It happened in the pharmacy of our Roman College that, while we were calcining tartar in a crucible with a reverberating fire, once the calcination was done we found at the bottom of the crucible a little golden globule the size of a pea. About this various disputes at once arose among those present: some thinking it had been extracted from the tartar, others holding that it had run down from other substances mixed with the tartar. I, suspecting what was actually the case, asserted that the gold had been melted out of the very material of the crucible by the violence of the fire. [Margin: Gold in the very material out of which crucibles are made.] To my opinion assented the most excellent **Jordanus** [?], Duke of Bracciano, most skilled in chemistry, who happened then to be present; and he affirmed that crucibles of this kind are usually made at Bassanello [Baßanellae] from a certain earth most rich in golden filings, which, imperceptibly mixed into the crucibles and then urged with a stronger fire and melted, is found collected at the bottom of the crucible in the form of little globules of mercury — and that the same thing had befallen other goldsmiths and apothecaries. But that gold, or any other metal, can be present in tartar — since tartar draws its origin from the vegetable nature — is impossible. The globule, of nearly three ounces, when committed to the cupel, gave one ounce of gold and two of silver, which had been mixed in along with those golden filings. From this it shines out plainly how easily alchemists delude themselves if, after the various mixing of ingredients into some composition, they find a bit of gold or silver — for from where that flowed, the demonstrated experiment makes clear.

[Margin: Deception of the senses.] In the same way those are deceived who, while they reduce certain herbs to ashes for extracting salt, find gold; and I have often heard that this happens in Hungary near the gold-mines. We give this explanation of it: that gold-bearing spirits, carried into the roots and the rest of the herbs' substance, are there coagulated by the cold of the surrounding air and the moisture of the plants, and as such spirits continually flow in, they at last rise up into a certain body — which is then found melted at the bottom of a vessel made glowing by fire. By this experiment men unskilled in natural things have utterly persuaded themselves that certain plants have a wonderful power of transmuting metals into perfect gold. But since these claims have been refuted in what precedes, we shall not dwell on them. It remains, then, that we now set forth the various modes, operations, and masteries [magisteria] of gold-making [Chrysopoeia], by which some...

some alchemists claim that, by the addition of any minerals whatsoever — gold and silver having first been put in — they can produce an augmentation. And this mode is true and lawful as well, provided it be shown, through expert goldsmiths

and gold-refiners appointed by the magistrate, to obtain its proper weight and qualities. For my own part, I am convinced that **Lull** [Ramon Llull], **Arnold** [Arnold of Villanova], **Rupescissa** [John of Rupescissa], and the other gold-making authors [Chrysopoeias] recounted above, made their gold — if indeed it can ever be proved that they made true gold — by no other than the following methods. But those who think that they made it not by this method, but by the Philosophers' Stone, assert this too rashly. So that the dispute may be settled, I shall reveal by what art they made that refined, pure, and natural gold, and by what trick they prepared a tincture of gold "multiplicative to infinity."

Chemical Arcanum I.

By which from one ounce of the purest silver a drachma of gold can be drawn out.

This secret was communicated to me by **Jacob of Negroponte** [Iacobo de Nigroponte], a distinguished iatrochemist, who testified that he had again and again verified the truth of the matter by experiment. One proceeds thus. [Margin: An experiment.] *Take one ounce of cupelled silver [Luna Cupellata], then five ounces of purified lead, which, melted together, are to be thrown granule by granule into common water. This done, take one ounce of mineral cinnabar and one ounce of antimony, which, ground to a powder and mixed together, are to be made into a* [continues on p. 291]:

For this **the first thing required is a chemical vessel** with the lute of wisdom; **second**, a copper crucible [Tigillum]; **third**, a place fitted out together with a lamp having an asbestos wick; **fourth**, the ingredients, which are silver, aqua fortis, mercury, and oil of vitriol. Take, then, first, for the chemical vessel, a glass vessel...

Diagram. An engraved apparatus for the slow "digestion"/circulation of the alchemical mixture over a steady lamp-flame. At the top, a tall cylindrical glass vessel (A) closed with a domed, lidded stopper (B) flanked by two flame-like decorative finials, set inside a sand-bath crucible (G–H) within a boxed cabinet; below, on a checkered tiled floor, stands a lidded lamp-burner (D) on a tripod, its flame (F) rising through a perforation in the abacus shelf toward the vessel above. The printed legend ("EXPLICATIO FABRICÆ" — "Explanation of the apparatus") reads:

- A: The glass vessel filled with the matter C.
- B: The cover of the vessel A, luted on.
- G H: The crucible [tigillum] filled with sand.

- D: The lamp filled with olive oil.
- E: The wick fitted with cork floats.
- F: The flame of the lamp.
- L L L: The air-holes [spiracula] of the following compartment.
- V X I K: The compartment [loculamentum] within which the glass vessel A is placed.
- V X M N O P: The shelf [abacus] on which the compartment is set; perforated in the middle at R S, so that the flame may nearly reach the bottom of the vessel G H.
- T Y: The tripod on which the lamp is set.

The whole apparatus is then to be closed up.

[The recipe of Arcanum I, interrupted by the figure, resumes on p. 291; its continuation below is the conclusion already begun on p. 290.]

stratify them in the crucible with the said grains and powder, so that the powders occupy the first and the last place in the stratification. Then let the crucible, sealed as exactly as possible with the lute of wisdom, be set apart until it dries out; once dried, let it be urged at the fire for about five hours — first indeed with a slow fire, and afterward with a strong one. Finally, removed from the fire, once it has cooled, you will find in the bottom of the open crucible a matter in the form of a loaf [panis instar], which, committed to the cupel, will give pure, refined gold, the thing sought. This is an experiment performed by **Jacob of Negroponte**; who, however, expressly says that no profit can be derived from it, but that he communicated the secret to me only so as to show what Nature can and cannot do. Certainly, whoever has well understood the suppositions we set forth a little earlier will be compelled to admit frankly that gold of this kind has come forth not by any transmutation, but either by a separation of the gold from the silver, or from the cinnabar, or from the antimony, or from all of them together, in which it was present to begin with.

Chemical Arcanum II.

By which quicksilver [Hydrargyrum] is said to be converted into the finest silver.

This arcanum was communicated to me by a certain great prince, whose name I deliberately keep silent, who also confessed that he had found the truth of the arcanum to his own great profit. One proceeds thus. Four things are required for the completion of this arcanum. **First...**

[continues on p. 291]:

silver previously cupelled; and three ounces of filings finely filed off, which, mixed together, dissolve into water within a quarter of an hour. This done, to this water add one pound of quicksilver, properly cleansed beforehand of its dregs (the method of cleansing the mercury is by pressing it through a leather purse). This too being done, you will carefully close the glass vessel with the lute of wisdom. [Margin: The lute of wisdom — out of what it is made.] The lute of wisdom is made of wheat flour, quicklime, and clay mixed in equal parts [anaticé — i.e. in equal portions], and kneaded with egg-white. Next take a copper pan [tigillum] in the form of a basin, a span [spithama] wide and a hand's breadth deep, which, packed with white sand, you will fill up to half the height of the vessel. Into the sand of this basin set the glass vessel, now luted, with such care that it stands within the sand at a finger's breadth distance from the bottom of the pan, but in no way touches the bottom. This too being done, take a lamp — or any other vessel of whatever material suitable for carrying out the work — filled with olive oil, within which floats an asbestos wick supported by cork floats; which, when lit, should give only as much light as a candle of ordinary household wax and middling thickness usually gives. Set this lamp within another receptacle closed on all sides, yet having some holes above and at the sides, so that the smoke and soot can escape through them, and the fire can enjoy the air it needs. And let this whole assembly be placed within a chamber which they call a "dry stove" [stufa sicca], or in a warm place steeped in heat. Then set the pan, together with its luted glass vessel, over the lamp, taking care that the flame does not strike the bottom of the pan directly, but is set off from it by a finger's breadth of space; and in this way leave it for the space of 14 days in its digestion. When these have elapsed, you will open the vessel, and to it add eight lots of oil made from vitriol, and with the vessel again closed with the lute, set it as before over the lamp. And after another 14 days have passed, you will open the vessel again, and at the bottom you will find one pound of silver fit for the goldsmiths' use, which nonetheless still requires the cupel. Set aside three of the pound's parts, taken out for your own use and profit, but restore the fourth part of the pound to the chemical vessel again. To it you will add as much mercury as a third part of the silver weighs, together with two ounces of the best aqua fortis and an equal number — two ounces — of oil of vitriol, so that the materials laid upon the quicksilver rise above it to the middle of the vessel; for only that much of the whole space is to be filled, not beyond. Then again let the luted vessel be committed to the lamp, for 14 days. When these have elapsed, opening the vessel you will find, as before, one pound of silver; from which, three parts having been separated for your gain, leave the fourth within the vessel, and again pour on as

much quicksilver as a fourth of a pound weighs, together with two ounces of aqua fortis and two of oil of vitriol, as above; and the vessel being closed and luted, again set it over the lamp. And after 14 days have elapsed, you will repeat the same: that is, one pound of silver — from which, three-fourths having been drawn off for your own use, leave one within the vessel; to which, having added afresh as much quicksilver, together with two ounces of aqua fortis and of oil of vitriol, set the closed vessel again over the lamp. And in this way, by the same process always continued for many years, you can (as they suppose) augment the silver in a wonderful manner.

Observe, however, that each day the lamp must be refilled with oil, lest, when the oil is consumed, the flame draw back from the bottom of the pan too far; the wick needs no snuffing, since it is twisted from threads of inconsumable asbestos. Nor does it matter if you leave the vessel in its digestion beyond 14 days, since the longer it lingers in it, the more perfectly the matter is digested and the purer the silver comes out. And those who take up more chemical vessels of this kind for carrying out the work, to them too a greater quantity of silver will accrue as gain; and to a larger vessel and more matter, a greater quantity and more wicks ought to correspond. And this is the chemical artifice by which a man can live comfortably his whole life long, according to the one who communicated it to me. But now it remains to be examined whether silver of this kind is truly and properly silver, and for what reason it takes on so great an increase.

Into this, then, there enter three ounces of pure silver, eight ounces of aqua fortis, one pound of quicksilver, and eight ounces of oil of vitriol — which, joined together, give 21 ounces, that is, two pounds less 3 ounces; from which, the 3 ounces of pure silver subtracted, there remain eight ounces. But on opening the vessel you draw out from it one pound of silver. [Margin: Examination of the process.] The question is asked: from where and how have 7 ounces of silver accrued to it? I answer: since in pure, sheer quicksilver, as also in the aquae fortes or in vitriol, silver does not actually exist, except for those least particles, that is, corpuscles of silver, that had been mixed into each of them beforehand by Nature (as is clear from the second supposition) — these particles, macerated by fire and circulated for the space of a half-month, at last cohere by a sympathetic confluence to that little portion of three ounces of silver, and so make up one mass of silver of 12 ounces. But because those corpuscles by themselves might seem too few to constitute a body of silver of seven ounces, it is necessary that the saline corpuscles too — which were scattered and contained both in the mercury and in the aquae fortes and in the vitriol — united together with the silver mass, have grown into a silver mass of 12 ounces. And unless we say this, we shall be

saying that the whole of the mercury, the aqua fortis, and the vitriol was transmuted into silver — to no purpose; since it cannot come about that what does not actually and essentially have something from itself and its own nature, should nonetheless give that thing. It remains, therefore, that the whole silver mass of seven ounces was constituted out of those silver corpuscles alone, mixed with the said ingredients, together with the saline corpuscles present in them. And this is clearly evident from the eleven ounces of liquor, or of dross, after the...

(continuing from CAPUT II, the mass-balance examination of Arcanum II — the quicksilver-to-silver process)

would have remained superfluous after the operation was completed, if it had really been produced by transmutation. For in a true transmutation the whole must be converted into the whole, so thoroughly that it may genuinely be called transmutation. The question therefore arises: can the silver obtained in this way be called true silver? My answer is yes — even though, when it is submitted to the cupel, it comes out in much smaller quantity because of the separation of the heterogeneous parts that had been mixed in. From this it is also clear that the business does not succeed at all if no silver corpuscles were already present in the said ingredients, and that more or less silver emerges in proportion to how much or how little of them was mixed in. I would add that this procedure [pragmatia] scarcely yields enough silver to recover the costs laid out.

ARCANUM III.

By which part joined to part produces gold. [Quo pars cum parte juncta aurum prodit.]

Take one ounce of pure silver, previously purged with white sulphur, and two ounces of laminated gold; let them be melted together. Then take 2½ ounces, stratify them together in an earthen or iron vessel, and calcine them in burning sand. Reduce what has been calcined to a powder, to which you will join an equal weight of sublimate of mercury [mercurium sublimatum], with five ounces of powder poured over it. Distill the whole together through a retort up to an oily liquid, three times over, and a precipitate will remain inside, which you will grind small. To this add four ounces of the following fluid. The fluid is made thus: take one ounce of white tartar, 3 of saltpetre, two of borax, sal ammoniac $\frac{3}{4}$, Venetian glass $\frac{1}{2}$ ounce; all ground small together. Of this, I say, join four ounces to the preceding precipitate, and once it is placed in a clean crucible and covered, expose it to the fire for one hour, and you will have a *regulus*. Grind this small

and cement it, which is done in the following way: take of filings of steel a sufficient quantity, two ounces of sulphur previously calcined, four ounces of antimony; let them be committed to a strong fire for fusion, for about one hour. Then take two ounces of this ground material, one ounce of green copper [or verdigris, aeruginis], one ounce of cinnabar, one ounce of sal ammoniac, four ounces of calamine [galaminae] — which, however, having first been calcined with an equal weight of common salt, you should dissolve again, and leave it boiled three times in strong vinegar to dry out. With this powder you will cement the *regulus* left above, and once this is done you will have what was proposed: gold that withstands every assay — indeed a little more gold than what, for the reasons stated, you had put in.

There follow Arcana which they call "Confirmation," and which is the fixed sulphur that tinges Luna [silver] into Sol [gold]. [Sequuntur Arcana, quam Confirmationem vocant, et est sulphur fixum Lunam in Solem tingens.]

I shall here set down some chemical Arcana which I have drawn out from the hidden and varied circles of figures and the wrappings of emblems — out of the mystical workshop both of the Arabs and of the followers of Lull [Lullus, i.e. the pseudo-Lullian alchemical corpus] — from which it will be plain that the Stone of the ancient Philosophers was nothing other than what we lay down here. For it can scarcely be told how much the deceptive emblematic figures do to drive home the affected structure of the Stone; how much the allegorical entanglement of words and names does, while very many — not the common sort only, but even the wise — rush headlong toward whatever may seem to them admirable or useful for attaining the highest blessedness, with no consideration of the matter, with no balance of reason brought to bear, tumbling into it as though driven by a vertigo, rabid with an anxious hunger for gold. This is plain from the very fact that some of the followers of Paracelsus not only venerated that mystery contained under an acrostic — which we mentioned above — but also adorned it with various emblematic and symbolic figures, so that the great work, which they do not know how to accomplish, they might at least make a show of putting forward as something supreme and unheard-of, by means of secret symbols and a counterfeit arrangement of names. But because the matter is worth setting out to demonstrate the vanity of the alchemists, I shall here append the Emblems.

A fraud extracted from chemical manuscripts. [Ex Chymicis Manuscriptis fraus extracta.]

"Then comes Xenophon's True Mandate." [Fiet inde Xenophontis Verum Mandatum.]

These are those marvelous arcana which the foolish ash-blowers [cinifones, i.e. charcoal-burning alchemists] present to the world under ridiculous figures and emblems, and whose interpretation I shall now supply — lest their trickery and deceit seem to have escaped its Oedipus; for I have always labored with great effort at unriddling such things.

In the first Figure a circle surrounds a triangle marked with a cross, within which are enclosed the figures ☉ [Sol/gold] and ☾ [Luna/silver]; in the circle stand these words: *Sala Vera Laudat Philosophiam Habentes Voluntatem Rectam; Fiat Inde Xenophontis Veberatio Mira* ["Salt truly praises Philosophy in those Having a Right Will; thence let come the Marvelous (utterance?) of Xenophon"]. If from these names you gather the initial letters of the words into one, this will come out: SULPHUR FIXUM ["fixed sulphur"] — which the triangle, together with the attached cross (the mark of sulphur in use among chemists, ⚞), also signifies. Here it is plainly evident that the Alchemist, in putting *sala* for *sola*, did not even understand the Latin language.

The second Figure has three circles with a crossed and inscribed triangle. In the first two circles are the same words as in the first Figure — so that the hidden mystery, and the arcanum that readers marvel at, might not at once be apparent: for the initial letters of the words denote the same thing they denoted before, SULPHUR FIXUM, which the chemical mark ⚞ also shows. The words placed in the third circle are the same as those described around the triangle in the first Figure — namely, *Lege omnes Sophos ergo sic tuos* ["Read all the Sages, therefore (read) your own thus"], with which words ...

(catchword: "con-")

words, foolishly constructed, they indicate that all the Sages — that is, the Philosophers — understood the first matter of the Stone to be fixed sulphur. The third figure was that of a certain stupid Alchemist, who took mysterious words extracted from Paracelsus and translated them into this figure, a circle surrounding a triangle.

In the circle these words are contained: *Visitetis Inferiora Terrae Rectificando Invenietis* ["You shall visit the lower parts of the Earth; by Rectifying you shall find"]; and in the other semicircle: *Occultum, Lapidem, Veram Medicinam* ["the Hidden (thing), the Stone, the True Medicine"] — the initial letters of which words, V I T R I O L U M, indicate, and beneath the figure these words are placed:

Diagram. Three emblematic alchemical figures presented as exposed frauds, captioned at center *Ex Chymicis Manuscriptis: Fraus detecta* ["From chemical manuscripts: the fraud detected"]. Each figure is an acrostic device in which the initial letters of the words running around the circle spell a chemical term.

- **Fig. I** (top left): A circle encloses a triangle marked with a cross at its apex; within the triangle is a face flanked by a crescent moon (Luna/silver, ☾) and (by the scheme) the Sun (Sol/gold, ☼). Words running around the circle: *Sala Vera Laudat Philosophiam Habentes Voluntatem Rectam · Fiat Inde Xenophontis Veberatio Mira* ["Salt truly praises Philosophy in those Having a Right Will; thence let come Xenophon's Marvelous (utterance?)"]. Initials → SULPHUR FIXUM. At the base of the triangle: *Confirmatio* ["Confirmation"]. Around the lower arc the running words include *Lege omnes Sophos · ecce sic tuos · Habentes Voluntatem Rectam* ["Read all the Sages; behold, thus (read) your own; (those) Having a Right Will"].
- **Fig. II** (top right): Three concentric circles with a crossed, inscribed triangle at center; the apex bears a cross. Words running around the rings (read with the acrostic) again yield SULPHUR FIXUM and repeat phrases of Fig. I: *Veritatis Mandatum · Sic Tuos · Rectae · Sola Fiet Vera Inde Lege Omnes Sophos · Igitur Homin es · Verum Philosophia* [partly retrograde lettering; several words mirror-printed].
- **Fig. III** (center/bottom): A circle (drawn on a long unfurled banner/scroll) encloses a triangle; inner ring labels read *Visitetis · Occultum · Inferiora · Lapidem · Reductio Triadis · in Monadem · Veram · Rectificando · Medicinam · Invenietis* ["You shall visit · the Hidden · the lower parts · the Stone · Reduction of the Triad into the Monad · the True · by Rectifying · the Medicine · you shall find"]. Initials of the outer words → VITRIOLUM. The banner ends bear the words *Fiet Inde Xenophontis ... Verum Mandatum* ["Then comes Xenophon's ... True Mandate"].

[Margin (against this passage), running gloss keyed to the figure: *Visitabis Inferiora Terrae Rectificando Invenietis Occultum Lapidem Veram Medicinam — Fiet Inde Xenophontis Verum Mandatum* — i.e. the expansion of the VITRIOLUM acrostic.]

"Then comes Xenophon's True Mandate." [Fiet inde Xenophontis Verum Mandatum.] — The initial letters of these give FIXUM. Under this figure, therefore, they indicate the matter of the Stone to be fixed Vitriol [Vitriolum Fixum].

Here you have, all you who are devoted to Alchemy, that the Stone is fixed Sulphur and fixed Vitriol — a stone that is certainly not the philosophers' but the diggers' own, which you may easily find anywhere. And what of it? For once this is known, I know just as much as I did before. I should indeed like to know what use there is for so mysterious a Stone. What, I ask, shall we do with such a Stone, with Sulphur and fixed Vitriol? Shall we draw gold out of it? I truly think just as much can be extracted from it as from the sweepings of a kitchen coal-bin. Is this not to contradict all the ancient philosophers, who by unanimous consent laid down that the first matter of the Stone is not Sulphur, not Vitriol, nor Arsenic, but Mercury? Indeed, they expressly banned every mineral or metal from the working of the Stone, in these words: *"The metal that enters our work is not the common gold or silver, nor any other imperfect metal or mineral whatsoever, but the philosophers' own."* In this way the fraud of Paracelsus is exposed, who places the arcanum of the Stone outside all the bounds of minerals — and yet in the process uses nothing other than metallic and mineral substances.

But I, grasping their intention more deeply, see the reason why they thought the secret should be veiled under these schemata: they had read a process for graduating to gold, and since they did not understand it, then — at least so as not to seem to be ignorant of anything — they hid it under insipid emblems of this kind. But lest I seem to have left anything here untouched, I shall set out the whole procedure of the matter according to the intention of the ancients, with a certain profit — though not so great as the alchemists imagine for themselves. Hence I have judged it should be plainly explained, not so much for the sake of gain as of the experiment, which is indeed a fine one.

Note first that by *confirmation* [confirmatio] the chemists understand nothing else, in this place, than a certain tincture — which is the same as fixed sulphur. This tincture is deservedly called the completion of the whole work (as they themselves hold), for like a thunderbolt it penetrates all metals and gives them a suitable color. And just as the whole mastery [magisterium] consists in these three things:

(catchword: "pon-")

in weight, fixation, and color — which are signified by the triangle set within the circle — so those three must be introduced into the matter in such a way that Luna [silver] mixed with Sol [gold] is changed into gold. But even if you obtain the weight and the fixation, they nevertheless cannot subsist when committed to the cupel without confirmation, that is, the tincture which they call *fixed sulphur*. How, then, that tincture or fixed sulphur is prepared, I now set forth.

PROCESSUS I.

Of the Confirmation, or tincture that converts ☽ [silver] into ☉ [gold].
[Confirmationis, seu tincturae ☽ in ☉ convertentis.]

[Margin: Processus I. The tincture converting ☽ into ☉.]

Take one half-ounce of the best sulphur and three half-ounces of crude antimony, which, committed to fusion, will give a *regulus* melted with colophony [colophonia] resin. From this take two half-ounces — that is, one ounce and a half — and together with it, of ☉ [gold] and ♄ [tin], one half-ounce of each; these, committed to a crucible, are melted together. Then, for four days, night and day, let them be exposed to digestion in a pot very well luted, in hot sand; and by this means the three things mentioned will no longer be separated from one another, and they become volatile according to the nature and whiteness of antimony. And this is the penetrating water; it is called the water that tinges to the 18th degree [ad 18 grad.]. Reserve this water for the use to be set forth later; and by the skilled it is called the water "graduative to 18" [aqua ad 18 graduativa].

PROCESSUS II.

Of the dissolution of fixed sulphur to volatility. [Solutionis sulphuris fixi ad volatilitatem.]

