers' Stone, and this Stone impossible to make without the seven grades of alchemy [septem Chymiae gradibus] which we set out earlier.

And so Paracelsus, in order to give a true specimen of the transmutatory art, first teaches the [transmutation] of various metals, one into another (μεταμόρφωσιν [Greek: *metamorphōsin*, "transformation"]), in his book *On the Transmutation of Metals* [Margin: Specimens of transmutation from Paracelsus put forward.]. And he thinks he can demonstrate that metals are not distinguished by species, but only according to greater and lesser purity. We, however, from his own experiments — which he calls transmutation — show, from his own words, that this is not a true transmutation but only an improper and accidental one, as follows. "The transmutation of metals," he says, "is a great secret in Nature, and can be accomplished only with difficulty, by reason of many impediments and adversities; nevertheless it is not contrary to Nature, nor contrary to God's ordinance, as many falsely claim."

But that the lesser and more impure metals, as they call them — Jupiter [tin], Saturn [lead], Mars [iron], and Mercury [quicksilver] — should be transmuted into the greater, purest, and most perfect metals, namely into Sun [gold] and Moon [silver], cannot be done without the tincture and the Philosophers' Stone. As for transmuting the rest among themselves, since that is not difficult, we set it forth.

EXPERIMENT I.

The transmutation of Mars into Venus, that is, of iron into copper.

This transmutation can be done in various ways. First, if filings of iron are boiled in vitriol-water [aqua vitrioli]. Second, if iron plates are cemented with calcined vitriol. Third, if red-hot iron plates are quenched in oil of vitriol [oleum vitrioli]. I add this: if thin iron plates are simply placed in vitriolated water. And these Paracelsus calls true transmutations — which we, as we taught at length earlier, deny; since we assert that this change is nothing other than the flowing-together, toward the iron, of the coppery corpuscles latent in the vitriol, which they naturally seek out [Margin: The magnetism of copper toward iron.]. For since a singular magnetism unites iron and copper — and since vitriol, whether calcined or dissolved into water, [is likewise magnetic] — the result is that, as soon as it has found the iron, it grips it in a most tenacious embrace and by its sharpness dissolves it into a slag [scoria], with which the vitriolated corpuscles, united by the wondrous sympathy they have for them, are mingled; and thus too they are easily concocted into the purest copper. The experiment of this is shown daily to strangers in my Museum. For if the transmutation were true and real, then the vitriolated corpuscles — whether calcined or raw, whether fixed or present in the water (for they are of one and the same nature) — would have to be converted

into the whole iron substance, which is contrary to experience. And so Paracelsus, in this place, [is false in]

[is false in] his own opinion. But let us look at the other transmutations he brings forward. "Iron filings can also," he says, "be reduced and transmuted as it were into lead, so that they become entirely soft, like native lead, but it does not flow easily. It is done in this way..."

EXPERIMENT II.

The transmutation of iron into lead, according to Paracelsus.

"Take iron filings; mix them with an equal amount of the best meltable powder [pulvis liquefactitius]; place them in a crucible; and in a windy furnace let a strong fire be made, so that the iron flows, yet stands as if in cement for a whole hour. Then strengthen the fire vigorously, so that it glows white and flows. Finally, when the crucible has been allowed to cool of itself, you will find in the crucible a button [regulus] of lead, soft and ductile, like native lead."

He calls this a transmutation of iron into lead, in which he contradicts himself [Margin: The transmutation of iron into lead is not true.]. For while he expressly says that iron filings can be reduced and transmuted "as it were into lead" — that is, into a certain likeness of lead — he adds that this does not happen easily, but that they merely soften. I assign a better cause of this matter, and it is this: that since iron consists of burnt sulphur and a slight moisture, so too, when the sulphur is burnt away along with the rest of the dross [loppa] by the efficacy of the fire, its parts are rendered more apt for flowing. This, therefore, is not a transmutation, but a mere purification — just as I have often seen in our Laboratory [Ergasterium] of the Roman College a bright and shining button made from Mars [iron], compounded of iron filings and antimony; which Paracelsus himself craftily conceals, when in place of antimony he uses the ambiguous term "meltable powder," which must be added so that there should emerge from it not a button of lead but of Mars [iron]. And so from these things, once again, Paracelsus's deception in his experiments is plain. But let us now see how he transmutes copper into lead, and whether this can be called a true transmutation.

EXPERIMENT III.

The transmutation of copper [aes], or Venus, into lead, or Saturn.

"First of all," he says, "reduce copper to white with sublimated Mercury and fixed arsenic, white like the Moon. Then, having granulated it, take equal parts of this and of the good reductive powder [pulvis reductitius], and first cement them,

then afterward melt them into a button, and you will have a true button of lead." That this cannot be a true transmutation is plain from this: that Mercury and arsenic, once they have flown off, leave the copper endowed with a white tincture; and, the burnt part of the sulphur having been consumed along with the rest of the slag, [the copper], purged as it were by fire, acquires the appearance of something whiter, softer, and more fluid than the button [Margin: That some things cannot be restored to their pristine state.]. And this can be proved by the appended experiment — how that button, which he calls lead's, can without any difficulty be reduced back to the pristine state of copper, which would not happen if it were a true and real transmutation.

EXPERIMENT IV.

The reduction of lead into copper.

Take plates of lead, or even the button which a little before he had drawn out from copper; stratify it with calcined vitriol or saffron of Mars [crocus Martis], cement it, and finally melt it; and you will see the supposed button of lead reduced into excellent copper [aes], heavy and malleable [Margin: The reduction of lead into copper.]. The cause is that, from the first reduction of copper into supposed lead, [a portion] of the copper had departed; and this is now, by the addition of calcined vitriol and saffron of Mars, restored to the pristine state of copper, that is, of red copper. This I would more justly call an alteration than a transmutation, and it is plain from the following experiment. For if such copper, reduced into thin plates, is stratified with tutty [tutia] or calamine powder — to speak in chemical terms — and finally, after cementation, is melted, you will find it passes into brass [aurichalcum], not unlike the splendor of gold. See what I said above more fully concerning copper [turned] into brass [Margin: in the [margin reference, illegible]]. For in this experiment there is no change of any substance, but the copper is merely tinged from red into a golden color; whereas this, as we have shown elsewhere, can again be reduced from golden back to red.

EXPERIMENT V.

The transmutation of Saturn into Jupiter, that is, of lead into tin.

But how lead can be changed into tin, Paracelsus teaches in these words: "Stratify lead, reduced into thin plates, with sal ammoniac; cement it, and finally melt it, as was said above. In this way the blackness and darkness of the lead's burden is removed, and in a most beautiful whiteness it will be seen to be most like English tin." The reason for this is none other than that the sal ammoniac resolves into smoke the fairly copious Mercury latent in the lead; and once this, together with

the soot of the lead, has been removed, [the lead] must necessarily degenerate into a harder and more splendid substance — namely tin, which for this reason they also call "white lead." Nor can this properly be called a transmutation, since the same Mercury, joined again to the tin by means of the sal ammoniac in place of the one that had flown off, can reduce it back again into black lead — as experience teaches me.

Having set out these transmutations, Paracelsus, to convince us of a real transmutation, adds a secret in a stony substance, the greatest of all secrets. I set down his words: "Likewise, know concerning the magnet, that it can be transmuted to a tenfold power and virtue, namely in this way:" Prick up your ears, doctors of the magnetic art, what a vast secret Paracelsus is about to disclose to you! "Take a magnet, and heat it white-hot in coals, yet in such a way that it grows very hot, but is nevertheless not [made] glowing [ignited]." But how the white-heating [candefactio] of the magnet differs from ignition I for my part cannot grasp [Margin: Paracelsus's ridiculous calculation in the matter of the magnet.]. "Which immediately quench in oil of saffron of Mars,"

"(...the magnet) which is made from the best steel [chalybs], so that it may drink in as much as it can hold. In this way you render the magnet so efficacious that with it you can pull keys out of a wall, and work other like wonders, which no other magnet can ever do." And in another place he asserts: "If you bury a magnet in the salt of the Echeneis, it will be of such great power that from it you can draw iron out of a well." These are Paracelsus's secret sacraments — all the more inept the more false they are. If this solemn Master had known even the first principles of the magnet, he would not have blurted out things so stupid. For who does not know — as I have taught by frequent experiments in my *Magnetic Art* [Margin: Paracelsus's ridiculous notion about strengthening a magnet in the salt of the Remora.] — that a magnet buried in coals is at once stripped of all its attractive virtue; and that nothing is so contrary to the magnet as intense heat — I will not say of fire, but even of the Sun itself, which it cannot endure without harm to itself, as I have found by frequent experiment? And who would believe that for this most impudent boaster a magnet buried in the salt of the Echeneis — which they call the Remora — acquires such virtue that it draws up a fallen iron from a well; or how can he say with truth that he himself performed an experiment of this matter? — when concerning the Echeneis, or Remora, whether it ever existed in the nature of things is most hotly disputed among the writers of natural history. And from where he got so many remoras, that he could extract salt from them, who can guess? You see, then, Reader, this man's headlong wit in asserting things, and his utterly intolerable audacity. It is therefore plain that

Paracelsus was of such a temperament that, if he heard anything new and wonderful in the nature of things, whether true or false, he straightway turned it to his own follies, lest he should seem not to know any of Nature's inmost mysteries — or rather fables. He had heard, and perhaps read, of the Remora as endowed with such great attractive virtue that a little fish of a hand's breadth could stop even cargo ships; whence he at once took it up for strengthening the magnet, without inquiring whether it truly exists in Nature, and whether it possesses the same species of attractive virtue as the magnet. But these kinds of imposture will be more fully laid open in what follows. Now [back] to the Rhombus, as the saying goes.

His disciples followed this man, driven by some I-know-not-what *δοξομανία* [Greek: *doxomania*, "madness for opinion / vainglory"] [Margin: The vanity of the Paracelsists.]. For since most of them were borne most greedily into a literal transmutation of metals, and yet could in no way fulfill their hope and greed, nor make good their grandiose promises by which they boasted that they had attained the goal of the great art — certain of them, with more than Thrasonical boldness, while indulging too freely in tricks and deceptions, paid the deserved penalties for their rashness, with the utmost mark of madness. Others, more cautious, lest they be branded with the crime of false arts [pseudotechnia], put on a deceptive cloak to cover their ignorance, and followed Lull [Lull] and his disciples — Ulstadius, Rupescissa [John of Rupescissa], and the other Masters of Paracelsus — with a biting pen, plucking at them with unworthy reproaches; nor did they ever cease to do so. The "Heaven of Lull" [Coelum Lullianum] and the quintessence they mocked and despised as a ludicrous thing, of no moment in the matter of transmutation; and yet, although they had copied everything from it, they nevertheless wove — under another sense, lest they be convicted of the crime of plagiarism — a new, but treacherous, web of gold-making, drawn from the parabolic, magical, and philosophical Hermes [Hermes Trismegistus], from the Turba Philosophorum, and from the rosary of Villanovanus [Arnald of Villanova]; which web, however — lest they be charged with ignorance — they thought fit to cloak with allegorical reasonings drawn from Ovid's *Metamorphoses*, Aesop's *Fables*, the Colchian Ram [Aries Colchicus, the Golden Fleece], the Song of Solomon, and other [works] that seemed in any way to suit their purpose. At last they reached such a pitch of impiety [Margin: The impiety of the alchemists in applying the sacred Scriptures to the signification of the Stone.] that they were not ashamed to accommodate to the Stone — with a truly impious daring — the supreme benefits of Christ our Savior: his Incarnation, Nativity, Passion, Death, and Resurrection, and the other parts of heavenly doctrine, and the hidden sacraments of the Gospel [Margin: Ridiculous.].

Some, again — followers of Paracelsus — having heard the word "Medicine" as the corrector of imperfect metals, transferred it not only to the medical faculty, but also defiled the art of pharmacy [pharmaceutice] with similar transmutations; not considering that this metabolic medicine of metals is idle and superfluous, if by one general [process] all things were converted into Sun [gold]. Hence again, certain ones, driven athwart, while they know not the method of transmuting perfect metals into gold, turned to certain apparent transmutations [commutationes] of imperfect metals into imperfect — that is, the transformations of Mars into Venus, of Saturn into Jupiter, of antimony [stibium] into lead — and, as if laboring at perfect metallic works, with the insane labor of Sisyphus rather than of philosophers, and without fruit, not without the laughter of the wise, they rolled and rolled them back again.

Quercetanus [Joseph Duchesne], a follower of Paracelsus, when he recognized the innumerable entanglements that occur in transmutation, lest he should waste both his effort and his oil [oleum] on useless work, became a deserter from Alchemy to medical Chemistry [Margin: Quercetanus, abandoning Alchemy, deserts to Chemistry.], and gives the reason for his decision in these words: "For what then, afterward, if you could make gold from quicksilver and from the mercurial parts of metal, and by that art procure misery for yourself, while in the meantime human health — which is more precious than gold and gems — is neglected?" Rightly indeed — if only he had added that he too did not know it. Therefore, having abandoned the camp of Paracelsus, and following Lull, he resolved to turn over for himself another stone, which, in a book he published *On the True Medicine of the Ancient Philosophers* — its matter, its mode of preparation, and its power in healing diseases — he set forth as extracted from the essence of wine. And this, he says, is the true stone intended by the ancient philosophers; and he proves it from that fictitious epiphonema [tag] of Morienus [Morienus Romanus]: "Our Stone is the water extracted and separated from our body, which is called prime matter [Margin: What the prime matter of the vegetable Philosophers' Stone is.]; for the gold of the philosophers," says Quercetanus, "or the stone, is nothing other than a medicine tempered by some art, which, as a form separated from its own body, has been reduced to such subtlety that, into any object whatever, ...prepared after the pattern of a heavenly form, by which Nature works upon its own material. But I ask: what affinity or proportion can a *vegetable* Stone possibly have with a mineral or metallic one? I can find no way at all to make sense of it. Whether one could draw an herb or a plant out of a beast, or a metal out of a plant — that is, draw it out by the very road that runs counter to Nature — let him look to that himself.

[Margin: Quercetanus extracts the Philosophers' Stone from the quintessence of gold (Llull's doctrine).] Others, who are ashamed of such inconstancy and confusion of speech, make excuses for Llull, Quercetanus, and the rest of Llull's followers when they make the Stone out of the fifth essence of gold: namely, that everything Llull set forth about his "vegetable heaven" is to be taken in a purely metaphorical sense. But anyone who reads Llull's book entitled *Caelum Philosophorum* [The Philosophers' Heaven] will see from the very procedure of the *Magisterium*, clearer than the noonday sun, that Llull there displayed nothing other than a certain Panacea, wonderfully suited to the cure of every infirmity of the human body. Hence, having thrown out the transmutation of metals as a lost cause, he devoted himself solely to this vegetable Stone, so important for preserving and even prolonging health.

But those who reach for the inestimable treasures of golden Nature beyond all measure — these men, rejecting both the vegetable and the animal Stone as incongruous and heterogeneous, threw themselves into making the *mineral* one alone, with tireless but utterly fruitless labor. And so that they alone might seem to possess the vast secrets of Nature, they wrapped the procedure of the art in such monstrous tangles of opinion that you could neither grasp them by understanding, much less imitate them in writing, much less even dream of rivaling them. And lest I seem to do them an injustice, I have decided to bring the whole procedure of the transmutatory art here to the anvil — so that the reader may see, most plainly, from the very χύτευσις [Greek: chyteusis, "smelting/pouring" — the casting-process] and from their manner of proceeding, that what is entangled in so many knots of contradiction, cloaked in so many absurd wrappings of comparison, and confused by the mismatch of so many things forced together, simply cannot hold up.

Caput III.

On the manner and method of making the Stone and Tincture of the Philosophers.

I will not speak here of the false chemists [pseudochymiaestae], but of the first-rank Alchemists' procedure in the construction of the Stone — so that from their manner and method it may become clear what is to be hoped of the rest. Among these the chief place, after the Arabs — the fictitious Hermes [Hermes Trismegistus], Geber, Rasis [al-Rāzī], Khālid, Hamuel, and countless others — is held by Llull, Villanovanus [Arnald of Villanova], the spurious author "Iohannes Azoth" [John of Azoth], Rupecissa [John of Rupecissa], Trevisanus [Bernard of

Treviso], Bernardus, Isaac Hollandus, Paracelsus, and all who, divided into various sects, cultivated this art.

The Arabs set out the working of the Stone and the Tincture in this way, on the authority of Geber, whom they followed:

Let there be taken *the stone known in the chapters* — that is, quicksilver, or the Mercury of the philosophers, which they call زئبق Zertbach [Arabic *zaybaq*, quicksilver] — after its preparation; but before preparation, the very stones from which it is drawn. Upon it the work of sublimation of the first degree is to stand continuously, with insistence of the work, until it is cleansed of the corrupting impurity and becomes most pure, and at last volatile. *How this is done by sublimation will be shown in the following procedure.* Thirdly, let it be fixed by the modes of fixing, until it rests under the harshness of the fire: here stands the goal of the second degree — that is, you now have the elixir fixed in the first degree. Fourthly, let the stone be treated also in the third degree, which consists in the final completion of the preparation, so that you make the now-fixed stone volatile by the modes of sublimation, and the volatile fixed. This you dissolve, make to fly again, and coagulate anew, until it flows — yet without smoke — and enters in, and tinges, and alters into the solar [gold-making] completion, and into the lunar [silver-making]; or until, by its projection, it makes complete gold and silver. This requires manifold repetition of the same labor. Here lies hidden an incomparable treasure, a most precious secret, above every secret of the sciences of this world.

So far Geber.

And because all this might seem to be said gratuitously, without further explanation, I will here append the procedure of Raymond Llull and of John of Azoth — who copied his from Llull almost word for word. Since it conforms to the Arabs' description, no one should doubt that Llull too took it from the Arabs.

The procedure of Raymond Llull and John of Azoth for the completion of the Great Stone and Tincture.

The crowd of Alchemists divides on this procedure into two sects. Some, for making the Stone, require the purest mineral gold; others think the business can be carried through without any addition of gold. And where the first sow the true and genuine seed in their philosophical earth, these instead sow tares — yet supposing all the while that they can arrive at the desired fruit of gold, than

which nothing could be more foolish. But now to the procedure of Llull and Azoth.

Pragmatia I.

The Sublimation of Mercury.

First, in his *Clavicula*, Llull teaches certain compounds of waters, necessary for carrying out the work toward the Philosophical Stone and Tincture. And first, indeed...

he teaches the sublimation of quicksilver, to which he directs that one pound of Roman vitriol and ten ounces of common salt be joined. But because the operation is rather tedious — too much for the reader to bear — I have decided to leave it out. So Mercury, brought by this operation to the highest purity, is to be set aside. Secondly, he teaches the preparation of the water which he calls "the water of life," in this manner:

Pragmatia II.

The preparation of the water of life, which is in fact nothing but aqua fortis [nitric acid].

[Margin: Llull's procedure for confecting the Stone.]

[Margin: 1. The preparation of aqua fortis.] **Procedure:** Take two pounds of Roman vitriol, as much calcined alum, and one pound of niter [halinitrum, saltpeter]; grind them, put them in a cucurbit, fit an alembic-head on top, and distill off aqua fortis according to the art — first over a slow fire with the joints well sealed, then a stronger one, and finally the strongest, until the alembic glows red. Then stop; you will have done your best if you obtain three or four pounds of this water.

[Margin: 2. The making of aqua regia.] Afterward, to have aqua regia [royal water], proceed thus: in one pound of the aqua fortis already prepared, dissolve a third of a pound [triens] of sal ammoniac, and it will pass from green color to citrine; and it will be able to dissolve gold and to dye the skin yellow — which by analogy they call the juice of celandine [chelidonia].

[Margin: The virtues of this water.] It also dissolves cinnabar, sulphur, and sublimated quicksilver. Keep this in a well-stopped glass, in a warm place.

This done, he teaches the preparation of the Mercurial Water in the following way.

Pragmatia III.

The preparation of the Mercurial Water.

[Margin: 3. The preparation of the Mercurial Water.] Take one pound of the aqua regia prepared just above, and six ounces of the Mercury sublimated above — pure, dense, clear, and heavy. Commit these to a strong cucurbit; into it cast the Mercury little by little, then stop up the mouth so that the force of the sal ammoniac does not escape, and set it in ashes of moderate warmth. Thus the water will dissolve the Mercury; and if after the dissolution anything remains, let it be dissolved by pouring fresh aqua regia over it, and so proceed until the whole is dissolved. Add the later dissolutions to the first, with a gentle motion so that it does not effervesce; and with the glass closed, they reserve the water for its use.

[Margin: All these things are reduced into the first matter in the Mercurial water.] The sign of this water's perfection is this: if a little copper plate cast in is tinged with a silver color. And this is the water by which they suppose all metallic bodies are reduced into Mercury, or the first matter. Now, how this water can be brought to the highest purity, he teaches in the following way.

Pragmatia IV.

The purifying of the Mercurial Water, which is then called the Mercury of the Philosophers, and which reduces metallic bodies into the first matter.