[Margin: Processus II.]

The second figure signifies the process of the dissolution of fixed sulphur to volatility. And just as in it the initial letters of the words, taken together, indicate fixed sulphur, so the figure — or chemical mark — ♁ placed in the middle (signifies) sulphur; but the triangle-mark inscribed within the circle signifies nothing else than the conversion of the fixed sulphur into ☉ [gold], which the conjunction of ☉ and ☽ in the first figure also indicates. But the process, which they have passed over in silence or did not know, we shall sincerely bring out into open light. In this way, then, the dissolution of fixed sulphur to volatility is prepared.

[Margin: Preparation of the dissolved fixed sulphur to volatility.]

Take a half-ounce of gold, or one *loton* [lotonem], which, filed into a powder, is to be set on a gentle fire for 8 hours. Then take three half-ounces, or 4 drachms, of tartar calcined to whiteness, a half-ounce of salt, and 4 *lotones* of sal ammoniac; mix all together. Of this mixture take up to one half-ounce, three fifths of one ounce of gold (note well: by "fifths" we mean drachms, and by "lotones," half-ounces); grind together with the aforesaid material, placed in a low alembic, over which you will pour the strongest water [aqua fortis], and, the alembic being set in a bath, distill six times in the manner of Maria [balneo Mariae, the water-bath/bain-marie] — and in the last three times with a fresh addition of aqua regia. For in this way, the ascent of the matter being completed, you will leave it exposed to a gentle heat for the space of 24 hours; then separate the strongest water from the ...

(catchword: "*fua*")

the *calx*, washing the strongest water away to sweetness; finally dry it out and fix it by the known art, and you will have what was proposed, whose use follows.

Take of the silver water "graduative to 18," set forth above in the first Process, one *loton* — that is, half an ounce — and as much of the prepared gold, and as much of tin; of antimony, 4 drachms. These, joined together and evaporated, leave a body, from which you will take 2 half-ounces, and 3 ounces of crude antimony, which are to be committed to fusion. When this is done, the gold draws into itself the tincture to the 18th degree, with the silver [Luna] subsisting, and it will obtain the highest degree of sulphureous color, equal to the best gold. This procedure too I find in Lull [Lullus] in his *Clavicula*, and in Isaac Hollandus [Isaacus Hollandus], though under other words and covered with a symbolic wrapping of language; and it accords with the mind of the ancient sages — with this one exception, that the ingredients in this work admit the addition of common gold and silver and of the other minerals, which the ancients nevertheless slyly deny, lest either the secret (if there is one) should be laid open, or they should be convicted of fraud.

Another way, by means of the first Process of Confirmation. [Alter per 1. confirmationis Processum.]

Take a half-ounce, or a *loton*, of silver [Luna] exalted to the 18th degree, as we prescribed in the first process, and of the gold prepared in the second process, a *loton* and a half, together with a *loton* and a half of tin; let all be placed together in an earthen crucible, and let the *regulus* resulting from it evaporate. Then add

over it one ounce of tin, and you will have the matter united by means of the *regulus*. Next, of the gold prepared in the second process and of crude antimony, take 1½ ounces; let them be placed in a descensory bladder [vesica descensoria], and press the distillation up to the sublimation of the *regulus*. This *regulus* you will then stratify with a powder burnt from old shoe-soles, and then "quarter" it to the utmost (to use a chemical term), and you will have the desired gold tinged to the 18th degree.

You will accomplish this again, more briefly. Take, as above, of the previously prepared silver exalted to the 18th degree, and of the prepared gold; to these join a *regulus* of as great a weight as the ☽ [silver] placed (in the bladder) weighs; let all be committed together to the bladder. When this is done, you will mix into this mass twice as much crude antimony as the mass weighs; then let it evaporate by fire, draw off the remainder through ♄ [lead, i.e. by means of lead/cupellation], and you will have the gold "exalted to the 18th degree," as they say — which, however, is no other gold than that gold and silver which you had put in, exalted by purification to the utmost, in whose tincture the other admixed minerals also share.

PROCESSUS III.

How the ancients, by the power of the Stone — that is, of fixed sulphur — exalted gold above all the degrees of native refined gold. [Quomodo veteres vi lapidis, sive sulphuris fixi, exaltarint aurum super omnes gradus auri mineralis obrizi.]

This process is carried out by means of the graduated *regulus*, in which lies hidden the fixed sulphur together with its ...

(catchword: "fua")

its addition; and it is the tincture by which silver [Luna] is converted into gold at the 26th degree, and withstands all assays; and the procedure is as follows. Take two ounces of crude antimony and 1½ ounces of gold; one ounce of copper; of the recrement of steel, or of the filings of iron, 3 ounces — from which, when melted, a *regulus* will come out. Then take Bismuth [Bismuthum], or ash-gray lead [plumbum cinereum], and crude antimony, three ounces of each, and besides 3 ounces of common lead — from which, when melted, another *regulus* will come out. This done, take of the silver prepared by the Process adduced above (first prepared, and exalted to the 18th degree), ½ ounce, which commit to a crucible; to it join from the graduated *regulus* prepared a little before, ½ ounce part

[partem]; and from the *regulus* of ash-gray lead, or the Bismuthic one, draw off in the retort seven times, 1 ounce — and you will have the addition of gold, from the *regulus* together with ☉ [silver], exalted to the 26th degree: gold that withstands every assay, of the best quality and (as they say) more excellent than refined gold [aurum obrizum] — which I would have understood of the utmost purification.

PROCESSUS IV.

By which fixed sulphur, through common sulphur encountered (in the operation), tinges silver — lightly purged in passing — into gold. [Quo sulphur fixum per commune sulphur obvium Lunam obiter purgatam in Solem tingit.]

Take ½ ounce of pure gold sulphurated with common sulphur, until it becomes brittle and the sulphur is consumed. Take this prepared gold and let it again be stratified with fresh sulphur to the combustion of the sulphur, and in this way proceed seven times. Then take the sulphurated gold, grind it on marble into a fine powder, and, having placed it in an alembic, pour aqua regia over it; once this has been drawn off to oiliness, pour it back over the gold, with fresh strongest water (or aqua regia) added; and you will do this a third time. When this is done, pour over it the strongest spirit of wine, expose it to a gentle heat; and when this is done, the spirit of wine will draw to itself all the other spirits, which are gently drawn off with the spirit of wine, and at the bottom you will find a liquid matter, which you will divide in two. The first part you will coagulate into a body by the known art — they call it the precipitate — which, reduced to a fine powder, you will store in a glass vessel; and the other half of the liquid matter you will pour onto it, and again let it coagulate into one body, and you will have the work consummated. With the help of this powder you will cement the purged silver, and you will have the gold sought — so that one part of this powder, to ten parts of purged silver in fusion, will tinge them into gold; although in the cupel-assay you will always recover somewhat less, and it smells somewhat sophistical.

PROCESSUS V.

The tincture of Confirmation, or of fixed sulphur, to be perfected by means of a noble cement. [Confirmationis tinctura, seu sulphuris fixi per caementum nobile perficiendus.]

Take 2 ounces of pure gold and 1½ ounces of common copper, which are to be committed together to fusion into a body; and while the matter flows, take about ½ [?] ounce of sulphur, which you will throw little by little into the fusion. This done, grind the matter that results with ½ ounce of mineral cinnabar [cinnabaris mineralis], small; then put the ground material into a vessel, and pour over it the following oil, well mixed. The oil is made thus: take 2 ounces of glass of antimony [vitrum antimonii], one ounce of saltpetre well purified; let these, ground into a fine powder in a low vessel, be set out in hot ash, the vessel being stopped with paper, and left in fusion for not too long a time. Then pour over the cooled matter the strongest vinegar of wine, until it covers the matter, and then draw off the vinegar through an alembic; and you will repeat this four times, and a fifth time more strongly, until nothing more is left of the vinegar. The oil that follows is reddest, like blood; from it the phlegm of vinegar, drawn off, will give the required oil. This oil pour over the aforesaid powder stored in the vessel, mix it well with the said powder until it gradually coagulates; then again, with the oil poured on as before, let it coagulate; and you will repeat this operation a third time, and you will have the cement prepared for converting silver [Luna] into gold.

You will find nearly the same things in Paracelsus, *Book on Graduations* [Lib. de gradationibus], although he wraps them in so many and such great obscurities that either he himself does not know what he asserts, or at least — if he did know — he seems, touched by envy, to have kept silent. He calls a tincture of this kind the *tincture of the Philosophers*; I, however, declare it nothing but a sophistical and metallurgical [tincture].

And from these my interpretations the deceptive ingenuity of the alchemists has become brilliantly clear to me: men who, lest they seem to have been ignorant of the great art, have shrouded it in marvelous figures; or, if their wit failed them for devising emblems, do not cease at least to cover the matter over by a steganographic [steganographico, cipher-writing] artifice. Some years ago, when I was surveying the Vatican Library [Vaticanam Bibliothecam], a vast arcanum was shown to me by the custodians, which they supposed to contain the true method of making the Stone — though the monstrous forms of the exotic

characters in which it was written had taken away all hope of penetrating it. They turned to me, then devoted at the time to interpreting hieroglyphs, asking whether, if it could be done, I would attempt the opening of the seal. I promised I would try. And having returned home, I at once arranged the characters, by my accustomed art, into an alphabet; the next day I showed the deciphered arcanum to the custodians of the Library, who indeed seemed to marvel more at the sudden unraveling of the characters than at the art itself. The arcanum was as follows.

An Arcanum of the Philosophers, for making perfect gold out of Saturn [lead]. [Arcanum Philosophorum, ut ex Saturno facias aurum perfectum.]

Take half a pound [libram semis] of Mercury [quicksilver], and two ounces of their sulphur [sulphuris eorundem]; amalgamate the two together, so that nothing of either appears...

(catchword: "pareat,") ...so that nothing [of either ingredient] appears, but there remains a black powder made of the two; take this and place it in a flask with a narrow mouth. Set it on a small stove or furnace, with an intervening pot, using sifted ashes — banked up, mind you — and arrange it so that the ashes do not rise up to the material. At the start, apply a gentle fire for eight days, so that the spirits do not rise; and if anything has risen during those eight days, fold it back into what remains at the bottom of the vessel, breaking the vessel every eighth day after the first material has been formed (which will be black). Breaking the glass in this way, grind your material and replace it in another glass vessel; do this every eighth day until you see your material take on the color of ash. Then reduce the ashes by one finger's breadth, so that no more than two fingers of ash remain, and set it over the fire; leave it until the material turns red. When you see it red, again reduce the ash by one finger, and so on in sequence, until it becomes as white as snow, and then turns back to a red color. Of this medicine, take one ounce and project it onto eight [ounces] of prepared lead [Saturnus], and the lead will become black and hard as iron. Of this hard, black substance, project one ounce onto eight ounces of lead, and it turns red. Of this red substance, project one ounce onto eight pounds of prepared lead, and you will have perfect gold. Praise be to God. So says Master Odomarus. In my own view, it is not the whole substance [that transmutes], but the tincture, which — once mingled with the other minerals together — saturates them into a single substance.

This, then, is the arcanum, concealed under such a diversity of characters, in which nevertheless there is nothing that promises you any of the profit you are seeking — since lead cannot be transmuted into gold without the philosophers' mercury extracted from gold or silver, by the common consent of all the philosophers. But mercury prepared in this fashion, and projected onto any metal whatever, is alleged to transmute that metal into what it [the mercury] itself is. Hence this arcanum too is utterly sophistical, and so I would advise no one to waste oil and labor on its ἐγχείρησις [Greek: encheirēsis, "handling, working-out"]. You can see from this trickery how little sincerity there is in all those arcana — or rather "recipes," as they like to call them — dressed up with the symbols of so many figures and veiled in so many secret letter-signs. I can indeed testify to this: that I have never found a single secret of the [philosopher's] stone hidden under ciphers of this kind (and yet I have on hand a vast quantity of them, rescued from their obscurity and unlocked by an art of my own) that was not contrived either to deceive or to torment men's wits. A clear proof of this can be that I have afterward found such "recipes," or arcana, set out in plain words — whether in Lull's *Clavicula* [Ramon Llull, the *Clavicula*], or in Paracelsus's *Archidoxa*, or even in run-of-the-mill writers like Porta [Giambattista della Porta], Wecker [Johann Jacob Wecker], Alexius [Alexius Pedemontanus], and others. Thus the world is toyed with by these clandestine cinder-stirrers [ash-fumblers].

[Margin: The trickery of the alchemists, false, in the concealing of their secrets.]

But now let us turn our pen to the interpretation of the third figure, which I said was Paracelsus's. Paracelsus, as I have often said, can deservedly be counted, more than any other, among impostors of this kind. For it can scarcely be told how he covered over those arcana — which he had previously lifted from the manuscripts of Llull, Arnold [of Villanova], or Isaac Hollandus, or Basil Valentine [Valentinus Basilus], and others — covered them over, I say, with a marvelously affected obscurity of words, or with enigmatic wrappings, so that he might not be convicted of the crime of plagiarism. And although he seems to say everything, he yet offers nothing that does not leave the reader's mind doubtful, dazed, and wholly ignorant of what one may think or believe about the veiled secret, leaving it altogether uncertain. The very men, moreover, from whom he had borrowed, he does not blush to call ignorant of these matters and falsifiers besides.

[Margin: Paracelsus's trickery.]

But let me adduce the words, full of intolerable boasting, that he sets forth about himself in the preface to the little book *On the Tincture of the Natural Philosophers* [*De tinctura physicorum*]. "In this age," he says, "the monarchy of all

the arts has fallen to me, Theophrastus Paracelsus [Theophrastus Paracelsus], prince of philosophy and of medicine. For to this I have been chosen by God (more truly, by Satan), that I might extinguish all the fantasies of schemers, and of false, fictitious, and presumptuous works and presumptuous words — whether they be those of Aristotle, Galen, Avicenna [Ibn Sīnā], Mesue [Yūḥannā ibn Māsawayh], or whosoever they may be, and of those who cling to them." It was not enough for him to have joined audacity to presumption; he even paraded as a prophet, foretelling things about his own monarchy, which he hints at in these words: "This theory," he says, "proceeding as it does from the light of Nature, can never be undermined, on account of its constancy, nor altered, and it will first begin to live in the year one thousand five hundred and fifty-eight." Certainly, since five years have now elapsed since the term of his prophecy, so far is it from being the case that anything worthy of such great knowledge has appeared up to now, that he has rather been everywhere taken by all for a pseudo-prophet and a most shameless impostor, and shown to be so by apologetic writings — so much so that his writings too have been struck from the Catalogue of Orthodox Books by the Holy Roman Church as impious and pernicious to the faithful of Christ, and forbidden; about which he seems to complain in the following words.

[Margin: Paracelsus's intolerable presumption.]

[Margin: Paracelsus's books prohibited.]

"This practice," he says, "will at length be confirmed by wondrous and incredible signs, so that it will become plain even to mechanics and the common people, and they themselves will fully understand how constant and unmovable, against the trifling of the sophists, that Paracelsian art stands — even though that sophisticated art is confirmed and defended in its follies by Papistical and Imperial privileges." He concludes at last: "By this arcanum," he says, "the last age will be manifestly illumined, as by a gift of grace and of the true spirit, and it will be recompensed, so that no like seed of understanding and wisdom has been heard of from the beginning of the world." He who a little before was asserting that the outcome of his prophecy would fall in 1658, now postpones it to the last age of Antichrist, or, as he says elsewhere, foretells it for the coming of Elias the Artist [Elias Artista]. Who—

[Margin: The arrogance of Paracelsus the prophet.]

Who, I ask, ever saw such a monster of boastfulness, or heard of a Braggart [Bombilio] of comparable arrogance? But lest we dwell on the cause of such great absurdities, let us now see what he has accomplished in this art worth noting. He

speaks thus in the book entitled *Aurora of the Philosophers* [*Aurora philosophorum*]. He took fixed vitriol [*vitriolum fixum*] for the prime matter [*prima materia*] of the philosophers, which he also demonstrated in the third Figure with these words: "You will visit the interior of the earth; by rectifying you will find the hidden stone, the true medicine." Thence will come the true command of Xenophon, whose initial letters — as we showed above — spell out *Vitriolum fixum* [fixed vitriol]. And by "earth" he understood vitriol itself; by "the interior of the earth," its sweetness and redness. For in the hidden recess, he says, of the vitriol there lurks a subtle, noble, and most pure juice and pure oil, whose mode of protection is not to be approached by calcination or distillation — because it must by no means be deprived of its greenness [*viriditas*], for if it were so deprived, it would necessarily be stripped at once of both its powers and its arcanum. "We have the arcanum; let anyone now make from it as much gold as he pleases." For my part, I judge this to be no specimen of the great art, but the mere trifling of idle men. And lest I seem to do Paracelsus an injustice, I shall here adduce the Magistery by which he supposes the stone can be made for tincturing gold, so that from it one may gather what is to be hoped for. He proceeds thus in *Aurora of the Philosophers*.

[Margin: The trickery of Paracelsus in the making of the stone.]

First, mineral vitriol [*vitriolum minerale*] — which in many places he had rejected as unfit for the art — he now, as if led by repentance, takes up into his Magistery; and just as it is liable to many viscous, muddy imperfections, so too (he prescribes) it must be freed from its impurities by repeated rectification, until its greenness becomes manifest. And lest this greenness turn to pallor, he directs that it not be exposed to the Sun, but kept in a warm hypocaust [*calido hypocausto*, a heated chamber], well guarded against the injury of dust.

Second. For the space of several months let him commit it, the glass thereafter being sealed, to digestion, until — with various colors running through in turn — at last the supreme redness appears. This is the common precept of all the philosophers. But just as this [redness] promises as yet no fixity, so too he says it must be further purged of its filth with vinegar, until it has been wholly freed from all impurities along with its dregs, and made absolute. And this he calls the true and best rectification of the tincture, from which the oil he names "blessed" must be drawn out by this procedure.

Third. From this tincture, placed in a glass with an alembic set on top — lest the spirit exhale, the joints being smeared with lute of the best quality — the spirit is to be drawn out by a gentle, slow fire, of ashes, that is, or of sand, and you will

obtain an oil sweeter than any balsam, free of all sharpness; and at the bottom of the cucurbit there will settle an earth, most white, gleaming, and shining like snow, which you must keep — once it has been separated from its redness. Now at last follows that arcanum of the heavenly marriage, by which the soul and the body — that is, the tincture, or blessed oil — being poured over the now brightly purified earth, bind themselves together so tightly that thereafter they cannot be separated from one another. And this is that *terra foliata* [foliated earth], which you will store away placed in a glass phial, and to which you will gradually pour on its oil; and the body will in a moment receive and embrace its soul. The marriage thus completed, it now remains to explain how it can be made fruitful.

Fourth. This foliated earth, then, saturated with the blessed oil, you will set within the furnace of the arcana — namely the Athanor — to be circulated for the space of forty days, and you will have a most perfect oil of wondrous perfection. By it, mercury and the rest of the imperfect metals are turned into gold, multipliable to infinity. By this procedure: Take corporeal mercury [Mercurium corporalem] — that is, the common kind — in a portion of two parts, onto which you will pour three parts of the said oil of equal weight, and let them remain together for 40 days; and you will obtain a proportion of weight and order by which the multiplication may be made to infinity.

[Margin: Of gilding. — Paracelsus.]

And this is the arcanum, the greatest of all arcana of every kind, which Paracelsus would urge not upon philosophers and men skilled in natural things, but upon the unlearned and exceedingly credulous common crowd. For I now undertake to demonstrate that this is a pure and unmixed lie.

First of all, by the consensus of all the chemical philosophers, the prime matter of the great Magistery is mercury not of the common sort [Mercurius non vulgi], not vitriol, nor any other mineral, but the philosophical mercury [Mercurius philosophicus]. This Paracelsus himself even admits in the book cited, chapter 10, where he refutes all those who have sought the stone in minerals, and charges them as men given over to stupid labor — although he himself is the first who attempted the work by means of mineral vitriol. Second, this mercury of the philosophers is to be extracted not from vitriol, nor from any other imperfect metal or mineral concreted juice, but from gold and silver, the perfect metals, so that the stone may be fashioned from it. But in this Magistery there is no mention either of the philosophical mercury, or of gold or silver added, but only of vitriol. So he accomplishes nothing, since vitriol cannot give what it does not have — even though tormented by countless purifications, digestions, and calcinations.

Thus all that this Paracelsus achieves is what any apothecary does when, from vitriol previously purified and rectified, he extracts a spirit and a deep-red oil free of all sharpness, as frequent experience in our own pharmacy teaches us. I grant too that a most white sediment remains in the cucurbit. But that the oil of vitriol just now extracted, poured over this earth and circulated for 40 days, and at last projected onto common mercury, should turn it into gold — this I have never seen nor heard. For what, I ask, is there in vitriol that—

[Margin: Paracelsus's false demonstration is refuted.]

—that could give weight to gold? What, I ask, [could give it] natural powers? What [could] confer color, since none of these is found to be present in vitriol? Vitriol is indeed turned by long cooking into an oil of a rosy color, but not into such [an oil] as gold by its nature desires — one shining with a tawny color, which vitriol alone, without the addition of other substances, cannot give. Unless you say that it gives a tincture to gold from coppery and golden corpuscles mixed into the liquid — which is already a sophistical [admission]. Certainly Llull, Arnold, and the other chief leaders of alchemy, in all their Magisteries — as is clear from the *Clavicula* and from the *Rosary* [*Rosarium*] — mix in some gold and silver in place of a ferment in the matter, so that consequently all those in the *Turba Philosophorum* cry out that nothing can be done in this work without Sun and Moon [Sol and Luna, i.e., gold and silver]. All of whom I could here adduce, if the matter were worth it.

[Margin: The alchemists' objection.]

But the Paracelsians will say that this Magistry is to be understood not literally, but in a higher, parabolic sense. I answer that this is the very mark of impostors: to signify one thing with mouth and pen, another in mind. Surely from a parabolic Magistry of this kind what else can we hope for than parabolic gold — which is born not from art or nature, but from the foolish imagination of men? He published similar specimens of the great Magistry in the cited book, chapter 11, where he produces a true and perfect arcanum and tincture from arsenic, and there inveighs against Geber [Jābir ibn Ḥayyān], Albertus [Albertus Magnus], Rasis [al-Rāzī], and Polydorus as falsifiers, and finds fault in them precisely for the thing in which he himself sins. Indeed, he is wholly absorbed in exalting the arcanum of the tincturing spirit that is extracted from it [arsenic]; for one part of this, projected onto sixteen parts of imperfect metal, tinctures them into most excellent Luna [silver] — by a tincture, to be sure, that is none other than the one by which, with familiar experience, we are accustomed to change red copper into white, of which [I treat] in the experiments of the following Book. As for what

Paracelsus further says about the virtues of *electrum* [electrum, the gold-silver alloy], in the book *On Compounds* [*De compositis*] — that [electrum], just as it takes its origin from silver and copper, so too, when cooked with various substances, must necessarily degenerate at last into a sophisticated mass of gold.

CAPUT III.

DISQUISITIO I.

On the Artificial Chrysopoeia of the Chemists [Chrysopoeia artificiali Chymicorum]

If there is indeed in the nature of things an intrinsic motion of the principles of any given body — which we may not unfittingly call *fermentation* — given that there is a tendency toward the perfection of such a body, or toward its change into something else (a thing which shines forth above all in the elementary variety of motions): then, just as these [bodies] consist of the smallest corpuscles, so too, set in motion either by Nature's own impulse or by occasion, they stir themselves and are stirred in a marvelous manner, draw apart from one another, and become entangled. Having through Nature's kindness acquired subtlety, they at once strive to fly off, but are held back by coarser little nets, lest they fly off entirely. Meanwhile the coarser ones are by the subtler ones cut up and thinned, in a wonderful struggle, until — exalted together with the subtler ones and borne aloft — they either acquire their due perfection, or complete the alterations designed by Nature; which is the whole sum of Meteorology. For from this arise Rarity and Density, opacity and transparency, flaccidity and liquidity, fixity; and from this — through the moist and the dry — softness, roughness, flexibility, and ductility take their origin in all things. But now let us return to the aim of our proposed argument.

[Margin: What motion in the nature of things is.]

No philosopher has hitherto denied that the whole is constituted of parts, whether similar or dissimilar. Hence too all metals, both perfect and imperfect, and the whole class of fossils — in short, all mixed bodies — consist of corpuscles, each one of which has the nature of the whole; [these are] not the atoms of the Democriteans, but true and real ones, indeed not inaccessible to the senses even when armed [with the microscope]. These, united together in concrete bodies, constitute some one thing; but by fire, or by any other heat, or — in certain substances unyielding to fire and heat, such as strong waters [acids] and acid juices — by the dissolution of their continuity, once separated, they are at once,

as if they had taken on wings, resolved into spirits with marvelous agitation and seethe up. Some of these remain stubbornly at the bottom of the vessel and are called fixed; some fly up on high, soon to return with the cold that meets them; some vanish entirely into smoke; and there are those that, flying off, return of their own accord by right of postliminium to the fixed [body] from which they had flown, as if led by repentance. And since no body in the nature of things is so purified that there does not reside in it some admixture of heterogeneous matter — which differs, as in heat, so also for the most part in nature, according to the condition of its dissimilar nature — hence it happens that those [corpuscles] which enjoy a likeness of nature flow together toward their like, by some powerful magnetism I know not what: golden toward golden, silver toward those that seek silver, iron toward iron, leaden toward lead, saline toward salt — especially those that nestle in concreted juices and in aluminous, nitrous, and vitriolated liquids. The sulphurous, the arsenical, the marcasitic, the orichalcic [brass-like] substances that gleam with a golden color join themselves to golden corpuscles; the leaden and tin and those that consist of antimony, magnesia, cadmia, bismuth, and the like, run together toward silver, or toward tin, or toward lead, by a certain kinship of nature. From the various—

[Margin: All mixed bodies consist of the smallest corpuscles.]

[Margin: The magnetic attraction of like toward like.]

—combination of these, by their concurrence, is born that immense variety of colors which we cannot sufficiently marvel at in the chemical peacock's tail [pavonis cauda]. You will ask how this comes about? I say it comes about from the mixture of various minerals, tinged with diverse colors, as soon as they have been dissolved; some of these are endowed with a like color and property, others incline this way, others that — some flow together from here, some from there — and by this differing and disjointed confluence of like corpuscles they display that variety of colors we have mentioned. But if you press the material with further torments of fire, it happens that — once each [kind] has been freed from so great a confusion of corpuscles — a separate place is assigned to each: some being resolved into waters, some into spirits, some coalescing into scoriae or a glassy material, others settling at the bottom. The material thus separated, those alone that delight in friendship with the perfect metals — being separated from the others, which are of inferior condition — are joined to gold and acquire a tincture from it; and moreover, themselves now tintured, they by a reciprocal benefit add bulk to the gold as well. And since all things mixed in Nature's threefold kingdom obtain their consistency and fixity from chemical salt, the element of

earth, and since all metallic things — and whatever minerals there are at last — are constituted, as to the consistency of their bulk, from saline corpuscles: hence it comes about that, when the mixed body has been dissolved in metallic fusion with gold pregnant [in the mixture], they are imbued with its tincture, and moreover, by their own confluence, give it [the gold] a greater quantity of bulk than it had before. They pursue, therefore, the golden tincture, the most potent of all, and all the particles of the remaining minerals strive to be clothed with its splendor — as will appear, clearer than the noonday light, from the chemical operations to be adduced a little later.

[Margin: How gold draws to itself the rest of the metallic corpuscles, and increases its own substance.]

Since chemistry is, even on this account, most worthy of all praise — that, from the resolution of mixed bodies into spirits (that is, into mercury, sulphur, salt), into water, into earth, it exhibits by experiment the corpuscles of which they are composed, manifest and obvious to the senses, and clearly demonstrates the elementary bodies, which [resolve] not into ἅπλα καὶ ἀσύνθετα [Greek: hapla kai asyntheta, "simple and uncompounded things"], that is, into simple and uncompounded [parts], but into those substances into which the parts become ultimately sensible — [for] physical things are resolved [thus].

Experiments by Precipitation [Experimenta per præcipitationem]

1. If you dissolve lead or litharge [lithargyrium, lead monoxide] with distilled vinegar, a certain most limpid water will be extracted, so like spring water or distilled vinegar that you can scarcely tell one from the other. Pour this into a glass, and pour over it distilled vinegar of a very similar color, and at once the water of litharge will turn into a most white color, like milk.

[Margin: To change a limpid liquor into white.]

2. If you boil antimony, calcined with niter, in spring water, you will have a most limpid and almost odorless filtrate; but if you pour over it any acid liquor whatever, then the water will be tinged with a saffron color, and will come forth with a most foul smell.

[Margin: To change a limpid liquor into a pitch-black one.]

3. If you calcine tin and mix with it liquefied salt of tartar, you will have a water tinged with a heavenly color — that is, a sky-blue [cerulean] one.

[Margin: To change a liquor into a cerulean one.]

4. If you mix limpid solution of galls with solution of vitriol, the former will at once be changed into a most black color, which they call ink [atramentum]. But if you pour over this a spirit of vitriol or Stygian water [aqua stygia, a strong acid], the inky color will turn back again into a most limpid water; and if you wish to reduce this once more to a black color, oil of tartar poured over it will do so.

[Margin: To turn a limpid liquor into a black one, and again into a limpid one.]

5. If you write something on paper with a limpid infusion of vitriol, the writing certainly cannot be read, inasmuch as it was traced with a limpid water; but if you wet the paper with water of galls, it will at once become visible in a black color and be read with no difficulty. But — marvelous to tell — if you wash it with spirit of vitriol, [the letters] will disappear as before; yet you will restore them again to their blackness once oil [recte: liquor] of tartar has been poured on.

[Margin: A steganographic secret.]

6. If you pour cerulean oil of vitriol [oleum cæruleum vitrioli] onto the blue tincture of violets, it will at once grow purple; and if you add to this a few drops of spirit of hartshorn [spiritus cornu cervini], you will turn the purple color into green. Again, the wood called *acanthicum*, which is also called *nephriticum* [nephritic wood], brought from Brazil [Brasilia], diluted with common water, deposits a pleasingly reddish tincture, not unlike red wine; and if you pour into this a little distilled vinegar, the liquor will appear limpid like white wine; but a few drops of oil of tartar will draw it back again into a purple. And if spirit of vitriol is poured into this once more, it will grow pale-yellow like Spanish wine. If you boil gum lac [gummi laccæ] together with added alum in limpid water in a bladder [vesica], a most beautiful color like ruby will be drawn from it. An excellent dentifrice.

[Margin: To turn a cerulean liquor into a purple one.]

[Margin: Various kinds of colors.]

7. If you pour syrup made from a confection of corals onto spirit of wine, you will have "virgin's milk" [lac virginis] — that is, a liquor white like milk, no less pleasant to see than sweet to taste. These experiments, indeed, were performed in our pharmacy. I could adduce here countless other experiments of this kind; but since they have been partly shown in what

precedes, and we shall partly set them forth in what follows, we have judged it superfluous to dwell on them longer. So nothing remains but to inquire into the causes of the said experiments.

[Margin: Virgin's milk.]

DISQUISITIO II.

The reason for phenomena of this kind, then, is not to be sought elsewhere than from the corpuscles twisted within the pores of any liquor: which, as to their site and position — being variously altered by some other liquor poured in — transmit the rays of their light, refract them in manifold ways, and reflect them; and—

[Continuation from the prior folio:] —from which it necessarily follows that the aforesaid alternation of colors arises, as one color destroys another, and yet a third revives the one that had been destroyed. For as we said a little earlier, since the subjects of colors have one composition or another, built up out of corpuscles and particles, certain particles of a transparent body are very like light, and so appear utterly limpid and translucent like crystal; from these the limpidity of liquors takes its origin. Other particles, however, belonging to opaque bodies, because they have a different composition, different in color and in nature, when these latter are poured over the limpid ones, tint them—according to the diversity of the color—now yellow, now purple, now blue, and finally black, and so induce opacity. For according as the particles contained in a liquor, when driven into closer contact by another particle poured in, interlock with one another, and are arranged now into these, now into those series of positions, the resulting diversity of color necessarily follows. Indeed a liquor of this kind, when assaulted by corpuscles minutely fractured, expresses as it were a battle-line of soldiers drawn up in fixed ranks—soldiers who now draw together, now spread apart, and now present this figure, now another.

[Margin: The cause of colors in precipitated liquors.]

When two transparent liquors, mixed together, produce a black tincture [atramentum], the reason is this: the particles contained in each—the limpid (that is, transparent) ones, and those that have the character of a more opaque nature—approach one another, and being arranged as it were in closed ranks, block the access of the rays of light. But as to why, when vitriol or some other liquor is poured in, the black tincture is expelled and the former clarity is recovered—the reason is that vitriol consists of the subtlest and sharpest spirits. Hence it happens that the spirituous corpuscles, by reason of their supreme voracity, as soon as

they attack those inky [atramentosa] gall-corpuscles, render the transparent ones opaque [the text is compressed here; recte: they separate the opaque from the transparent], cut them apart, and segregate them completely. Indeed, by the infusion of transparent vitriolic corpuscles of bodies akin to them, they furnish a great increase by the kinship of nature; from which the former clarity arises.

[Margin: The cause of colors in liquors of different kinds.]

But because oil of tartar consists of fatty, glutinous, and opaque corpuscles, it happens that the clarity now restored to the water, when a fresh liquor is poured over it, makes the vitriolic corpuscles gather together again, become darkened, and as it were be glued together by a certain viscosity; and so they tint the limpid liquor back into its former blackness. For although in each liquor clarity is at first prominent, and no difference of color is perceived by the senses, nevertheless the mixed liquors soon, as though a battle had broken out, struggle most fiercely, and one is at length forced to yield to the other in proportion to its strength.

[Margin: Oil of tartar transmuted into another color.]

As to why the tincture of violets turns purple when oil of vitriol is poured over it: the reason is that the blue vitriol-tincture, added to the blue tincture of the violet, changes it into a third thing—that is, into purple, which is close to blue. For [whatever the genus of the mixed liquors may finally be] [text truncated at the column break]...they take on the color which saline bodies, variously tinted and mixed together, display.

But how a clear water of litharge, when distilled vinegar (equally clear) is poured over it, turns into a milky color—if you ask this, I answer: it happens because of the leaden corpuscles dissolved by the vinegar into white-lead [cerussa]. From the vinegar poured over it, the ceruse-particles present in the litharge-water, at once flowing together by likeness of nature as the vinegar settles to the bottom, are condensed and packed together; and so, now packed close, they display the same color that they naturally possess.

We have now seen clearly, unless I am mistaken, the source from which that diversity of colors arises in the precipitation of one liquor into another. Now we must likewise examine—to return to our undertaking—how those various differences of color arise in chemical operations; and what those spirits are that are now volatile, now fixing, now separating one thing from another; and how those saline corpuscles, present in all minerals, are at length brought together into one by likeness of nature. This we will show by chemical experiments.

Experiments with Tinctures [Experimenta Tincturarum]

Experiment 1. If you wish to make graduated gold [Aurum graduatum], proceed thus. First, let gold of weak and pale color be melted with antimony, adding tartar, by whose violence the impurities and foreign matter of the mixture are burned away; and then the color, exalted, becomes more ruddy. If one operation is not enough, let a second and a third be applied. The regulus thus produced is then refined with lead in an ashy crucible (a cupel, or *test* [testa], as they call it), and you will have the graduated gold you sought. This succeeds well when the gold has mercurial, sulphurous, and similar superfluities present in it, and when it has been corrupted by various fleeting mixtures and imperfect metals. If you ask the cause of this graduation, I say it is none other than the golden tincture which lies hidden partly in the antimony, partly in the lead; in these, by the efficacy of fire, the dissolved golden particles, soon flowing together amicably toward the gold and adhering to it (now purged of impurities), not only give it a nobler tincture but also furnish an increase—though always a sophistical one.

[Margin: How graduated gold-color is induced.]

Experiment 2. If you wish to give a silver color to copper [aes], you will achieve it with calcined talc and tin, or with silver by co-liquefaction, or even by casting on a powder made of white calx of mercury nourished with oil of tartar; and you will have what you sought. Some persons of little skill suppose that copper whitened by lead, reduced and sublimed in a cupel, will become silver; but since copper of this kind, committed to the cupel, is reduced back into the components from which it coalesced, they certainly pursue their aim with vain effort. Nevertheless this counterfeit silver can serve for making various utensils.

[Margin: How copper is tinted with a silver color.]

Experiment 3. To impart a white and golden color to black lead [plumbum nigrum].

[Margin: To impart a white and golden color to black lead. Experiment.]

We once amused ourselves with a water made from quicksilver sublimated with sal ammoniac by deliquescence, in which we found copper and iron quenched and imbued with a silver color. *To impart a white color:* let a powder be made from white arsenic, calx of tartar, rock-salt [sal gemmae], and sal ammoniac; soak it, drenched with vinegar, for 7 days; then cook the macerated mass to dryness. They throw the fine powder of this over molten black lead and render it white, not unlike a silver color—very suitable for making various utensils. A pretty

experiment indeed, but of little use, since the expenses incurred in making it are greater than would be spent on true purified tin.

To impart a golden color to the same lead, proceed thus: make a medicine from verdigris [aerugo], calamine, yellow [citrina], sulphur, cinnabar, orpiment [auripigmentum], and sal ammoniac; let it be reduced to powder and kneaded with bull's gall or with oil of egg-yolks; then let it be dried again, and turned over hot coals in pans without scorching; and finally, when this is done, let it be cast into the molten lead, and you will obtain lead gleaming with a golden color. The reason for this depends on those ingredients, all of which are imbued with a golden color and possess an inborn tincture of golden brightness; thus they readily flow together toward that which they naturally seek, and adhere to it. These are our findings; whoever desires more, let him read Birelli [Birellus], book 6, chap. 2, and book 12, chap. 41.

[Margin: What sophisticated mica is. [Quid sit proprie sophistica mica.]]

In experiments of this kind, then, many think the moving cause is the [Greek: ποιότης (poiotēs, "quality")], proceeding from the potency of matter (as some put it), which from the depths and hidden recesses produces a color into the surface and into view, in which there is some mark of perfection. But we say that this is produced from the predominant particles of the dissolved bodies, particles which look toward some metal, and which exist in the materials not in potency but in act. For these particles, while they lie hidden under the confused throng of the elements packing them in—as they are by no means apparent—so, when the elements are either sublimated or evolved from the depths, at last, packed together, they become perceptible to the senses. This we confirm by the following experiment.

Experiment 4. Take Indian lead, which is called *caloëmum*; mix this with ash-colored lead (which others call marcasite, or sublimated bismuth, and some call the regulus of white magnesia) in an iron spoon brought to the coals. Soon, what was before of a silver color you will see transmuted into various colors—golden, silver, black, blue, green, purple—to the point of a miracle. The reason for this is none other than that bismuth (by the common opinion of the chemists, most prolific in mercury) has all colors present in it; and these especially present themselves to view when, by the efficacy of fire and frequent cooking, the matter composed of differing particles of the mixtures is drawn out to the surface. For bismuth, just as it teems with a varied medley, so too with corpuscles which, dissolved by fire, are revealed by the sympathetic flowing-together of like to like;

from which comes that wonderful variety. But of these matters we will speak at length in the final book of this work, *On the Art of Metals* [de Arte Metallica].

[Margin: Experiment.]

Nothing in alchemical operations is more celebrated than the work of fixation [opus fixationis], by which alone metals are imagined to be truly and really transmuted into gold and silver. Whether this is really so, let us set forth. Now this is accomplished by a threefold mastery: of salts, of oils, of liquors. Fixation, according to the mind of the alchemists, is nothing other than when a body receives a tinting spirit and removes its volatility—which is done by frequent repetition, until a body of perpetual duration is produced and the whole remains in the fire, according to that common saying of the alchemists: *make the volatile fixed and the fixed volatile, until the lower becomes the upper, and conversely*; that is, until the parts attain a homogeneous, uniform, and similar nature, after the pattern of pure gold. Hence so much study and striving in fixing metals and minerals: some have sought it by fixing-waters and by salts with marvelous cements; some by sublimations and prolonged reverberations—of which kind are those who tried to force quicksilver, shut up in iron tubes, by fire. Some chose styptic and astringent medicines as fixatives, such as vitriol, alum, verdigris, *crocus martis* [saffron of Mars, calcined iron]. Nor were there lacking those who imagined that volatiles could be bound and fixed by means of things that withstand fire; with what success, let us see.

[Margin: The various modes of fixation.]

Experiment 5. Fixation by cinnabar. Grind artfully a third part [trientem] of common cinnabar on hard marble, adding aqua fortis; then, having put this into a cucurbit, soak it with the following oil: extract by strong vinegar the essence of litharge; the vinegar being removed, pour over the litharge-powder, in a glass, the strongest spirit of wine, and again extract it after the manner of tinctures. Cook the extractions to the consistency of an oil, over which you will pour the cinnabar-oil prepared a little before; let the mixture be cooked to dryness, and a fresh oil poured back on, and this a third time, until the matter, when thrown onto burning coals, gives off no smoke; and you will have it prepared for fixing a metal into silver. This is the fixation of cinnabar, in which many, having wasted their labor and oil, when they despaired of the effect, turned to the cookings of lead and consumed even their lifetime upon them in fruitless toil.

[Margin: The fixation of cinnabar is futile.]

Do they not see that no solid fixation can be hoped for here? Since at last, when committed to the cupel or the ash-test, and dissolved by so many cookings and distillations, it is at last resolved back into the things from which it had coalesced. And what can you hope for from cinnabar, which teems with mercury; or from litharge, which you may rightly call calcined lead? I do not see. You will indeed obtain a mass, but one fused together [text continues]...

out of heterogeneous materials, which, being joined by no bond of friendship, are just as easily separated. For either the quicksilver will be fixed, or not. If the former, that cannot yet be said, since nothing is more controverted than the fixation of quicksilver. If the latter, you have wasted your oil and your labor. But what, I ask, is that thing which fixes a metal into gold or silver? Surely you will find nothing whatever to produce this effect, except the mercury in cinnabar and the lead in litharge. But since these are heterogeneous species, it cannot happen that they be converted into gold. It is plain, then, from this, the ignorance of the alchemists.

I am not unaware that some try to fix cinnabar with vitriol, kept for eight days under warm sand, until it flows like lead in fire; but this can only improperly be called fixation. Some do the same with silver. For if they fuse twelve pounds of cinnabar with one mark of silver, they promise themselves sixteen *besses* (or drachms) of silver, of which half is gold—from which they boast of fabricating sublimated mercury, which, often driven aloft, is fixed into a white medicine. But these are idle boasts of the alchemists, which leave nothing behind them but ashes and smoke.

Let us now see how Paracelsus institutes fixation by means of strong graduating waters [aquae fortes gradatoriae], oils, and liquors, which are as it were certain menstrua by whose help metals are said to be fixed.

[Margin: How fixation by Paracelsus's graduating waters is accomplished.]

He proceeds thus, in his *book On Graduations* [Liber de gradationibus]: *Take cinnabar, arsenic, antimony, of each 1 part; saltpetre 2 parts; sulphur the same amount; let them be ground, mixed, and distilled into an aqua fortis over a most violent fire. Afterward take two parts of this water; common alum, plumose alum, 1 part; vitriol, verdigris, crocus martis likewise 1 part; let all these together be distilled into an aqua fortis over a most violent fire. Then, to this whole water add 2 parts of caput mortuum [dead-head residue], 1 part of antimony, verdigris, cinnabar, and sulphur. Distil these strongly from their dregs, driving them forcibly into a receiving vessel. Then in this clarified water dissolve 1 part with 10 parts of*

flowers of copper and crocus martis, and let them digest in it; and at last there will be in the bottom more gold than is credible to art. Thus Paracelsus.

You will ask, then, from where this gold residing in the bottom flowed. Paracelsus ascribes it to transmutation. But I say that gold—if those golden corpuscles which previously existed in the arsenic, antimony, sulphur, crocus martis, cinnabar, and verdigris, dissolved from their bodies by frequent distillation, and by an inborn power separated to the bottom from the rest—flowed together. But if gold of this kind is of notable quantity, I say that it has coalesced into a single mass from the saline corpuscles of the alum, vitriol, and saltpetre, after the moisture had evaporated—joined to the gold and tinted by it. You will make proof of this in the assay-cupel, in which those substances, again separated from the gold, leave only that gold which was present in the said minerals. But let us examine another experiment, in which he carries out the tincture by means of an oil.

Experiment 6. By which, through oil of antimony, the Moon [Luna, silver] is said to be turned into the Sun [Sol, gold]. Paracelsus operates thus: *Take 1 lb. of antimony, half a pound of sublimate of mercury; let both be distilled together over a violent fire through an alembic, and there will ascend a certain redness, thick like blood, which tints and graduates any Moon [silver] into Sun [gold], and brings this pale [metal] to the highest degree of permanent heat.* O blessed apothecaries, who can so easily convert silver into gold out of oil of antimony! We ourselves indeed very often, in our own pharmacy, are accustomed to draw off a ruddy oil of this kind from antimony [stibium] and sublimate of mercury, and we have phials full of it; but we have never been able to discover an effect of this kind, since, although it does tint molten silver somewhat, yet, when committed to the cupel, the silver is soon restored to its former whiteness, the tincture vanishing, along with the previous mass.

[Margin: Paracelsus.]

But perhaps some will say that this Magistery is to be understood not in the literal but in the mystical sense. If so, I would say, more truly, that it has congealed in the mystical Moon—that is, in the dizziness of the brain—rather than in the concavity of a material vessel.

Experiment 7. By which, through an oil or liquor, the Moon is said to be converted into the Sun. *Take oil made from sublimate of mercury and aqua fortis, distilled together so many times until it has been turned into an oil; into this oil drive the spirit of aqua fortis over a most violent fire; then put in the Moon [silver], and it will be converted into granulated Sun [gold]; finally let it be cemented with*

royal cement, and the best gold will be obtained. These things are indeed easily said, but they are not found to be so in fact. So in this case it offers us nothing other than a certain accidental and extrinsic tincture, which, when assayed in the ash-test, soon leaves the silver imbued with its former color, the tincture vanishing.

[Margin: Paracelsus, in practice.]

There now follow the transmutations of metals from one into another; concerning which, as we have shown in the preceding, there are as many contentions as there are fancies of the authors—who, if they knew in what the true, real, and natural transmutation of things consists, would certainly judge otherwise about the chemists' transmutatory art. I myself indeed think that art, apart from nature itself, cannot attain to natural transmutation, whatever the alchemists may say. That this may be understood, it must be noted that a threefold transmutation is here to be considered.

[Margin: Transmutation can be taken in various senses.]