[Margin: The Mercurial water is poured in.] Pour the Mercurial Water just described into a cucurbit with a long, narrow neck. Set it in well-rotted horse dung for the space of fourteen days, in a vessel exactly closed; and there, in the putrefaction — the dregs being separated from the watery body and settling to the bottom of the glass — a yellow and citrine water will be left. Then transfer the glass out of the dung to a furnace of ashes, and through the alembic, according to the art, distill the water with a gentle fire; and there will come forth a most clear, heavy water, which in this operation they call the Virgin's Milk, the sharpest vinegar, and the perennial water. [Margin: The Virgin's Milk; the sharpest vinegar; the perennial water — what it is.] Continue the fire until you have drawn out the whole clear liquor; this done, with the fire lessened, let the furnace cool, and reserve the water. The sign of perfection is this: if a drop poured over a brass plate made glowing-hot at once penetrates it, leaving a white trace behind. And this water, brought to the highest purity and stripped of all corrosive qualities, reduces metallic bodies into the first matter — whence it is also called the Mercury of the Philosophers. Now, how by its agency metallic bodies can be reduced into the first matter, he teaches in the following practice.

Pragmatia V.

How metallic bodies are dissolved into Mercury, or the first matter.

If you intend to dissolve silver into Mercury for yourself, work thus. Silver purely refined [fulminatum] and repurged, reduce into filed dust [scobs], or into very thin leaves drawn out by the goldbeater's tool into the form of paper. Grind this with the prepared salt on marble until an exact powder is made; wash it with hot water free of all saltiness, dry it, and when dried place it in a basin. Steep it in oil of tartar and dry it again, repeating the same again and again. At last, when it is dried out, grind it into a calx; the ground material put into a cucurbit or phial. Pour on the Mercurial Water we prepared a little before, to the height of two fingers; and this done, set it over a gentle fire among ashes, and the Mercurial water will turn the calx into Mercury. [Margin: The Mercurial water reduces into the first matter; that is, it reduces the Mercury.] If the whole is not converted, pour off the first water with its Mercury, pour on fresh, and proceed likewise; pour off the water carefully into another glass, but put the Mercury back into a pan or glass cup. To make it clean, wash it with salt water; then, the moisture dried off, squeeze it through a cloth or a leather pouch. If nothing remains, well and good; but if anything undissolved remains, the repetition must be undertaken, until, when squeezed through the whetstone-cloth [pannus cotenaeus], nothing remains. The first signs of the perfection of this Mercury are: a greater slowness in its course than that of common quicksilver; and second, if, placed upon a glowing plate, it exhales and leaves behind it a mark of fixity. If you wish to augment this Mercury, take four ounces of the Mercury prepared a little before — or as many as you like — add half as much filings of purest silver, and let an amalgam be made. Mix this with the best purified quicksilver...

in twelve parts; put it into a glass which you will close well, place it in a fire of mild ash, and keep it there for a month, so that the resolution into Mercury takes place. Then it will be said that the wholly volatile overcomes the wholly fixed; and this same one he makes volatile, and you can repeat this operation at will, for any augmentation. Llull and Azoth say this is the whole and only secret of the Philosophers.

[Margin: Operations toward the great Magisterium.] But the same procedure holds good if instead of silver you take gold.

And up to this point everything is said rightly and skillfully, inasmuch as it does not contradict experience. It remains, then, for us now to teach how — and whether — by means of this we can attain that which has been so greatly desired for so many ages now, that is, that Stone or Tincture; and by what road and

method the Physical Tincture can be confected by the Alchemists, with the help of the apparatus set out above.

[Margin: What is the Tincture, or Elixir?] They say, then, that the white and red tincture, which they call the Elixir, made from the Mercury of the Philosophers alone and projected upon Mercury and upon all imperfect metallic bodies, can be transmuted into bodies true, perfect, and better than the natural ones — from the Mercury of the wise alone, I say, which is not the Mercury of the common crowd, but is the first matter of metals, from which all Alchemical virtue is said to be drawn. To this they hold that no foreign thing is to be added, except gold and silver, as certain co-adjutors in the fermentation of the Stone, through which the true chemical work is perfected. For as Nicolaus Barnaudus says, the material of chrysopoeia [gold-making] is the finest gold drawn from the ore — not wrought, nor mixed, but of the best mark.

[Margin: Gold of Ophir and Havilah — best for the Alchemists.] "Gold," he says, "of obrizum [refined gold] — such as is found in Genesis, chapter 3 [recte: chapter 2], in Havilah by the river Pishon of Paradise, or as occurs in Ophir." But just as the location and situation of both regions is disputed by interpreters to a wondrous degree, so too it is ridiculous for the chemists to banish us, for the sake of the Stone, to unknown gold-mines of this sort. Indeed, I am astonished that this author did not pack us off as well to the Rhipaeen mountains, to the Hyperborean griffins, guardians of the most excellent gold — so that at last we might obtain gold suitable for the chemical business. But let us leave these trifles of the Alchemists. Others choose gold ἄπυρον [Greek: apyron, "unfired" — not having undergone fire] for their purpose. Whatever may be the case with gold and silver of better mark, you will make nothing at all — to which we ourselves wholly and utterly subscribe — although this was not the intention of the ancient Philosophers.

But now let us see and examine the operations by which they assert that the Tincture of the Stone is perfected through sublimation — by which, as by a single one, the other seven grades of the operations are contained, namely distillation, ascension, descension, coagulation, putrefaction, calcination, and fixation. They proceed thus:

Operation I, which is called the corporeal preparation of Mercury. Place the Mercury of the Philosophers, prepared above, in a phial; close the mouth Hermetically, so that it cannot escape. Set it to be suffocated in its little bed, well laid out with a temperate heat, for the Philosophers' month, under a gentle warmth, until of itself it sweats, and no longer ascends or descends, but rests and

is coagulated into a black earth — which is called the raven's head [caput corvi], and is called earth, black dregs, the brass [aes] of the Philosophers, black sulphur, the man and the male: one thing under diverse names. [Margin: The raven's head — what it is to the Alchemists.] And so from this first operation, by coagulation, what was liquid becomes thick; from cold-moist, as they say, hot-dry, by separation of the elements.

Operation II, by which the black earth is whitened, proceeds thus. Take two parts of the raven's head, or black earth; add to them one part of the Physical water reserved — that is, of the Mercurial water prepared above — so that the dry earth drinks in the water until it has consumed it all, and the water itself wholly passes into the body of the black earth. [Margin: The whitening of the raven's head.] As soon as it has been mixed, close the glass and place it in an ash cupel; apply a temperate heat, and let it be dried, as on a soft bedding, by continuous warmth for eight days. For then it will begin gradually to whiten; take it out of the glass, and again give it the virgin's milk to drink. After it has drunk, put it back into a sound little trough or phial, and into a bed of temperate warmth, so that it may be dried out again, as before; and this through four turns. By this operation, then, you have reduced the black earth, or Raven's head, sufficiently purged of all foulness, to the intended whiteness. Keep this carefully, for you have what — as they say — you can desire: the white foliated earth, the white sulphur, the white magnesia, by which they suppose the conjunction of gold and silver to be made, and the revivification of dead bodies. By this imbibition any fruit emerges a hundredfold, so that toward the goal nothing else remains but the fermentation, by which the foetus is said to be in some manner animated. [Margin: Fermentation.] According to that saying in the *Turba Philosophorum*: "Sow your gold in the white foliated earth, and it will bear you a hundredfold fruit" — whose virtue they say is so great that it is multiplied to infinity; and that this is that desired white Elixir, tinging Mercury and every imperfect metallic body into Luna, that is, into truest Silver. Yet they add that the ferment cannot enter the dead body except by the mediation of the mercurial water, which, like a bridesmaid [paranympha], completes the marriage.

Here, reader, you have the entire pragmatic procedure for the confection of the Stone and Tincture, freed from all the obscurity of parabolic expressions as to the letter, as far as could be done, most clearly set out, evolved, and unrolled — so that henceforth no Alchemist can complain either that the terms were less than rightly understood, or that much was deliberately omitted to keep the art hidden. But if they do assert this, I say: no chrysopoeial artificer is ever to be believed, but

rather [we should hold that] for the sake of winning some reputation for themselves through knowledge of the great Art...

they have put forward anything whatever for anything whatever, with the highest and most intolerable imposture. By such modes of speaking it can scarcely be told how greatly they prejudice the possibility of the Art. Since, therefore, the words are clear and the practice methodically set out can easily be reduced to practice by everyone, it now remains for us to weigh the individual points on the physical balance, and to show whether the intended secret of chrysopoeia of this kind can be obtained. For I would not have the reader persuade himself that I am so credulous as to revere and adore, like a sacrament of the Gospel, whatever wonders the Alchemists prattle of — especially since most of them possess no knowledge of hidden physical things, nor are skilled in the art of combining things, by which alone truth is sorted from falsehood, the legitimate from the illegitimate, the discordant from the consonant. Nor let them think me so unskilled that I could not pass a fair judgment on the Chemical Art. Since this is so, let us now begin the web we have started.

If anyone should go more deeply into the working of the Stone [Greek: ἐγχείρησις, *encheirēsis*, "undertaking/operation"] put forward by John of Azoth — who took the whole of it from Lull — and compare it with other authors of the same flour [i.e. of the same stamp], he will first find that there is great diversity in the manner of operating. In some points they indeed agree, but in others, and indeed in more, they differ so much that the business has split into two divisions.

[Margin: Paracelsus asserts the Stone can be made without gold.] The Paracelsists contend not only that the Stone can be made without taking up mineral gold or silver, but they imagine that they can attain the intended end of the work by the Mercury of the philosophers alone — while they draw out the spirit of Mercury extracted by the help of wine, which they say nests now in the vein of cinnabar, or the fossil vein of minium [red lead], now in the liquor of sublimate. But how, without gold and silver, a red or white elixir could tinge anything whatever into gold — in which it never was — who will believe? Unless perhaps the cinnabar, minium, or antimony (which he puts in place of the liquor of sublimate) happened to contain, or had taken up, some gold. But on this footing it will indeed make a red or white elixir, yet from it will never draw out the multiplicative virtue of the tincture — only just so much gold as was mixed in the cinnabar, minium, or antimony from a vein of gold. From which the imposture of Paracelsus plainly appears, who promised from the pure ore of Mercury that which by Nature is not in it. And this even one of the not-least Alchemists among

the rest, Basilus Valentinus, knowingly teaches (*De rebus naturalibus*); and Llull subscribes to him in these words: "Our Mercury must be made from gold and silver by the mercurial water, joined with a proportional quantity of quicksilver." But how cinnabar, or fossil minium (in which generally only mercury nests), could be so prepared that from it a gold-making stone should result — who will believe? How will it give what it does not have? They say, perhaps, "from the seed of gold [χρυσοῦ, chrysou] existing in its inmost center." But who, I ask, has sought out the seed of gold in cinnabar, unless it has accrued there from nature? Surely no one...

[Margin: Another procedure toward the Stone.] ...unless he is ignorant of the principles of Nature, and consequently an impostor. But of this dyed-over metamorphosis, more in what follows.

I come to those who do take up obrizum gold, and silver of a nobler mark, for the work of the Stone; but these too disagree among themselves in their method. Some believe that gold, from which the mercurial seed is extracted, can be reduced into its pristine nature: so Nicolaus Barnaudus, in the confection of his Stone. But let us see his manner of operating.

"Take," he says, "two ounces of obrizum gold, and ten times as much Mercury elaborated with great art-skill; mix them, and dissolve over a languid fire, until the mercury escapes and the weight of the imposed gold remains, reduced into a black powder — which, however, once melted, can be converted back into the pristine nature of gold. From this powder he draws out, by the help of a dew-bath [balneum roris], the mercury, until the powder turns into a snow-white calx. This being purified by a sevenfold washing, there will at last come forth from it Azoth, a living spirit, whose earth is the ferment, the water [aquamas], the calx the seed — by whose embrace is born the infant, that is, the stone. This purified calx, or the sun [Sun] of the philosophers, in a stopped vessel let putrefy, and set aside to digest for 40 days, until it liquefies into a white and thick humor; to which, at fixed intervals of days, you will pour on the aged mercurial water, and leave it, until it recovers its strength and joins together again — and this as many times as needed, until it has imbibed all its water. Then the womb [uterus] is closed, so that nothing escapes, and the desired stone is born. If you place it upon mercury in an open sealed egg [ovum sigillatum], then put it to two drachms; give a strong fire; afterward you may add borax, and you

will have one drachm of gold. And if you know the multiplication, you will not need the stone."

So far Barnaudus. In this Pragmatia I find many mystical words, but no usefulness, no profit from so great a promise. This one thing I gather from the text: that after so many months of labors, after so many vigils and sweats and expenses laid out, the man who had set down two ounces of obrizum gold as his first material body found — besides the loss of the quicksilver he put in — nothing but one drachm of gold; and that not, as he himself supposes, from a transmutation of Mercury into gold, but that very gold which he had put down in the first place, even if diminished by a twelfth [1/12] of a grain. And at this indeed no one should wonder, since through so many torments of fire and water it was partly consumed into the excrementitious parts mixed in with the gold, partly into smoke, and partly at last by the corrosion of the waters. Yet, so as not to seem to have done nothing, he exhorts the reader to the multiplication of the material — which, however, after the deliberate custom of the Alchemists, lest so great a secret should lie open, he kept silent.

[Margin: Invective against the Alchemists.] O wretched Philosophers! If you promise us no other riches than those gotten at such expense, at such mastery of labor — certainly so far is it from making us richer than Croesus, that rather, soon reduced to our last counters [ad incitas redactos], we find ourselves cheated by words, deeds, and smoke, and poorer than Irus and than Codrus. Whatever, therefore, they may do...

they may act, this certainly does not deserve the name of a *philosophical* solution. Rather — as Libavius rightly shows — it ought to be called the work of metallurgists and goldsmiths (who, however, achieve the intended result with greater dispatch, greater ease, and indeed greater profit).

Besides these, there is no lack of men who do take in gold of better quality for the perfecting of the work — gold being the substance from which they are accustomed to extract the Mercury of the Philosophers, the prime matter of the art — but they hold that it must be so prepared that it can in no way be restored again to its original nature. So Morienus [Morienus], in the *Turba Philosophorum* [*Turba Philosophorum*]: "In our magistry, whether you take gold, or silver, or hydrargyrum, or Mercury, all things are so altered that they can by no means be brought back. For our gold, after dissolution, is so altered that it can be liquefied by no other substance than our mercurial water. Hence it is no longer essentially gold, but modified — and this gold, thus *mortified* or *modified*, is nothing other than what the artificers symbolically call black earth, black stone, dead body, the

raven's head. After it has been quickened by the mercurial water and by heat, then the Laton [Laton], or the Ethiopian — that is, the raven's head or black earth — is whitened. Therefore let the son of doctrine be forewarned not to burn that black powder too much, but to leave it so disposed that it can become watery again, which was its ancient nature, namely fluid and liquid." Thus the *Turba Philosophorum*.

[Margin: A contradiction of the *Turba* concerning the tincture of the stone.]

If you weigh these words carefully, you will find in them a vast knot of contradiction. For that gold, dissolved by the mercurial water into earth or black powder, either will be gold or it will not be gold. Now the *Turba* says expressly that it is not true gold. But if it is not true gold, how can it be exalted, through the mercurial water, into the tincture of true gold? — since it is impossible for gold that is not true to produce true gold, unless we are merely playing with words. There you have the first contradiction.

[Margin: A second contradiction.]

A second shines forth in the quicksilver taken up into the magistery, as the text shows: for although it cannot be brought back to its original form, the *Turba* nevertheless says plainly, at the end, that the black powder becomes watery again through the Mercury — which was its ancient nature. And so, according to the *Turba*, Mercury can be *drawn out into* but not *brought back to* its first nature — which involves a manifest contradiction, than which nothing is more absurd in true philosophy.

But they will say that, through the seed of gold imparted to the mercurial water, it is raised up again into new gold far nobler than the mercurial. But I now ask: what exactly is this seed? They will say it is the seed of gold, extracted and dissolved into prime matter through the Mercury. I press further: how do you prove that this seed has not been destroyed by so many dissolutions, calcinations, and all the other torments of both fire and corrosive waters? For if you cook and re-cook the seed of any plant whatever, and then commit the cooked and re-cooked thing to the earth to sprout again, I say it is so far from any new shoot being raised up from it, that rather, the form having been destroyed by such frequent decoction, the vegetable power of the seed must perish along with it. For, as the Philosopher [Aristotle] rightly says, there is no return from the privation of a form to its possession; you will get from it only as much as if you had committed a stone to the earth to flower again.

But they will say that it is one thing with the seeds of plants and another with the seed of metallic bodies — because in the mercurial water extracted from mineral gold there lies hidden the seed of gold, which, together with the water poured over the black earth, the raven's head, the black powder (for so they call the mineral gold, taken up and utterly destroyed and mortified by calcinations), revives the dead body and, by a white or red tincture, converts it into Moon or Sun [silver or gold] according to the proportion of silver and gold.

Against this I argue as follows. That seed either is multiplicative of its own species, or it is not. If you say the former, you are then necessarily compelled to enroll it among the number of vegetables, and so you will exalt it to the second grade of nature, and consequently you will attribute life to mineral and metallic bodies — than which nothing is more absurd in physics. But if you say it is vegetable only by analogy, you will be saying the same thing as that a painted man can beget a true man — which it would be ridiculous, not to say stupid, to assert. And if you say that by a certain modification it is true seed of gold, as the *Turba* puts it, you will fall into a still greater error, since a modification, or mode, being a pure and simple accident, adds nothing of substance, by the common judgment of the philosophers.

Since, then, no reason remains by which the *Turba* could prove that it can transmute the not-true gold (that is, the raven's head) into true gold through the mercurial water, nothing else remains to be said but this: that the tiny scrap of gold which is left after the whole magistry of so much labor and expense has been carried out, did not come from any seed of gold residing in the mercurial water — a seed which, from its very first origin, has through so many alterations acquired a heterogeneous form, utterly different from true gold — but rather has duly emerged, by proper depuration, from the mineral gold originally taken up, indestructible in its nature, though with earthy dregs that had accrued to it. But these matters we shall pursue more fully in what follows, so that it may become plainly evident how shamefully the alchemists sin against the first principles of philosophy.

CAPUT IV.

The Magistry of the Great Art is examined as it has been perfected, from Lull, the *Azoth*, and the rest.

[*Perfectum Artis Magnae Magisterium à Lullo, Azotho, caeterisque examinatur.*]

And now let us return to the *operation* [Greek: ἐγχείρησιν (encheirēsīn, "operation," "manual undertaking")], by which the mystery of the Stone is completed. When this is duly examined according to the philosophical standard, we find that — apart from parabolic expressions — it establishes nothing certain toward the making of the Stone amid such a variety and disagreement of methods, over which the authors quarrel among themselves. The *Azoth* corrects Llull [Ramon Llull], Libavius corrects the *Azoth*, Paracelsus corrects them all — so that scarcely anyone (as has partly been shown up to now, and will partly be confirmed in what follows) seems to agree with another.

Llull, then, in his *Clavicula* [*Clavicula*] (which the spurious author Iohannes [the "Iohannes" of the] *Azoth* set forth) — after the sublimation of the hydrargyrum, after the preparation of the *aqua vitae*, the *aqua fortis*, the *aqua regia*, the mercurial water, after the purgation of the same and the dissolution of bodies into Mercury, after labors as it were inexhaustible — at last proceeds to the final completion of the great Stone, which consists in fermentation, in this manner:

Continuation of the process, concerning the universal fermentation of the Azoth and the completion of the Stone.

"If you wish to ferment the white earth to the white Elixir, so that, on completion, the tincture may stand upon the diminished bodies and upon the mercury in every assay: Take of the whitened earth, or *foliated earth* [*terra foliata*] — that is, of the parts of the dead body — three parts, and of the reserved *aqua vitae* two parts, and one part and a half of ferment. Let the white ferment be prepared into a white, fixed, subtle calx, if you intend to prepare the white work. But if the red, then let it be the calx of the most citron-yellow gold, and let there be no other ferment, because the ferment of silver is silver, and of gold, gold — since in these bodies are inherent the tinging rays of the rest of the bodies, in pure redness or in pure whiteness; and in these, according to the nature of the most pure substance of substances, a thing is found that pertains to the specimen of the stone. Make each species with its own species, and each genus with its own genus: with white it is to be whitened, with red reddened; do not mix the work of one stone with the work of another, otherwise you will err.

"The white foliated earth is the *body*; the ferment is the *soul*, which gives the body life by means of the water, which is the *spirit*. Compound, therefore, these three parts into one, matrimonially, by grinding upon a clean stone, and by producing one chaos through its least particles, so that they become one confused *hyle* [Greek: ὕλη (hylē, "matter")], and are at last reduced into one inseparable body.

Afterward place it in its proper vial — that is, a warm, tempered *thorus* [bridal-bed] — so that it may be coagulated and fixed, and may become one white body.

"This done, take out again the white blessed stone, and grind it finely upon the clean stone, and again imbibe it with a third part of its own water, so that it may drink up the draught. Place it in its proper vessel, clear and clean, and set it in its tempered warm bed, so that it may begin again to sweat, and allow the draught of imbibed water to dry up within its bowels. Thus repeat many times over, until through these degrees of reiteration you have prepared a most excellent white stone, fixed and standing fast in the fire, and most swiftly passing through all the bodies of the imperfect metals and sustaining the combats over the fire of molten water: a Stone that tinges the mercury and all imperfect things into true silver, better than any natural silver.