The first is natural transmutation, which nature alone, and intelligence abstracted from matter, knows. *The second is that which is properly called alteration*, and is nothing other than the dissolving of metallic and mineral particles—the whole being dissolved through fire—their agitation, and the separation resulting from this; by which, when each particle has been given its freedom, it flows together toward the body more akin to it and neighboring it by kinship of nature. This, however, cannot be said to happen through a true transmutation of one into another; nor should we attempt to admit a penetration of bodies, since those corpuscles of Sun and Moon, and of the fixed salts, always remain incorrupt and permanent in the body.

remain; and according to this species of imperfect transmutation, all that has been handed down hitherto must be judged to occur. *The third species of transmutation* is nothing other than a certain mixing of one thing with another, which, just as they can be dissolved with no difficulty, so too accomplish nothing in the great art, as is well known.

There are besides some who dream that heterogeneous species can be transmuted into one homogeneous thing in the great work. But just as, according to the laws of good philosophy, penetration of bodies is not granted (which nevertheless would occur, if a mass equal in weight to those things which they had put in were composed of them), so too that transmutation is brought about in vain. Whenever, therefore, gold or silver is drawn out from various minerals, and

a single body appears, that body must nonetheless be judged nothing other than a mixture—certain things from various earthy and watery materials mixed together, and so closely united that corpuscles of a heterogeneous nature can scarcely be separated from one another. Yet this body must not be called either pure gold or silver; for with the repetition of a more vehement fire, the heterogeneous corpuscles are at last separated, leaving only that gold which nature had produced. Of this matter we give the following experiment.

[Margin: Experiment, against the asserters of true transmutation.]

Experiment 8. Take three ounces of silver, 9 oz. of copper, 9 of mercury; let them, mixed together, be exposed to a charcoal fire for 24 hours. Then let that compound, first well washed with water and dried, be sublimed by strong fire for 7 or 8 hours—at each operation washing the bottom of the vessels well, and stratifying what has been removed with the sublimate. When this operation is finished, the whole will coalesce into a hard mass; from which, committed to the cupel, you will obtain at least five or six ounces of silver. The question here is: from where did the three ounces of silver, beyond the ounces you had put in, accrue? I answer: not from transmutation (which the alchemists falsely persuade themselves of), but from the flowing-together of the silver corpuscles mixed with the copper, in the resolution of the bodies into their own likes—that is, into silver things; which would not happen if silver had not previously, and indeed copiously, existed in the copper. So that no one should think that the copper or the mercury was converted into silver, but rather that the corpuscles of copper and of mercury were so closely and tenaciously united with the silver put into the mixture that they cannot be separated except by extreme torments of fire.

And this same thing is plain from another experiment. Take one ounce of lead, one ounce of marcasite of tin, and 2 oz. of mercury, which, mixed together, will dissolve as it were into flowing mercury of the common sort; so that one might suppose the lead and marcasite to have been converted into mercury by a true transmutation. But if you put it to the test, you will find it altogether sophistical, not true mercury. For mineral mercury, put into a cucurbit with fire applied, at once flies off, which does not happen in this mixture. For you will recover one ounce of lead, and likewise one ounce of marcasite, together with the two ounces of mercury of which the mixture consisted—the mercury indeed having escaped into the receiver, but the lead and marcasite remaining in the bottom of the cucurbit. But if, from such a mass committed to the cupel, some little gold or silver should remain, this must by no means be ascribed to transmutation, as the

alchemists boast, but to the silver particles which had previously existed in the lead.

[Margin: Whether there is a transmutation of imperfect metals into perfect ones.]

I will not speak here of the transmutation of imperfect metals into imperfect ones, since we have already said elsewhere how that can occur; but of the transmutation of imperfect metals into perfect ones. Among other things, the alchemists have indeed labored greatly to convert quicksilver into silver and gold. But whether they have accomplished this is still in dispute, nor can it be said that anyone has accomplished it—except either by some hidden imposture, or by a master higher than human understanding.

But now I hear the alchemists yapping back at me: that it has been accomplished by very many. To prove this, they bring forward various histories of those who are said to have made the purest gold in the sight of many; some of which we will append here.

[Margin: Various histories of Penotus about mercury converted into gold.]

There was (they say) at Rothenburg on the Tauber [Rotoburgum ad Tubarim] a certain monk, whose name, however, they deliberately do not add, lest they be convicted of lying. This man, they report, threw a certain powder upon an ounce of quicksilver heated in a crucible; and when this was done, a crackling arose, and the quicksilver was at once turned to redness; and this, further urged by a strong fire and melted, at last flowed together, taking on a metallic solidity—which, examined also by a goldsmith, was reckoned the best gold. But how this was done, we will afterward show.

[Margin: The history of Penotus.]

Penotus the alchemist [Penotus], in a letter to Guibertus [Guibert], says that a certain Scoto-Briton converted 48 [pounds—recte: the figure reads "48½"] of lead into true and pure gold by means of a red powder of the smallest quantity. Another adduces Hoghelande [Hogolandus] as witness, who relates that a certain German (a *vagabond individual*, I more truly interpret it) in a certain city of the Venetian dominion turned quicksilver into true gold. I hear Libavius [Libavius] objecting to me that a certain Scot at Cologne [Colonia] made gold from lead; from iron and lead at Rotterdam [Roterodamum], Amsterdam [Amstelodamum], Frankfurt [Francofurtum], Strasbourg [Argentina], and Basel [Basilea]; and that he even promised, if ordered, to perform the experiment for sixty thousand gold pieces. Anyone can easily promise great and lofty things, but to deliver them in

actual effect—of that one might rightly doubt. Yet whoever that Scot was—or, as the etymology of the name teaches, a "shady character" [tenebrius]—is unknown. Whence I conjecture, not unfittingly, from so many places and cities traveled through, that he was more truly one of the number of the *Apyri* [those who shun the fire]—whose habit it is not to stay settled in one place (lest they be charged with the crime of fraud), but to run about as vagabonds through the world to empty the purses of the foolish common folk.

[Reading order: reconstructed from the printed folio numbers and catchwords. The four PDF pages bear printed page numbers 305, 304, 307, 306 (PDF order). By page number and catchword chain — p. 304 ends "ha-/bent" → p. 305 "bent itaque"; p. 305 ends "gra-" → p. 306 "granum"; p. 306 ends "au-" → p. 307 "aurum quidem"; p. 307 catchword "finem" — the running order is 304 → 305 → 306 → 307, i.e. → 1 → 4 → 3. The translation below follows that order.]

[Fol. 304 — LIBER UNDECIMUS, Sect. III]

[Margin: Kelkelaiar's procedure.] To make his own experiments concerning transmutation seem worthy of belief, Penotus [Bernard Georges Penot] exalts Kelkelaiar [?], who, he says, transmuted an entire pound of quicksilver into the purest gold at Prague, in his own presence, with a single droplet of a deeply red liquid. So one mule scratches another. He testifies that Nicolaus Bernardus Hogolandaeus [Nicolaus Bernardus Hogheland?] did the same — yet Hogheland afterward declares that, to his own peril, he learned this came about largely through the agency of a demon. Certainly Guibertus [Nicolas Guibert], in his book *On the Ruin of Alchemy* [*De Interitu Alchymiae*], proves with not unfitting testimony that this Bernard was a most wicked man, addicted to atheism, and the author of that detestable little book *On the Three Impostors* [*De tribus Impostoribus*]. See then, reader, how much trust is to be placed in scoundrels of this sort.

Neander, in a certain letter, testifies that Paracelsus [Paracelsus] converted quicksilver into gold in his presence. But whatever Neander commends in so many words, Libavius [Andreas Libavius] overturns in just as many. [Margin: Paracelsus and his followers testify of the alchemists' deceit.] "The chrysopoeia [chrysopoeia, gold-making] of Paracelsus," he says, "is of use to those who make progress in it for nothing but the gallows — just as Paracelsus himself writes of his own disciples: that the hangman carried off twenty-one of them, the fate the rest deserve by their imposture." There are those who, scattering some powder — now black, now green, now red — onto molten metals, appear to convert them into gold. And to persuade the world more vividly of their riches, they now fling

that powder into rivers with the greatest ostentation, [Margin: The imposture of certain pseudo-chemists.] now cast it heedlessly into the mud and scatter it about, so as to seem to value powder of this kind — of which they never lack a supply — as little as the goldsmith's flock. For my part, I should reckon powder of this sort to be made rather from mouse-droppings [*Muscerda*] than from gold. For if you ask where they got so great a secret, they will pack you off to Brussels in Flanders, to the confessional seat of some monastery or other, where (they say) in such-and-such a place you may find the secret hidden away. If you ask further why they do not enrich their own parents with so great a treasure, they will answer that while they live they are unwilling to disclose the secret, but after death they will be found to have transcribed it in a will. Once found after death, the secret is discovered written out in so many and such dreadful characters that no Oedipus, however great, could unriddle it with all human industry applied. I hear there was a man of this stamp at Florence, whom they commonly called *Prete Nero* [Black Priest], of whom they tell marvelous tales. For my part, I judge rather that men of this kind — if they have produced gold not by some elaborate trick full of cunning, or by a colored powder — have at least learned it from him who is the author of all iniquity, as their Master.

The alchemists relate that one Tarvisinus [the man of Treviso] made gold before the Venetian magistracy. But Fallopius [Gabriele Falloppio], an outstanding doctor both of medicine and of chemistry, writes thus of him in his treatise *On Fossils* [*De fossilibus*]: "Tarvisinus, a certain apothecary, is said to have made gold in the presence of the Venetian Senate; but I say that, just as he made sport of those Senators, so too he was punished, as his own arms know it"; "and in fact he made so much gold that he nearly died of hunger, and in his own workshop

[Fol. 305 — DE ALCHYMIA SOPHISTICA]

[Margin: The imposture of the Arabs.] there are scarcely any pharmaceutical vessels — from which it is plain enough that it is mere foolishness to say that the art makes gold, and that one has no gold unless it is dug up." I shall not speak here of the gold of Raymond Lull [Ramon Llull], of Arnold [Arnald of Villanova], or of Rupescissa [John of Rupescissa] — gold rejected even by Paracelsus himself as counterfeit; on this I have treated at length in what precedes. So if anyone should examine histories of this kind more curiously according to all their circumstances, and ἀκριβέστερον [Greek: ἀκριβέστερον (akribesteron, "more exactly")], he will in the end find them to be nothing but the fictions of the idle mob, deliberately devised by the alchemists to win some authority for their art. So much so that men of this stamp seem to do the very same thing as the

astrologers, who, to establish the certainty of their art, recount marvelous fulfillments of their predictions. I could here append a whole book on the paradoxes of the astrologers — or rather, the prophecies of false-speakers — which nonetheless, if rightly weighed on the balance of astrological discipline, you would judge to be nothing but old wives' ravings, resting on no astrological foundation, contained and explained by no aphorism. [Margin: Astrology and alchemy go hand in hand.] Since, then, astrology and alchemy are true sisters — the former foretelling the state and condition of the future life, the latter anxiously aspiring to a blessedness heaped up with vast treasures of riches — it is no wonder that the enemy of the human race should for the most part insinuate himself, through secret commerce, into the minds of mortals: minds at once troubled by the foreknowledge of things to come and greedy with the hope of riches, which he lures on. But let us now return to our subject.

I say, then, that if it should sometimes be established from histories that from some powder ([Margin] for this is the term of a "vague individual" that the fabricators of lies generally use) cast over quicksilver or over other metals, true and pure gold was produced, I should subscribe to this without much difficulty. But that this gold emerged from mercury and from other imperfect metals by a true, real, and natural transmutation — this I deny. So if you ask by what way and method it was produced, I say it could have been accomplished by a twofold method: I shall demonstrate the first first, the second afterward.

[Margin: The goldsmith's fraud detected.] Those who make a show of transmuting into gold from a powder cast over quicksilver — I affirm it is indeed true gold, but produced by a most deceitful trick. To make this plain, I add the procedure. They work thus: they put a notable quantity of gold, minutely cut into little gold leaves, into a crucible; over this they pour either quicksilver or aqua regia, and within a certain span of time they find it eaten away and dissolved into a liquid substance. This they then place in a crucible and commit to the fire, by whose efficacy the quicksilver — by itself and by its nature most volatile, like lead too — vanishes into thin air, leaving at the bottom a substance which, once thoroughly dried, they convert into a black powder, which they keep for use. But if they want a green powder, they cook it into verdigris [*aerugo*]; if a red one, they tint it with the most ruby-red oil of antimony. They thus

[Fol. 306 — LIBER UNDECIMUS, Sect. III]

[Margin: With what the alchemists excuse themselves when the business does not succeed.] take a grain, perhaps drawn from sand or from a brick, and add it for ceremony's sake, so that he might be thought to have done something great. The

golden water poured over these — when liquefied, with the mercury exhaling away — gives back the gold which it had infused in the form of water. And these are the miracles of the alchemists, worthy not of the golden chain such as the one this man had received from the prince as a prize, but of the kind that executioners are wont to give to such men — a golden rope. So great is the audacity of scoundrels of this sort that they do not blush to bewitch even the minds of princes with their trifles and fraudulent arts. Such are those who boast that from mercury they make a fixed Luna [silver], which they afterward tint with certain substances that resist the manifold assay of the cupel — as there are certain tinctures which, however often the fusion is repeated, can scarcely be separated out, and so grade the silver up to 18 carats, owing to the violence of the mineral spirits that nest in the strong waters [aquae fortes]; for they cling so tenaciously to the perfect metals sympathetic to them, and are so stubbornly glued on, that they cannot be separated except by mighty torments of fire repeated many times.

[Margin: Sometimes the business does not succeed.] I have heard some who boasted that they most surely held the art and who often claimed to have ascertained the truth of the art by experiment — yet, to the extent that they did not attain their wishes, they plead either their own inadvertence, or the omission of some circumstance, or of some other necessary thing; though they could, and ought, more wisely have confessed ignorance in place of inadvertence, and a false promise in place of the omission. And this is the impostors' method, by which they are wont to bewitch the minds of mortals.

From which it is gathered: If some impostor of richer fortune were to reduce 100, or 200, or even 1,000 pounds of gold into powder (which a few are recorded to have done, to win for themselves from this fictitious art an immortal name), he would doubtless everywhere perform false miracles of this art, to the astonishment and admiration of all, in a brief span of time, without all those concoctions and sublimations and the fermentations of many months. Would that those whom we have just reviewed had not done so, along with the rest of the gods of the greater nations, pointed out here and there in what precedes!

[Margin: Imposture.] Again, there were some who, having suddenly grown rich by treasure found in a field, and to avoid being compelled to cede a portion to the treasury as the laws require, are said to have professed this art — that by a small portion of powder added to quicksilver and to other metals they could convert the metals into gold — in order, by this cunning, to veil the riches of gold acquired from elsewhere. A game wholly of dice, which many have paid for with golden chains, with gibbets and with nooses, as one reads of Bragadino, of the

Scot, and of others adduced above. But how easy it is to impose by this fraud upon inexperienced men greedy for gold, who does not see? When they cannot conceive how, by a small portion of black powder

[Fol. 307 — DE ALCHYMIA SOPHISTICA]

cast over metallic bodies within a brief span of time, gold should at once come forth — whereupon, seized by astonishment and ecstasy, while it is not permitted even to suspect the hidden industry of the fraud, they marvel only at what has been done. [Margin: The deceived in the truth of the fraud — paint upon truth — the simplicity and obstinacy.] Hence, when from the report spread abroad those doubts are put forward by more skilled inquirers — doubts that may smack of some imposture — they at once reject them, not without indignation; they will hear nothing of reasons; nay, ten and a hundred times over they retort: "I saw it with my own eyes; I observed it done in the presence of such-and-such men, in such a house, in such a workshop; the powder I cast in with my own hands at the artist's bidding; we gave the gold produced to goldsmiths to examine, and with all assays applied, we found it sound, pure, far more excellent than common gold." Others, informed of so memorable an event, cry out again and again: "I heard it from those who were present and handled it with their hands, that to this very day a portion of the said powder is preserved with such-and-such a man as a perpetual memorial of the thing, so that any who wish might have the means of testing its truth; and already by the very deed several have made trial of the matter with the desired outcome, so that no one ought any longer to doubt the truth of the art — and let those who place no faith in this most true art be banished from the number of the wise." And in this way lies are linked to lies, which are not only scattered into public fame but also committed to books, to the utmost harm of the commonwealth and to allure the minds of others with this lucrative novelty; and — *res μετὰ τῆς ὑπερβολῆς* [Greek: μετὰ τῆς ὑπερβολῆς (meta tēs hyperbolēs, "with exaggeration")] — they are magnified beyond what they can be. So that I should reckon that ridiculous tincture of gold, infinitely multiplicative, to have drawn its origin from nowhere else than from these things. And he alone will be unable to be ignorant of it who, taught by experience, knows what nature can and cannot do, and has thoroughly grasped the contrivances of scoundrels prone to such frauds and deceits. Let no one therefore say hereafter, "I saw, I heard, I handled the truth of the art with my own hands," since the same thing happens to him as is wont to befall mountebanks and quacks [agyrtæ, circulatorēs]: who, when they pretend to gash their own belly, to devour serpents and toads, to convert leaden, copper, and iron rings by sudden transmutation into gold, fill the surrounding crowd with such

astonishment that they seem utterly unable to deny what had been demonstrated with such evidence. The senses are a slippery thing, and it can scarcely be told how easily they bewitch — I will not say the ignorant mob, but even the learned and wise — so that they persuade themselves a thing truly is, which is not, out of a corrupted imagination; especially if they are driven out of their wits by skilled and zealous architects of fraud, by the cunning of a similarly deceitful art. But let what has been said of the first point suffice. Let us therefore proceed to the second mode of making gold proposed above.

[Margin: What kind of gold the genuine chemists produce.] But the alchemists who labor without fraud in transmuting metals into Sol [gold] and Luna [silver], if they proceed sincerely,

[Now the experimental section. On Fol. 305 (recto), the lower portion of the page carries the heading EXPERIMENTUM and a procedure translated from the Arabic; on Fol. 307 (recto) appear the numbered Experiments 9–12 and the opening of the Combinatory Table. These are transcribed in their folio positions below.]

EXPERIMENTUM [Fol. 305]

[Margin: The imposture of the Arabs.] To these I add a history which most alchemists commonly allege to confirm the truth of the art, and which — drawn (they say) from the school of the Arab alchemists — I judge to have happened more truly in Utopia than in Galbania, a city of Egypt (a city of which not even a trace appears in the geography of Egypt, whether from ancient or from modern times). They say that a certain man came to a certain goldsmith (for the alchemists especially use this term of a "vague individual" when they wish to extol the marvelous effects of the Art), promising him a great reward if he would, in his presence, undertake a true and real proof of his art. Boasting golden mountains [Margin: An imposture present before a certain prince.], he was eager to transmute the sea into gold. He therefore set about the work. Into the crucible is placed a certain quantity of mercury

[At this point, on Fol. 305 the type continues with the procedure that on the page is interleaved with the prince-narrative (the compositor has set two threads on the page). The EXPERIMENTUM proper — the Arabic recipe — reads as follows:]

Experiment. Take one part of the said powder made from gold, and one part each of saffron of Mars [*crocus Martis*], of burnt copper [*aes ustum*], and of sal ammoniac. Let the sal ammoniac be dissolved, and mix it well with the three aforesaid ingredients; then put the mixture into a cucurbit, and with a gentle fire

— either in the sun or over an ash-fire — digest it until all these are thoroughly tempered together and incorporated, and, once the moist matter has been consumed, it has congealed. From this you will make the said powder, which you will keep for use.

This done, take a pot-bellied vessel with a narrow neck, into which [put] lead, and within the neck [put] one thin gold leaf, either above the orifice — that is, [the quantity] of ounces — you will set a golden denarius, so that it may draw up the vapor of the dissolved lead. Then take the aforesaid leaf, by turning and returning [it through] the aforesaid vapor; in this way the leaf becomes so brittle that it can be ground into powder with the fingers. And this is the powder that changes silver into gold.

The burnt copper [*aes ustum*] that enters into the secret ought to be prepared thus: copper-scale [*aes fegili* (recte *aes fissile*?)] pulverized in the same way, wash it so many times with triple water or with brine until it is wholly clean, and from this make a powder. Behold the secret of the Arabs revealed to you in few words.

This experiment is indeed certain, yet it is like the one they accomplish by addition. For gold, taken in a fairly adequate quantity and prepared from the said species — saffron of Mars and burnt copper — and likewise duly purged with sal ammoniac, and then [poured] over molten silver, by its tincture (which exists abundantly in the said species) not only tints the silver into gold, but also confers on it a mass and no small increase mixed in. Yet, just as those [tinctures] cannot endure the long torments of the cupel or of the ash-test without at last being separated into what they were, so here too we cannot admit any true and real transformation. This very Secret was afterward also found, in a few small details, in Paracelsus, who however wrapped it up — as some great mystery, lest it be laid bare — in riddles too, after the fashion usual with impostors.

I myself have known a Prince, whose name I deliberately spare, who, having entered into dealings with one of those rogues who promise the masteries of this flour [i.e. of this stamp], had promised him a great reward if he would, in his presence, undertake a true and real proof of his art. He ordered two silver cups to be cast and melted down for himself; once these were liquefied, the other [man], pressing in a certain green powder while the silver still flowed in the crucible,... [Margin: The Arabs' imposture.] and, after raising both great smoke and a great noise, a little later he finds the silver converted into the purest gold. The goldsmith, astonished at so great a spectacle and stirred by the desire of making the powder, with all the submission he could muster begged his guest to reveal to him the secret so worthy of admiration — which he did not at all unwillingly

grant. This history is told in an Arabic book *On the Conjunction of the Sun and Moon* [*De Solis et Lunae congressu*], and it teaches the secret in the following process, translated by me from Arabic into Latin, as follows.

[The numbered procedure here is the same EXPERIMENTUM transcribed above (Take one part of the said powder made from gold... — the page sets the recipe both in *italic* at the foot and the narrative above it). It is not repeated.]

[Fol. 307, the Experiments. Set in the left column following "aurum quidem... producunt":]

The [alchemists] produce gold indeed, but not pure and refined, but mixed and sophisticated. Let us set down a few experiments.

9. Experiment. [Margin: Fixation of Luna and Sol by means of cinnabar.] I shall not deal here with making gold by the [philosophers'] stone, which they call the philosophical [stone]: for we say that this is a figment of the abstracted intellect, for the reasons set down above. Rather [I deal] with the augmentation of gold, which arises by addition, or part with part.

In this way, then, by means of cinnabar and quicksilver they make Sol and Luna. Take a part of the best gold, first reduced to a calx by means of crude mercury; place this in an alembic, and a little later pour over it the following water; then by an eightfold cohobation draw it off. This done, the dissolved gold, ascending into the alembic, draws off its phlegm to the point of density. This infused spirit indeed cannot be dissolved from the gold except by its oil, which is poured over the cinnabar prepared above, so that it projects a little above [it]; then let it coagulate, reduced by the help of borax, and you will have the gold sought.