"(Note that, when the order of this completion is reiterated — by dissolving, coagulating, grinding, and roasting — the goodness of this medicine is multiplied so much the more, and it tinges the more, so that, if in its first washing one part tinges 100, in the second 1000, in the third 10000, in the fourth 100000, in the fifth 1000000, in the sixth infinite thousands. One grinding and one imbibition do not suffice.)" Thus the *Azoth*.

But lest I should seem to have approached so great a mystery, so to speak, with unwashed hands, or lest I should incur the charge of speaking like the ignorant who have not understood the terms, I shall first set out the terms of this operation according to the mind of the alchemists, and then I shall disclose what may be established about the matter itself.

[Margin: What the foliated earth is.]

1. The white foliated earth is nothing other than the raven's head already whitened, from which is made that Sun-making and Moon-making Elixir [the Elixir that makes Sun and Moon, i.e. gold and silver].
2. "To stand on completion of the tincture" is, by the projection of perfect silver, to confer perseveringly and in a moment its color and nature upon the quicksilver and the imperfect metals — which are also called *diminished*.

[Margin: What the white earth is.]

3. The white earth is called the *dead body*, with respect to the animation that soon follows; what this animation is will be explained later.

[Margin: What the body, soul, and spirit are.]

4. In the composition, *Body, Soul, Spirit* are mentioned. They call the foliated earth the body, the ferment the soul (which gives life to the body by means of the water, which is the spirit). These three, however, are called by various differing names, as may be seen in Isaac Hollandus [Isaac Hollandus], *On the Fabric of the Stone* — so that consequently what is wrapped up in so many tangles cannot hold together. If the art be true, surely there must necessarily be one road to it, one operation, one method — unless one wishes to go utterly astray. But how much industry is required to animate the foliated earth with the mercurial water can scarcely be told, since it can scarcely be settled how much mercurial water is needed. For if you take a great quantity of it, you will scarcely, or scarcely even, coagulate the earth...

If a small quantity, dryness will forestall the legitimate limit of moisture, so that you can in no way attain a proper coagulation. Therefore, just as the perfection of the work consists in a certain individual point, so too it cannot be attained, because of the weakness of our intellect.

[Margin: What the reserved water is.]

5. The reserved water is taken as the *spirit*, by which the marriage is consummated; and it is divided into two parts for imbibing and coagulating, and again into two parts for the coupling of the marriage.

[Margin: What the ferment is.]

6. The ferment in this practice is nothing other than purest native silver from the ore, reduced to a calx by means of the Mercury. This, they say, is of such virtue that — just as a little wheaten leaven raises the whole wheaten mass into swelling and penetrates it intimately — so too this philosophical ferment is so exalted that, like a most perfect seed-bed, it acquires the power of generating many things like itself according to species, inasmuch as it turns the whole into true and formal gold. Indeed so much so that, even in the tiniest little portions, it is as the whole, and can thence be increased to infinity; and so that what they grant to spiritual substances — that they are whole in the whole and whole in any part — this the alchemists wrongly and ignorantly attribute to their tincture.

[Margin: What the matrimonial union is.]

7. The matrimonial coupling is the *first birth of the stone*; the rest were only preparations. Of this they very truly say that, if it be unknown, the whole art is unknown; for they speak so confusedly and divergently about this matrimonial conjunction with the foliated earth that not even they themselves know what they are saying.

[Margin: What the Oil of Mercury is.]

8. The Oil of Mercury is nothing other than the Mercury of the Philosophers.

[Margin: What the Chaos, the *hyle*, the prime matter are.]

9. The Chaos is a mixture, or paste, in which all things are so incorporated together that none of the things of which it consists appears; whence it is also called by others *hyle*, or prime matter, in which all things have the character of a passive potency, and out of which, nevertheless, by the external heat of the spirits and the internal heat, the thing is brought into the actuality of the desired form.

[Margin: What the Sun and Moon are.]

10. By the *Sun* he understands the sulphurous power, by the *Moon* the mercurial — whence the union. And this is the sum of the perfection of the stone, set forth by Llull, Arnold [Arnold of Villanova], and the spurious author Iohannes of the *Azoth*, who copied it almost word for word from Llull. All the subsequent authors of the Great Art, the gold-workers, have looked to it as the archetype of the art, both for its method and for the clarity of words with which it describes the secret; and we too have deliberately selected it for more easily discussing the process of the art, the rest being intentionally passed over.

[Margin: The process of Cornelius Drebbel.]

Among others there was Cornelius Drebbel [Cornelius Drebbel], who held that the whole art described by Llull could be understood under a recondite physiology that consists in the admirable transmutation of the elements among themselves and in the effects resulting from this — the doctrine of the *Azoth* handed down above.

[Margin: Melchior of Sibiu (?).]

Third among the alchemists comes Melchior Cibinensis [Melchior of Sibiu (Hermannstadt)], who exhibited the art to Ladislaus, king of Hungary and Bohemia, not in a philosophical manner nor in the way customary among the

wise, but — seized by a kind of insane derangement of mind — did not blush to defile the sacred and adorable mysteries of the Liturgy with his coals and black smoke, no less irreverently than impiously, in parables and allegories drawn from the *Song of Songs* [*Canticum Canticorum*]. Let him who wishes read the sum of the art in the *Theatrum Chymicum* [*Theatrum Chymicum*], and he will marvel — not without laughter mixed with indignation — by what means it could enter into a man's mind to wish so basely to mock the world, so boldly and without shame, with mysteries that are not mysteries but crimes, with a knowledge that is not knowledge but imposture.

[Margin: George Ripley.]

Following him was George Ripley the Englishman [George Ripley], who, apart from what we have already said about the traditions of the *Azoth*, has nothing peculiar or different — except words concealed with marvelous artifice. And although he promises everything with more-than-Thrasonical bombast of reasoning, he nevertheless brings forward nothing but the utmost obscurity joined to equal confusion, so that he seems not even to have understood himself, what he had said.

[Margin: Sendivogius the Pole.]

To these is added Sendivogius the Pole [Michael Sendivogius], who, when he had stirred up the world with unheard-of promises in twelve little treatises on the Philosophers' Stone — and had, by a specimen of his art exhibited before the Duke of Württemberg, together with the impostor Mühlenfels [Mühlenfels], drawn the prince into a rather sinister suspicion of an imposture practiced by them both — the one (Mühlenfels) was indeed stripped of his garments, shut up in a tower, and at last, convicted of his crime, paid the penalties worthy of his malice and wickedness; but Sendivogius, having slipped almost naked out of prison, never afterward appeared — so that from this too it may be plain what you may hope for from such men.

[Margin: Paracelsus.]

After these, Paracelsus [Paracelsus] at last presents himself, who, aspiring to the primacy of the alchemical art, while he joins Astronomy to Magical and Cabalistic things and Physics to Theological ones, brought forth not so much new doctrines as monstrosities of opinions. For whatever he handed down in his *Archidoxa* and his books *On the Nature of Things* concerning the mysteries of the Great Art, was culled partly from Llull, partly from Isaac Hollandus, with the name of each suppressed, and he made it his own and his own invention — in which, however,

you will find nothing differing from them and nothing alien as to substance, apart from a farrago of foreign and monstrous names.

[Margin: Llull.]

Llull, then, was the first who — being not unskilled in the Arabic language — rendered into Latin the books of the Arabs on alchemy, vindicated from all obscurity, as became clear to me when I compared the two doctrines; and indeed, in the book which...

he calls the *Clavicula*, bequeathed to posterity, he set forth the art according to its genuine sense — though Arnold of Villanova [Arnold of Villanova], as will be seen later, contradicted him in everything. Following these chiefs of alchemy, countless others — who, all the more greedily clinging to gold and riches, hoped to secure the fruits of those wondrous effects which they expected from the benefit of the "blessed" (or rather *cursed*) stone — thus prostituted all their effort, study, all their resources, and indeed life itself, basely and without any fruit. Hence there was found scarcely anyone — I will not say a philosopher, but even a craftsman from the lowest commons — who did not set his mind to an art of such moment. The philosophers and physicians, that they might boast of knowing something above the rest, also published the art in print; and the princes, together with the common people — allured, whether by greed or by curiosity, by so many and such great promises, especially concerning the Chrysopoeia [Greek: χρυσοποιΐα (*chrysopoïia*, "gold-making")], of so great a rarity — neglected the affairs of the commonwealth and shut themselves up, together with the charcoal-burners' ash-heaps, within hidden workshops which they call *Laboratories*, to gather the fruits of the art and to practice it.

But what in the end? With the treasury exhausted and the people indignant, they brought back nothing worthwhile but smoke, charcoal, and ashes. For who could ever affirm that any prince either gained anything by the practice of this fraudulent work toward attesting the truth of the art, or thereby became richer? Indeed, of many — whose reputation I deliberately spare — it is established that by the fatal pursuits of these scoundrels they were so, I will not say *driven mad*, but rather *so blinded*, that they reduced a household otherwise wealthy to utter ruin. But lest I should seem to do the alchemists an injury, let us now proceed to the weight of the arguments by which — God granting it — we shall plainly demonstrate that alchemy, and the processes adduced a little earlier, are not only vain and idle, but also unworthy to be admitted or held in admiration by princes.

CAPUT V.

In which it is taught that the processes of the Great Art adduced a little earlier cannot stand.

[*Quo Alchymicos Magnae Artis processus paulò ante adductos subsistere non posse docetur.*]

Although the vast variety of contradictions (by which the alchemists are continually tossed, as it were by a kind of ebb and flow, in the construction of the great Stone) could be a most sufficient argument of falsehood — nevertheless, lest they snarl at me that the truth under that contradiction is understood only by the sons of the art and lies concealed, but, hidden beneath it, lies far removed from the capacity of the *philosophasters* (as the inscription of the Hermetic School teaches: "Far hence, far hence, be the profane"), and that it *seems* a contradiction but is not — yet these arguments, since they put forward I know not what *irrationality* [Greek: ἀλογότητος (alogotētos, "irrationality," "absurdity")], and are more like a brutish than a human philosophy, I likewise leave to be resolved by fools, to whom alone nothing is easier than to be persuaded that white is black, heavy light, gold not gold.

The alchemists say that the gold which constitutes the stone is not gold; that the Mercury in the great art is not Mercury; and yet they take up gold and mercury for the great work, and say that the gold, like the mercury, has first passed into another, better form. I ask: if it passes into a better form, that form will be distinguished from mineral gold either specifically (to speak as the Schools do) or only by accidents. If the former, only a madman would assert that gold to be distinct in species — since in any genus of things whatever the species is single and incommunicable to another. For, as the Philosopher [Aristotle] rightly says in *Metaphysics* VIII [l. 7, met.]: "The species of things behave like numbers." Most alchemists, when they say that chemical gold is not true gold, consequently assert that it is distinguished in species. Others, who taste of something loftier, contend that it is indeed gold, but far nobler and more excellent than mineral gold and gold begotten by nature — inasmuch as it is living and multiplicative.

[Margin: Objections, and the solutions of the objections.]

I ask: whence did so great an excellence come to that gold? They answer: from the depuration and the vivifying seed of natural gold. Again I ask: by what means could that seed be extracted, without a subject remaining in which it might subsist? They answer that the subject and the seed are the mercury abstracted

from the gold. Against this: either that mercury is mineral, or it is not. If the former, it must now be seen how it did not vanish, impatient of heat, through so many torments of fires and corrosive waters. If the latter, then it will be mercury and not mercury — and consequently, from a non-mercury, without a matrix, gold will be produced far nobler than the natural. But since these are contradictory, they do not deserve to be refuted. These, then, are all pure chimeras and the stupid phantasms of a deluded imagination and a raving mind. For if what is produced from that imaginary mercury is not true gold, how will true gold come from it — since to make a true thing from a non-true is *impossible* [Greek: ἀδύνατον (adynaton, "impossible")]? Or if it differs in species from mineral gold, what else can we conclude but that, from such gold, it produces a gold distinct in species from the natural — different in essence, property, and powers, utterly different — than which I do not see what could or should be called more absurd and stupid in natural philosophy. But since they were ashamed of this madness, some, as though from a certain tripod of Apollo...

they shroud this mystery beneath so many fables, beneath so many monstrous names of barbarous coinage, that to the unlearned crowd they may pass for Hermes revived, but to true philosophers they look like nothing more than "gilded"—not to say "long-eared"—asses. And so it remains, unless they would rather be thought stupid in every branch of sound philosophy, for them to admit frankly that chemical gold cannot be produced in any way without mineral gold—as indeed we have shown abundantly and more than abundantly above, from the words of Lull [Ramon Llull], the *Azoth*, and Arnold [Arnold of Villanova]. And just as this is perfectly true, so too the whole of that chemical gold which they boil out with so much labor is one and the same as what they took up at the start to set the work going—even if, after purification and refining through so many distillations, sublimations, and calcinations, it is found somewhat diminished and, consequently, of a finer grade.

Now as for their claim that mercury must first be reduced to the prime matter of the metals, here again they say nothing. Either that prime matter is visible and accessible to the senses, or it is not. If the former, how can they observe it in their operations, since prime matter—or even secondary matter—is imperceptible? If the latter, then it is no longer prime matter but a compound, made up of its own prime matter and form. It remains to say something—so that the truth may come to light—about the "seed of gold," restorative and infinitely multiplicative through the tincture, just as their process promises.

[Margin: The prime matter of the alchemists cannot stand.]

These wrongheaded fire-workers boast that not only gold but—by the benefit of their marvelous Stone—a tincture can be made, whether white or red, of such power and such fecundity that the fermented Stone is able to change 100 parts of imperfect metals into perfect metal. And if you imbibe this a second time—that is, dissolve and coagulate it—it becomes so fecund that one part can do a hundred times more, that is, a thousand parts. If a third time, ten thousand; if a fourth, a hundred thousand it will tinge. In this way they say the Stone tinges by a thousandfold proportion, on and on without end—so much so that one of them, with foolish boastfulness, was not afraid to say that if the Ocean were mercury, the Stone would turn it into gold, and would thus steep even the swelling waves of the sea with gold. These are the most idiotic boasts of the pseudo-philosophers, all the more intolerable in that, with their utterly shameless lies, they impose upon the world more grandly and—without any shame, indeed quite insolently. For if the often-repeated imbibition of the Stone is brought to the calculating scale, it follows necessarily from their promises that at the twelfth imbibition of the Stone, twelve millions of millions of gold-units would result—a number so excessive that it can scarcely be conceived in the mind. Indeed, the whole globe of the Earth could be coated over with the chemical gold resulting from a projection of this sort. And then what vessels, furnaces, materials, or what place will the stupid alchemists find in which to ply their art? For the entire mass of the Earth would not suffice—unless perhaps they cook it in the devil's own workshop, which I would gladly leave to them. But, lest I be convicted of misrepresenting them, I append the table.

[Margin: The foolish promise of the alchemists.]

TABULA

Lapidis multiplicativa Auri. [The multiplicative power of the Stone over gold.]

Projectio	I	1000
Projectio	II	10000
Projectio	III	100000
Projectio	IV	1000000
Projectio	V	10000000
Projectio	VI	100000000
Projectio	VII	1000000000

Projectio	VIII	10000000000
Projectio	IX	100000000000
Projectio	X	1000000000000
Projectio	XI	10000000000000
Projectio	XII	100000000000000

Centum milliones millionum tingunt. [A hundred millions of millions they tinge.]

I have thought it worth setting this table down here so that even children, simple women, and the dregs of the lowest crowd may see through the foolish promises and contrivances of the alchemists—their humbug, rather—and laugh at them. *Happy the men for whom these riches are born in their cooking-pots!* [Felices homines, quibus hæ nascuntur in ollis, Divitiæ.]

For since that multiplicative tincture of gold, discovered by Midas's wand [ex Midæ virgula], is—besides being fabulous, as we shall afterward prove by experiment itself—who, I ask, will persuade a philosopher of sound mind that this mercurial seed of the Philosophers' Stone (what it even is, they do not know; and among all alchemists it is still in dispute)—who, I say, will suppose it to have a power of such fecundity that it can multiply gold without end? Hence I argue thus. Either this seed is endowed with a vegetative soul, or it is not. If you say the former, you will be forced to assign to all inanimate things—such as mineral and metallic bodies—the second grade of Nature, namely the vital grade, and so to assert that all things have life formally within themselves. And since this runs counter to every principle of natural philosophy, it does not deserve refutation. But if you say it is not vegetable, then how, deprived of vital motion, will it propagate itself into such fecundity? If things endowed with life cannot do this, who will say it can be granted to things destitute of life? If these wretched smoke-sellers [fumivenduli] knew the secret process of Nature in producing metals, they would not dare to blurt out such shameful nonsense. And so as not to be forced to repeat it over and over, I refer the reader back to the first chapter of this work.

I should like to know just what it is that has given the Stone so great a power of tinging. They say it is the highest and most perfect purification of mercury, far removed from every earthy dross. But even if someone reduced wine cohobated seven times to the highest subtlety, it would follow equally that a single droplet of that elixir of life would transmute a whole cask of water into the noblest wine—which is repugnant both to reason and to experience; nor could anyone over-

—whatever the alchemists may babble about the heavenly, supernatural power and efficacy of their Elixir, which does not exist in the nature of things. O stupid race of men! while they strive, by a rash daring, to attribute to their Stone the power of accomplishing—and of actually effecting—what, with the unanimous zeal of all philosophers, has now for two thousand years and more been sought after and disputed as something infinite; the question, I mean, that has been stirred for so long by the loftiest phoenixes of human genius, and that to this very day, the case still pending, remains undecided—they boast that they can accomplish it merely by the imagined perfection of the Stone alone! Do these subverters of Nature not know that no substance in the nature of things can be so refined to infinity by the power of fire that it does not at last, with all its spirits vanishing away, dwindle off into pure air or evaporate?—especially in the subtilizing of mercurial water. And if you have shut this water up in Hermetic vessels of whatever firmness and solidity you please, or under any sealing of lute, I still say it cannot be brought about that the most fugitive spirit, by its usual cunning, does not slip out through the very pores and exhale away. Isaac Hollandus [Isaac Hollandus], a celebrated alchemist, does not blush to confess this very thing in his little book *On the Stone of the Philosophers*:

[Margin: The alchemists alone admit an infinite power of the Stone.]

If the tincture, he says, reaches the fourth degree of exaltation, it arrives at so great a subtlety that it can no longer be held in by any barriers; indeed, glass of any thickness whatever—even ten fingers thick and of adamantine hardness—cannot contain it. If, then, when subtilized to the fourth degree it cannot be contained, what will you say of a tincture exalted to the tenth, hundredth, thousandth degree? And do these men not know that the more gold is purified, the more portions fall away from it?—since there is nothing in the nature of things that can be so purged by sublimation that there does not always remain something still to be purged, until at last it is reduced almost to nothing, as experience teaches in cohobations repeated very frequently by distillation; unless, that is, the alchemists were aiming to reduce their material to the simplest body—which, just as it cannot be done, so they are deservedly convicted of utter ignorance of natural things.

[Margin: The more subtle the spirits into which things are sublimated, the less they leave behind of quantity.]

[Margin: No mixed body can be so purified that something impure does not still remain in it.]

[Margin: No vessel is capable of holding the most subtle spirit.]

And so, from these things so clearly shown, it plainly appears that this Stone, infinitely multiplicative of gold, is a pure and outright figment of a flighty imagination. For whom, I ask, will the alchemists point to who has taken experience of it? No one at all, surely, unless some most lying—not to say most beggarly—impostor. Add to this that it cannot be brought about that a tincture of this kind could be produced by human ingenuity—on the testimony even of Paracelsus himself, in his book *On the Transmutation of Metals*. I quote his words at length. *Through man, he says, the separation of the elements is impossible*

[Margin: *Book On the Transmutation of Metals*.]

[Margin: Paracelsus, on the impossibility of the art.]

—that is, in the great art, the separation which, although it may appear, is nevertheless not real; whatever may be said of Ramon Llull and of his noble golden "English coin," commonly the *rose-noble* [Rosenobili], which he is falsely supposed to have fabricated. *For Nature herself has within herself her own separator, which rejoins what it separates, without any human help, and assigns best of all the proportion of each element*—and not man, whatever the writers, with their erroneous, frivolous, and false processes and prescriptions, may fable about that volatile gold of theirs (as was shown a little before): Llull, Richard the Englishman [Ricardus Anglus], and Rupescissa [John of Rupescissa], with their gross errors. Whom now, in this art, are we to believe? Paracelsus, or the chief champions of alchemy? Certainly neither these nor him—that they ever penetrated the art, or knew what they were saying, no one will deny that I have affirmed on the surest and best of grounds.

But let us proceed to the weight, number, and measure, and to the most exact proportion, by which they assert the Stone must be fashioned. And who does not see that this proportion—just as God [Deus], the best and greatest, the Architect of all Nature, alone knows it (he who knows how each of Nature's compounds is coupled into the fellowship of friendly union)—is likewise as far removed as possible from all the industry of human ingenuity? Yet all the alchemists admit that this proportion is altogether necessary in the construction of the great work. But that they can arrive by art at this exact proportion, which consists in an indivisible point, can be persuaded, I think, to none of the wise.

[Margin: Man cannot attain the most perfect exactness of weight and measure.]

For (as Paracelsus puts it) if you take a little more of one than of another among the ingredients of the great Stone, the seed cast into the field must necessarily be choked, so that it cannot live long enough to be perfected once united by the mercury of the philosophers; but if you take too little, it cannot be dissolved at all, so that it produces something abortive or fruitless. Arnold too complains of this: If you add more or less of earth than Nature allows, the soul will be choked without any fruit, with no necessary fixation following. The same is to be understood of the water too, if you take more or less. For if you take too much water, the material is rendered excessively moist; if less, it is rendered too dry. Again, if there is too much air present (to use Paracelsus's words), the tincture imprints itself too much; if too little, the body turns out pallid. Likewise, if the fire is too violent, the material is scorched; if too gentle, it has no power of drying, nor of dissolving, nor of warming the other elements.

[Margin: Taking too much or too little destroys the work of the Stone.]

What will the wretched alchemists do in this hopeless business? Surely Arnold and Paracelsus, when they could find no way to roll this Sisyphean Stone to its desired end, judged that the whole process must be entrusted not to human adaptation but to the working of Nature alone. For as Paracelsus reasons: *Nature knows her own operations and the weights of the elements, whose separations, rectifications, and couplings she herself carries out without the aid of any operation or mineral artifice, provided only that the material be kept in its secret and in a hidden vessel.* He could certainly have said nothing better. Let them therefore leave to Nature what they think cannot be supplied by themselves—Nature, who from the very first beginnings of the nascent world, by her own un-

[Margin: Nature alone knows her power of producing metals.]

failing industry, has produced this noble metal in such abundance in her own womb that we have no need of the alchemists' counterfeit gold. For she knows how, by the benefit of the secret subterranean fire, to produce the metals by joining actives to passives; she turns away from the alchemists' "secret fire" as unsuitable; she knows the hidden vessels of the subterranean wombs—not the retorts, bladders, alembics, cucurbits, and the like monstrous wombs of the pseudo-pyrotechnicians.

CAPUT VI.

Omnia Chrysopœias tentamina frustranea esse ex ipsis Alchymistarum Coryphæis, Arnoldo, Villanovano demonstratur.

[That all the attempts of chrysopœia [gold-making] are futile is demonstrated from the very chief champions of the alchemists, from Arnold of Villanova.]

Paracelsus, aspiring to the monarchy of the Alchemical Commonwealth, when he saw that he could not by any effort of intellect penetrate the way of making the Stone, set out upon new schemes for that fictitious Stone and devised, in his book *On the Transmutation of Metals*, various and novel processes for the Stone. These, even if in substance they differ in nothing from the processes of Llull, Arnold, Rupescissa, Richard [Ricardus], and Bacon [Roger Bacon]—from whom he filched everything of his own—he nevertheless cloaked these borrowed inventions in so exotic a garb of monstrous names that, like the crow decked out in others' feathers, he seems to have set himself up not as the monarch of the chemists, as he calls himself, but as the cuckoo among the birds. *I, he says, shall deservedly correct the Spagyrist after my long experiments, and shall separate the false and the erroneous from the true, since by my exceedingly lengthy investigations I have discovered how I may rightly censure such things and change them.* And a little later, after rehearsing the long labors of the ancients: *They would have had, he says, a shorter road to attaining the treasure of the red lion, had they learned the concordance of my Astronomy with Alchemy, which I have demonstrated in the Apocalypse of Hermes. And since every single day, as Christ says, has its own proper essence for the consolation of the faithful, the labor was great and heavy for the Spagyrist before our times—a labor which now, in this latter age, will be relieved by my theory through the aid of the inflowing Holy Spirit.* And a little further on: *The old Spagyrist would not have needed such prolix labor and such tedious repetition had they learned the work from my School; they would have attained their wish far more quickly and at less expense.* Such are the boasts of the Monarch of the Chemists.

[Margin: Paracelsus's instance/objection.]

But what Bombastian Astronomy and the analogy of the celestial bodies have to do with the Stone, I can in no way make out. For since the nature of things always acts in the same way, under whatever arrangement of the planets and aspects of the stars; and since the generation of metals—whether natural or fabulous—has only the most remote dependence (as we have shown in what precedes) upon the heaven and the stars of the alchemists: therefore, without Astrology and the

influences of the stars, in the great work of the Art, you will accomplish nothing, Paracelsus dictating though he be. And what the assistance of the Holy Spirit has to do not only with this most empty work, but with so impious a man, I do not see—though I see well enough what that Thrasonical [boastful] breast craves. For when he saw that this could not be done by human art (with all the other alchemists, however many there have been, agreeing), he showed by the following words that he wanted the Art to be granted only by God through revelation:

[Margin: Man does not act to bring about the success of the great work in respect of the heavens.]

Many secret things exhibiting transmutations are found—though by few, that is, only by the sons of the art illuminated by God; and although they be revealed to someone by the Lord God, not on that account does the report at once burst forth along with the arts, but the Almighty gives along with them the understanding to conceal these and other things until the coming of Elijah the Artist, at which time nothing so hidden but it will be revealed. O ridiculous philosophy! What concord has Christ with Belial? What has divine revelation to do with an art so wicked and so utterly fabulous? Do these men not know that so far is it from God being thought to lend supernatural aid to an art exposed to so many Satanic illusions, that he has rather hinted in Sacred Scripture that it is to be shunned, in express words, as if with oars and sails: *They who wish to become rich—that is, the alchemists—shall fall into many temptations and snares of the Devil.* [1 Timothy 6:9] Is it possible that God, the best and greatest, should have omitted to reveal this art to so many holy men, full of the spirit of God, whom he knew would not abuse it—and yet should have inspired so great a gift only into alchemists like Paracelsus and his kind, men for the most part wicked, given to evil arts, greedy, proud, and abusers of the divine mysteries? But these things we shall pursue more fully in what follows. Let them therefore turn, roll, revolve, and wrap up that Stone, the worker of such great marvels, as much as they please; yet they will roll out of it nothing but worthless scraps and dross of words, and afterward, too, coals, ashes, and cinders.

[Margin: Alchemy, according to Paracelsus, is inspired by God, etc.]

Strange words, such as *Azoth*, *Agathron*, *Anathron*, *Usisur*, *Rebis*, *Martagon*, *Sernec*, *Ribric*, *Realpas*, *Saltaberi*, and countless others met with in the books of the chemists—especially the Paracelsian ones (which not seldom, in familiar conversation held with such men, have moved me to laughter)—contribute little to the matter, if from some other quarter no supports are at hand for

demonstrating the truth of the art; nor does the promise of such great things, or the boasting of certain peevish ash-mongers [ciniflones], contribute anything to proving the art, while, swollen with pride from their supposed possession of the secret Stone, they promise, under the likenesses of various things, what cannot be conceived in the mind—not to say grasped by human knowledge. Surely, to cure so great a madness, there would be need of no other medicine than a vomit of Hellebore; so highly were they es-

[Margin: Monstrous words contribute nothing to the matter.]

[Margin: Monstrous names contribute nothing to perfecting the matter.]

teemed, by which they vomit up those red lions, birds of Hermes, green lizards, serpents, dragons, phoenixes, peacocks' tails, ravens' heads, bats, and similar chimerical phantasms—together with the heaven and all the imaginary planets—as someone not inaptly jested about them in the *Chemical Work* of Beguinus [Jean Béguin]; so that at last, their brains purged, they may learn to think more sensibly. Surely these men seem to have followed Lexiphanes [the word-monger of Lucian], who, after drinking down hellebore juice, at once belched forth those formidable words—*topper*, *stlempus*, *redantruo*, *gnarneres*, *ascalabotio*, *carbaster*. The very same thing happened to them as to that Plautine cook who, rejecting the common seasonings—garlic, fennel, coriander, and the like—prattles on and haughtily recommends only his own *Cilicendrum*, *Polindrum*, *Sanscapsidem*, *Cataractriam*, *Hippalopsiden*, by whose aroma Jupiter dines daily, and however many feed on them prolong their life even to two hundred years.

I do not doubt that here the alchemists, stung by frenzy, will rise up against me, ready to accuse me of either ignorance or indiscreet zeal; I do not mind, nor would I buy at a trifle—to speak with Plato—whatever slanders fury may suggest to them. I speak the truth; the clearest experiments persuade me of it; Nature herself—the one weigher of truth, the exact balance of operation—dictates to me what she can and cannot do. But they will rise up again, and press the more boldly: that it seems unjust to charge Llull, Arnold, and Paracelsus—the sole oracles of the art—too presumptuously with falsehood in constructing the Stone. But if even the most-cited chief champions and standard-bearers of the great Art feel the same as I do, who will reproach me? And lest I should seem, by an inexpert judgment, to be tearing the art too much to pieces, I have thought it worth appending in this place a most ample discourse on the futility of the magistry of the Stone—a discourse which Gerard Dorn [Gerardus Dornius], his interpreter, inserted into Paracelsus's book *On the Transmutation of Metals* under the name of Arnold of Villanova. From it, whatever I have hitherto said about the

vain and futile labors of the alchemists will appear clearer than the noonday light.

Discursus Arnoldi Villanovani apud Paracelsum, lib. de Transmutat. metallorum. [The Discourse of Arnold of Villanova, as found in Paracelsus, in the book On the Transmutation of Metals.]

The greatest difficulty of this Art (says Arnold in his *Rosary* [Rosarium]) [is that] [Variant readings of the names assigned to this material of the Stone—certain most hidden ones, drawn chiefly from likenesses—they have predetermined: they called it *vegetable*, *mineral*, and *animal*, not according to the literal sense (as the wise easily understand) but [?]] [Margin: text appears displaced — see parsing note below].

Many have tried to coagulate mercury by means of the liquors of vegetables, fixing them as it were by fixative waters, thinking to convert it into Luna [silver], reckoning that whoever by this route could coagulate the aid of the metals would attain the greatest magistry. But although the liquors of some vegetables do effect this, it will be judged to come about from no other cause than the resin, fattiness, or earthy sulphur in which they greatly abound. This attracts the moisture of the mercury, and is mingled with its substance, coagulating it without any usefulness. For coarse and external sulphur—and none such is found in vegetables—is fit for perfect projection in alchemy; and this many have learned by experience, not without the greatest cost. Although some, on account of its intense heat, thought that they had coagulated mercury with the white, milky juice of *tithymal* [spurge], whereas in fact it was the cold within it that did so by a manifestly contrary cause—wherefore they called it "Virgin's Milk" [Lac Virginis]—this was nevertheless a false foundation.

[Margin: Tithymal juice does not coagulate mercury.]

The same is to be judged of the juice of *celandine* [Chelidonia]: although by its color it deceives men's eyes, as if endowed with gold, those who gathered something vain from it dug up this vegetable at a certain fixed time, from which they hunted out a "soul," or "quintessence," to make from it a coagulating and transmuting tincture. But from this too nothing arose except foolish error. Others boiled down this juice to the thickness they call "consistency," and exposed it to the sun so that it would coagulate into a hard mass, which afterward, pounded into the finest powder, they cast upon mercury (as they supposed) so that the projection would turn it into Sol [gold]—which they found to be false. Some mixed sal ammoniac into this powder; others, *colcothar* of vitriol, thinking that

by this route they might at last arrive at the wished-for end. Afterward they brought the solutions into a wash-water, so that this salt might give the tincture entry into the substance of the mercury—yet nothing came of it.

[Margin: Celandine juice is of no use.]

Some, in place of the aforesaid, [used] the juices of peach, *bufonaria* [toad-plant], dragon-wort, willow leaves, tithymal, *cataputia* [caper-spurge], *flammula* [lesser spurge], and the like: they kept these together with the mercury itself, enclosed in a glass vessel, in ashes for several days. The result was that the mercury was turned rather into ash, or powder—but wrongly and to no fruit. For those men were deceived by the empty rumors with which it had been spread abroad.

[Margin: The juices of peach, *bufonaria*, dragon-wort, etc.: no fixation occurs.]

[Margin: *Lunaria* of Llull, of great power.]

An example of this is offered by the *Lunaria* of Ramon Llull, which puts forth flowers of wondrous powers—most familiar, however, to the philosophers. This name was not given by an imposing opinion, as if by it were understood some projection upon the metals, or a preparation; but the abstruse mind of the philosophers looks far elsewhere. By a similar name they called the material *Martagon*, to which likewise they applied a hidden chemical operation drawn from this source, although it denotes nothing at all of the kind, beyond a certain hidden likeness.

[Margin: *Martagon*: what Llull means by it.]

No small error, too, arose in the liquors of vegetables, with which very many have tried to coagulate mercury, and afterward seem to have repented of it; for mercury must be coagulated apart from the metals, as we mentioned before. Many have extracted from vegetables salts, oils, sulphurs, and so forth—but in vain, since through these no true coagulation of mercury [is achieved]...

[Margin: Vegetables are of no use to the art.]

[Margin: Salts, oils, sulphur of vegetables accomplish nothing.]

[The discourse of Arnald of Villanova continues, on the alchemists' vain attempts.]

for they reckon that no true coagulation, perfect tincture, or projection can result — by a likeness to the Philosophers' only, not by substance. They compare their material to a certain tree of seven golden boughs, understanding that in its seed it

encloses the seven metals, which lie hidden within it; and for this reason they called it vegetable. They did so, too, because, just as natural trees in their season put forth various flowers, so the material of the Stone displays its loveliest colors in the production of its own blossoms.

[Margin: Metallic bodies are said to be vegetable on account of this likeness.]

Likewise, because from the Philosophical earth a certain metallic body rises up — like a sprout from the earth, sponge-like — they said the fruit of their tree reaches up toward the sky. Hence they declared that the whole hinge of Nature's art turns upon vegetable things, not upon mineral material; and also because their stone, like vegetables, contains within itself soul, body, and spirit.

By a not-very-different likeness they said this material was the "Virgin's Milk" and the blessed blood of rosy color — which, however, belongs only to the prophets and the sons of GOD. From this the Sophists concluded that the material of the Philosophers consists in the blood of animals or of men, taking their occasion from the fact that animals are nourished from vegetable things.

[Margin: The coagulation of mercury is not found in the blood of men.]

Some looked for it in hair, in the salt of urine, in the kidneys; others in hens' eggs, in lime, in milk, and the like — by all of which they supposed they could fix mercury. Some extracted salt from fetid urine; nor were there lacking those who believed the material to be little stones found in men.

[Margin: The parts of an egg accomplish nothing.]

Others macerated the membranes of eggs in the harshest lye, to which they also mixed the eggshells, attributing to these the secret of fixation for perfecting mercury. Others, likening the egg-white to silver and the yolk to gold, chose these as their material; mixing in common salt, sal ammoniac, and burnt tartar, they sealed all this together in glass and let it putrefy in a water-bath, until the white color turned into the most ruddy, like blood. This they distilled into a most foul liquor, utterly useless for the work they sought. Others let the white and yolk of eggs putrefy, and from this a basilisk was generated, which they burned to a most ruddy powder, and with it they thought to tincture. The author of this was Cardinal Gilbert in his *Treatise on Alchemy* [Gilbertus Cardinalis, *Tractatus de Alchymia*].

Most of them, mixing the gall of oxen and other animals with common salt, macerated it and distilled it into a liquor, with which they thought to soak the powders for cementations, so that these might tincture their metals by some

mystery — which they call "part with part" [partem cum parte] — and from this nothing came of it. Some, choosing tutty [tutia], seduced by various additions such as dragon's blood and other such frivolous trifles, attempted to turn copper or electrum into gold.

[Margin: Tutty contributes nothing but its color.]

Others, following what they called the method of the Venetians, would shut up twenty more or less skinks [stelliones] in a pot and starve them to madness, so that one ravenous one might devour the others, with a single survivor left, which they then fed on filings of copper or electrum —

[Margin: The ridiculous taking-up of skinks as material.]

— supposing that this kind of animal could, by digestion alone in its stomach, accomplish the longed-for transmutation. Finally they burned this animal to a most ruddy powder, which, believing it to be gold, they were miserably deceived. Some, at last, found gold in fish called trout [trutta], wholly burned up by liquefaction — for no other reason than that this kind of fish is accustomed, taught by nature, to gather and devour in the rivers the little scales and golden sparkles carried there by the torrents, sometimes washing down from a mountain; yet this very rarely happens.

[Margin: Trout, when burned, contribute nothing to the work.]

Such impostors are found above all in the courts of princes. Truly, the material of the Chemical Philosophers is not to be sought in animals — of this I would have all warned once and for all.

[Margin: The material of the Philosophers is not to be sought in animals.]

There is, however, something to be known: that the philosophers called their stone "animal" because, in their last operations, by virtue of this most noble fiery mystery, a dark and ruddy liquor, like blood, oozes out drop by drop from its material and its vessel. From this they brought forth a prophecy — that in the last times a most pure man would come into the world, through whom the liberation of the world would be accomplished; that this very man would send forth drops of rosy or ruddy color and of blood, by which the world would be redeemed from its stain.

[Margin: An impious application of the Philosophers' stone.]

In like manner, the blood of their stone, in its own kind, freed leprous metals, and likewise men, from their contagious infirmities. For this reason they not without

cause called their stone "animal." Of this, Mercurius speaks to King Chalid in this manner: "This mystery," he says, "is permitted only to the prophets of God to know — whence it comes that the stone is called animal. For in the blood of this stone its soul lies hidden; it is composed, moreover, of body, spirit, and soul." By a similar reasoning they called it their "microcosm," because it has the likeness of all the things of the whole world; and from this again they say it is "animal" — just as Plato calls the great world an animal. The ignorant joined in, believing the stone to be threefold and secret in a threefold kind — namely, vegetable, animal, and mineral — whereby it came about that they also sought it among minerals. But this opinion is far removed from the Philosophers' view; for they assert that their stone is uniformly vegetable, animal, and mineral.

It is to be noted, in addition to these things, that Nature has distributed its mineral seed into various kinds — namely, into sulphurs, salts, boraxes, sal-ammoniac-nitres, alums, arsenics, atraments [vitriol-blacks], vitriols, tutties, hematite, orpiments, realgars, magnesias, cinnabar, antimony, talc, cadmias [cachimiae], marcasites, and so on — in all of which our material has filled the world.

[Margin: Where the material of the Stone is found among minerals.]

Although in some of the said species it sometimes reveals itself with a marvelous appearance, as far as concerns the transmutation of imperfect metals. For long experience of fire, through manifold exercise, shows transmutation in mineral material — not only out of...

some colors into other colors, but truly also out of one essence into another, and from the more imperfect into the more perfect. And although Nature herself sometimes makes demonstrations of this sort through these mineral intermediaries — many preparations intervening — the Philosophers nonetheless do not want the material of their Stone to proceed chiefly from any of the mineral intermediaries, even though they call their stone "mineral." Hence the Sophists, taking occasion from this appellation, have hounded Mercury itself with various tortures: some with sublimations, coagulations, precipitations, with mercurial waters and strong waters [aquae fortes], and so on — all of which are erroneous paths to be avoided, along with the rest of the Sophists' preparations of minerals, purgations, and fixations of spirits and of metals.

[Margin: Strong waters [aquae fortes] are not the material of the Stone. Albert. Geber's operations are sophistical. Roquetaillade an impostor. Geber handed down sophistries.]

Therefore the very many preparations of the Stone — indeed all of them — that are described from minerals in this manner, such as those of Geber [Geber], of Albert surnamed the Great [Albertus Magnus], and the like, are merely sophistical: purgations, cementations, sublimations, distillations, rectifications, circulations, putrefactions, conjunctions, solutions, ascensions, coagulations, calcinations, and incinerations utterly useless — whether in the tripod, the reverberatory furnace, the athanor, in mud-bath, acid-bath, dung-bath, ash, sand, and the like, or in the cucurbit, pelican, retort, phial, fixatory, and other vessels of that kind. The same judgment is to be made about the sublimations of Mercury through mineral spirits "to white" and "to red" — as through vitriol, saltpetre, or other alum, or through crocus of Mars [crocus Martis, iron oxide], and so on — about which Johannes de Rupescissa [John of Rupescissa / Roquetaillade] falsely spins fables in his *Treatise on the White and Red Philosophers' Stone*, which together with the others are all lying dreams, miserably seducing good and simple men.

[Margin: The sulphur of metals does not coagulate Mercury.]

Those particular sophistical tricks of Geber are also to be fled — such as the sevenfold sublimations or mortifications, likewise the revivifications of Mercury with their preparations through the salt of urine, or through the "sepulchre of the wise," each of which is utterly false with respect to the Stone. Certain others, who tried to fix mercury with the sulphurs of minerals and metals, were utterly deceived. I have nonetheless seen Mercury brought by this art into a metallic body through fixations of this sort, feigning and representing in all respects and through and through good silver — yet in the assay, on the cupel-sherd or the cupel, it proved and also appeared false.

[Margin: Oil of sulphur is applied in vain. (margin truncated: "Oleum sulphuris frustraneum")]

Some of the Sophists tried to wring a fixed oil out of this Mercury, sublimed seven times and as many times dissolved — by means of strong waters, by which they brought imperfect metals of any sulphur whatsoever to perfection — but they were compelled to abandon that fruitless work.

[Margin: Vitriol accomplishes nothing.]