[Margin: Preparation of the water.] The water to be poured over the gold calcined by mercury is prepared thus. Take saltpeter 1½ lb., arsenic 3 lb., green copper [verdigris] 8 *lotones* or half-ounces, filings of iron or of steel 1 lb.; let the whole compound be put into a retort and distilled into a water. Of this water pour 8 *lotones* over sublimated mercury; you will draw it off, and the whole will be dissolved into a water suitable for fixing Luna [silver]. Take again sublimated sulphur from vitriol, and let there be a stratification (to speak chemically) over 4 *lotones* — or, what is the same, half-ounces — of fixed Luna, and 2 *lotones* of sulphur; then let it gradually evaporate. To the rectified sulphur join four times as much glass of Saturn [*vitrum Saturni*, glass of lead], and while it is in fusion infuse the calcined Luna into it; and place it, twice fulminated, for 20 days into the water already prepared, and you will have fixed silver with the mean of gold — not pure indeed, but sophisticated. [Margin: Fixation of mercury.]

10. Experiment. *To fix mercury.* Take 1½ *loton* of green copper, that is, of verdigris; one *loton* of crude mercury, which, kneaded into the green copper, let be sublimated in a glazed earthen cucurbit so long until the green copper is united with the mercury, and you will have it fixed. [Margin: Silver made from mercury.] Again, take the whole compound, which, first ground most finely on marble, you will put into a retort to be distilled over a strong fire; and what is not yet fixed recedes from the green copper. Take this and reduce it, by the following flux, into pure Venus [copper], so that it may be drawn off by the lead following, placed in a melting-pot; and from one drachm of mercury there will remain three drachms of silver pregnant with gold.

The flux is made thus. Take urine, which you will concoct into a stone and let the spirit fly off; take of it four times as much together with tartar, and you will work as was said a little before.

11. Experiment. *To convert into gold the Luna made from common mercury.* [Margin: Silver made from mercury converted into gold.] First, let aqua regia be made from vitriol and saltpeter, one pound of each; then green copper and sal ammoniac, 4 *lotones* of each; filings of iron, ½ lb.; let all these, mixed and minutely ground, be dissolved by a strong fire into a water; and place this water in an alembic and gently draw it off, by the heat of a [water-]bath, to the consistency of oil. Then take as much as you wish of crude antimony, and pour over it the oil a little before prepared, to the height of a finger; then, placing this in a low cucurbit, draw it off so many times until the oil is perfectly united with the antimony; and you will have a powder, which they call the red lion. Take therefore the fixed Luna from mercury; beat it into thin leaves; if you stratify these in a melting-pot and leave them in the cement for 24 hours, then you will have silver [turned] into the purest gold — exalted, however, only in color.

12. Experiment. *To exalt gold of weak color.* [Margin: To impart a genuine color to gold of weak color.] Take of sublimated mercury and of cinnabar 2 *lotones* of each, of antimony one *loton*; and twice as much vinegar, to which you mix as much verdigris as you can take up with two fingers; let them be put little by little into a separating pot or retort, and a liquor beautiful to look at will come out. Then take a part of cinnabar, which you should imbibe with the liquor a little before elicited; and draw off the liquor anew, committed to a glass retort, from the cinnabar. Afterward, placed in an alembic sealed with the seal of Hermes, let it coagulate in sand for 12 days, and you will have a powder. This done, take pale gold of imperfect color, or fixed Luna, 8 *lotones* or 4 ounces, over which you will

expose to fusion 6 drachms of the prepared powder, and you will have it exalted to that degree than which none greater can be desired.

The same will be done without powder in this way: spread silver or gold into thin leaves, place them in the oil or in the aforesaid liquor before it coagulates, and expose them to a gentle heat, as above, for 24 hours, until you see the oil somewhat stirred by ebullition, and you have what you sought.

I could adduce countless experiments of this kind in this place; but since there is almost nothing in one that does not also enter into another, and so as to embrace much in little, I have thought fit to attach here a Combinatory Table [*Tabula combinatoria*], by which whatever others hand down in whole books may here be exhibited in a single synopsis.

IN THIS TABLE.

Minerals regard metallic bodies, and combine perfectly with them. Each one of these can be reduced into its elements — salt, water, spirit, oil; hence, by strong waters, royal waters, and Stygian waters [aquae fortes, regiae, stygiae] which are compounded from salts, the bodies are dissolved, calcined, pulverized; but by the power of fires they are sublimated, purified, digested, fermented, fixed; and by the help of external agents — such as vinegar, tartar, spirit of wine, and the other acid juices and subtle ones — they are diluted, washed, purged. And at last, through a new solution and coagulation, [they reach] the ultimate end of the art

Diagram. A full-page engraved combinatory diagram (*Tabula Combinatoria*) occupying the recto, marked "Tom. II 30[7]" at the upper right. The plate is a synoptic web: two vertical columns of substance-labels — imperfect substances at the left, perfect metals at the right — joined by ruled straight lines that connect (in principle) every left-hand entry to every right-hand entry, producing the dense lattice of crossing lines that fills the field. Across the top of the field runs the operative dichotomy **SOLVE** (left half) / **COAGULA** (right half); along the bottom runs the legend "**Mediante igne Solvuntur et coagulantur**" ("By means of fire they are dissolved and coagulated").

Engraved title and subtitle (verbatim, top of plate):

TABULA COMBINATORIA, Qua Whatever is contained in the whole of Alchemy is here set before the eyes of the curious reader as in a recapitulatory synopsis [in Synopsi anacephalaeotica]. Nor, outside this table, need you look for anything — whether you are considering the

construction of the [Philosophers'] Stone, or the metallurgic art, or the mixtures of metallic bodies, or again the generation of their kinds — that is useful and fruitful for chemical operations.

Column headings and labels:

- **Left column heading:** *Imperfecta Metalla* ("Imperfect metals")
- **Right column heading:** *Perfecta in sua specie* ("Perfect in their own kind")
- **Top legend, left half:** SOLVE ("Dissolve")
- **Top legend, right half:** COAGULA ("Coagulate")
- **Bottom legend:** *Mediante igne Solvuntur et coagulantur* ("By means of fire they are dissolved and coagulated")

Left-column entries (top to bottom), with English glosses:

- Mercurius — mercury (quicksilver)
- Sulphur — sulphur
- Arsenicum — arsenic
- Auripigmentum — orpiment (arsenic trisulphide)
- Macasita [Marcasita] — marcasite
- Antimonium — antimony
- Cinnabaris — cinnabar
- Sal commune — common salt
- Sal nitrum — saltpetre (niter)
- Alumen — alum
- Vitriolum — vitriol
- Sal Ammoiacū [Sal Ammoniacum] — sal ammoniac
- Sal gemmae — rock salt (gem-salt)
- Ærugo — verdigris
- Tutia — tutty (zinc oxide)
- Galamena [Calamina] — calamine
- Bismathum [Bismuthum] — bismuth
- Cadmia — cadmia (zinc/cobalt ore)
- Talcum — talc
- {braced group:} Ex Vegetabilibus / Tartarum / Spiritus vini / Acetum —
"From vegetable substances: Tartar / Spirit of wine / Vinegar"

Right-column entries (top to bottom), with English glosses:

- Aurum — gold
- Argentum — silver
- Cuprum — copper
- Ferrum — iron
- Stannum — tin
- Plumbum — lead
- Mercurius — mercury
- Sulphur — sulphur

[Fol. 308 — close of the introductory matter to the *Tabula combinatoria*, completing Sectio III, Caput III, then the new Sectio IV, Caput I.]

they attain their end. And although the alchemists who deal in the secret of the great Magistry wrap it up under various riddles and parables, nevertheless, if you strip off the parabolic rind and examine the marrow, you will find that they follow the very same process as those who profess the metallurgic and sophistic art, and that they use the same ingredients drawn from those listed in this combinatory table. For without gold and silver — as even Lull [Ramon Llull, here the pseudo-Lullian author] himself admits in his *Clavicula* — gold and silver cannot be produced; and from the rest, imperfect metals are vainly tinged into perfect ones and transmuted, unless gold is present in them, by which (as through a kind of accretion) the gold receives a certain increase. But all these things will lie open to the wise philosopher in the Combinatory Table, if he knows how to apply it rightly; for no combination of the art can be devised that is not found within it.

SECTIO IV.

CAPUT I.

JURIDICUM SIVE LEGALE.

Whether chemical gold [Aurum Chymicum], made by whatever method, may lawfully be sold as genuine?

I raise here a Question that the jurists claim for themselves by the greater right; yet, lest I should seem to have omitted anything, I judged that it ought not to be passed over. Before we begin this question concerning chemical gold, it must be noted, first, that four kinds of art can be considered in this place.

The first is the **Metallurgic Art** [Ars Metallurgica], which by a singular skill separates the pure from the impure, the heterogeneous from the homogeneous, out of the ore of gold and silver; and the remainder it cooks down, by the aid of fire, into pure gold and silver. This skill has been treated very fully in [the section on] metallurgy, that is, the metallic art. [Margin: *Metallurgia in quo consistat, & quomodo licita* — "In what metallurgy consists, and how it is lawful."] And inasmuch as this art is so necessary to the human race that without it — given the supreme usefulness of metals — no administration of empires, kingdoms, or human commerce could subsist, so too it is so far from being judged unlawful by the laws that the jurists rather reckon it worthy of all praise, as the very foundation of human commerce.

The second is called **Chrysopoeia** [Chrysopoeia — gold-making], whereby the alchemists boast that, through a true and real transmutation of one metal into another, they can convert it not only into natural gold but into something even more excellent. [Margin: *Chrysopoeia an licita* — "Whether chrysopoeia is lawful."] And if this were true, they certainly could sell and dispose of that gold without any scruple.

The third is called the **Spagyric Art** [Ars Spagyrica], the method by which certain chemists separate, by a singular skill, true and natural gold that has been mixed with various metals — such as silver, copper, iron, lead, arsenic, marcasites, and the like; they sift it out of the sands of rivers and riverbanks by frequent washings [per frequentia tormenta], and melt it into little ingots. [Margin: *Spagyrica quomodo licita* — "How the spagyric art is lawful."] Such gold — being, to be sure, but little, and natural — no law forbids.

Fourth is that **gold-making** [aurificium] whereby the alchemists know how, by addition (or, as they call it, "part with part" [partem cum parte]), to augment gold and to give it its due tincture. [Margin: *Aurum quod per additionem, an licitum* — "Gold [made] by addition, whether it is lawful."] And it is of two kinds: one is called **Collybistic** [Collybistica], the other **Sophistic** [Sophistica]. Concerning this last there are varied debates among the jurists.

For our part, we shall resolve the doubts of each of the proposed branches by the Canons, both Civil and Canon, after we have first set down a few remarks concerning the *Extravagans* issued by John XXII, Supreme Pontiff [Pontifex Maximus].

John XXII [Pope John XXII], a Gaul, by birth a man of Cahors [Cadurcensis], from the province of Aquitaine, raised to the Pontificate in the year 1316, besides the

constitutions of his predecessor *Clement V*, also himself published many [decrees], which he calls *Extravagantes*; on which *Zenzelinus de Cassanis* [Jesselin de Cassagnes] issued ample commentaries. [Margin: *Extravagans Ioannis XXII. Pontif. de crimine falsi* — "The *Extravagans* of John XXII, the Pontiff, concerning the crime of forgery."] Among the other *Extravagantes* there is also one entitled *De Crimine falsi* ("On the Crime of Forgery"), in which he condemns all those who give their effort to making gold: he denounces the Art in wondrous ways. But — to embrace many things in few — I shall here append the said *Extravagans*, in which you will find whatever we have hitherto adduced concerning the falsity of Alchemy confirmed by Apostolic authority.

EXTRAVAGANS

On the Crime of Forgery [De crimine falsi].

JOHN XXII, Supreme Pontiff.

Preface to the Extravagans.

Here the alchemists are forbidden and punished — those making gold and procuring it to be made — since they ought to bring into the public [treasury], to be distributed to the poor, as much of true gold and silver as they have laid down of false and adulterated [metal]. And if their means do not suffice, the penalty shall, at the judge's discretion, be commuted to another, and they become infamous. And if they are clerics, they are deprived of the benefices they hold, and are rendered incapable of holding [any]. See the *Extravagans* of John, which begins *Prodiens*, and is placed under the [rubric] *cc, cit.*

[Fol. 309]

THE TENOR OF THE EXTRAVAGANS [Extravagantis Tenor].

The poor alchemists promise riches that they do not deliver; likewise those who deem themselves wise fall into the pit that they themselves have dug. For without doubt the professors of this art of Alchemy delude one another — being conscious of their own ignorance, they marvel at those who claim to have said something of this kind above [beyond] themselves; and when the truth they seek is not at hand for them, they waste their days, exhaust their fortunes, and with words dissemble their falsity, so that at last, by a sophistic transmutation, they may fabricate as true gold or silver what does not exist in the nature of things. And by this their rashness sometimes proceeds, from the condemned to the condemnable, so far that they strike, with false dies, the characters of public money [the legal

currency], in order to delude with false appearances the common crowd that knows no other furnace-fire of the alchemists. [Margin: *Alchymitum pro Alchymicum* — "(The text reads) *alchymitum* for *alchymicum*."] We, therefore, wishing these things to be banished for all time, ordain by this edictal constitution that whoever shall have made such gold or silver, or, once the deed is done, shall have ordered it to be made, or, knowingly, while it was being made, shall have ministered to those making it, or shall have knowingly used either such gold or silver in selling, or in giving in payment, shall be compelled to bring into the public [treasury], by way of penalty, true gold or silver of as great a weight as the alchemical [metal] amounts to, in respect of which it shall have been established that they offended in any of the aforesaid ways — to be distributed to the poor; the makers being nonetheless, together with the alchemical gold or silver itself (or those knowingly using it, as is premised), branded with the perpetual mark of infamy. But if, to pay the aforesaid pecuniary penalty, the means of the offenders themselves do not suffice, the discreet moderation of the judge may commute the penalty into another — namely of imprisonment, or another — according to the quality of the matter, the difference of persons, and other circumstances to be weighed. But those who shall have broken out into so great an ignorance of misfortune that they not only sell coins but condemn the natural precepts of law, exceed the bounds of the Art, and violate the laws among other [crimes] — namely by knowingly striking or casting, or causing to be struck or cast, adulterated money out of alchemical gold and silver — we command to be struck with this animadversion: that their goods be assigned to the prison, and they themselves be perpetually infamous. And if the offenders are clerics, let them, beyond the aforesaid penalties, be deprived of the benefices they hold, and be rendered utterly incapable of holding [any].

This is the Constitution of John XXII, Supreme Pontiff, concerning which marvelous things are spread abroad. The alchemists pretend that the Pontiff was most devoted to Alchemy, and that, when he could not attain to the great work of the Art, he framed out of desperation this so rigid constitution. *Platina* [Bartolomeo Platina] indeed, in his life [of the pope], reports that after his death an enormous quantity of gold was found in his keeping; but if this is true, it must nevertheless be believed that such a treasure of gold was by no means procured by the benefit of the Chemical art — though the alchemists try to prove [the contrary] by fair means and foul, [maintaining] that the Pontiff framed this constitution for that very reason, lest anyone besides himself should attain to the secret of the art, and that he did so out of envy.

However that may be, I would not wish to suspect such things of the Vicar of Christ. Hence, if Platina is to be believed, I judge that this treasure of gold was — as we said a little before — by no means procured by the benefit of the great Art; since he himself, in his own *Extravagans*, condemns it in open words. Rather, I judge it more likely that the aforesaid treasure grew out of various collections, whether from revenues, or from gold acquired into his private purse by his own industry, or even by gift; since to the Pontiffs the means for procuring such things are never lacking.

[Margin: *Liber Alchymicus falsò Ioanni XXII. Pont. adscriptus* — "An alchemical book falsely ascribed to John XXII, the Pontiff."] Not long ago I came upon a book written in the French tongue, whose title is: *L'ART TRANSMUTATOIRE DU PAPE JEAN XXII. DE CE NOM* ("The Transmutatory Art of Pope John XXII of that name"). In it is treated the manner and method by which the said Pontiff is supposed to have had true and natural gold made, by the benefit of the great art, in his Palace at Avignon [Avenionensi]. It begins thus: *Or commence le livre d'Alchimie, que le Pape Iean fit ouvrier en Avignon, du quel ouvrage il en avoit 200 roellez, à un chacun pesant un quintal* [French: "Here begins the book of Alchemy that Pope John had wrought at Avignon, of which work he had 200 round ingots, each weighing one quintal"]. Then it describes at length the process of the whole Magistry. For my part, indeed, when I had examined the manner of operating in it rather thoroughly, I freely confess that I found nothing in it of any singular merit that would surpass either the genius of the ancient alchemists or the precepts and style of the first Masters in the art — nothing beyond certain common received recipes, described elsewhere. Whence, and consequently, I have conjectured — not without manifest arguments — that this is nothing but a supposititious offspring, which someone among the desperate alchemists thrust into the public light, both to confirm the truth of the art and to win for it some esteem under the name and authority of the Pontiff. But, lest I should seem to do injury to anyone, I trust I shall make my case from the very process set before the eyes of the experts.

THE PROCESS [Processus]

Wrongly ascribed as alchemical to John XXII, the Pontiff. Which, translated by me from the French tongue into Latin, I render word for word as follows.

Take the strongest vinegar, 4 pounds of white lime; let it stand in this manner for 4 days. On the fifth day, put the material into a glass alembic, and distil it, and keep the distillate well. When this is done, take salt, and urine with Alexandrian Indigo [Indico Alexandrino], 1 pound; of sal ammoniac, 6 pounds; half a pound of

prepared common salt, and likewise half a pound of vinegar. Of the said things [take] 5 pounds; first, having warmed them with vinegar, distil; and afterward you will add the salts, which, when they have melted, you will put together into the alembic to be distilled. When it has been distilled, if anything mixed remains in the bottom, and is not yet stripped of its dregs, you will repeat the distillation, the water that comes out being poured over it anew; and you will repeat this so many times until all the water has gone out from the material.

[Fol. 310 — blank verso; no text, faint show-through from the recto only.]

escaped. Once this is done, you will find at the bottom of the vessel a mass congealed like ice or crystal; keep it carefully and apart. Next, take living sulphur [sulphur vivum] steeped in a strong lye, which you will sublimate, together with 4 ounces of the Moon [Luna, i.e. silver]; let all these be placed in water according to the precept to be given below. Once the said substances have thus been dissolved, put them into an alembic, and after you have distilled them with a strong fire, a mass will remain at the bottom. Take it out and set it on a glass plate in a cellar, or in some other damp place, until it has dissolved into a liquid, which again you should keep. Then take the mass extracted in the first operation, named above, and likewise expose it on the glass plate in a damp place, as before, to dissolve. When this is done, mix together these two waters produced by the first and the second operation, and let them congeal into a single mass. When this is congealed you will have the perfect medicine. From it, if you cast a small part onto 18 parts of Mercury melting together [in fusion], you will obtain the whole, within a short time, converted into the finest Moon [silver], proven sound by every assay.

And this is the first process, in which either the writer's utter ignorance or his negligence is plain. He sets down 43 ounces of calx of silver, together with the same number of ounces of sublimated Mercury — in which there is a manifest error. For since silver reduced to a calx is brought back to its former nature, the calcined silver necessarily costs more than the profit from the transmutation of the Mercury would bring in — as anyone can see from the proportion of 43 ounces of silver to the 18 parts of Mercury that the process says are to be transmuted into silver. We have therefore corrected the error by adding 4 parts of calcined Moon [silver]. But whatever this author may say, certainly nothing else is to be hoped for from this process than a certain silvery mass formed from the congelation of mercury and the calx; and so this process, the whole of it, is sophistical and unworthy of anyone's wasting useless and fruitless labor in testing it. But let us now examine the same author's process for making the purest gold. He puts it thus:

Processus II. *Pour faire Soleil bone fin* — [French; recte: *bonne fin*] that is, to make the best and pure gold. Take burnt copper [aes ustum] and sulphur of vitriol [sulphur vitrioli], 2 pounds of each. Grind each one separately and finely on marble, then commit them, thoroughly mixed, to an alembic well sealed with the lute of wisdom [lutum sapientiae] so that no spirit escapes; and, placed within the ashes of a small furnace, distill the material at a gentle heat, and keep the water drawn off in a glass flask. Afterward take two drachms of pure gold and 4 drachms of quicksilver, which you should amalgamate together in the goldsmiths' manner. This done, work the amalgam as thoroughly as possible for the next three days with the water kept above in the glass flask — that is, grind it in the manner of painters. When this too is done, concoct the material, worked as described, committed to a gentle fire, for 12 hours. When this is finished, grind it again with the said water, and what has been ground thoroughly, cook again, always repeating the same procedure 18 times, until you observe the color of vermilion. Then take a quantity [pondus] of this material, test it, and cast one quantity onto 18 of lead, and you will have gold most thoroughly proven by every assay. But the lead onto which the medicine is to be cast is prepared by long labor, in this way:

[Margin: Preparation of the lead.]

Take thin little plates of lead and arrange them in layers [stratify them] inside an earthen vessel with salt ground into a fine powder, continuing layer upon layer until the whole vessel is full; then close the lid of the vessel tightly, leaving, however, above an opening fit for letting out the smoke. Then commit this vessel to a suitable fire for 6 hours, and afterward, when the vessel is opened, you will find the little plates of lead corroded and very white. Place these in a strong and hot lye, and the salt will descend together with the lye, the plates likewise remaining pure and white at the bottom. Then take these out and grind them on marble, fresh spring water being poured over again and again, until you find the water clear. When this is done, repeat the grinding with the powder of the remaining water, with water of alum and of common salt and of tartar added, and let it be dried over a fire; and do this so many times until the whole material appears completely white. In this way commit the whole to fusion in a pot, and you will have lead prepared, which is to be converted into gold.

And this is the process — which, such as it is, has been drawn in part from the *Clavicula* of Lull [Raymond Lull; *Clavicula Lulli*], so that from this very fact its spuriousness is recognized, since Lull became famous in the world long after John XXII [Ioannes XXII], the Pontiff; nor is it likely that Lull borrowed this

process from John XXII. Let the reader now judge what is to be hoped from this process of a desperate work. That spurious author adduces very many other processes for the transmutation of quicksilver [hydrargyrum] into silver and gold. But since he has copied them from others, and they are altogether of the same flour [i.e. all of one kind] as those found in Ripplaeus [Ripley], Birellus, Isaac, Lull, Arnold [Arnold of Villanova], and the rest, I judged that in describing them more account should be had of the time than of secrets of this sophistical kind. Nothing further remains, then, except that we set down here the juridical aphorisms on chymical gold laid down by various jurisconsults.

Caput II.

Juridico-Canonical Decisions: On chymical gold, false and true.

[Margin: Whether alchemy is lawful, by its own distinction.]

1. It is asked whether alchemy is a lawful art. Reply: that alchemy is lawful which produces genuine and natural gold. Thus Oldradus, *Consilium* 74, and Ioannes Andreas [Johannes Andreae], in the title *De crimine falsi*, in the addition to the *Speculum*. But if it produces sophistical gold [aurum sophisticum], it is unlawful; so most of the Doctors of both the Civil and the Canon Law. Thus Joannes de Plat[ea], on l. 1, *C. de arg. pret.*; Joannes de Clavasio, in his *Summa*, under the word "Alchymia."

[Margin: Whether true gold can be made by alchemy.]