Some purged vitriol seven times by solution, calcination, coagulation, and the addition of two parts of sal ammoniac, and by sublimation, so that it dissolved into a white water, to which they added a third part of quicksilver, so that the water might be coagulated; and afterwards, as many times, they sublimed the

mercury from the said vitriol and sal ammoniac, so that it passed into a hard stone. This they affirmed to be the red sulphur of the Philosophers conceived from vitriol — with whose solutions and coagulations they proceeded — but in the projection, nothing came of it.

[Margin: Mercury coagulated into a mass of alum does nothing to the purpose.]

Others coagulated mercury by means of alum-water and into a hard mass like alum, which they fixed uselessly with the sharpest waters. The Sophist presumes to himself very many methods of fixing mercury — yet in vain, since nothing perfect or stable is held in it. In vain, therefore, do they add minerals to it through sophistical processes, by all of which it is roused to greater malignancy, and is made more and more living, and impure rather than perfect.

[Margin: All the methods of fixing Mercury are useless.]

The material of the Philosophers, therefore, is not to be sought from it, since it is an imperfect thing, which, even if it could be brought to perfection, would be very difficult — indeed impossible — by the processes of the Sophists, since there is nothing in it that can be roused or forced into perfection. Some took arsenic, sublimed several times and many times dissolved in oil of tartar and coagulated, and pretended to fix it, so that they might turn copper into silver — and that brought nothing but a certain sophistical whitening.

[Margin: Arsenic accomplishes nothing in transmuting copper into silver.]

For this can by no means be fixed unless the tincturing spirit in it has been thoroughly recognized — in which indeed almost all the Philosophers have slumbered, trying in vain to make something good out of arsenic. Whoever, therefore, are ignorant of this spirit, let them also have no hope of fixing it, nor any power of imparting through something else, by which it might acquire the perfection of transmutation. For which reason I make known to all who expend their labor upon it that the whitening of which mention was made is drawn from a false foundation, and that by it copper is only falsely whitened, and not otherwise altered.

[Margin: Sophistical whitenings.]

The Sophists, having likewise masked and painted Venus [Venus, copper] in this manner, mixed it with twice its amount of Luna [Luna, silver] and sold the mixture to goldsmiths and minters. But in the end they transformed themselves into false coiners — not only those who had sold, but also those who had bought. Some of the Sophists took red arsenic in place of white, and this very thing, as

before, passed into a false art; for, in whatever way it is prepared, it exhibits nothing but whiteness. Some proceeded further to common sulphur, which, being yellow as it was, they cooked in vinegar, lye, or the sharpest urine for a day and a night, until it came out white. Afterwards they raised it from common lime and from the lime of eggs, cooked it, and sublimed it, and that many times. Nevertheless it always remained combustible, though white; yet with it raw they tried in vain to fix mercury into gold. Nevertheless from it resulted a cinnabar most beautiful and the best of all that I have ever seen, which they thought to fix with oil of sulphur by cementation and fixation — but...

[Margin: Sulphur is applied in vain.]

nothing did it hold; but it turned out otherwise than the thing itself was desired. Others reduced common sulphur into the form of a liver [hepar, "liver of sulphur"], cooking it with the admixture of linseed oil, brick-oil, or olive oil in vinegar, then pouring it out upon a marble stone. This very thing they distilled into a citron-colored oil, at first over a slow fire — but to their own loss they experienced that it did nothing they wished, namely that it had by no means turned Luna into gold. Therefore, as the number of minerals is infinite, so too the preparation of them is a great variety, of which I have here deferred to make mention, because they require a treatise of their own.

[Margin: Sophistical oils are to be guarded against.]

One must also beware of the sophistical oils of vitriol and of antimony, likewise of the oils of perfect and imperfect metals, even of gold and silver — because, although their operation is most powerful in the nature of things, nevertheless their true process is to this day known to very few. One must also abstain from the sophistical preparations of common mercury, of arsenic, of sulphur, and of other similar substances, through sublimation, descent, fixation with vinegar, saltpetre, tartar, vitriol, sal ammoniac — yet by that path or method which the books of the Sophists teach.

[Margin: The tinctures of marcasite and crocus of Mars are sophistical.]

Likewise flee the sophistical tinctures drawn from marcasites and from crocus of Mars, and from that sophistication which is called "part with part" — fixed Luna and similar trifles. For although they exhibit some superficial appearance of truth — and indeed this fixation of Luna is of little labor and skill — nonetheless a progress of preparation of this kind is null and invalid.

From this most ample reasoning of Arnald and Paracelsus it appears clearly that no method has, from the first publication of the Philosophers' Stone in Europe to this very day, been prescribed which Paracelsus [Paracelsus] has not repudiated in this discourse as vain, idle, and useless — in which he most especially mocks the method of both Geber and Llull [Lullus / Ramon Llull], and teaches in open words that the gold which Raymond [Ramundus] had offered to Richard, King of England [Ricardus, Angliae Rex] as made by himself through the Chemical art, under the form of a noble rose [rosa nobilis, the "rose-noble" coin], was false and sophistical. He likewise reckons the work of Rupescissa as worth nothing — so that, with all the methods combined, none is left by which this Monarch of the Chemists might satisfy himself in any way.

[Margin: Paracelsus determines the material of the Stone.]

What, then, in the end does this Monarch do? To destroy a work of the Stone so admirable was nothing other than to destroy the monarchy of the Chemical Art so greatly coveted by himself. So that he might seem, above all others, to know something higher and more sublime, and that he might appear among the Alchemists like a cypress among the wayfaring-trees [*viburna*], he prescribes another mode of making the stone, found by himself through divine illumination. But what could that so great secret of the art be, which has come into the mind of no one until now, but only of Paracelsus — inspired, I know not by what divine power's breath? Let us lay open a thing full of curiosity and not unworthy of consideration; and that this may be done more knowingly, let us set out first the words of the great process by which he described it.

"With so great a labor," he says, "the ancient Spagyrist would not have needed [the work] if they had learned the work from my school. Therefore I, Paracelsus, say to you (we apples are swimming): take the blood of rosy color from the lion, and the glue from the eagle; which, after you have joined them together, coagulate according to the ancient process: you will have the Tincture of the Philosophers, which infinitely many have sought, very few have found.

[Margin: The process of Paracelsus.]

Thus the Alchemist composes certain simple things, which he corrupts — as is the art's way — and from there he prepares another thing, and so on, until one thing is made: this accomplishes more than Nature herself could by herself. Rightly and thoroughly, that you may understand me: seek your lion in the Orient, and the eagle taken up to the south, for this our work.

[Margin: The ridiculous process of Paracelsus.]

You will find no better instruments than Hungary and Istria produce; but if you wish to draw it out of unity through duality in trinity, with an equal permutation, you must direct your journey toward the south, and so you will obtain your vow in Cyprus."

By these words he sets out the highest secret, unknown to this very day, veiled with a truly ridiculous likeness. But the trick does not escape an Oedipus. For what else does he hint at by "the blood of rosy color drawn from the lion" but the sulphurous, most ruddy tincture of arsenic? What by "the glue of the eagle" but sublimed quicksilver [hydrargyrum]? — which, joined and coagulated together, give the desired Tincture of the Philosophers, as he supposes.

That this interpretation is most true, he himself confesses, advised — if the gods please — from the Sibylline oracle. For thus the Sibyl says: "I have nine elements [letters], and I am four-syllabled; perceive me: the first three syllables are each made from two letters, the rest remain among the remaining, of which there are not five vowels," and so on. By this oracle, Paracelsus says, the Sibyl hinted at nothing other than the material of the great work, which is ARSENIC — that very thing, namely, which in his earlier discourse he had rejected as useless to the art — because, according to the Sibyl's riddle, it consists of nine letters, is four-syllabled, of which the first three syllables are constituted from two letters each, thus: Ar, Se, Ni; the rest remain among the remaining, and the whole word is composed of five consonants, and they are R, S, N, C, M. And these things indeed agree rightly, if the following matters correspond as to the number which is said to lie hidden in the letters. Nevertheless, since we have explained above that the Sibyl hinted by this at a far different signification, I have judged it not to be repeated. Yet granting — though not conceding — that the Sibyl by the whisper of her voice stirred the mind of a great prophet, and that she indicated arsenic as the material of the wondrous Stone by the said riddle: what then? Is it therefore to be held as if one of the articles of faith — which, however, he subordinates to this? Away with these ravings of infatuated petty-prophets [Prophetastri], to be purged with hellebore! We know what arsenic is, and by what powers it is strong. We have also learned, by the testimony of Pliny [Pliny], that it contains something of gold within itself, from the pyrotechny of Gaius Caligula [Caius Caligula]; but that this single thing is the material of the great work — neither he himself, as is clear from the preceding discourse, nor any other of the Chemists has thought.

has thought — not to say taught. Because not even this escaped him, he judged that some arsenic of the tincture was to be joined in his process — namely, the "glue of the eagle"; that is, he held that the blood of the Lion was to be saturated

with sublimed mercury. Moreover, in the process he asserts that this Lion — that is, arsenic — is to be sought in the Orient, moved by the authority of Pliny, who says that Gaius the prince [Caligula] had ordered the chief Arsenic to be carried from Syria, which abounds in it, to Rome from the Orient, for the extracting of gold from it; but mercury he thinks is to be sought in Istria, which teems with the most fertile mines of quicksilver, at a place which is called Hydria [Idrija] (about which we have treated abundantly in the preceding sections).

[Margin: The interpretation of the riddle propounded by Paracelsus.]

"But if you join all these things together under proportion 1 to 2 in a legitimate permutation, you will not be able to accomplish it unless, by a journey directed straight from Hydria to the south, you obtain your vow in Cyprus" — by which he hints at nothing else but that the material is to be sought in the island of Cyprus, to the south of Istria, which abounds in it. And this is that admirable secret of the Stone which Paracelsus, illuminated by the Sibyl, feigns — by a most empty effort — to have revealed to the world.

But what that secret is — hear and laugh: it is nothing other than Vitriol, familiar to Cyprus, and indeed the name [chalcantum / vitriol], as Arsenic [is]. Its mystery he points to under an acrostic, which I demonstrate from his own words. For, intending to conceal the secret of the Cyprus island, in which under an acrostic he points to the material:

[Margin: *Visitabis Interiora Terrae; Rectificando Invenies Occultum Lapidem Veram Medicinam* — "You will visit the inner parts of the Earth; by Rectifying you will find the hidden Stone, the True Medicine."]

"You will visit the inner parts of the Earth" — that is, of Cyprus — "by Rectifying you will find the hidden Stone, the True Medicine." For if you gather the initial letters of these words into one, you will have the name *Vitriolum* [Vitriol], as follows:

**Visitabis Interiora Terrae, Rectificando In- venies Occultum Lapidem
Veram Medicinam.**

O how great a mystery this master has opened to us — unknown, perhaps, only to little boys! Who...

does not know that Vitriol holds the principal place in all the processes thus far? Was this, then, so foreign to Paracelsus that he himself reckoned this secret divinely inspired into him from heaven? Is he not convicted of the crime of the most open imposture, by this very fact — that what in his preceding discourse he

had rejected as useless material, he now receives into his magistrery as an incomparable secret? Certainly, if Paracelsus was striving to acquire among the common run of Philosophers the esteem of a great name, he could not have carried out, in a better way, that which is the mark of impostors and sycophants, than by veiling his trifles under an affected and most lofty reasoning of words and of the most abstruse matters — so that they might seem to be something — and by clothing in a ruddy mantle the Ape that he was playing.

[Margin: The imposture of Paracelsus.]

If this is the mark of Philosophers, then certainly I have no doubt that boys, delirious little old women, cobblers, and barbers can soon, by this art, turn out as the highest Philosophers. I detect very many things in Paracelsus's monuments not unlike this, which, if I wished to refute them all, there would be need not now of a few leaves, but of a whole book; and therefore I cannot sufficiently marvel how men otherwise skilled in Philosophy and Chemistry dare to lend an ear to Paracelsus — since yet, except for a few things that savor of Physics, all the rest are wrapped up partly in Cabalistic, partly in Astrological and Magical opinions; and most of them are linked to an ambitious retinue of barbarously concocted names and words, and show a man full of nothing but ambition, who has not been ashamed to prescribe for himself, more obstinately, by fair means and foul, the primacy of literature and of iatrochemistry [iatrochymia]. Certainly, if you distill what he has written into a quintessence, you will scarcely extract five ounces of good things which are his own. But now to other matters.

CAPUT VII.

The objections against the said processes, and their authors, are refuted.

[Margin: Objections against the said processes.]

The Alchemists object to me, first, that it seems unjust to want to repudiate an Art now accepted by the common reckoning of the wise for so many thousands of years (as they wrongly persuade themselves). Second: that gold made by the Chemical art, both by the industry of the ancients and of the moderns, is established from the most trustworthy testimonies. Third: that to flog with the censor's rod, with such severity, men who are Alchemists, professors of the true art, men devoted to GOD and bound by sacred religion, who — many of them illumined by divine light — have practiced [it], and to convict them of the crime of open imposture, cannot in the least be tolerated. These are the chief points

which the Alchemists are accustomed to object to their Antagonists for demonstrating the truth of their art. To each of these it is now time that we respond.

That it seems unjust, therefore — let the Alchemists be persuaded that it is by no unjust, but by a most just right, that I assert against them that an Art enduring now for so many thousands of years in the profession of its truth is reproved by me. As for the antiquity of the art, whatever it may be, I have already sufficiently shown above that, from the times of the Roman Emperors, nothing was known of it; but those who derive it even from Adam himself — as Paracelsus and his followers do — since [their derivations] are uncertain, useless, frivolous conjectures, resting on no foundation whatever, so too I would waste time if I wished to refute them. For it is proper to the Alchemists that, at even the first mention of any gold occurring in the sacred books, they straightway [claim] that the Holy Spirit by this very thing pointed to nothing else than the admirable secret of this Stone — with greater faith, perhaps, than they would believe even the most sacred mysteries of the faith themselves. But, leaving these vanities aside, let us turn ourselves to those...

let us turn now to those [arguments] which seem to carry greater weight for proving the vanity of alchemy — namely, the claim concerning chemical gold [aurum chymicum], made at every period by wise men.

[Margin: Refutation of those who say they have made gold.]

To this I reply. That they have made gold, I freely admit. But that they have ever produced — by means of that tincture of their Stone, infinitely multiplicative upon gold — that gold which they imagine they can produce, this they have merely dreamed. By what means and by what art gold is in fact made, I shall show a little later in several ways. But that they have ever perfected, through the said infinitely-multiplicative tincture of the Stone, a gold a hundredfold nobler than natural gold — more excellent, more brilliant, endowed with finer qualities — this I deny, and deny again and again.

But they press the point: what has at some time been done, no one will easily deny can still be done to this very day; and that such gold has indeed been made, the testimonies of the chemists demonstrate in countless histories. *Therefore* [the art is valid]. They prove the minor premise by induction:

[Margin: Who are the famous makers of the Philosophers' Stone [chrysopoeia].]

from Raymond Lull [Ramon Llull], Arnold of Villanova [Arnoldus de Villanova], Rupescissa [Jean de Roquetaillade], Bernard [of Trier], Trevisan [Bernard of Treviso] — and which of them, in the end, [is not cited]? For Raymond Lull, they say, made the purest gold by chemical art in the presence of Richard, King of England; and Arnold did the same in the presence of Robert, King of Naples.

But all these claims — as became clear from his discourse set out above — Paracelsus, the monarch of the chemists, asserts to be false.

[Margin: Paracelsus's judgment on the gold of the alchemists.]

He also asserts that the gold coin which the common people call the "noble rose" [rosa nobilis], said to have been struck from gold he himself had made, was utterly sophistic and of no value — a verdict to which very many of the physicians of England subscribe. As for Rupescissa, so far is he from being said to have made gold that he rather seems to assert the contrary of himself, in his first book *On the Quintessence* [De quinta essential], part 1, chapter 22. There he first states that he does not teach the transmutation of metals [transmutatio metallorum], because he was forbidden to do so by the rules of the Order of St. Francis, to which he had consecrated himself; and second, that chrysopoeia is false and dangerous, and can be taught only by divine revelation. He shows this in these words:

[Margin: Rupescissa, on the alchemists.]

"I confess before all evangelical men, calling God to witness, that if, at the devil's instigation, they slip into alchemical operations, they are easily given over to a reprobate mind. And I know that it is a path of perdition, and so evil that no philosopher has written the truth in his books, except feignedly and under parables that cannot be understood nor grasped by the human mind. And I know too that no one can attain to the sublime [secrets] of this art unless his mind has first been made godlike through the loftiest contemplation and the holiest life — so that he not only knows all the inner workings of Nature, but also knows how to transmute transmutable nature; and this has been granted to very few. And commonly these are followers of fictions and sophistications, and they become counterfeiterers of coin and of the seals of prelates and princes — vagabonds, deceivers, men of damnable life — of whom that saying of Paul (2 Corinthians 3 [recte: 2 Timothy 3:7]) is verified to the letter: 'ever learning, and never coming to the knowledge' [of the truth]; because, when they cannot arrive at perfect knowledge, they turn to useless sophistications, and are commonly shut up to an evil end."

These things were rightly said by Rupescissa, the most celebrated alchemist of his time. Would that, just as he detested the study of alchemy as false, empty, indeed exposed to diabolical illusions, he had also said that he did not know it — for then he would truly have given an excellent testimony of his own genuineness. But since he asserts that he received it not by human study but by divine revelation, I cannot but enroll him in the same number as the other impostors. For he says that both his chemistry was divinely inspired in him — his medicines, I mean, which heal all diseases as if by miracle, indeed which can in a moment's space convert even imperfect metals into gold and silver — and that he received it in prison, through divine revelations. But how a man shut up in prison, and not deluded by Satan, could test the truth of the assertion he had made, who will understand?

[Margin: The panacea of Rupescissa is of no value.]

And as for that panacea, the universal cure of all diseases, inspired in him from heaven — who would believe it, when (as will be plain to anyone comparing the one with the other) he copied it almost word for word from Lull? Certainly Francesco Pico [Gianfrancesco Pico della Mirandola] testifies, in these words, that the man was utterly addicted to vanities — his own, and those who court "vainglory" [Greek: ψευδοδοξίαν (pseudodoxian, "false glory / vainglory")] — and to prophecies: "We read that John of Rupescissa, an otherwise learned theologian, fell into such madness that things he had affirmed about the future he would not retract — neither by threats nor by the prison in which he was held by the minister of his Order — but rather always asserted them the more insistently. At last a lying spirit was found in his mouth; and now a hundred years and more have passed since he was shown to be a liar." The same things are read in Philip of Bergamo [Jacopo Filippo Foresti].

With this madness of mind all the alchemists, to a man, have labored. And although Lull, after his holy conversion, led a holy life crowned with martyrdom, and — having rejected vanity and embraced truth — resolved to consign all his books on alchemy to the flames (had they not been secretly carried off by the diligence of his disciples), nevertheless, before his conversion, that he led a free [i.e. dissolute] life and was much given to vanities is gathered from his own *Life*.

[Margin: Lull, on the panacea.]

Indeed, in the preface to his *Art of Operation* [Ars operativa], he shows in these words that his art was divinely conferred upon him: "One night," he says, "as I rose from sleep, the following things were revealed to me — most vile and

unworthy sinner that I am — which had indeed been distinctly set apart [and] revealed earlier to Blessed Giles, dwelling in the hermitage."

[Margin: Lull, [received] his art by revelation. (catchword on prior line)]

If, then, Lull was skilled in the great art of the Stone, and made gold in England (as that same Robert, an alchemist, testifies of him) by the divine revelation in which he glories — surely by this very fact he taught that it cannot be done by human art. But whether he made that gold by the power of the Stone, in the manner customary to the false alchemists, will be examined afterward. Certainly some dispute the history; others have strenuously denied it, and Paracelsus and Bernard Trevisan have shown it to be empty. Of these, the latter says that [he interspersed among his] books...

we cannot deny that there are four books composed by Lull — which, however, mislead one from the right road rather than direct one to the goal.

From all that has been brought forward, the fashioned and counterfeit ingenuity of the alchemists is plainly evident in their deceptions; so that no faith whatever is to be placed in the gold-making art. And so the alchemists themselves — long and much turning the wheel in their alchemical kitchens, like Ixion, with fruitless effort, at the greatest expense, their labor spent uselessly, accomplishing nothing in the great work of the art — driven, as it were, across [the field] by despair, deserted the Hermetic camp and betook themselves to that far nobler and more useful chemistry which consists in the care of the human body and the cure of all diseases, as their books teach.

But I proceed to the third objection, by which the alchemists are said to have been men devoted to God, merciful and generous toward the poor, and illuminated in the great work of the art.

[Margin: Solution of the third objection.]

Let us now unfold a little the sanctity of these men. What sort of man Lull was before his conversion has been declared above — though, afterward illuminated by the divine light, he came to recognize his errors and vanities, and so, in works of penance, having repudiated the utterly vain exercise of his former studies, he followed the eremitic life for a while; and then, devoting himself wholly to works of charity toward his neighbor, at last, in Africa, while propagating the Christian faith, he is said to have ended his life with the happy end of martyrdom, overwhelmed with stones.

[Margin: Lull crowned with martyrdom in Africa.]

See his *Life*, described by Fr. Caussin [Nicolas Caussin] no less piously than elegantly.

As for Arnold, Paracelsus shows clearly enough that the gold he made in the presence of Robert, King of Naples, was sophistic.

[Margin: Arnold given over to illicit [arts].]

And how much he was given to magical arts, Francesco Pico testifies: that he attributed magical bindings to the powers of nature; and that, besides being not very well versed in natural things, he was also infected with much superstition, Pico shows in his little book *On the Operative Part*. He also lays claim to the gift of prophecy, as the same Pico, cited, reports:

[Margin: Arnold laid claim to the gift of prophecy.]

"Arnold the Spaniard," he says, "besides what he had conjectured about the future coming of Antichrist, adduces a certain revelation, [made] of many and great matters, in his book *On the Mysteries of the Cymbals*, and [concerning] the coming of Antichrist, [given] to the monks of the Ladder of God — for which he fixed a hundred years for the events. But two hundred years have now elapsed, and it is established that the prophecy is still unfulfilled."

[Margin: It is established that this man came to such madness — Arnold impiously asserts.]

It is established, moreover, that this man came to such madness that he boasted he had perfected a perfect man by the chemical art; and "when," he says, "he had found in the chemical vessel [in vitro] an embryo furnished with all its organs and members, he ceased from the work, lest he should seem to compel God to infuse a rational soul into it." O impious doctrines! O Satanic machinations of men! Here you have the author of the diabolical "deification of man" [Greek: ἀνθρωποτεχνία (anthrōpotechnia, "the artificial making of man")] of the arch-chemist Arnold — worthy of the flames rather than of any praise of genius, and consequently rejected by God.

And yet do the little chemists [chymicatri] reckon such scoundrels devoted to God?

There follows Paracelsus, whom — since they report that he was defiled with the whole sink of every crime — who will persuade himself accomplished anything either in medicine or in the great work of the art?

[Margin: What sort of man Paracelsus was.]

But, that I may not seem to have done him an injustice, I shall here attach the most trustworthy authors, [reporting] what was written about the virtues of Paracelsus by Oporinus, first his amanuensis and servant; what by Heinrich Bullinger [Heinrich Bullinger], Erastus [Thomas Erastus], Gesner [Conrad Gessner], his fellow countrymen — hear and shudder. Bullinger, in order to test what religion he practiced [writes]: "I lived with him once and again, [discussing] various matters, even theological, and of religion; but from all his conversations it was possible to perceive nothing of piety — but much rather of magic, which, I know not how, he was always feigning. For the most part he was an inseparable companion of carters, in whose company he took delight, and he was their boon-drinking comrade." And a little after, with Oporinus and Erastus subscribing: "In short," he says, "he was filthy in everything, and a foul man; rarely or never did he enter the sacred assemblies, and he was seen to care lightly for God and divine things." Behold the man's distinguished sanctity! In driving out diseases he used for the most part magical exorcisms; and when learned men took this ill, he is said always to have burst out in those German words: "Will Gott nicht helfen, so helf der teuffel" — "If God will not help, let the devil help."

[Margin: Examples from the life of Paracelsus.]

Oporinus, in a certain letter to Johann Weyer [Johann Weyer], writes thus among other things about the life and character of his master Paracelsus: "He was so given over to drunkenness and excess all day and all night (during the two years that I lived intimately with him) that it was scarcely possible to find him sober for one or two hours. And when he was most drunk, returning home, he used to dictate to me something of his philosophy — yet, the whole time I lived with him, he never undressed; for the most part he went to bed only when drunk, late at night, and just as he was, dressed, with his sword laid beside him (which he boasted had belonged to a certain executioner), he would throw himself onto the bed. But often, rising at midnight, he would rage about the room with the drawn sword, striking with such frequent blows at the floor and the walls that more than once I feared my head would be cut off. Meanwhile he pretended to prophesy certain things and made a show of having knowledge of certain secrets; but I never saw him pray, nor heard him do so."

Gessner too — physician and philosopher, and most skilled in chemical matters — testifies to these things: "In our time," he says, "lived Paracelsus, who practiced medicine wandering through various regions of Switzerland [Helvetia], Germany, and Poland. When he ran short of money — and the little he acquired he gave

over to wine and gambling, as constant report has it — he would treat people [for nothing]; he employed a familiar demon, as I heard from his disciple; he was more learned by nature and eloquence than by letters and study; thoroughly inconstant, now a theologian, now a physician, now a magician, often a drinking companion and gambler among the peasants. Indeed he confessed himself a murderer, as Erastus attests, and was several times thrown into prison on that account, or even for other reasons." And these are the virtues of Paracelsus...

worthy of a prophet.

[Margin: Paracelsus contemptuous toward all physicians.]

But how Paracelsus behaved toward all the physicians of past ages — Galen, Hippocrates, and as many as followed them — how unheard-of his stubbornness of mind, both in repudiating the writings of better authors and in exalting his own — let anyone who has leisure read the book he titled *Paramirum*, and he will be astonished at the utterly intolerable insolence of an immoderate mind. And this is to be "a man devoted to God"!

For if, besides a brain perpetually steaming with the drunkenness of wine, and a belly, he acknowledged no other god; if he was a cultivator of demonic magic, of the Cabala, and of depraved arts — who will allow that the knowledge in which he glories was received from divine revelation? How will you suppose that into a soul subject to so many and such great vices and sins, the wisdom of God, or the gift of prophecy granted to few, could enter? Surely such men by no means have God for their master. Who will persuade himself that that man was wisest precisely when he was most raving mad? Who will judge that all men of sound mind were surpassed in the pursuit of wisdom by a raving and foolish scoundrel?

[Margin: Praise of Hippocrates and Galen.]

All confess that none was more learned than Hippocrates; that in simple medicine none has written more or better — with such fidelity that he wrote nothing he wished us not to know; with such skill that few after him have known what he did not know. Truly Galen marvels at his "thoroughness" [Greek: τελειοτάτην πραγματείαν (teleiotatēn pragmateian, "most perfect treatise / treatment")]; he freely acknowledges this man's immense diligence, by which he enclosed Greece and Latium in a single volume, gave novelty to old things, authority to new, luster to the obsolete, light to the obscure, charm to the tedious, credit to the doubtful. Yet this man, together with Galen and Avicenna,

[Paracelsus] reckons of no account — about whom that drunken glutton, in the preface to his *Paragranum*, says that "he received his letters from Galen out of hell"; that "with Avicenna, in the vestibule of hell, he disputed about his own potable gold [aurum potabile], the tincture of the physicians, the quintessence, the Philosophers' Stone, the Mithridatic, and the Theriac." All of which, as they are far removed from the mind of a wise man, so too you may judge them to be the dictates of nothing but a drunken and besotted mind. And this he indicates also in what follows, with utterly intolerable and unexampled boastfulness, in such words as these:

[Margin: The arrogance and pride of Paracelsus.]

"This," he says, "be told to you, O physicians: the most foolish cap of the back of my head knows more than you and all your writers; and the buckles of my shoes are more learned than your Galen and Avicenna; and my beard has more experience than all your academies. As I please, so I shall judge in this very hour, when you drag us into the mud; you must follow me, not I you. You shall all follow me — Arabs, Greeks, Latins, French, Italians, Germans, Sarmatians [Poles], all of you, I say, shall follow me, not I you. Not one of you shall remain even in the most hidden corner, where all men make water. I shall be monarch; mine shall be the monarchy; I shall wield my monarchy and shall gird your loins."

[Margin: Paracelsus despises all the leaders of medicine.]

These are the words of Paracelsus, of which you will find a huge mishmash in the book he calls *Paragranum*...

where, in so many obscene, dishonorable words — words that would lash chaste ears in an extraordinary manner — he rages against the most consummately wise men of all wisdom: so that nothing more foolish, more superstitious, more obscene and immodest can be uttered by a creature endowed with reason; and thus he can seem not so much illuminated by God as possessed by a demon.

[Margin: The scurrility of Paracelsus.]

For what is more alien to reason than to call the glorious monuments of all the sages of the Greek school "excrements, filth, leavings" — not [to say] that they know more, as he says in his *Paragranum*, "than a Swiss cow understands"? O how much better it would have been if Paracelsus, in his *Paragranum*, had prepared a grain of salt [granum salis], mixed with a pound of hellebore — so that, his brain thus purged, he might have grown wiser, and so that the most shameless scoundrel, the trivial buffoon, the most insolent braggart [Thraso],

driven by infernal furies, might have been freed from so great a madness of mind.

[Margin: Paracelsus, blinded by his own genius.]

For my part I can truly testify that, with the greatest diligence, I have perused all his books with the keen eye of a discerning mind — impelled both by curiosity and by love of truth, that I might learn what lay hidden in them, which others so greatly admired. But after I had duly annotated everything except a few small points — which, however, were not his own — [I found] nothing but trifles, affected verbal formulas, conjectures founded on air, experiments falsified: not only concerning the properties of natural things, but also concerning the virtues of minerals, little stones, gems, and metals, and their causes — for the most part received from miners and from quack apothecary-women. All of which I could refute in this place by contrary experiments, if both time and the argument of the work permitted, I found [to be so].

[Margin: The crime of plagiarism in Paracelsus.]

Almost all of it is filched, partly from Lull and Arnold, partly from Isaac Holland [Isaac Hollandus] and Basil Valentine [Basilus Valentinus] — whom, however, lest he be found guilty of the crime of plagiarism, besides reproachfully reproving those from whom he had stolen his doctrine for their useless labor, he also wrapped in such a thick fog of similitudes that, in the clearest waters, by a flood of the blackest color, he more truly played the cuttlefish [polypus] than the spring.

[Margin: The impious cultivation of the Cabala.]

I have seen, moreover, that whatever he wrote about the Cabala, he drew entirely, to a man, from the superstitious workshops of the Hebrews and the Saracens — as I have demonstrated at length in the *Oedipus* [Oedipus Aegyptiacus], Volume II, *On the Cabala of the Hebrews and the Saracens*. To both the Hebrew and the Saracen Cabala the impious man placed such great faith — in his *Paragranum* and *Paramirum*, in the *Archidoxa*, and indeed in the books *On the Origin of Invisible Diseases* [De origine morborum invisibilium], in the *Manual on the Philosophers' Stone*, in the book *On the Vexations of the Alchemists* — that he asserts, no less stupidly than impiously, that all the prophets of the Old Testament accomplished their prophecies by no other means than the help of the Cabala. And yet neither of the two — I will not say did he understand, but he could not even read, hindered by his ignorance of the languages. For, employing only the familiarity of certain Jews and Turks, [he drew] from those Satanic workshops...

some things — and indeed, the more impious and diabolical they were, the dearer he held them — he inserted into his miscellaneous notes [schediasmata] here and there, supposing that some great thing lay hidden beneath them, something that had proceeded from Satan, his teacher and master.

[Margin: Paracelsus the superstitious.]

For whatever the Cabalists teach about incantations [enchantments], exorcisms, superstitious amulets, charms, and phylacteries, he adopted into his store as if they were sacrosanct mysteries. From this source flowed out into the world that impious and Satanic fiction which, impiously and in their usual manner, they call "Mosaic philosophy" [philosophia Mosaica], and the armary ointment [unguentum armarium], which they teach to be compounded in manifold ways.

[Margin: Mosaic philosophy [taken] from the alchemists, impious.]

In this you will find scarcely any ingredient that has not been wrung from the hand of an executioner — just as the sword of some notorious executioner or other, Paracelsus's inseparable companion mentioned above, sufficiently demonstrates. From this same source proceeded the "transplantation of diseases" [transplantatio morborum], filled with countless superstitions and ravings; and as these are unworthy of being recounted, so too — since I have refuted them in our *Magnetic Art* [Ars Magnetica] and in other works — I now say nothing of them.

But how given over to magic Paracelsus was, he himself testifies in his book *On the Composition of Metals* [De compositione metallorum], where, after he had long discoursed about Electrum and the virtues hidden beneath it through all the ages, he at last adds:

[Margin: Paracelsus given over to magic.]

"Yet I cannot fail to mention what and how great a miracle I saw in Spain, when I was with a certain necromancer who had a bell of perhaps two pounds' weight. By the magical ringing of this bell he summoned and brought forth many and various specters and visions of spirits. For when he had inscribed certain words and some characters on the inner part of the bell, the moment its sound and ringing were heard, the spirit appeared in whatever form he wished. Moreover, the ringing of the bell was of such power that it would produce and bring into the midst, and take away, as many other visions of spirits — of men too, and of beasts — as he wished: many things of this kind I saw at his place. This, however, I

observed: that if he was going to work anything new, he would renew and change the characters and the [name of the] mistress."

[Margin: The magical bell of the Marquis of Villena.]

"But I did not come so far that the man would communicate to me the secret of the words and characters. At last I myself desired to investigate this matter more deeply — so that things came into my mind which we shall here pass over in silence. Know, however, that there was more import in that bell than in words. And I wish you to believe me most firmly: that the material of that bell was our Electrum." Thus far Paracelsus.

But about ten years ago, a copy of a bell of this kind — in the shape of a basin, marked with countless magical characters (which the Spaniards say belonged to the most celebrated magician, the Marquis of Villena) — was transmitted to me from Spain through the most learned Father Thomas de Lyon [Thomas de Léon], a most distinguished theologian and a "polyglot" man [Greek: πολύγλωσσον (polyglōsson, "of many tongues / master of many languages")], with the intention that I should explain what all those many and great characters and the display of exotic figures meant. What I was bidden to do, I performed; in which I found whatever the necromantic arts hold hidden, as it were compiled in a kind of epitome. See the explanation of this in the *Oedipus*, Volume II, part 2, *Syntagma on the Magic of the Egyptians*, where I warned that the things Paracelsus so greatly desired to know are to be shunned, with all oars and sails, by all who are imbued with the fear of God, like the nets of Satan.

[Margin: The qualities of the things produced by the chemical art.]

One thing I cannot pass over, and it is this: that Paracelsus, gradually overstepping the bounds of natural philosophy, and following the above-cited Arnold — a man of no degenerate genius — boasts that he can generate a true man by his chemical art. But, that I may show how great a thing the impious alchemists dare against all the divine and human laws of Nature, by Satanic machination, I append the process.

[Margin: The chemical art impiously claims to produce a man.]

Thus, then, he says, in book 1 *On the Nature of Things* [De natura rerum]: "There was a question," he says, "among certain of the ancient philosophers (of whom, however, besides Arnold, I know no other) whether by art and nature a man could be made outside the female womb and the natural matrix. To this I answer that it in no way contradicts the spagyric art and Nature — nay, it is quite

possible. But that it may be done, one must proceed in this way: Let the sperm of a man putrefy by itself in a sealed cucurbit, with the putrefaction of a horse's belly [i.e. the warmth of horse-dung] (this is a vessel familiar to chemists), for forty days, or until it begins to live, move, and be agitated, which can easily be seen. After this time it will be in some manner like a man, yet transparent and without a body. If now, after this, it is daily nourished and fed, cautiously and prudently, with the arcanum of human blood, and kept for forty weeks in the perpetual and even heat of a horse's belly, it becomes a true, living infant, having all the members of an infant born of a woman, but much smaller. This we call a homunculus; and it must afterward be raised, in the same manner as any other infant, with the utmost diligence and care, until it grows up and begins to be wise and to understand. This now is one of the greatest secrets which God has revealed to mortal man, subject to sin; for it is a miracle and a great work of God, and an arcanum above all arcana, and deservedly ought to be kept among secrets until the last times, when nothing shall be hidden, but all things shall be made manifest."

[Margin: The qualities of the things produced by the chemical art.]

He says, next, that of old there were — and even now still are — Satyrs, Nymphs, "Evestra" [Evestra, Paracelsian astral/elemental beings], Mountain-spirits [Montani daemunculi], Pygmies, and Giants, sprung from this kind of chemiurgy. For these men, produced by art, when they have reached the age of manhood, turn out to be miraculous men, and become instruments of great affairs, renowned and illustrious for mighty victories; moreover, all these, as they obtain their life by art, so too acquire all the secrets and hidden things of Nature.

I strongly suspect that Paracelsus himself may be one of these so wondrous offspring; for, since in his *Paramirum* he glories that no one knew more than he, and besides testifies in many places that he was "self-taught" [Greek: αὐτοδίδακτος (autodidaktos, "self-taught")] — that he learned his knowledge of the hidden mysteries of Nature from no one else — I would assert outright that he was conceived, if not from his mother's womb, then certainly from some Ephialtes [incubus-nightmare], or from an Incubus, or from some other horrendous demon, as from a rotten and poisonous fungus...

[Continuation of **Liber XI "Chymiotectnicus," Sectio II "De Lapide Philosophorum," Caput VII** — the Paracelsus invective and refutation of the alchemists.]

that this monstrous thing was conceived and brought forth as a spurious offspring of its nature — a son of Fauns and Nymphs, more like a demon than a man.

[Margin: An author detected by his lurking foul nature.]

From this foolish alchemical handiwork [Chymiurgia] it is plain how reckless this man was in making assertions, with what ill-considered haste he had the audacity to blurt out whatever he pleased, and how rash he was — rash, I say, in matters from which not only God and Nature, but even reason itself shrinks back. What physician or anatomist does not know that it is as impossible to generate a man outside the female vessel as it is impossible for the seed of a brute animal, cast into the earth, to bring forth a brute of the same kind? Who will assign, in a glass cucurbit, a heat utterly heterogeneous to the maternal warmth and contrary to nature itself? Who will provide nourishment, proportioned and conveyed through the umbilical vessels and veins — indeed, the portion of maternal seed necessary for forming the fetus — by means of human blood (as Paracelsus himself prescribes) that has already died outside the veins and is wholly ineffective? Surely no one can fail to see that this has been granted neither to an Angel nor to a Demon. And who will infuse a rational soul into an embryo already organized? Or do you perhaps suppose that God, the Best and Greatest, can be solicited by Satanic ministers of this sort to lend His concurrence to such a horrendous genesis? Yet who does not know that even to think this is impious, blasphemous, and atheistic? But grant — through an impossibility — that a soul were infused into this diabolical embryo: would it not follow that such a human monster, just as it would be exempt from the common laws of human generation, would likewise be immune from original sin and from the other miseries of the human condition that are subject to sin? And I do not see what could be said more impious and blasphemous than that. O the patience and long-suffering of Divine mercy, which does not overturn the prodigies of such monstrous men by the example of Korah and Abiram! But let this suffice to set before the eyes of the truth-loving Reader the enormous and plainly prodigious offspring of Bombast [Paracelsus].

[Margin: The Brothers of the Rosy Cross are Magicians.]

Like these are those brethren who take their name from the Rosy Cross — an impious breed of men, swollen with diabolical commerce. Of this kind were Cornelius Agrippa [Cornelius Agrippa von Nettesheim], famous for his learning in every branch of the diabolical arts — a man whom, as is more than sufficiently established from his life, the demon finally strangled, so that he paid the penalties

his crimes deserved. Such was Sendivogius [Michael Sendivogius]; such was Robert de Fluctibus [Robert Fludd]; such was the Marquis de Villena [Enrique de Villena]; and countless others whom it is irksome to recall — all of them Magicians and Alchemists. Their doctrine was that it is permitted to learn something from the devil, provided it concerns the knowledge of natural things.

[Margin: The doctrine of the Brothers of the Rosy Cross.]

And these men, indeed — instructed by the devil, the enemy of the human race — are said to have made gold and to have cured all kinds of diseases, but on this condition: that for every ten they cured, they should always kill one. Their insane doctrines are such that they are more worthy of eternal silence and darkness than of light. Hence the learned Conring [Hermann Conring], in his distinguished book *On Hermetic Medicine*, rightly observes: *However sharp Paracelsus's wit may have been, still he was not of a temperate character, such as the wrestling-school of truth demands; and certainly his own morals do great prejudice to the Paracelsian doctrine. For what indeed can one expect of solid doctrine from a man of bad character? Indeed, I would not deny that the demon may even breathe into a man something of true knowledge; but it has not hitherto been found that anyone has become wise by the demon's aid without at the same time being led into very many errors — the father of lies compensating for one betrayed truth with a thousand falsehoods.* Since, then, Paracelsus was such a man, who could ever persuade himself that so great a fabricator of lies actually made gold — not to say that he knew the art? I am well aware that he had many followers, and that countless treatises *On Gold-Making* have appeared and continue to appear daily. Yet all these, since they rest upon the weak and feeble foundation of the very men we have cited, will likewise — whatever they say, write, boast, swear, and forswear about the structure of the blessed (or rather, the cursed) Stone — bring forward nothing at all that deserves belief.

But lest I seem to judge unjustly, like a blind man about color or a deaf man about sound, let me now at last disclose by what methods, by what arts, and with what dexterity they have deceived both princes and common folk — and do not even now cease to deceive — so that the truth may finally come to light.

[Margin numbered: 1 Imposture. 2 Imposture. 3 Imposture. 4 Imposture. — keyed to the four frauds described below.]

has no vegetative life at all, neither on the part of the agent nor on the part of the patient — who does not see this?

[Margin: The hindrances that keep the alchemists' art from reaching its intended goal.]