2. It is asked whether true and real gold can be made by the alchemists through transmutation. Reply: that it cannot. So Avicenna, cited by Albert [Albertus Magnus], on whom there was full discussion in the preceding pages — because such alchemical gold has only the outward appearance of gold, yet is not true gold. So St. Thomas [Aquinas], *Summa* 2.2, q. 77, art. 2; Cardinal Alexander [de Imola], on c. 1, *Quae sint reg. in usibus feudorum*. If nevertheless anyone were to effect this by a true transmutation, there ought to be no doubt that the gold too would then be true. But let us hear the words of St. Thomas — whom many wrongly say not only to have approved alchemical gold but even to have made it, in order to establish the falseness of the art by the testimony of so great a man; yet they can easily be refuted from his very own words. "Alchemy," he says, "although it is difficult" — [Margin: St. Thomas's view on chymical gold.] — "is not however impossible, which we say is known at least to the angels or to demons, who alone know the hidden paths of nature, along which they can operate perfectly. If, therefore, the gold made by the alchemists is not true, and not such as it is when made by nature, then its sale as true gold is fraudulent and unjust;

but if it is true, it may be sold for true gold (as is that which is extracted from the various metals with which it has been mixed)." And concerning truly alchemical gold he speaks thus, 2 *Sent.*, dist. 7, q. 3, art. 1:

[Margin: Gold cannot be made by the alchemists' art, as being repugnant to nature — St. Thomas affirms.]

"Art can indeed induce certain substantial forms of natural agents into matter; there are, however, certain forms which art can in no way produce, because their proper active and passive principles it cannot find and apply, but it can well make something similar to them — just as the alchemists" [Margin continues:] "make something similar to gold as regards the external accidents, yet they do not make true gold, because the substantial form of gold is not produced by the heat of fire, which the alchemists use, but by the heat of the Sun in a determinate place, where the mineral power [virtus mineralis] is vigorous." From these words it is luminously clear that St. Thomas held a view of alchemy far other than what they impute to him through supposititious offspring [false attributions].

[Margin: Whether chymical gold may lawfully be paid out.]

3. It is asked whether it is lawful to sell alchemical gold, and to pay it out, as true and natural gold, and whether by this the sale or payment is rendered just. Reply: if the alchemical gold differs in nothing from the natural, it can be sold and paid out; otherwise, it is by no means lawful. So St. Thomas and Albert, adduced above; Andreas de Isernia; Baldus; and Cardinal Alexander, on the dist. c. 1, *Quae sint regalia*. For those who whiten by means of "whites" and turn yellow by means of "yellows" [i.e. apply superficial tinctures] while the species of the prior metal remains in the matter — these are without doubt deceivers; and in this way nearly all of them proceed, in whole or in part, and (Albert himself being witness) they fall into many deceptions. And such men are punished, according to the established laws — so Joannes Andreas, in his addition to the *Speculum*, in the title *De crimine falsi*. For besides the loss of value, he says, gold and silver of greater worth also have certain virtues that are not present in other metals, nor in gold and silver made sophisticated by alchemy — such as against melancholy and other afflictions of the mind observed by skilled physicians. And Brother Bartholomew of San Concordio [Bartholomaeus de Sancta Concordia] subscribes to these things, in his *Summa*, under the word *Empti*, § 4; Faber [Fabius?] de Monte, *De emptione et venditione*, p. 8.

[Margin: Whether gold learned by magic art may lawfully be sold.]

4. It is asked whether anyone may sell gold which he has learned to make from a diabolical master, or by the magic art. Reply: that just as it is not lawful to learn anything from the devil, so neither is it lawful to sell such gold acquired by an evil art — since there can always lurk beneath it the suspicion of some deception by Satan, the hater of holy truth. And in this way both the art and the gold produced from it have been prohibited, as is held in *C. de auro publico*, l. 10 [*per se* 10].

Caput Ultimum

[Greek: ἀνακαιφαιλωτικόν — recte ἀνακεφαλαιωτικόν (anakephalaiōtikon), "recapitulatory," a summing-up]

In which is briefly opened up what, properly, the Philosophers' Stone, so much sung of among the ancient alchemists, really was, and what at last the early philosophers and their modern followers understood by it.

We have seen, partly in this present Section and partly in the preceding ones, the admirable works of nature that occur both in metallurgy and in the manner and method of making gold. We have also discussed all those things that the ancients handed down concerning the admirable mysteries of the Philosophers' Stone; and by many weighty arguments we have shown —

[Margin: The author's view, namely that it was sophistical and false.]

— that up to now there has been no one who, by a true and real transmutation, has carried over Mercury or the other imperfect metals into true and natural gold; but that all that operation of the alchemists has been false and sophistical, and indeed that the gold or silver produced from it has been nothing other than gold either mixed with other added substances or introduced by a dye [*fucus*]. So that from what has been said we may rightly and with good reason infer:

That all the gold or silver which up to now is reported to have been made by various alchemists has been made either by some cunning and the deceitful craftiness of the impostor's art, or by the magic art out of a pact made with Satan, or finally out of mineral gold reduced to powder; which gold, however, if you commit it to the balance of the cupel and of the ash-test [*cupella et cineritium*] or of the cement [*cementum*], does not subsist, but is resolved into the things out of which it had coalesced. This first became known to me when, not long ago, I had at length discoursed here at Rome with the most expert separators [*refiners*] of gold about this matter; and they solemnly affirmed —

[Margin: The separators, whom they call spagyrist, on the judgment concerning chymical gold.]

— that they had received from various alchemists various offerings of gold and silver, submitted to assay; and that some indeed had resisted the cupel through seven repetitions of the purification, owing to the most stubborn adhesion of the foul mixture, and at last had yielded true gold — not, however, formed by the transmutation intended by the alchemists, but (as they afterward perceived from the men's own confession) extracted from a marcasite pregnant with gold, decocted by the metallurgical art, with a profit of gold from one pound of marcasite. And although innumerable miracles of this art had been displayed to them, nevertheless, from the time they had professed the spagyric art, they said they had found nothing that did not smack of a dye, or that had not coalesced out of false mixtures by a sophistical composition.

This Albert too confirms, *De metallicis*, book 3. For he says that gold has by the chymical art been brought to that point where, when it had sustained six or seven fires, at last, consumed, it was resolved into dregs. [Margin: Albert's view on chymical gold.] "When therefore the alchemists say that they make gold out of Mercury and the other metals, which resists the cupel by any means whatever, do not believe them; for once the cement has, by longer torments of the fire, with the heterogeneous parts separated, left only as much gold as you had put in. There was no need of this, that the truth should be found out by so many repeated assays — since they could easily have ascertained it by a single assay, without error, by an art known to few, with a great quantity of lead committed to the cupel."

[Margin: Conclusion.]

I conclude, therefore: whatever the Arabs once, whatever Lull, Arnold, Rupescissa [John of Rupescissa]; whatever Isaac, Basil [Basil Valentine], Rhipaeus [Ripley], Sendivogius, Paracelsus and his followers handed down concerning the gold made by themselves — it was not true and natural, but sophistical, fashioned by those arts that we have just reviewed.

[Margin: Whatever has been published up to now about chymical gold rests on numbers.]

Hence, whatever about the Great Art [Ars Magna] of the Stone has up to now been put forth in published books is as certain to contain nothing other than what we have said, as it is certain that one who has died naturally cannot revive — which, nevertheless, they everywhere boast of their stone as the raiser of a

dead body. [Margin: The Authors who deal with the Great Art.] So those labor in vain who imagine they can attain the secret of the transmutatory art from the *Theatrum Chymicum*, the *Turba Philosophorum*, from the works of Isaac the Hollander [Isaac Hollandus], of the Count of Treves [Bernard of Trier], of Basil Valentine, of Trevisanus, of Bernard, of Bonus, of Joannes Petrus Faber, of Libavius, of Mylius, of Rhenanus, of Porta, of Wecker, of Alexius, or from the codices of innumerable Manuscripts and their received teachings.

That this is so certain that even the first Masters of the art have confessed it — those whom Paracelsus, the Monarch of the Alchemists, cites in his book *De transmutatione metallica* and in the book entitled *Aurora Philosophorum*.

[Margin: Paracelsus is reproached for inconsistency on alchemy.] But since we have, word for word, alleged his very full discourse above in Section II, Chapter VI, we refer the reader there. Although by it he reproves the efforts of all the alchemists up to now with such severity, he himself is nevertheless reprehended for having sinned in the very thing he carps at in others: when he says that the secret of the whole Mastery [Magisterium] consists in three things — namely Arsenic, Vitriol, and Antimony — as we have taught in the preceding pages.

Whatever, therefore, has up to now been written about the Great Art, or handed down in it, was the whole of it (as we have said) accomplished either by the metallurgical or by the sophistical art, and so no other benefit can result from it than what true chymistry — never sufficiently to be praised — teaches.

[Margin: The praise of true chymistry.]

For, first, it hands down the method of extracting, decocting, and purifying gold and silver from the metallic ores. Second, it shows how to find a certain tincture, with an added mass, out of the various gold and silver mixed with the remaining metals and minerals; which, although it is always more imperfect than the gold and silver themselves mixed with it, can yet lawfully serve for ecclesiastical furnishings, table services, and other utensils. Third, it teaches — to the great benefit of kings and princes — the method of alloying with gold and silver copper, tin, and similar metals, which they call *collybistica*, commonly *legam* [the alloy/"league"], which each of the princes may employ at his pleasure in his states by his own right. Fourth: in place of gold sought by fruitless labor, it has uncovered many illustrious secrets, useful to the human race — both in vegetables and in animals — for the use of medicaments, which consist chiefly in extracts, magisteries, and quintessences, and are in no way inferior to gold.

These, indeed, as they are most worthy of praise, so too we have deliberately transferred them to the last book of this work — lest we confound false alchemy with true chymistry — in which book the curious reader will find whatever can be desired concerning the various secrets of nature to be drawn from the threefold kingdom. Since, therefore, there is no hope of producing by alchemy the gold so greatly desired by all, someone might rightly object to me — indeed might charge me with rashness —

— that he could accuse me of rashness, while I labor too presumptuously to refute that art which venerable antiquity always supposed to be most true and most certain, and which we see attested by so many and such great writings of the philosophers. Most could object to me that to charge all of these with imposture is the harassment not of a wise man but of an imprudent slanderer. Therefore, lest I seem to do them an injury, and to free myself from the indictment of cavilling, I shall at last open up — with all the perspicuity and clarity I can — what the ancient philosophers understood by the Philosophers' Stone, and what by the Great Art.

[Margin: What the ancients understood by the Great Art.]

Mercurius Trismegistus [Hermes Trismegistus], the author of the whole recondite doctrine, when by the utmost subtlety of his genius he had penetrated the things shining forth hidden in any majesty of Nature — lest such great sacraments [mysteries] in the recesses of the world should become open to just anyone — undertook that ingenious architecture of the hieroglyphics, by which he concealed the individual mysteries of great moment under certain symbols, devised after the likeness of all-shaped [pantamorph] Nature, in such a way that they should nevertheless not be left impervious to those whom he judged worthy and like himself in sharpness of genius. Hence, to priests and philosophers chosen for this end — for whom the sole hope lay in the throne of the Kingdom — he communicated the secrets of his mind, expressed through the said symbols, lest along with himself such great fruits of discovered things should perish; and he had them carved on stones against every injury of the ages. But since the knowledge of such great things could not be expressed in few words, he devised, by truly subtle investigation, certain ideal symbols which should hold an analogy embracing many things — of which kind the hieroglyphics are — by which all those things that could not be described without many discourses might be laid open both by the sole and by the mystical conception of a single symbol; concerning which see our *Oedipus* [*Oedipus Aegyptiacus*].

[Margin: What the hieroglyphic doctrine of Hermes signifies.]

Since, then, he perceived that all things lie hidden in all things under a certain analogy — nay, beheld that the higher are contained in the lower, these in the higher and the middle, by a wondrous method — he distinguished a fourfold World: the Archetypal, the Genial, the Sidereal, and the Elemental, as was amply demonstrated above in the *Oedipus*, in *On the Hieroglyphic Alchemy of the Egyptians*, and in the *Obeliscus Pamphilius*; in which he set the orders of things and the grades of beings with such ingenuity that there existed no lower being of the World which did not have its own being, in both the Sidereal and the Genial World, consonant and proportioned according to the intended analogy — which beings, indeed, in the Archetypal World, separated by a certain ideal analogy according to our manner of conceiving, are nevertheless in reality considered under the one ratio of the simple divine essence. And from this those chains — the Egyptians call them σειραί [Greek: seirai, "chains, series"] — which we have treated everywhere in the cited *Oedipus*, found their origin.

The higher World has its own Sun, Moon, and the other Planets, to which from the higher World of the Intelligences just as many presiding Genii are assigned; and the lower World has these too. Since, therefore, in the Sidereal World he had found nothing more excellent, nothing more outstanding and more divine than the Sun, and in the medley of the lower, elemental World had recognized nothing more beautiful, more efficacious, and more excellent than gold, he called gold — on account of its virtues analogous to the Sun — the Sun of the lower World. In this way, seeing that the Moon is next to the Sun in excellence, he willed the Silver of the lower World to be the Moon, and so on with the rest of the planets, connecting each one by analogy [ἀνὰ λόγον] to the corresponding metals of the lower World. Hence it came about that by the symbol, for example, of the Sun, he exhibited a fourfold sense — namely, that he considered the secrets of the Archetypal, Genial, Sidereal, and Metallic (or Elemental) Sun, under a fourfold analogy, as one single thing; so that whatever mysteries of the divinity of the supreme Godhead he handed down, the same in their own way might be understood of the mysteries of the Genial, the Sidereal, and the Elemental World.

But since he recognized nothing in all of Nature more wonderful than the metallic operations, he set forth the manner in which Nature proceeded in generating them under the same mysteries by which he had set forth the sacraments of the Supreme Godhead and of the other Worlds. The Greeks afterward, following him in everything, hid the nature of things under not dissimilar riddles; about which let the reader consult the second part of the second volume of the *Oedipus*, where at length we showed that the Histories of the Gods — that is, the fabulous narration about Osiris and Isis, Horus, Typhon —

looked to this; together with the Mythology of the Greeks, by which we signified that the nature of things working wonders in the Elemental World was pointed at.

Hermes did not stop here, but, advancing from the world of minerals to the vegetative and animal, found the Sun, Moon, and planets in all things according to the intended analogy; so that there was nothing in the nature of things which he did not express under the monstrous likeness of animals and the rest of things. Hence he called the Sun, or Osiris, μύδρος [Greek: mydros, "a red-hot mass"] — that is, the inflamed rock pervading all things by its virtue; and Typhon he called Vulcan's subterranean fire, corrupting and restoring all things. There too you will find the interpretation of the *Tabula Hermetica*, or *Smaragdina* [Emerald Tablet] — which not undeservedly can be called the oracle of the alchemists — which is so far from teaching the fabrication of the Stone that rather it sets forth nothing else than the universal process of Nature shining forth in the generation and corruption of things.

I add that this Tablet was mentioned by none of the Writers before the times of Lull, nor do I find it inserted in the monuments of the Arabs. Hence no one ought to doubt that it is wholly supposititious. For if by Hermes to Abraham —

Liber XI, Sectio IV, Caput Ultimum (continued)

compiled at the same time [synchrono], how is it that so great and so celebrated a monument escaped the notice of Pliny [Plinium], Solinus [Solinum], Aelian [Aelianum], and all the other writers most curious about natural things — indeed, of all the other historians, ancient and modern alike? And if it was ever seen, I ask: where? in what place? in what city? If it was written down, I ask: in what language? in what tongue? in what script? For it would matter a great deal to know, from this most ancient monument, the earliest letters and characters used after the Flood — a subject on which there is such great controversy among the authorities. So a man is blind and out of his senses who would not — I will not say *believe* such things, but even take them into his mind so as to persuade himself they are true, or be led to accept them. But I have treated these matters more fully and professedly in my *Alchymia Aegyptiorum Hieroglyphica* [The Hieroglyphic Alchemy of the Egyptians], where you will see the author exposed by plain demonstration as a trifler and a peddler of smoke.

The later Arabs, lacking foresight and failing to understand the words of the ancient philosophers — by which those ancients meant the moving force of all things, which they understood as the solar force, or the Sun — themselves took

"gold" [aurum] κατ' ἐξοχήν [Greek: kat' exochēn, "by eminence," i.e. par excellence] and understood the process of producing it. I will cite the Arabic words contained at the opening of a work on alchemy written in Arabic that I possess, which run as follows:

[Arabic, with Kircher's own Latin gloss following — translated from his Latin:]

قال بعضهم ان العالم كله محبوب عاشق و معشوق و طالب و مطلوب قال الامام

[Margin: Omam, in his Alchemy.]

This means:

Some say that the whole world is love: lover and beloved, seeker and sought. Thus says Omam [the Imam].

[A second Arabic passage follows:]

قال هرمس الدرة الموصوفة ذات النظر الماحي الدائم العديم الموجود وهو في كل شيء وهو في كل بيت موجود وطوبى لمن فهم سرها ووفق عملها ان سر كل شيء الماء والماء قابل للتربية من الناس وغير ذلك وفي الماء سر عظيم ... قال مرقونس ما في الدنيا يباع اكثر منه وهو عند كل احد وكل احد يحتاج اليه يكون عنده ولا بد له ... منه ولا

This means:

Hermes says that the said pearl [margarita] exists in everything and is living water — perpetual, primordial — and is found in every thing and in every house. Blessed is he to whom it falls to understand its secret and to use it fittingly. He said, moreover, that its secret is water, and that water takes its nourishment from men. And Mercurius said that all the things which are in the world are sold for more than that water [is], for it is in the possession of every single person, and every single person has need of it. It is with him, and does not desert him, nor does its spirit depart. And Aba Amil said, speaking of the said water, that it is found in every place — in the plains, the valleys, the mountains, and with rich and poor alike, with the strong and the weak; and this is the parable which all the wise have in view; and it is the spirit of the moist.

Now this whole hieroglyphic conception of the universe denotes nothing other than a certain moving force of Nature in all things — which Aristotle [Aristoteles] not inaptly called ἐντελέχεια [Greek: entelecheia, "actuality," entelechy], and others a certain heat or fire present in all the members of the world, by which all things are moved, corrupted, altered, dissolved, digested, fermented, and fixed. [Margin: The heat of the Sun and of the subterranean realm constitute all things.]

And this is that celestial fire — the Sun, I mean — which by its influx into the elementary world kindles and cherishes a fire not unlike itself, lurking in the innermost recesses of the earth, in the manner we demonstrated in the fourth book of this work. Here on earth this fire — which the chemists also call Vulcan or the Archeus [Archaeus] — generates, cherishes, and conserves all the things which the earth holds in its womb as in a kind of furnace. It diffuses sulphureo-saline-mercurial vapors everywhere through the innermost fibers of the earth; and wherever these vapors fall upon proportionate matrices (of which there is an innumerable multitude established by the Architect of the world as so many chemical vessels in the workshop of the subterranean world), there it produces gold, silver, or some other metal, or a mineral, according to the condition of the earthen matrix. But outside the body of the earth this same fire — the solar force — vivifies, cherishes, alters, corrupts, dissolves, concocts, sublimates (and what is sublimated it reduces again), ferments, digests, and fixes...

fixes — being the cause of all generation and of the corruption of natural bodies. The Egyptians [Egyptii], most ancient of all peoples, contemplating in every age this admirable power of Nature, which resides in fire, that is, in heat — whether celestial or elementary — called the life-giving rays of the Sun "the fingers of Osiris [Osiris], the arranger of all things." [Margin: The fingers of the Sun, which the Egyptians called...] And the power of Nature that accomplishes such great things they named "the art of Isis [Isis]" — that is, "the increase of provident Nature," as Plutarch [Plutarcho] holds, by which all visible things are brought about. [Margin: Isis, the increase of provident Nature.] This same power they called, in the celestial world, the Moon [Lunam]; in the elementary world, Rhea [Rheam]; and so they called it the subterranean Moon. By all this the Egyptians by no means pointed to an Alchemy by which, through transmutation, either mercury or any other metal could be converted into gold; rather, they understood only the provident and admirable progress of Nature in producing gold, silver, and the other metals — both within the innermost realm of Typhon [Typhonis], that is, the subterranean world, and outside it, in the economy of plants and animals — that is, ἡ ψυχὴ τῆς βοτανολογίας [Greek: hē psychē tēs botanologias, "the soul of botany," the living principle of the plant-world], so necessary to the use of the human race. [Margin: What the ancient sages understood by the transmutatory art.] And the Greeks [Graeci] and the other wiser philosophers and alchemists who followed them, in every age, hid this beneath great clouds of riddles and parables — as we taught most fully in our *Alchymia*, by way of hieroglyphics, at the place in *Oedipus* already cited.

But lest I seem to have asserted anything tending to discredit the art out of ill will, I will here set forth in order the sayings of the ancient sages, from which it will shine out most plainly that the old alchemists understood by the transmutatory art nothing other than the fire of Nature — that is, that fiery power, solar or Vulcanian, and, by a certain analogy, the salt of Nature; and both of these are diffused through the innermost recesses of the universe. For this fire, as we said above, alone and singly performs all those things which the alchemists, false interpreters of the sages, supposed could be done by that fire of Vulcan and of the kitchen. For as the Philosopher [Aristotle] rightly says (*De Caelo* II), "the heavens, by their light and motion, bestow upon each thing its own proper heat." But it cannot happen that heat be so tempered by human industry that the alchemists could match the heat which Nature employs in producing gold — since Nature, in producing all her things, uses an even heat, one that is, as it were, indivisible. The alchemists therefore go astray in their operations, since the very ore and matrix is nothing other than the most subtle fire, that is, the sulphureo-mercurial salt of Nature, which, brought from potency into act, at last generates gold — that is, a mixture compounded of water, air, and earth, which, by a sulphureo-saline-mercurial vapor, purified by the resolution of the moist, is converted into an ignited ash through the salt existing within it. [Margin: What the salt of Nature is. The continuous progress of Nature.] And this is that white Elixir turned to red — that is, gold, by the continuously succeeding fire.

The philosophers also call this gold the permanent water [aquam permanentem], and the torment and nourishment of fire — that is, the radical moisture of the ash, or the permanent water, in that heat of the fire which serves it in place of soul and living spirit. It differs from the mercurial moisture as the stable from the unstable, the fixed from the non-fixed, inasmuch as it does not persist at the bottom of the vessel but is resolved into smoke, and, fleeting, washes away the blackness and stench of the combustible matter — a blackness inherent in the sulphureous and fatty parts existing within the ash, as they pass off into black soot, which the alchemists call "the damned earth," volatile, fetid, putrid, and "burning sulphur." Against this, they call the calcined ash, on account of the abundance of fixed salt within it, "incombustible sulphur," since when set to the fire and purified it is at last fused into glass. And this kind of ash the sages thought fit to call the "salamander" [Salamandram], inasmuch as it lives and is nourished in that fire. [Margin: What the salamander and the phoenix are among the alchemists.] Others called it the "phoenix" [Phoenicem], because kindled ashes are nothing other than the body of that Phoenix which is revived from its own ashes and lives renewed. And this kind of fire is denoted by the sages through that terrible dragon [draconem] which devours all things and converts

them into itself, and likewise through the basilisk [basiliscum] that kills all things; [Margin: What the dragon and the basilisk are.] for by this very fact — that the ash is ignited — there exist in it quicklime, salt, sulphur, and quicksilver. And this is, according to the mind of the sages, "to raise the dead and to kill the living" — that is, to deprive of life such an ash, which is the conjunction of East with West, of heaven and earth, of the spiritual and the corporeal, the conjunction of Sun and Moon, since the ash itself is a clear flame, and a volatile water which bears within itself a red smoke; and this, finally, decocted at the bottom of the chemical vessel, is fixed. [Margin: What the whitening water is.] And this is the water that whitens, that blackens, that reddens, that vivifies, that kills, that sublimates water — a lime dissolving and coagulating, putrefying and corrupting, and degenerating into diverse sprouts of wood; and, by the testimony of the Philosopher [Aristotle], when fire is applied to combustible matter, it grows to infinity. And this is the first process of Nature, namely the fire of Nature, which the sages described under various shadowings of symbols.