We have also said that it is impossible for those who work from this exemplar to attain their intended end. For through so many calcinations, sublimations, dissolutions, putrefactions, and fermentations, so far is it from happening that the one so greatly desired form of gold emerges, that rather — through so many torments of fire and of the most pungent waters — the whole matter is carried over into a thousand other forms, and at last that whole intended form perishes and is destroyed. There is the further point that the degree of heat is unknown, and the combination of the substances to be matched together rests on an indivisible point, which it is denied to human ingenuity to attain. We have also brought forward the contradictions of even the foremost Alchemists, met with everywhere — which by their plain testimony indicate that what is exposed to so many difficulties, disputes, dissensions, and quarrels cannot stand firm; for truth is one and simple, and once revealed it is never deprived of its certainty.

But since the whole business turns on the golden argument [aureum argumentum] as its hinge, and since men are borne by a kind of natural gravitation toward that which can make them happy and bless them with the possession of every good thing, it is certainly no wonder that gold is sought with such zeal, with such great labors, with such keen effort; that it is so anxiously desired; and that the common crowd so readily believes it can in the end be acquired by applied study. But lovers fashion dreams for themselves. And this, I think, is the one reason why — as today, so in past ages — no art has been more eagerly pursued than this gold-bearing one, none more ardently desired, none exposed to so many deceits and impostures; the Devil, the enemy of the human race, for the most part mixing himself into endeavors of this kind, while men hope to grow rich through the art. From this there have crept into the World monstrous superstitions, diabolical illusions, irreparable harms to commonwealths, and the ruin of Kings and Princes.

[Margin: The author's intention in exposing the imposture of the Alchemists.]

Therefore, so that the falsehoods and solemn impostures of these little men [homunciones] may be uncovered — for the glory of the Divine Majesty and for the good of the whole literary commonwealth — I have judged that I should here set forth the frauds and deceptions by which they are accustomed to drive mad not only princes, but even learned men themselves, and the common people too.

Who does not marvel and stand astonished at the stupendous feats by which, for the sake of gain, mountebanks, hucksters, street-charlatans, tightrope-walkers, and the rest of this stamp of men circumvent the unschooled crowd by sleight of hand and bodily agility? Even though these tricks are empty, futile, false, and deceptive, they nonetheless earn such credit among the surrounding multitude that they can pass — if not for the illusions of demons, at least for miracles of Nature. They promise mountains of gold; indeed, they promise that by the chemical art they will turn the sea into gold and the sand of the sea into silver, by means of that counterfeit mercury of theirs. And lest they seem to waver in their credibility, some free their reputation by the following sophism:

The first imposture. [Margin: 1 Imposture.] They take a certain powder, red or white, of which they boast so greatly. Then they pretend that they need a certain sum of money to complete the art; once this is given, they mix it together with the powders into a crucible, into the metal which they claim they will transmute, thoroughly stirring it over the fire with a hazel rod. At last, when mercury has been poured over the whole mass, the bystanders see the whole mass either gleam red or shine with a silvery color, as though it had turned into gold — and, like dolts, stand astonished at the unaccustomed marvel of the thing. They proclaim themselves blessed if only they might share in so great a secret through this short shortcut to wealth, and so they promise anything whatever to gain possession of the secret. Once they possess it, they produce a spurious birth of gold — which, when shown to the money-changers [Collybistae], is found to be nothing but that ordinary metal, steeped in a useless tincture; and they extract only as much gold as the price of the injected powder had been.

The second imposture. [Margin: 2 Imposture.] Some put a powder of gold or silver — in a way that will be taught later — into hollow wooden tubes, with Greek pitch or colophony resin added, so that at the mere smell of the fire it readily melts into a fluid like wax. This done, with the crucible set on the fire and filled with whatever metal you please, they pour in the golden powder, stir the material around, and the powder placed in the hollow rod sinks to the bottom and is restored to its original nature; while the mercury, dissolved into smoke by the burning heat of the fire and the remaining metals separated out, they find gold at the bottom — to the great admiration of the dolts.

The third imposture. [Margin: 3 Imposture.] Some disguise the fraud by putting golden powders into a larger hollowed-out coal, or even into the channel of the bellows; then, while they pretend that the metal is throwing off its scum, they blow out the golden powder with marvelous dexterity, together [with the scum],

into the cucurbit in which it is melted. By this trickery, once the operation is finished and the gold extracted, they persuade the bystanders of the infallible certainty of the art.

The fourth imposture. [Margin: 4 Imposture.] Jeremias Mader [Jeremias Mader], in his *Acroamatica*, reports a truly amusing example of this fraud and of this nimble [literally "leaping"] art. Two chemists, he says, entered into a partnership confirmed by agreement: that the one should profess to hold the most certain art of gold-making [Chrysopoeia], while the other should play the *Rhizotomus* (root-cutter) — that is, an empiric mountebank — and among other things should sell gold-filings dyed black as a "lunar powder" [Lunary powder]. Ernst [Ernst], Margrave of Baden [Ernst, Markgraf von Baden], was wonderfully devoted to this pyrotechnics. So the first of the pair approached him, promising mountains of gold and the halls of wealthy Croesus. Everything is sought out, and now, with everything arranged by a pretty fraud, [he claims] that only one of the ingredients which would produce the intended effect was still lacking — one called **Rech** [רֶחַ], that is, "the head of the matter" [caput rei]; and he says that the powders of this can easily be found at any apothecary's, especially at the *Rhizotomus*'s. To him the Margrave sends a boy to buy the powder. Meanwhile the other had conveniently set out his wares in the palace entrance, and — as this kind of men is wont [usually does] — was proclaiming in a stentorian voice that he lacked nothing. The prince's boy approaches him [to ask] whether the root...

[Margin: Greek root: רֶחַ Rech / Resh — Hebrew, "head."]

[Printed p. 282 — verso, running header "LIBER UNDECIMUS, Sect. II."]

called **Rech** [רֶחַ] he had. The man at once takes a [piece] drawn out from a smoky little box and weighs it out as worth one solidus. The boy carries the purchased root [Rech] back to his master, ground into a powder. The impostor [the gold-maker] then sprinkles that powder over the quicksilver, produces gold, and when it is melted down it is found to be true gold. The matter is wonderfully pleasing to the Margrave, and he, kind and grateful to the Master, dismisses him with the gift of no small sum of money. He presses on to pursue gold-making, and indeed — while the most happy success of **Rech** continued — once the powder was used up, he ordered it to be sought everywhere.

They submit the mass to assay; and when they find [the residue]... ...[the powder]. Others take up gold and silver vessels and tint them with the color of copper or iron; then, by pouring mercury onto them, they separate out the gold and silver, and in this way they extract what was rubbed off the gold by the corrosion of the

mercury, and sell it as gold and silver, though it was drawn out of copper or iron. Some pretend to extract mercury from lead, and promise to fix this into silver; and just as they perform this in countless fictitious and counterfeit ways, so too they inflict very grave loss on those who put their trust in such scoundrels.

[Margin: The author detects an imposture of this kind by impostors.]

I myself, too, more than once learned firsthand the audacity of darkness-loving rogues of this sort, who would deliberately come to me — whom they knew to be devoted to the secrets of Nature — to share, as it were, the most profound, great, or rather ruinous secrets of their art, but on this condition: that I should provide the expenses for the trial of their art. I promised I would do so, if they would first show me the method and procedure. Although unwilling, they were nonetheless compelled, and began to reveal the method to me. I at once caught the scent of the fraud; and after I had convicted them of open imposture, when at last they begged me to forgive their boldness — confessing that, pressed by poverty, they sustained their lives by such means — I first scolded them soundly, then dismissed them with the gift of some alms, but with the warning that they should support their lives by a better art, lest at some time they should pay for this rashness, hung up by a golden rope.

The fifth imposture. [Margin: 5 Imposture.] There are, furthermore, others who dissolve a golden powder in water until it settles under the appearance of oil; afterward they say that with this powder they will bind a metal so as to convert it into gold. Others pretend to extract the soul from gold and silver by means of cinnabar, from which, when the mercury is separated, that [residue] remains fixed; into this they then slyly mix gold or silver, and then together, by chemical sublimation, they extract the cinnabar, which they assert has been converted into gold by the power of the soul. Others, by sleight of hand with which they hide the golden powder, then order some instrument or other to be handed to them by a bystander, and meanwhile they throw the counterfeit gold into the crucible; once this is extracted, they are accustomed to drive the bystander out of his wits.

[Margin: Various impostures.]

There are also those who fill certain little caskets with various powders mixed together with gold and silver powder, on which — to cover the fraud — they impose exotic names of herbs and minerals. Afterward they approach one of those whom they know to be devoted to chemistry, and offer to sell him a vast secret of the Great Art for a few coins, promising that they will teach him the truth of the gold-making art by experiment — provided that the expenses

incurred in making the gold be repaid; and [the impostor promises] that, if [the buyer] should not find the truth of the matter, he will subject all his own goods to confiscation. They therefore order [the buyer] to purchase gold powder, already dissolved by aqua regia into a sickly and friable substance; they begin the work, and to the admiration of the bystander draw out the purest gold. Hence the spectator, made bolder by the acquisition of so great a good, and more credulous than he ought to be, and being a man of rather simple mind, asks for the art at whatever price he pleases. The impostor names such-and-such a sum, and once the money is taken, immediately makes off. The other, spurred by excessive desire to have the art communicated, while he more eagerly seeks that powder christened with some exotic and monstrous name, and finds the material neither at the apothecaries' nor at the herbalists', at last finds himself cheated of his purse and emptied of his coins.

[Printed p. 283 — recto, running header "DE LAPIDE PHILOSOPHORUM."]

[Continuation from p. 282, left column — Kircher's account of the Hebrew booklet:]

[Margin: The foolish contrivances of the Rabbis.]

Not long ago there was sent to me a little book written in the Hebrew tongue, stuffed full of the secrets of Nature — or rather, of lies. In it, among other things, an herb was described, by the name of **boriza** [בוריצא], by which that insipid Rabbi asserted that any metal whatsoever could be turned into gold. And since the matter is worth it, I append the ridiculous procedure, from which it will be apparent with what incongruous things sycophants of this stamp are wont [accustomed] to impose upon people. He speaks thus: בוריצא והיא עשב ששמה — לונאריא — *Boriza, and it is an herb whose name is Lunaria.* But omitting the Hebrew words, as being rather long, let us set down the translation itself. Hear it, then — and laugh, Reader — at these foolish promises:

Send the juice of this herb into quicksilver, and make it boil in this juice, and it will become a red broth; from this make a powder, which, thrown upon copper, will turn it into gold; and one ounce of this powder suffices to convert a hundred ounces of copper into gold. This herb is born by springs and rivers, and on high mountains (as I reckon, more truly in Utopia). It has a red and violet stalk, and a milky sap like saffron (I interpret it as Celandine [Chelidonia]). Take the juice of this herb and place it upon quicksilver, and it will become copper — O great profit! And if you place some of it upon lead, gold will result. The juice of this herb placed upon iron will become silver; and the powder of this herb placed upon silver will make gold;

and if you put it into urine with spikenard, and let off one ounce daily, it will transmute old men into young men.

But these foolish contrivances of the Cabal... ..of the Cabalists, let us leave to be refuted not by Philosophers, but by delirious old women.

I could bring forward here countless examples from the solemn frauds of the Arabs, which are found scattered throughout their books on the minerals of Nature and inserted there concerning gold-making. But since they are unworthy to be reported, I have judged that they should be suppressed in silence.

Caput IX.

That the Demon Mostly Mingles Himself with the Devotees of Alchemy

[Quod daemon ut plurimum se Alchymiae cultoribus immisceat.]

[Margin: The love of gold drags most men into ruin.]

Most truly did St. Paul say, in his Epistle to Timothy, chapter 6, verse 9: *Those who wish to become rich fall into temptation and into the snare of the devil, and into many desires that are useless and harmful, which plunge men into ruin and perdition; for the root of all evils is greed [cupiditas], which some, in their craving, have wandered away from the faith and entangled themselves in many sorrows* [1 Timothy 6:9–10]. So it is. It is the immoderate desire for riches — the net of the evil demon [cacodaemon] — with which he does not cease to drag a great part of the human race, as of old, so always down to this very day, into the ultimate ruin of their souls. Since there is nothing in human affairs that is sought with greater desire, or pursued with greater anxiety, than the heaping-up of treasures and riches — for that by the possession and unjust seizure of these a door has been opened to every kind of vice and crime, countless examples teach us. For those who abound in riches can obtain whatever they wish, whether power, or the ambitious acquisition of honors and dignities, or a worldly life swollen with pride and crammed with the rest of the delights of the flesh.

[Margin: By what methods Satan deceives those greedy for gold.]

Hence it is no wonder that Alchemy — the one most deceitful promiser of such great riches — is so highly esteemed, and so anxiously courted by all men of whatever condition. The enemy of the human race is not ignorant of this burning thirst for gold, and so he assails incautious mortals with arts the more dangerous, the more hidden they are. It thus happens that, while they pant after gold with

excessive desire, and are for the most part hindered by the insuperable difficulties that arise in the Great Art, all hope of attaining the art being taken away — and since nonetheless, anxious between hope and fear, they pursue the longed-for possession of riches all the more eagerly — at last, driven sidelong by desperation, they either give themselves over to treasure-hunting, or, summoned by the magical arts of the evil demon, they implore his aid to perfect the art. And so at last, bound by a Satanic pact, having fallen headlong into every pit of impiety, they end their lives in wretchedness, without any fruit at all.

I myself have known many deceived by illusions of this sort — especially the more curious students of learning, who without prior examination, without light, ill-advisedly and with utterly rash daring, embraced the vanity of Alchemy, and, by the just judgment of God, were deceived by the devil and perished, dashed against a thousand precipices of error. For how dear it is to the demon's heart to assail men devoted to such arts, we have demonstrated at length in the first Part of the *Oedipus* [*Oedipus Aegyptiacus*], On Idolatry. For demons mingle themselves secretly not only in those mockeries of the magical arts, but in all the other vain and insane practices that take their origin from these — astrology, divination, and the cabalistic arts, and all those kinds of things that take their name from μαντεία [Greek: manteia, "divination"]. By these they circumvent the curious through their excessive credulity, so that those who neglect to be on guard against their snares vanish away in their own thoughts, and while they believe themselves wise and workers of marvels, become fools, until at last they have, as the master from whom they profit, the partner [demon] of both impiety and eternal exile. Especially does the enemy of the human race assail those devoted to Alchemy in marvelous ways; and sometimes he so dazzles the keenness of their eyes that, while practicing pyrotechnics, they have sworn that they made true gold and silver by transmutation. Yet afterward, although they attempted the same work again, even repeatedly and with great care applied, they testified that they could never find any success.

[Margin: A marvelous example of a man deluded by the demon.]

Countless instances of this matter are read everywhere among the Authors: Delrio [Martín Del Rio], Pererius [Benedict Pereira], Quibert [?], Hogeland [Ewald von Hoghelande] — to whom let the Reader turn. Here I shall narrate only what was related to me by word of mouth by a man most skilled in the chemical art (whose name I deliberately keep silent), who had been deceived by the demon through a similar illusion. He had heard of my experiments in this study; and so he came to me, asking what I thought of the great mysteries of the art. Discussing

the argument back and forth, I at last concluded that the great mystery of the art, like that of the Stone, consists of mere metaphysical speculations, and that those allegorical senses, which both the Arab Alchemists and the Latin chiefs of this art concealed under such great similitudes of things and under enigmas, are of such a kind that they can easily be accommodated to anything whatever — as I had set forth in the hieroglyphic Alchemy of the Egyptians. He answered: *You have said well, Father. Hear what happened to me.* From boyhood [I had been devoted] to this kind of study... ...[having spent] many years, [and] several pious [men] in it, with no profit; and when on a certain day, [my] aim being intent on the alchemists' goal — that is, on making the Stone — while I was wholly absorbed in it, and was thoroughly persuading myself that I had penetrated the arcanum, a certain man, previously unknown to me, came up to me. After greeting me with very kindly words and wishing me well, he asked what I was doing, and to what matter I was devoting myself with such great solicitude. When at first I delayed to answer, he said: *I see from your chemical vessels and from the heap of materials that you are attempting something great in the chemical art; but believe me, you will achieve very little of what you intend.* I answered: *If you know anything better, I should like you to teach it to me.* He said: *I will obey your wish willing[ly]...*

[The narrative of the man deluded by the demon continues beyond this opening.]

[Conclusion of Caput IX of Sectio II "De Lapide Philosophorum" — the chemist's narrative of the demon-stranger, continued from the prior page.]

willingly; so sit down and write out the true method of proceeding. I at once seized a pen and took down the words he dictated, divided into twelve points; and once I had taken them, he said: "Now let us carry these into practice, with you doing the operation, in exactly this order and according to the prescription of the precepts." When this had been done, at the master's bidding I drew out of the chemical vessel a substance shining like oil, and a mass that had soon congealed when the liquid was poured over it. I reduced this to a powder and threw it upon more than 300 pounds of quicksilver [hydrargyrum], and it turned the quicksilver into pure refined [obrizum] and most noble gold, far more excellent and noble than natural gold — gold that among the goldsmiths would pass the assay of the finest and most perfect gold.

Astonished at this unheard-of result, I could scarcely contain myself for joy. I now believed I had become a Croesus brought back to life, that I had won for myself the riches of the whole world. But what thanks I rendered to so generous a master, you, my father, can imagine better than I could explain in many words. When I asked him where he was from, and where he had learned so divine a

secret, he answered that he wandered the world, needing no one's help or wealth; that to his friends, when they wore themselves out in the desperate pursuit of the great art with fruitless labor, he would from time to time share something of his art with a generous hand, to spur them on in their study. With these words he refused the lodging I had kindly offered, and went off to a public inn.

The next day, at first light — for I had spent the night in continual wakefulness, out of excessive joy at the art I had attained — I went to the inn to give renewed thanks to my munificent benefactor. I asked for my guest, but the innkeeper said he had had no such guest that night. I went round all the inns of the city, but everyone said they had not even heard of the man I was looking for. I searched every more notable house in which I could suspect he might have stayed the night, but in vain: he had vanished, gone, slipped away, to my very great sorrow — for I had hoped to receive from him many more of this art's secrets.

So I returned home and, without delay, set about producing a fresh specimen of the art I had just acquired, following the precise tenor of the precepts he had dictated. But when the operation was carried out, I found no success in the matter. And because I believed this error had come about either through some carelessness of mine or through the omission of some of the ingredients, I repeated the operation with the greatest possible diligence. Yet again I was cheated of my hope, and I began the operation again and again, at so great and so many expenses that I spent all that gold I had acquired in the first projection. And just as the hope of gold made me wonderfully restless, so too, by repeating the work, I incurred so many expenses that the matter nearly drove me to despair.

[Margin: The fraud of Satan is exposed.]

And when I had disclosed my mental affliction to a certain religious man, learned and pious, he at once added: "Do you not see, sir, that this is a most manifest delusion of the devil, who appeared to you in the guise of a man? In order to rouse you to pursue the work, he first deluded you with gold obtained elsewhere, by his usual deceit — so that he might afterward lure you, as you pursued the work with fruitless labor, into consenting at last to some pact, or else, once all your goods were consumed, drive you to despair, and thereby seize as his prey both your soul and your body." At this I shuddered, and from the words that strange foreign guest had spoken to me face to face, I recognized that he could have been none other than Satan. So at once, led by repentance for my past life, I returned home, broke up all the furnaces, smashed the chemical vessels of iniquity, and consigned to the fire [Vulcan] the books I possessed on the subject; and from that day I devoted myself wholly to more profitable and useful studies.

Blessed be God forever, who in his infinite mercy delivered me from such great perils.

I wished to set down this truthful history here so that from it may be clear how greatly the demon strives to delude men greedy for gold, and by how many and how great means he labors to draw them into his snares — both by deceptions and by the thousand tricks of his arts. Whoever desires more of this kind should read the commentaries of Hoghelande [Hoghelande], who experienced similar things, *On the Vanity of Alchemy* [*De vanitate Alchymiae*], and the other authors I have cited above.

SECTIO III. DE ALCHYMIA SOPHISTICA

On Sophistical Alchemy

That is: on that alchemy which, joining gold and silver to copper, lead, and tin, thereby fabricates gold with great increase.

CAPUT I.

On the various false and illicit sophisticated operations of various men.

So great is the cunning and craftiness with which some mortals are endowed by nature, so great their loquacity and eloquence in cloaking their schemes, that they will sell almost anything as anything — not, I will say, only to the more ignorant common folk, but even to princes themselves — when they put on display experiments contrived with such hidden guile that in their presence scarcely anyone, whether philosopher or theologian, dares to make a sound.

[The text continues at the foot of printed p. 285, top of column. The following resumes from printed p. 285.]

[Printed p. 285 — running header: "DE ALCHYMIA SOPHISTICA."]

But the bystanders are so dumbfounded at the display of marvelous things, and conceive so deep a faith in the truth of the deeds performed, and so impress it on their minds, that they seem unable to be torn from it by any weight of arguments or firmness of reasoning.

[Margin: The obstinacy of those who must be trusted in their impostures.]

If anyone should try to charge the impostor with some fraud lurking beneath the experiment, they at once oppose him with these and similar words: "Whatever

the philosophers may say, I truly cannot and will not subscribe to it against the evidence of my senses. With my own eyes I saw it, with my own hands I handled it — a thing beyond every exception. You tire your brain in vain in refuting things we cannot but believe to be true." These people truly do not realize that the same thing happens to them as to Aesop's dog: while eating a piece of meat beside a river, and seeing in the water the reflected shape of a dog that seemed to hold a larger piece of meat in its jaws, it let go of the smaller piece and went after the larger one in the water — and so lost them both.

It is indeed a great thing, and one requiring very keen wit, to distinguish things that resemble one another, and to tell the false from the true, so that the saying "I saw it with my own eyes" carries no weight — since it can scarcely be told in how many ways a man may be deceived, and how easily a deceived imagination persuades itself that it sees or feels something other than it truly is. So it is no wonder that there are found some Pseudo-chemists [Pseudochymici] — men shaped and fashioned for every kind of fraud — who quite presumptuously promise that, with a tiny portion of a contrived powder, at the fire and in a tiny span of time, they can convert lead, tin, copper, iron, and mercury into the purest gold and silver, with the bystanders standing as if stupefied and thunderstruck at so great a secret. Yet to the wise, as nature dictates, this seems utterly ἄλογον [Greek: ἄλογον (alogon, "irrational," contrary to reason)] and devoid of all reason. And although nothing is better known than that, at the fire — by what they call cupellation [capella] — all the other metals are separated from gold and silver, they nevertheless do not know that this can be done by that powder, which they wrongly call the "soul of gold" [anima auri]. For they claim that by the chemical art they reduce one ounce of gold to the quantity of twelve grains, and that one of those grains, projected upon an ounce of any metal whatever, gives that metal body and thereby converts it into gold — since, as they prattle, this grain is nothing other than the very soul of gold.

Now who is so utterly devoid of natural philosophy as not to know that matter cannot receive any form whatever unless it is fit and has a disposition suited to receiving such and such a form? For if nature did not have sufficient power, when it generated copper, iron, lead, and mercury, to introduce into it the form of gold, how could the form or soul of gold — which form, however, cannot be said to be separated from a body, unless we wish to prattle childishly in philosophy — how, I say, could that powder, which they call the soul of gold (a soul, mind you, exceedingly corpulent!), be introduced into metals when its own proper subject has been abandoned: into lead, tin, iron, copper, each of which is

already constituted with its own proper form? Who could conceive of such a philosophy?

[Margin: What of the soul of gold?]

Will there not then be two forms in one and the same subject? If they deny that this is absurd, let them tell me, please, what is to be said of the soul of the lead. Perhaps you will say it has been annihilated; but, lest you betray gross ignorance, watch what you say. And if the form in the powder was separated from its subject, will you then suppose that the subject can subsist without form? But this too is an absurdity equal to the former. You see, then, how stupidly those men philosophize who strive to persuade the inexperienced that such things can be done out of a certain asinine ignorance.

This powder, therefore, which they call the soul of gold — the transmuter of any metal whatever into gold — can by no means be called the soul of gold; rather, it is true and natural gold, turned into powder by the power of strong waters [aquae fortes] or by the corrosive power of mercury, a perfect compound consisting of matter and form. For if such a powder, projected upon some metal, converts it into gold by the power of a soul, then surely there is no reason why a powder made from wormwood [absinthium], for example, and thrown upon the dry, dead stalk of wormwood, should not by the same logic revive it into the herb. The same must be said of a powder made from a burnt animal and thrown upon the corpse of the same or another animal: to believe that an animal would thereby rise again would be the act of an utterly stupid man. Since, then, motion — as the Philosopher [Aristotle] testifies — is the life of all things existing by nature, how can it be that things which have no soul, as metals do not, can nevertheless give life? O the supreme blindness of mortals! — that to some cunning charlatan [Greek: ἀγύρτης (agyrtēs, "charlatan," begging quack-priest)] and busybody [Ardelio], who, apart from his chattering loquacity, possesses no knowledge of things, and so spews forth his frauds and deceits from the depths of his heart — that to such men so great a trust should be given, I will not say by the common crowd, but even by princes themselves, so that among them they are not only esteemed as a kind of oracle of Apollo, but are all but adored! But let us proceed to other sophisms.

[Margin: Sophism 1.]

There are some who boast that they possess an augmentation for gold which yields twenty-five, or even fifty, per hundred. I say that what they promise is not true gold, since it can be separated by the action of fire through cementation

from those things to which it had been joined — which cannot be said of true gold. It is therefore merely a certain tincture which, in outward appearance, so dazzles the eyes with a golden splendor that even the mint-masters [Monetarii] are deceived by that color. Some likewise do this with certain menstruums of aqua vitae, tutty [tutia], and sublimate: these, when dissolved and added to gold and burnt copper [zes ustum] in strong waters, seem to augment the gold. And they say they can sell it as pure gold without scruple of conscience, on the grounds that it has already been approved by a prince as true gold...

[Margin: Sophism 2.]

[Printed p. 286 — running header: "LIBER UNDECIMUS, Sect. III."]

is, in which, however, they greatly deceive themselves, as we shall show in what follows. For such men do the same as the wolf in the fable: he had been bound under conscience not to kill, for his daily food, more animals than would weigh six pounds of their flesh; but, seeing a cow with its calf coming his way, he attacked and killed them both, judging in conscience that the cow weighed only four pounds and the calf only two, which together make the six pounds appointed for his food.

It is clear, then, that those are entangled in a notable error who think that gold can be augmented with something that is not gold. And although they say it is approved by mint-masters and money-changers [Collybistae], I say this happens either from the negligence or from the ignorance of the mint-masters. Negligence is shown in this: that, to avoid labor, they are accustomed to examine this sophistical gold only superficially — applying no proper cementation, or what they call cupellation — using only obvious and commonly known means requiring little effort. And they show their ignorance in this: that, just as they purchased that office for a fixed sum of money, or were promoted to so important an office by the favor of princes, so too — since they do not hold even the first principles of the metallurgical art — they do not know the method and procedure of testing, examining, and forming a sound judgment about the goodness of gold and silver. From this innumerable injuries to the commonwealth arise, and to many people the door is opened to similar frauds and deceits, to every license.

[Margin: Sophism 3.]

There are others who boast that they possess two secrets of different kinds, which they say the whole world cannot but accept as true transmuters of gold and silver. The first of these is as follows: They take gold and silver in equal portion, well tested beforehand at the cupel; then of tutty, crocus of Mars [crocus Martis,

iron oxide], and crocus of Venus [crocus Veneris, copper oxide], they take four ounces of each, and of oil of vitriol seven ounces. These are placed within a bladder [vesica], and the said mixture of ingredients is gradually incorporated. When this is done, the bladder is left in horse dung for fifteen days; and once the digestion is complete, the whole mixture is taken out and dried in warm ashes into a powder. A quarter part of this, projected upon one part of silver, changes it into gold of 24 carats, as they call it.

[Margin: Sophism (—).]

The other is as follows: They take gold and silver, first filed into shavings, and while they are being melted, they add to them as much of tutty and sublimate as the gold and silver together with the ingredients weigh. Then, ground and milled as finely as possible, they place them in a sublimatory vessel; and when the sublimation is complete, a mass remains at the bottom, which, committed to the cupel, separates gold of eighteen carats. This is the secret which many greatly esteem. Yet I, examining everything duly, do not know what an unproportioned vegetable crocus contributes to the essential tincture, since tutty, crocus of Mars, and crocus of Venus suffice for the tincture. But if Sol and Luna [Sol and Luna, i.e., gold and silver] enter into this operation, I do not see how tutty, iron, and copper can add anything to the gold beyond a tincture; for even if they coalesce into a single golden mass, the whole is nevertheless not pure gold, but only apparent gold, since with the help of the cupel all the added metals can be separated from the gold. There is therefore no usefulness lurking in secrets of this kind, except that they get back the very gold and silver they put in; and at the least, since it readily yields to the hammer, it can also be of some use in making household plate.

[Margin: Sophism 4.]

There are besides those who say: "I know how to prepare a tincture for silver, by which I can increase gold threefold, by means of a powder made from leafed copper [cuprum foliosum], mercury, and cinnabar — which, calcined by a water composed in equal parts [analogically] of vitriol and saltpeter, brought to a first circulation and then through the fire of fusion [ignis fusionis], with two parts of cupelled gold and silver added to these. I can also make cinnabar so fixed that it tinges silver into the best gold. I proceed thus: I steep cinnabar, placed in strong waters, macerating it for 24 hours; then I submerge the dried-out matter in salt water; then with fresh water I draw off the saltiness into sweetness, and with the remaining powder I make layer upon layer [stratum super stratum], and finally, having cemented it, I cast it into the best and purest gold." But I, examining this

process, do not find how gold of such purity could emanate from fixed cinnabar, since it cannot give what it does not have. And if you say that it holds gold added to it by nature — and so the matter does stand — I say that the golden powder mixed in, together with the gold accrued to the cinnabar, yields only as much as was first put in, though a little purer. Nor do I see any usefulness in this operation, except useless labors and expenses. I know indeed that cinnabar teems with quicksilver, but that it can be converted into gold by any preparation whatever — that I have never seen nor heard, unless perhaps the quicksilver inhering in the cinnabar as in a mineral matter is tinged into gold, which is mere vanity.

[Margin: Sophism 5.]

Another speaks thus: "I too can make real gold, the sign of which is that in strong water it remains 'quartered' [quartatum] together with silver — and the mint-masters and money-changers require nothing more. I proceed thus: I take as much as suffices of bronze or leafed copper, and an equal amount of cupelled silver, which, melted together, are drawn out into thin rods. Afterward, with sulphur melted, into which I place the rods first imbued with sulphur, I press them with kindled coals until all the sulphur is burnt off; and this done so many times, until the rods entirely turn into scales [scaly form]. Then I commit the scaled mass to the cupel, and there will remain somewhat less than the silver was before. Then from this silver one-ounce rods are made, and they are placed on the raw, still-muddy edges, in such a way, however, that below and above they have a layer of prepared salt...

[Margin: Sophism 4.]

[Margin: Sophism 5.]

[Printed p. 287 — running header: "DE ALCHYMIA SOPHISTICA."]

and when this is done, they are placed within a furnace; and when they have been cooked, the rods will appear to be of a tawny [Leonine] color. You will place them in strong waters, and you will have, for every ounce, one drachm of the purest gold, 24 carats. Experience indeed confirms it." But I say that this drachm of gold does not come from the transmutation of copper or silver into gold; rather, that drachm of gold was either extracted from the silver — which is never wholly free of some small portion of gold — or perhaps from the copper, and was separated out by a powerful fire.

[Margin: Sophism 6.]

Yet another, boasting, says: "I know a way of making silver without so much labor." If you ask how, he says: "I take arsenic wrapped in a linen cloth — what they call *pezzas* — and cook it in common oil; cooked, I sublime it repeatedly, and it becomes fusible like wax. A fifth part of this I project upon copper, and it will tinge it white, of six 'leagues' [ligas]; but if I put in one part of cupelled silver, it will withstand the assay of silver of six leagues, as they call them. The same I shall obtain if I take two parts of silver, one of copper, and one of antimony: these, melted, will give a mass not unlike true silver." I myself indeed know that the same can be done if you take iron and soften it with sulphur; if you mix this with copper or Venus while they flow in the fire, they will at once embrace one another by a certain natural sympathy, by which Mars pines for Venus. But if you mix this with silver and commit it to the cupel, the copper will be separated and there will remain an iron-silver mass. But who will say this is true silver, since, when it is separated from the iron by strong water, only the silver that had been put in remains.

[Margin: Sophism 7.]

Furthermore, there is no lack of those who shamelessly boast — as I recall having heard from some such men in conversation: "I know a way of making a mineral of silver, and another of gold, from which I take only as much as suffices to support many people." Such men proceed thus: They take four ounces of lunar mercury [Mercurius Lunaris] and 32 [ounces] of cupelled silver, from which they say they extract, for each ounce, one drachm. This done, they take cupelled silver first reduced to filings by the file, to which they add one ounce of common salt; and when these have been sublimated and all duly reduced to powder, they place them in a crucible over kindled coals, and at once it will flow; and within a short time a circle will be seen within the crucible, and at the bottom a mass of mercury, which is taken out; and what remains is silver with sal ammoniac and sublimate. "Keep the mercury you have taken out, for it is of great value for multiplication. Proceed thus: Take 4 ounces of this mercury, and one of filed silver, which, placed in a glass bladder, are to be set in the furnace for two months and urged on with a sharp degree of fire, one each week; then the mixture, projected or precipitated, will be transmuted into a Leonine color, and this is the medicine so greatly desired for multiplying the mineral. Now proceed with the multiplication thus: To each four ounces of the said medicine add one ounce of cupelled silver, and five ounces of common mercury, and, placed in a similar glass vessel, let them be committed to the fire for the space of a month, and you will find one part of such medicine converted into silver — or into gold, if you add one ounce of gold to the medicine. And this is the secret which some

say they obtained — I do not know from what physician or secretary of the Great Emperor of the Turks, or even of the Sultan of the Persians, perhaps born in Utopia, while they were oppressed by harsh servitude in those parts."

But whoever commits this sophistical contrivance to the cupel will at once find that the mercury has gone off into fume, that the mineral slags have been separated out at the bottom, and only as much silver as they had put in — although, mixed previously together with the slags, it would press out the whole mass as silver.

[Margin: Various sophisms of various men.]

Another tried to persuade me of the truth of the transmutation of metals by this mastery, denying the truth of the thing [otherwise]: "I take a powder — namely, a medicine — which, projected upon 22 parts of mercury, converts it into gold or silver, according as the medicine is prepared from gold or from silver. I proceed thus. I prepare a double water: one from two parts of sublimate, the other from antimony; then I extract an oil from two parts of antimony and one of sublimate, prepared however without alum and without any arsenic, reduced to powder only with salt and vitriol. This I place within a well-luted retort, sealed with a plaster made of lime and white of egg; then they are distilled, and these, from the thick and black matter, after often-repeated cohobation [redistillation over the residue], will at last pass off into a most subtle and clear liquor. Again let the mercurial water be rectified seven times; and as often as the rectification is done, pour over it a sixth part of oil of antimony; then I divide the whole mixture into two parts, in one with silver, in the other with gold placed in foliated form. These, in a closed vessel, within a short time will pass off into a flux, liquefied like fat. Let these two vessels, within a certain receptacle closed on all sides, be digested by the two-month heat of a lamp, the wick always being increased; and within the first little vessel you will find a black medicine, in the other a white one. And this is the medicine which, projected upon mercury, converts it into gold or silver" — namely, nothing other than what was first put in. Tell me, please, good sir, what do the sublimate, oil of antimony, salt, and vitriol do in this mastery, when the golden and silvery powder, and beyond that another quantity of gold and silver placed in the oil and mercurial water, restore to you the whole of that gold and silver which you had put in? What, I ask, can be conceived in the said salts that could produce any effect of gold? For I know that these salts are of no use for anything except the dissolution and purification of gold and silver.

As for the claim that from it one can prepare a medicine that, by projection, "multiplies" gold and silver, I flatly deny it. It is nothing but the empty and utterly

worthless conviction of men who thirst and dream of nothing but gold. I do indeed grant that a medicine of this kind — which they also call a "tincture" — can act only in the proportion of its own projection onto the matter: that is, only as much as if one drop of water were thrown onto a whole measure of wine. And in that case, what would emerge from the projection except the same wine, with no transmutation of wine into water at all?

But to this a man replied with the utmost obstinacy: "You, Father, deny the true and real transmutation that I have already shown you. But to demonstrate it to you more clearly, take the following experiment. Take pulverized cinnabar and form little pellets kneaded with egg-white. Then reduce silver or gold to powder, and make a layer of the said cinnabar pellets and a layer of the metals, stratifying them alternately one upon the other. Place them in cement for 24 hours over a non-fusible fire. Then remove the matter, set it in a cementing vessel, and you will find the cinnabar converted into that metal with which it had been stratified, together with the cinnabar." [Margin: An experiment.]

What a fine experiment! If it were true, in how short a time and with what ease would many men grow rich — especially if the stratification were done over gold or silver! But experiment proved to me that another pseudo-chemist had made silver by such a secret; yet once it was duly examined, he was accused as a forger, and was compelled to restore — not without danger of prison and of his life — the money for which he had sold the said silver.

After this man, another presented himself who claimed that the true transmutation could be demonstrated from this: that iron is changed into perfect copper by the following experiment. "Let thin, fine plates of iron be put into vitriolated water, and at once you will find that, by a natural sympathy, the coppery matter adhering to the iron will leave copper behind it." But when, by the experiment itself once taken, I showed him the contrary — and demonstrated that this can in no way be called or held a true transmutation, but only a dissolution of the iron into dross, and a uniting of the little copper bodies that had previously been scattered through the vitriolated water, now gathered together by the iron's attraction, which when afterward melted yield copper — when, I say, I had demonstrated this, he fell silent, convinced either by shame or by his own ignorance.

I append a similar experiment most worthy of wonder. [Margin: An experiment.] If hairs, or the shavings of hair, are boiled in an iron vessel until they take on the form of a glue, and then the vessel is driven with a stronger fire, the result is that if you put other hairs into this glutinous broth, they become so steeped in the

coppery spirits lurking in the vessel that they look like threads of the purest copper — and no one could persuade himself that they are hairs, so brightly do they shine. The same will happen if iron that has been cemented with sulfur, and has acquired a certain friability, is sprinkled with the powder of burnt glass: for although this is pure iron, it will nonetheless appear as copper. But to test how much copper is present in vitriol or vitriolated water, proceed thus. [Margin: An experiment.] Let vitriol be boiled in water until it is wholly dissolved into a liquor; let this liquor be thrown onto mercury, and when you have left it to remain so for a little while, then with the liquor placed within a retort, distill it over a fire; and as the mercury evaporates, copper will remain in the bottom. When this is weighed, you will learn how much copper was in the water; and in this way you can easily find out, whatever the metal may finally be, how much gold and silver it contains within itself. These experiments do not show a transmutation, but only an alteration, that is, a separation of one thing from another, as we have shown in the various foregoing examples.

[Margin: Sophism.] After this man, another presented himself who claimed that the transmutation [continues — see p. 289]:

whatever the metal may finally be, how much gold and silver it contains within itself. [Note: this final clause of p. 288's text continues; the second column of p. 288 set the running matter of the "Sophism" paragraph, which resumes the main treatise's argument below.]

[The treatise's main argument resumes.] A mark [marca] contains eight ounces, or sixteen lots [lotones], and goldsmiths use these units. With these premises laid down, let us now take up the work.

We say, then, that the art of the alchemists is at times lawful, provided the gold it produces is not below 22 carats. And it is twofold. The first is **monetary** [Monetaria], which they also call *Collybistic* and commonly *Lega*; the other is called **alchemical** [Alchymica], which by the addition (as they call it) of another metal to gold or silver "multiplies" the gold. [Margin: What is the finest gold?] Both are lawful, if each stays within its own limits. The monetary kind, for the striking of coins, generally adds to gold or to silver another kind of metal — such as bronze, that is, copper — which they call *Lega*; provided that, as we said, it not be below 22 carats. So too the other, the alchemical kind, although this latter cannot easily be put to monetary use, but only for vessels and for the furnishing of gold and silver household ware. The monetary kind, however, by the prince's pleasure, can issue small money struck of any alloy he likes — though only within his own principality, and not put into circulation outside it. But since these

matters are commonly known, we shall not dwell on them. Here we shall only examine the alchemical art: whether, by the addition of other metals and minerals, it can produce true and pure gold, or only a mixed gold. And so that this may be done with greater method, certain things must first be supposed.

It is supposed, **first**, that there is no metal or mineral that does not have some gold or silver mixed into it — in one more, in another less. [Margin: Every metal contains gold and silver.] This is what the unfailing experiment of the microscope first taught us. For in minerals and metals, whether perfect or imperfect, ground to a fine powder, as soon as we examined them under the applied microscope, we always detected some grains of gold or silver — just as in gold and silver we found some particles mixed in from other imperfect metals. Hence I came to know with certainty that there is no metal so perfect that it does not also have joined to it some admixture of the others. And this admixture seems to draw its origin from the fact that in ores rich in gold or silver you always find adjoined heterogeneous lumps, whether of minerals or of imperfect metals, as we showed at length above in the *Sectio on Metallurgy*. Whence it comes about that the various lumps coalesce into one another, though by an intermixture scarcely perceptible except to armed eyes.

[Margin: Vitriol-water does not lack gold mixed into it.] **Second.** We find the same thing in the various species of salts and juices, especially in vitriol — whether congealed into a solid or dissolved into a liquor. For since vitriol-water, drawn from a pyrites ore through which it passes, continually scrapes off certain minute corpuscles both of the pyrites and of the gold mixed with it, it comes about that these, while they are dissipated confusedly and scattered through the water without union, soon — when another metal, especially a sympathetic one, is joined to it — seek out that metal by a kind of magnetic confluence, and being drawn by it are united with it. These then first become manifest when they have been committed either to the cupel or to the cement.

[Margin: Antimony, marcasites, etc., hold gold.] **Third.** This same thing is to be seen in antimony, marcasites, magnesia, tutties [Tutiis], cadmias, arsenic, orpiment [Auripigmento], ochre, and the like, which always have some gold or silver mixed in — a fact only that man will deny who has not made the experiment with the use of the microscope. Hence it is no wonder that alchemists are vehemently deceived, when they suppose they have transmuted into gold what was already in those substances to begin with — as we shall explain more fully in what follows. But let us now confirm our doctrine by experiments.