Aros, in the *Turba Philosophorum*, says: "*Every man knows this fire, and he who does not know it knows nothing.*" [Margin: Aros in the Turba of the Philosophers.] But this fire has scarcely been recognized by any of the alchemists; therefore the fire of the philosophers is not that by which the alchemists complete their work.

Morienus says: "*This thing, which is worth much, does not enter into the Magistery; yet among the alchemists it is so prized that they seem to lose every substance in procuring it, in order to acquire it.*" [Margin: Morienus in the Turba.]

Pythagoras [Pythagoras], in the *Turba*, cries out together with the others, etc.: "*Our work is the work of women and the play of children.*" [Margin: Pythagoras in the Turba.] But the work of the alchemists is so difficult to discover that it is still in dispute wherein it consists.

All the sages say in the *Turba*: "*With our work no one can stand still, nor can it be touched without harm; it tinges all things, it corrupts all things; from...*"

common gold so familiar and domestic to the alchemists, that it always remains without harm.

Arnoldus [Arnold of Villanova] says: "*Potable gold and the red Elixir, which is the gold of the philosophers,*" is potential and invisible gold. [Margin: Arnoldus.] The gold of the alchemists, by contrast, is actual, real, and visible, obvious to all the senses.

Alfidius says in the *Turba*: *"The gold of the philosophers is everywhere found excellently prepared and purified, and is sold at a cheap price,"* inasmuch as it is of profit to everyone, to the poor as much as to the rich. [Margin: Alfidius.] But the gold of the alchemists few possess, inasmuch as scarcely anyone has ever seen or touched it except as something sophistical. Again, in another place, Alfidius says: *"In producing this gold of the philosophers, all the operations are done at one and the same time."* The gold of the alchemists, by contrast, requires diverse operations, besides an enormous waste of time.

Raymond Lull [Raymundus Lullus] says: *"Without this gold, which we call the fire of Nature, no one can sustain his own life."* [Margin: Raymundus Lullus.] From which it follows that all who lack the alchemical Gold have long since been dead. Besides this, he says that this gold makes malleable glass — which becomes evident when glass, decocted in the furnace, can be stretched and beaten into whatever shape the craftsman pleases, and yet, when melted and plunged into cold water, becomes so brittle that one may handle it with the hands no differently than wax. This cannot be said of the gold of the alchemists, for once melted it can neither be stretched nor beaten, nor is it frangible in natural water.

Iesus [Hesus?] [?] says in the *Turba*: *"Our Sun preserves the warm and the radical moisture in a young man, and restores it when it has begun to fail; our fire cooks all the foods which serve for nourishment, and warms the old, who are cold and dry."* [Margin: Turba.] This the gold of the alchemists does not do, since it neither digests nor is digested, as the heat of fire is.

It is said in the *Turba*: *"Our gold is the Sun, a luminous Sun, which warms, alters, corrupts, putrefies, digests, generates, rarefies, dissolves, and illuminates the other stars."* [Margin: Turba.] This can in no way be said of the gold of the alchemists, since it neither shines of itself nor gleams in darkness, as do the celestial and elementary fire. The *Turba* cries out: *"Our gold can be multiplied to infinity"* — which can be said only of the fire of Nature, by no means of the gold of the alchemists. *"Our gold,"* they say, *"always resists fire without any corruption."* But this cannot be said of sophistical gold, which is calcined by corrosive waters, corrupted, and reduced into another form.

They say: *"Our Elixir is the most potent of all poisons, which destroys all things."* Who does not know that fire does this, and not the gold of the alchemists?

Hortulanus [Hortulanus], in the *Turba*, says: *"In our work the Stone is called everything by which the four elements can be separated from one another; out of*

which separation is born a certain crystalline substance, just as a stone..." [Margin: Hortulanus in the Turba.]

has discovered by the stalactic art very many things highly necessary to human nature, but that the fictitious Stone of the alchemists never even entered their minds.

Geber [Jābir ibn Ḥayyān], in the chapter on Medicine, says: *"Unless the medicine be such that, in a moment, it strips a liquefied body of its first form (which was under the water), and removes all imperfections, and likewise reduces it to the ultimate simplicity of prime matter, and in the same moment introduces another new form, namely that of the Sun [gold], it is not yet a perfect art or nature."*

[Margin: Geber.] By which words he describes nothing other than the infallible effect of Nature in producing gold, which the alchemist can scarcely, or scarcely at all, imitate.

Saturnus Trismegistus, in the *Turba*, says: *"Blind is he who thinks to make the art out of a combustible thing, since the divine operation is from a pure substance which endures in fire without any combustion"* (as we said about ignited ash), *"for all other things are destroyed and consumed by the combustion of fire."* [Margin: Saturnus Trismegistus in the Turba.] All of which is to be understood of the fire of Nature, that is, the Sun — not of the fire of spurious alchemy.

Again **Trismegistus** [Trismegistus]: *"The philosophers did not write their books except for their sons — and by their sons I mean those who understand their sayings, and not according to the letter; for an operation according to the literal intention is a squandering of riches and a loss of time. Many possess our Stone, but do not know its virtue; and if they should know its virtue, it would avail nothing, unless they also knew its operation. But the operation cannot be done except by the greatest gift of GOD, or by the teaching of a most skilled master, and the whole of it depends on the will of GOD."* [Margin: Trismegistus.] These words are so plain concerning the false doctrine of alchemy that they may easily be understood even by the unlearned. To this subscribes even the very Monarch of the alchemists himself, **Paracelsus** [Paracelsus], in his book *On the Transmutation of Metals*: *"Whatever burns is sulphur, and nothing catches flame except sulphur; whatever passes into smoke is Mercury, and nothing sublimates itself or ascends except Mercury; whatever is reduced into ash is salt, and nothing but salt can become ash."* [Margin: Paracelsus.] By which he plainly signifies the three proximate principles of Nature, of which all things consist, as has now often been said. When these are exalted by fire — that is, by the solar force or celestial spirit — they pervade the economy not only of minerals but also of plants and animals,

and bestow on each and every one life, soul, and spirit; while they separate the dissimilar, they gather the similar, dispersed by the heat of fire, and arrange them toward the end intended by Nature. In this way the Sun alone was created by GOD in this world, to rouse the resting fire in all things — by its own fire to solicit the rest of the planets surrounding it, kindled in the celestial world and lit up, toward fruitful influxes; and in the subterranean realm of Vulcan, by acting through the Archeus upon mineral matters, to produce at last planets analogous to those. From which it plainly appears that the Sun of the philosophers was nothing other than that fire of Nature which animates all things. [Margin: The Sun of the philosophers is the fire of Nature.] But since all this has been most fully set forth elsewhere in this work — especially in the *Oedipus*, in the *Syntagma de Alchymia Aegyptiorum Hieroglyphica* — I refer the reader there.

CONSECTARIUM [Corollary]

From what has been said up to this point it is established that the sages, by the gold and silver of the philosophers and the other planets, gave a meaning very different from that of the common metals. Whence he is blind who, maddened by this excessive thirst for gold, does not see this — or, if he sees it, stubbornly denies it. That gold was ever made, by the substantial transmutation of quicksilver and the other metals, by no mortal — except perhaps by some illustrious trickery, or by the magic art — we have shown in many and various ways in the foregoing. Those, however, who think that the authority of Albertus [Albertus Magnus] and St. Thomas [D. Thomae, Thomas Aquinas] supported the art are greatly deceived, since they said the very opposite. But let us hear the words of St. Thomas (*Sentences* IV, dist. 7, q. 3, art. 1), where in express words he subscribes to what was alleged above: [Margin: St. Thomas.] *the gold of the alchemists is not true gold, but only like true gold*; and if elsewhere he said that they do make true gold, this is to be understood as meaning that they can draw out true and genuine gold from various mineral and metallic bodies — which is nothing more commonplace among metallurgists — yet St. Thomas says this can be drawn out by art not through transmutation but only through separation, as is clear from the words cited above. To this Avicenna [Avicenna] lends his support in his *Commentary on the Meteorologica*, in these words: [Margin: Avicenna.] *"Let the practitioners of the alchemical art know that the species of metals cannot be transmuted, although things like them can be made; for even if they can tinge bronze [as] with whatever color they wish, until it is very similar to gold, and can wipe away the impurities of lead so that it appears to be silver, nevertheless in substance they will always remain bronze and lead."* Albertus agrees (*On Minerals* III.9), when he says: [Margin: Albertus Magnus.] *"Those who whiten by white*

things and yellow by yellow things, while the species of the prior metal remains in the matter, are without doubt deceivers, and do not make true gold and silver; and in this way nearly all proceed, whether in whole or in part. And for this reason I had alchemical gold, which was brought to me, tested by experiment; and after it had endured the fire six or seven times, at last, when further ignited, it was consumed and lost, and as it were reduced to dregs."

Pico della Mirandola [Picus Mirandulanus], no novice in alchemy, in his *On the Overthrow of Single Combat* (book 1, ch. 29, §7) [?], though he says the art is not impossible, nevertheless says it has such great attendant difficulties that they can scarcely be overcome; whence he concludes: [Margin: Picus Mirandulanus.] "*One should not,*" he says, "*devote effort to that art — not because it is impossible, but because it is of such great difficulty that it is more useful to leave it alone than to practice it; and indeed the very richest men have been reduced to great poverty, because, with the greatest expenses laid out, they either never attained what this art promises, or...*"

[Reading order reconstructed from printed page numbers: printed 318 → 319 → 320 → 321. The non-linear PDF order is sheet-imposition: each opening's verso and recto are split across the scan.] ...or else attains it only very rarely, and only in small part, so that the expense is far greater than the profit. It is therefore better to devote one's effort to other, more useful arts, which for the most part deliver what they promise, than to this one, which because of the hidden things of nature very rarely reaches its goal. So far Pico della Mirandola [Giovanni Pico della Mirandola].

[Margin: Arnaldus]

Let us now look at what Arnaldus [Arnaldus de Villa Nova] has to say — the man whom the alchemists look up to and revere as an oracle. "There are," he says, "certain foolish and blind men who claim they know how to make potable gold from common gold, or who believe this to be the best remedy for healing every illness; and there are certain physicians who boil ducats in water, saying that this is the best thing for healing — which is the exact opposite of the truth (saving always their reverence) — namely, that this should be potable gold, or that such water should be good to drink for healing. But I do say this much: that ducats are excellent for buying up confections and for paying physicians; and it is also true that it would be a good thing to have one's hand full of ducats and to show them to the sick man, since seeing the gold would do him much good. Those, then, who understand this 'medicine' to be about common gold are blind, and worse than blind — they are deceivers."

[Margin: What Trithemius thought of Alchemy]

I am well aware that many have enlisted Trithemius [Johannes Trithemius] into the company of the art, so as to lend it a certain authority; but anyone who works through his writings will find that he thought entirely the opposite. So that his mind may be more fully and plainly seen, I will set down here his own words, in which he depicts the vanity of the alchemists most vividly. He speaks thus in his *Polygraphia*, folio 598 of the old edition: "Alchemy," he says, "has many household maidservants, who guard their mistress with unceasing vigilance and pose under her name, so as to keep her forever safe from the dealings of importunate suitors: Vanity, Fraud, Deceitfulness, Deception, Sophistication, Greed, Falsehood, Lying Confidence, Folly, Want, Poverty, Despair, Flight, Proscription, and Beggary — these are the handmaids attendant on Alchemy, who, pretending to be the mistress herself, keep their beloved inviolate, and yet willingly prostitute themselves to her well-moneyed, greedy, stupid, and silly seekers." So far Trithemius — words that may rightly stand as a summary of everything said up to this point. And yet a great many do not blush to assert that Paracelsus [Paracelsus], as their master, was likewise privy to the secrets of the great art.

From all this it is most clear, by the very testimony of the alchemists themselves, that this art is vain and worthless. But perhaps here they will say that all this was said of the pseudo-alchemists, not of the true philosophers. Yet since not one of those first philosophers has ever been found of whom it can be demonstrated that he produced true, pure, and genuine gold by the transmutatory art — as we have shown at length in what precedes — surely on this very ground the whole objection of our adversaries collapses. That they knew the art κατὰ τὴν θεωρίαν [Greek: katà tēn theōrian, "in theory," i.e. as a matter of contemplation], indeed that it is possible, I will not dispute; but that they reduced it to practice — that is what we are asking, and it is on this alone that our whole dispute turns.

and that the matter could not be handled better than through the very contradictions by which the alchemists undo themselves, tear themselves apart, and attack one another. From these it will be evident that something resting on such rotten foundations cannot stand. And as far as the boastfulness of the art is concerned, they are plainly giants; but if you look to the force and effectiveness of their words, you will find only dwarfs fighting with leaden daggers. So that you may see their contradictions more openly, I have decided to set down here an Antithetical Corollary.

Antithetical, or Contradictory, Corollary [Consectarium Antitheticum, sive Contradictorium]

That the whole of what the true Philosophers understand by the Magistry of the great art is something altogether different from what the false alchemists promise is shown here in summary, drawn from what has been said up to this point.

The False Alchemists [Falsi Alchymistae]

1. For making the Stone they require distillations, sublimations, conjunctions, separations, congelations, dissolutions, triturations, whitenings, reddenings; and without these, they say, it is impossible to reach the goal. So Hugortius Lilius.

2. The pseudo-alchemists require for their work gold, silver, copper, iron, tin, lead, mercury.

3. The pseudo-chemists require water, vinegar, salts of various kinds, sulphur, antimony, arsenic, orpiment, realgar, and the like.

4. The Stone of the pseudo-chemists is made from combustible and impure minerals, by various operations.

5. The pseudo-chemists posit different grades in their magistry, namely the seven operations cited in the preceding pages, and they busy

The True Alchemists and Philosophers [Veri Alchymistae et Philosophi]

They say none of these things contributes to the structure of the Stone; for the operations Nature employs are otherwise: distillations, sublimations, conjunctions, separations, congelations, triturations, whitenings, reddenings. So Hugortius Lilius, *On the Philosophers' Stone*.

The true alchemists say that none of the common metals enters into the secret making of the Stone — not gold, not silver, not iron, not copper, tin, lead, or common mercury.

The true alchemists say: our water is not the water that the false alchemists use; our vinegar is not the common vinegar; nor are our salts like the salts of minerals, nor is our sulphur common sulphur — not arsenic, orpiment, realgar, or such things.

Our Stone is made from incombustible and most pure minerals, by means of natural fire.

Hermes [Hermes Trismegistus] in his allegories says that the regimen concerning Saturn is nothing other than putrefaction; concerning Jupiter,

The False Alchemists [Falsi
Alchymistae]

themselves with natural metals and minerals.

6. The pseudo-chemists say that all the chemical operations are distinct, and they require different fumes, vessels, and fires for the work.

7. Into the magistry of the pseudo-chemists enter metals, earths, stones, concreted juices.

8. The pseudo-chemists say that in the tincture of the philosophers there occurs a penetration of bodies, since by it they transmute bodies.

9. The pseudo-chemists assert that, by means of the soul extracted from quicksilver, any other metal whatever can be transmuted into gold or silver.

The True Alchemists and Philosophers
[Veri Alchymistae et Philosophi]

the operation is washing; concerning Mars, separation. The operation concerning the Sun is nothing other than washing it clean from the blackness of Mars; concerning Venus, the operation is nothing but conjunction — that is, of the moist with the dry, and the hot with the cold — and it is called allegorical copper. The operation concerning Mercury is nothing other than combustion; and concerning the Moon, nothing other than heating, roasting.

The true alchemists say there is only a single operation, and that all the operations are nothing but one thing; that one does not need different furnaces, vessels, fires, but one furnace, one vessel, one fire, kept at an even heat — and that heat is [the heat of natural fire].

Into the philosophical magistry there do not enter metals, earths, stones, concreted juices.

The true chemical philosophers deny this, as a false principle contrary to nature. Rather they hold that the tincture is brought to perfection by the agency of Nature alone.

The true chemists deny that one and the same specific form can inform any other metal differing in species — just as the soul of an oak cannot inform a pine or a juniper; and so neither can lead, or copper, [become] gold or silver.

The False Alchemists [Falsi
Alchymistae]

10. The pseudo-chemists say that the matter of the Philosophical Stone must be extracted from natural ore.

11. The matter of the Stone, for the pseudo-chemists, is moist and cold Mercury.

12. The pseudo-alchemists say that corrupted gold passes over into another form.

13. The false alchemists call the gold they make — Alchemical gold — true gold.

14. The false alchemists speak of Alchemical gold in material terms.

The True Alchemists and Philosophers
[Veri Alchymistae et Philosophi]

Geber [Jābir ibn Hayyān / Geber] and the other true philosophers say that the matter is to be found in all things, in every place and time — in man, in animals; and as Senior testifies, in the *Turba Philosophorum* [*Turba Philosophorum*], "every man knows the Stone, and he who does not know it knows nothing."

The matter of the Philosophers' Stone is hot and dry Mercury.

The true philosophers deny that this happens: just as gold consists of a perfected mixture, so too it cannot be corrupted.

The true alchemists say it is not true gold, but only similar and analogous to true gold.

The true philosophers speak of it mystically and allegorically, saying it is nothing other than a certain fiery power, or the fire of Nature diffused through the pathways of the whole World.

[After the table, p. 319, foot:]

From these things it is plainly evident what one ought to hope for from Transmutatory Alchemy, entangled as it is in so many contradictions — especially when there is added to all this the dreadful confusion of names and terms, the abuse of the differing meanings they employ in expounding the art, and the disparity of the senses themselves, which are truly as many as there are heads. (Meanwhile I pass over in silence the fierce attacks with which they assail one another.) The result is that no one seems able to make out what any of them feels, understands, or grasps. And so, that no one may waste good hours on an art so confused and so

[Top of p. 320:]

[Margin: The alchemists' rejoinder]

[arranged] in no order or method, so patched together with fables and trifles, and so wasteful of money and expenditure as to consume one utterly, I would counsel.

I do not know, however, by what fate it has come about that this golden Nymph Χρυσοποιΐα [Greek: Chrysopoīia, "gold-making"] has so deranged a great many men — and what is astonishing, even men otherwise wise — that they seem intoxicated by her as if by some magic potion. And the greater the audacity of such impostors, the greater for the most part is the credence given them by those who, infatuated by such κενεμβατεία [Greek: kenembateia, "treading on emptiness," i.e. groundless illusion], listen to them. Some of these are indeed of such temerity — not to say impudence — that, when questioned before kings and princes about the certainty of their art, they answer with more than Bombilian arrogance, in these and similar words: "I have no place, nor the means, nor the riches, to practice my art; but if Your Highness or Your Majesty deigns to supply me the necessary funds, I will make so much gold for you that with its aid and use you may easily set yourself up as Master of the World." Of whom, however, one may rightly pronounce: "They have an art without art, a part without a part, whose middle is — to lie; their life — to go begging."

Others, by contrast, seem to proceed in the opposite manner. They boast that they need no mortal's help; they despise the favor of kings and princes, scorn their riches and treasures as beneath their own, and deign to serve no one. They glory in possessing the wand of Midas [Margin reference: the touch of Midas], always ready and at hand for turning everything into gold; they claim to lack for nothing — while in the meantime, wandering across the world, never settled anywhere, and turning to tricks and frauds to sustain a life from which money is failing, they fleece with marvellous dexterity the purses of the simpler folk: selling powders for gold, axle-grease for ointments, mouse-droppings for civet, until at last, caught in the very act, they pay for their impostures either by a gallows-dance, or — if dealt with more mildly — by servitude at the oars in the galleys.

[Margin: No monarch ever made rich by Alchemy]

Who ever saw a king or prince made powerful by the alchemical art? Who ever heard of one set up as Master of the World by its aid? And yet now hundreds and thousands of years go by, through which this foolish promising of the alchemists endures — yet so far is it from achieving the desired effect that we know the

contrary to have happened. For how many have we seen stripped by the wickedness of this art of all their goods? How many have we read of who were reduced to utter ruin by the loss of everything? How many have we observed driven sideways into despair, given over to illicit arts and to commerce with demons, who — while they aspire to what they hope for — at last brought their lives to a close in a pitiful death?

[Margin: Harms to the commonwealth from Alchemy]

I pass over here the enormous damages that such men inflict on the commonwealth. [The "alba albificant..." clause:] until at last, caught — to speak with Alberto [Albertus] — they whiten the white, they yellow the yellow, they strike false coin, until at last they are caught.

[they] pay the penalties for having misused the gift of Vulcan. And there are others who, while they breathe nothing but secrets, think nothing is any longer a secret once it has been made public: they feel that whatever is shared with others perishes for themselves; they lay claim to the trust — or, as they call it, the credit — of the people, and to a reputation for hidden powers. And this even while, through magical attempts, they devise seals, pentacles, words, characters, touches, constellations, mirrors, homunculi made by their own art, sympathetic ointments, Brasidillae, Magurreones, Thesaurinellae, Evestra, and similar diabolical monsters of the workshop — through magico-cabalistic, Micro- and Macrocosmic triune mysteries.

[Margin: An exhortation to princes]

Since this is so, it falls to kings, princes, magistrates, and academies to restrain, proscribe, and utterly root out so dishonest and fraudulent an audacity of the pseudo-chemists — lest, as the number of impostors gradually grows, a window be opened to every license, to the practice of wicked and unlawful arts, and to every impiety. A model of sound censure, worthy of being imitated by all, was once given by the Athenaeum of Paris in the matter of the chemical writings of Petrus Palmarius [Pierre Le Paulmier], which, extracted from Libavius [Andreas Libavius], I here append.

The Parisian Censure of the Alchemical Book of Pierre Le Paulmier [Cenfura Parisiensis in Librum Alchymicum Petri Palmarii]

"Having heard the report of the censors to whom the task was assigned, of examining the booklet published by M. Pierre Le Paulmier, whose title is *The Dogmatic Philosophical Stone* — and having also heard the responses of the same

Le Paulmier, cited to that very end in a special article — the College of Physicians in the University of Paris, lawfully assembled, by unanimous consent condemns that booklet as full of errors, frauds, impostures, and lies, and judges it unworthy of the light of day. It decrees that within six months Le Paulmier shall, by public writing, acknowledge and abjure errors, frauds, impostures, and lies of this kind, and shall profess that he will remain steadfastly within the doctrine of Hippocrates [Hippocrates] and Galen [Galen] and the discipline of the School of Paris; meanwhile, that he be deprived of all the emoluments of the School, these to be paid out to the poor of the Hospital. If within the half-year he does not duly satisfy this decree, he shall be struck from the catalogue of regent doctors, and stripped of all the School's emoluments and of the University's privileges, etc. Given at Paris, 28 January 1609."

Such was the constitution issued by John XXII [Pope John XXII] against the alchemists, which decreed that gold-makers of this kind were not only to be driven out, but to be punished with the utmost rigor of justice, by whatever penalties — as men guilty of the crime of forgery — and that their books were to be consigned to the flames. And if this were done in our own day too, the pseudo-chemists would not rage with so many scandals, so many impostures, so many monstrous offspring of their wits, to the common detriment both of the political and of the literary commonwealth, whether by their writings or by their deeds. But the same thing that Tacitus [Tacitus] once said had happened in the case of the astrologers, [Margin: The verdict of Tacitus]

[Top of p. 321:]

we see verified down to the present day concerning the astrologers and the alchemists. "Such a class of men," he says, "will always be forbidden, and yet will always be retained."

[Margin: Objections of the alchemists against the author]

I am not unaware that there will be, among the petty chemists who hate the truth, some who will rise up against me with insolent tongue, and throw my ignorance in my face. But I am not troubled: my business is not with barbers and the unskilled rabble of alchemists, but with philosophers, men learned in the practice and experience of things, ἀληθεῖς φίλοις [Greek: alētheis philois, "true friends" (of truth)] — who, if they weigh my judgment on Alchemy in the fair balance of reason, will not easily deny what I have said. I am a German; with a German breast I profess the truth. I too could adduce countless secrets of the transmutatory art under the appearance of truth — but far be such a crime from

any human breast. I know what Nature can do and what it cannot. I know that Nature can never be overcome by art, unless perhaps these θεογιγαντόμαχοι [Greek: theogigantomachoi, "those who war against the gods like giants"] should irreligiously attempt to do something more excellent — something they everywhere confess to lie beyond human art — than God does through nature, which Plato [Plato] calls "the art of God." Let them see to it what they say.

But perhaps here they will raise an outcry against me: that they marvel that I, who have never had experience of coals, ashes, and little furnaces, and who am moreover unskilled in the secrets of the chemists, have nonetheless not feared to rise up with rash daring against an art I have not practiced. There is no reason for me to answer them: whether I am experienced or unskilled, ἄπρακτος καὶ ἀνεγχείρητικός [Greek: apraktos kai anencheirētikos, "without practice and untried by hand"], it is not for me to determine. I commit the estimation of me in empirical philosophy — to be decided from such works as have hitherto issued from the weakness of my talent, whatever their quality — to the Literary World, ready to bear with even mind both fair and unfair judgments. Yet it is true that I have not defiled my hands with coals and clay, nor filled my face and beard with cinders, but have always for that reason kept clear of the noxious and poisonous exhalations of minerals as of a very Lerna of all evils — lest I be joined to the company of those who, their brains scorched by smoke and soot, have always philosophized as foully as they have labored grievously.

[Margin: The author's excuse]

I confess that I have always pursued the experiment of things above all else — yet only such experiments as do not smell of smoke, mud, coals, of the kitchen and the barber's shop, but which are not at odds with honest labor. Even these, though, I have by no means thought I should refuse on account of the ἐγχειρήσεις [Greek: encheirēseis, "handlings, manual operations"] of the basest sort of work; rather I had them carried out — not without small expense — by Manipulators, as they are called, in my presence, in the Laboratory of the Roman College, most fully equipped with everything necessary for performing chemical experiments, hired for this purpose (as I said a little earlier): Manipulators German, Polish, French, Italian. And so I would have you be assured for certain that nothing is brought forward in this work in the matter of experiments that has not been verified — partly by myself, partly by the said chemists skilled in their labors, in my presence. My part was to give the orders and prescribe the method; theirs, to carry out what was ordered and prescribed — just as it is unfitting for physicians to compound medicines themselves, open a vein, administer clysters, but they are

accustomed to entrust these, partly to the apothecaries, partly to the surgeons, whose proper office this is. An architect does not prepare the lime and cement, nor dress the stones himself, but in his own design commits them to be fitted together by the stonecutters and masons according to the model. But that we may at last set the coping-stone on this Book —

[New paragraph, p. 321:]

I would have the Reader understand that in this place my quarrel is only with those alchemists who keep rolling that Stone of theirs — no differently than Diogenes [Diogenes] his famous tub — now turning it, now turning it back, now rolling it down, now rolling it round, by a useless labor; and with the rest of the pseudo-chemists. So let no one therefore suppose that I am hostile to Chemistry; for I know its supreme dignity and excellence, and I never cease to extol it sufficiently, as it were the one gateway of natural philosophy and of the more hidden medicine, through which access is granted us to the inmost mysteries of Nature. Nor would I be understood [as inveighing] against the ἀρχοιμάχους [Greek: archoimachous, "leaders" — best read here as the foremost, the masters] among physicians and chemists, singular in the practice of things and in long experience — even when perhaps I inveigh rather severely against the alchemists. Nor against princes who, led not by the love of riches but by a praiseworthy curiosity, take delight in experiments of this kind, to relax the mind after weightier business. Nor would I have those touched who devote themselves now and then to such exercises not from love of gold but for the sake of inquiring into the truth.

[Margin: Excuse of the author]

Since these matters could not be treated in this Eleventh Book of the *Mundus Subterraneus* [*Mundus Subterraneus*], owing to the more diffuse argument of its subject-matter, I have judged it more advisable that they be deferred to the last Book — in which the curious Reader will find gathered, with multiplied interest, whatever may be desired in experimental philosophy and in the inquiry into the secrets of the various arts.

CONCLUSION [CONCLUSIO]

And so, from what has been said, the Reader will doubtless understand most clearly how greatly, in every age, the accursed thirst for gold [sacra auri sitis] has filled human minds; with what care and anxiety they have sought to possess it; with what labors and dangers they have exposed themselves to acquire it —

Nature herself showing that gold is toilsome to find, hard to keep, full of anxiety in its pursuit, and set, in its enjoyment, between pleasure and pain. Therefore let no one devoted to true wisdom much seek or desire it. Blessed, then, is the man who, despising and rejecting the enticements of this base earth, and content with no more than the necessities, so orders a tranquil life, purged of all the passions of the soul, that he truly and from the heart carries out the Wise Man's counsel: "Give me neither poverty nor riches, but grant me only what is needful for living" [Proverbs 30:8].

LIBER UNDECIMUS, Sect. IV

[The opening of this page continues the prose from the previous folio.] Let us therefore stop seeking permanence amid the perpetual, perishing turmoil of these things. Let us leave acorns to the pigs, hay to the oxen, and a perceptible foreknowledge of storms to the frogs and crows; let us leave the filth and the devouring greed for gold to the misers. We, for our part, rely on higher principles — on what is stable, not on what is in flux within this economy of the sublunary world; not on goods subject to fickle time, but on those laid up forever in treasuries above the heavens, set utterly apart from all rust and from the ravages of the worm. Upon these let us keep watch with every effort and exertion of the mind.

So that the reader may find nothing wanting in this work among the things that pertain in any way to the study of chymistry, I have decided to set down here the marks or chymical characters by which the alchemists are accustomed to veil their secrets. Then, if a reader ever comes upon authors who generally make use of them, he may arrive at the true knowledge of the words those characters stand for.

Hieroglyphic marks, or Chymical Characters, by which they are accustomed to conceal their secrets

[The following is a two-column table of symbols and their meanings. The symbols themselves are alchemical sigils; each is described where it can be read, and the Latin name is translated. Many sigils are idiosyncratic; the names are transcribed and translated in full.]

Symbol (as printed)	Meaning
⚡	Vinegar [Acetum]

Symbol (as printed)	Meaning
✠ (variant)	Distilled vinegar [Acetum distillatum]
A	Air [Aër]
⚗	Alembic [Alembicum]
O	Alum [Alumen]
≈	Camphor [Amphora — i.e. camphor] [?]
ā ā ā	Amalgam [Amalgama]
ā an.	Equal part / "of each" [Ana]
♂	Antimony [Antimonium]
▽	Water [Aqua]
▽ (dotted)	Strong water / nitric acid [Aqua fortis]
▽ (crossed)	Aqua regia [Aqua Regia]
♄	Sagittarius [Sagittarius]
∴	Sand [Arena]
☾	Silver, or the Moon [Argentum aut Luna]
☿	Quicksilver, or Mercury [Argentum Vivum, aut Mercurius]
♈	Aries [Aries]
o—o	Arsenic [Arsenicum]
o=o	Orpiment [Auripigmentum]
☼	Gold, or the Sun [Aurum, sive Sol]
B.	Bath [Balneum]
MB.	Bath of Maria / water-bath [Balneum Mariae]
VB.	Bath [Balneum]
C.	Lime / quicklime [Calx]
⚔ (Calx viva sigil)	Quicklime [Calx viva]
♋	Cancer [Cancer]
♏	Capricorn [Capricornus]
(death's-head sigil)	Dead head / caput mortuum (residue) [Caput mortuum]
♂	Steel [Chalybs]
(ash sigil)	Ash [Cinis]

Symbol (as printed)	Meaning
☿ (cinnabar sigil)	Cinnabar [Cinnabaris]
CC.	Hartshorn [Cornu Cervi]
⚖	Crucible [Crucibulum]
♀	Copper / bronze [Aes]
⚗ (distill sigil)	To distill [Distillare]
♂ (day sigil)	Day [Dies]
℥	Dram [Dragma]
♂	Iron [Ferrum]
♊	Gemini [Gemini]
(hourglass sigil)	Hour [Hora]
△	Fire [Ignis]
♃	Jupiter [Iuppiter]
♌	Leo [Leo]
♎	Libra [Libra]
⚖	Pound [Libra — i.e. the weight]
☾	Moon [Luna]
♂	Mars [Mars]
☿	Mercury [Mercurius]
☿ (variant)	Sublimate of mercury [Mercurius sublimatus]
☿ (variant)	Precipitate of mercury [Mercurius praecipitatus]
☾	Month [Mensis]
⊖ (nitre sigil)	Niter [Nitrum]
o o	Oil [Oleum]
⋈	Opposition [Oppositio]
♊	Pisces [Pisces]
♄	Saturn; Lead [Saturnus; Plumbum]
⊕ (powder sigil)	Powder [Pulvis]
⊞	To precipitate [Praecipitare]
□	Square [Quadratum]

Symbol (as printed)	Meaning
Q.E.	Quintessence [Quinta essentia]
℔	Retort [Retorta]
✱	Sal ammoniac [Sal Ammoniacum]
⊖	Common salt [Sal commune]
∇	Rock salt [Sal Gemmae]
⊕ (nitre sigil)	Niter / saltpeter [Sal nitrum]
♄	Saturn [Saturnus]
♏	Scorpio [Scorpio]
♊	Sextile [Sextilis]
☉	Sun [Sol]
☿ (Sp. sigil)	Spirit [Spiritus]
☞	Spirit of wine [Spiritus vini]
♁	Tin [Stannum]
S.S.S.	Layer upon layer [Stratum Super Stratum]
☿ (sublimate sigil)	To sublime [Sublimare]
♄	Sulfur [Sulphur]
×	Talc [Talcum]
♄	Tartar [Tartarus]
♉	Taurus [Taurus]
▽	Earth [Terra]
△	Trine [Trigonum]
♀	Venus [Venus]
V.	Wine [Vinum]
♍	Virgo [Virgo]
⊕☿	Vitriol [Vitriolum]
☹	Urine [Urina]

JURIDICA SIVE LEGALIS

[This page opens with the conclusion of the prose argument, then begins the alphabetical Tabula.] The cast of mind of the alchemists is such that they

habitually wrap up any great mysteries whatsoever — which in fact they do not understand — not in clear and lucid terms, but in obscure ones: in parables and riddles alike, in portentous and fabricated names of things and words, barbarous and wondrously corrupted out of the Arabic tongue, transformed every which way so as to lend a certain false reverence to an art that shuns the light, cloaking it all in deceptive ornament. And so the books of the alchemists are so full of these things that scarcely a sentence is free of them. This they do not only in veiling the secrets of the great Art, but even in the common nomenclature of minerals: for salt, niter, vitriol, antimony, cinnabar, and the rest, they invent — with a kind of lying boldness — names that mean nothing in themselves, barbarous and strange, drawn more truly from the devil's kitchen than from the economy of the minerals. I cannot see what could be more foolish than this.

For what does it contribute to one writing about minerals and metals, that in place of names — which by their own nature ought to be clear and lucid — he should impose on the different species of minerals, and to indicate their meaning, names that are discordant, barbarous, and obscure? By no reasoning can I make this out. Is this not to adulterate the science of things rather than to explain it? What else is to be gathered from it but a fraudulent mind, abject ignorance, a glaring imposture — by which, what they do not know, they are not ashamed to cover up and conceal, if not in fact then at least in words, lest they should seem to have known nothing? So that the reader, whenever he stumbles upon the frantic writings of these men, may understand what the shifty smith of all this, Paracelsus, has hammered out under all those *nostoch*, *gas*, *blas*, *leffas*, *moxos*, *boxos*, and countless other absurdities — I have decided to append a catalogue of them here.

TABULA

In which the more obscure terms of the barbarous names commonly used among the alchemists are set out in alphabetical order.

A

Abessi — the same as *Rebis*, namely the ultimate matter of foods.

Acetum Philosophorum [Vinegar of the Philosophers] — that is, the Virgin's milk [*lac Virginis*], or mercurial water, by which metals are dissolved.

Adamita — a species of Tartar.

Adech — the invisible inner man, who gives form in the mind to all the things that the outer man makes visible and tangible with his hands.

Alcohol — a most subtle powder. *Alcohol of wine* (without the epithet "dried") is when all superfluity is so separated from the wine that, once kindled, it burns until the whole is consumed, and no dregs or phlegm remain at the bottom.

Alcofol — is stibium, that is, antimony.

Alcali [Alkali] — is salt extracted from the ashes or calx of all things, from the burnt bodies; and it is present, proper to itself, in all things, whether liquid or solid.

Alcahest — is Mercury prepared as a medicine for the liver.

Alembrot — the salt of the Philosophers. The key of the art.

Alembrot dried — some call it the salt of Tartar, the Mastery of masters.

Almizadir — green copper-rust [verdigris].

Almarcazida — litharge of silver. Argyritis.

Amalgama [Amalgam] — is the kneading-together of gold or silver with quicksilver.

Amisador — is sal ammoniac.

Ammis alcalisatus — is water drawn through the calx of earths.

Anathron, or **anachthron** — a species of salt which grows on rocks; some call it niter-salt [*sal nitrum*].

Andena — a species of steel in the Eastern regions, which is smelted like copper and silver.

Annus Philosophicus [Philosophical Year] — is the common month.

Anontagius lapis [Anontagius stone] — is the Philosophical stone, the gift of God, sulfur fixed by nature.

Aqua permanens [Permanent water] — is Sun and Moon dissolved in water and joined together; it is also called *aqua caelestina* and the Mercury of the Philosophers.

Aqua Saturnina — is water generated from the three first principles in the channels of the earth, dissolved out of transparent pebbles, such as the medicinal acid waters are.

Aquastor — is a certain vision, representing some thing which is not the thing itself.

Aquila [Eagle] — a well-known bird; but in the Spagyric art sal ammoniac is so called. Theophrastus [Paracelsus], however, also calls precipitated Mercury by this name.

Aquila Philosophorum [Eagle of the Philosophers] — is the Mercury of the metals or of bodies, when the metals are reduced to their first matter.

Archeos — an invisible species, wandering about and separating itself from bodies: the medicinal force and power of nature.

Archeus — is a man producing things out of the *Iliastes*, the dispenser and composer of all things.

Ares — the disposer of nature, consisting in the three first principles, from which all things are constituted; it generates the form, species, and substance of things, so that each thing has its own proper nature, form, and species, and not another's.

Ares — bestows on each species a nature and form of its own, different from the others, as appears in plants, each of which has its own particular root, stem, flower, leaves, and the like.

LIBER UNDECIMUS, Sect. IV

[The Tabula continues, A through L.]

Artanck, artaneck — Arsenic. Of which there are three species: white, yellow (or tawny), and citrine.

Arsanech — sublimated arsenic.

Astrum [Star] — is a heavenly luminary; then it is taken for the force and nature which things acquire in their preparation. Thus the "star of Mercury" is its sublimation, which makes it astral. So too sulfur becomes astral when it is sublimed. Likewise the dissolution of salt, performed by itself, is called the "star of salt."

Athandar — the distilling Philosophical furnace; the *Turbo Clibanus*, or liquefying oven of the Philosophers.

Atincar, baruch, Borrax, Boras [Borax].

Azoth — the Mercury of the metallic body. Theophrastus [Paracelsus] gave this name to a certain universal medicine; some think it was the Philosophical stone.

Barnabas or **barnaas** — saltpeter, urine of saltpeter, the sharpest vinegar.

Butyrum Saturni [Butter of Saturn] — is of Althea lead [?], that is, sweetness.

Callega — is a species of saltpeter.

Cauda vulpis rubicundi [Tail of the red fox] — is lead.

Cenisiatum — that is, calcined.

Cheiri — is also taken in many senses. For it is said of an herb; and when we speak of metals, quicksilver is meant; but some take it otherwise — some hold it to be potable gold, others antimony.

Cheiri flores [Flowers of Cheiri] — white elixir from silver.

Clissus — an occult force wandering hither and thither and returning, as the virtue of the root passes first into the stem and then returns into the root.

Cohop, or **cohopare** — is when matter is often imbibed with a liquid, and by distilling the liquid is drawn off again. Likewise when herbs are reduced by pounding, then purified in the same glass through a water-bath over four days, until the pure can be separated from the impure.

Colcotar — is the stone from which copper too is cooked, soft in nature. **Chalcitis** — red or citrine vitriol [*atramentum*]; but in Theophrastus it is vitriol calcined to redness.

Cornu cervi [Hartshorn] — that is, the cap [nose] of the alembic.

Cycima — litharge.

Cydar — that is, Jupiter [tin].

Derses — smoke, or the vapor from which trees grow.

Divertallum — are the generations of the elements.

Dubelcoleph — is a composition of white coral and amber [carabe].

Dulcedo Saturni [Sweetness of Saturn] — ceruse [white lead].

Duelech — a species of tartar in man. A spongy stone causing danger and pain [a calculus].

Edir — iron, or steel.

Elixir — also a fermented medicine, made either from gold alone or from the seven metals.

Elephas — strong water [aqua fortis]. Among physicians it otherwise signifies leprosy, elephantiasis, the Herculean disease, the Lion, satyriasis, leontiasis.

Entali — is split alum [*alumen scissum*].

Enur — is the hidden smoke of water, from which stones are generated.

Essatum essentielle [Essential exhalation] — is the virtue, potency, or force that is present in every wood, plant, and all other things.

Essatum vinum [Exhaled wine] — when to distilled and rectified wine herbs are added, so that it may extract their essences. As wine of Melissa, which is excellent for asthma.

Fel vitri [Gall of glass] — is the scum of glass.

Fida — gold or silver.

Filius unius diei [Son of a single day] — the Philosophical stone.

Filletin — plates of iron.

Filum arsenicale [Arsenical thread] — sublimated arsenic.

Filum — from feathered alum [*alumen plumosum*].

Flos sectae Croci [Flower of the Croci sect] [?] — some understand by it crocus, the flower of saffron; others the extracted flower of celandine.

Fenix [Phoenix] — the Philosophical stone.

Fons Philosophorum [Fountain of the Philosophers] — the water-bath.

Gamahei — are stones marked with celestial figures and images according to the constellation.

Gibar — a metallic medicine.

Gnomi [Gnomes] — lowly earthly spirits.

Guma — Mercury, that is, quicksilver.

Heinricus rubens [Red Henry] — vitriol calcined to redness.

Ignis leonis [Fire of the lion] — ether, *pyr*, *ethos*, Jupiter, *argēs*. The element of fire.

Ilech, ileias, ilcadus — is the first principle. *Ilech primum* [the first Ilech] is, from the stars, the conjunction of the supercelestial and of the firmament of the stars with the heavenly bodies — truly the union of inferiors. *Ilech crudum* [raw Ilech] is the composition, from the prime matter of the three first principles — Mercury, salt, and sulfur — from which all things are composed.

Ileidus — elemental air, *Heoe pheresbios* [?], the heaven; but in us it is the spirit which passes through all the limbs.

Iliastes — the prime matter of all things, consisting of mercury, salt, and sulfur. Chaos: for there is nothing in the whole nature of things that does not consist of these three.

Iliaster primus [the first Iliaster] — is the term of life, life itself, and the Balsam of man.

Iliaster — that from which all things grow, are nourished, and multiply.

Kakimia — the immature ore of any metal, which still subsists in its first being and still lies hidden in the impurity of the earth, like an infant in its mother's womb.

Koboltum or **Cobaltum nigrum** [black Cobalt] — sometimes it is smelted and rolled almost ash-gray, but it lacks the metallic color, and therefore it is not fixed, but carries off the better metals with it through the smoke. It is *Cadmia*, the stone from which copper is made, useful in medicine, an airy stone — *Climia*, *Cathimia*, calamine stone.

Lac virginis [Virgin's milk] — mercurial water.

Lapis [Stone] — in chymistry, every fixed thing that does not evaporate.

Leffas — is the hidden, fermenting smoke of the earth, through which plants grow.

JURIDICA SIVE LEGALIS

[The Tabula continues, L through Z.]

Luna compacta [Compacted Moon] — is fixed silver, or white gold.

Magnesia — is marcasite of any metal.

Magnesia Philosophorum [Magnesia of the Philosophers] — is silver joined by art with mercury into a metal that flows easily. It is also their matter, from which they make their stone.

Malk Arabicum [Arabic Malk] — is, to the Latins, salt.

Marcasitha [Marcasite], pyrites, *pyrototus*, *lapis aerarius*, *lapis luminis* — is an ore having much of red sulfur.

Martach — litharge.

Mensis Philosophicus [Philosophical month] — is the time of chymical digestion.

Mercurialis seva [Mercurial tallow] — is alum-water, in which mercury is generated.

Mercurius laxus [Loose Mercury] — is mineral turbith.

Mercurius metallorum [Mercury of the metals] — is the precipitated mercury of the body.

Mercurius mineralium [Mercury of the minerals] — the oiliness extracted from the ores of gold and silver.

Mercurius regeneratus [Regenerated Mercury] — is the first being [*primum ens*] of mercury.

Missadan — quicksilver. **Minium** — saffron [crocus] of Saturn.

Nebulgea — salt formed from the moisture of mist that often falls upon stones in the meadows, hardened by the force of the Sun.

Nostoch — the purgation of the stars; others understand it as wax.

Nuba secunda — a species of *tereniabin*, or manna of rosy color, such as falls in Hibernia [Ireland].

Operimethiolim — is the spirit of an ore.

Opodeltoch.

Orizeum — is gold.

Pulpezia or **pulpelzia** — astonished stupor, apoplexy, sideration. **Pygmei** [Pygmies].

Realgar — taken by itself, is the smoke of minerals, whatever is arsenical, or has the nature of orpiment.

Rebus — the ultimate matter of things.

Rillus — a chymical instrument into which liquefied metals are poured.

Sagani — the spirits of the four elements.

Sal Chrystallinum [Crystalline salt] — is what is made from human urine.

Sallena — a species of saltpeter.

Sal Mercurii [Salt of Mercury] — is spirit of wine, which inebriates.

Sal practicum [Practical salt] — is a mixture from saltpeter and ammoniac in equal parts, joined in a new unglazed pot and set in a cellar, which clings to the outside of the pot like hoarfrost.

Samech — tartar, a remedy for all wounds.

Serpheta — a medicine that liquefies the stone. **Sibar** — quicksilver.

Spara — a mineral force from *Ilech*, of the first substance, from the first being — that is, from the greater minerals.

Sperniolum — frog-spawn, otherwise the brood of frogs: *molurides*, *gyrinoi* [tadpoles], *batrachides*.

Stannar mater [Stannar the mother] — is the hidden smoke from which metals are generated.

Sylo — the whole world. **Sylphes** [Sylphs].

Terra argenti [Earth of silver] — litharge of the Moon.

Terra auri [Earth of gold] — litharge of the Sun. **Terra fidelis** [Faithful earth] — silver.

Thisma — the vein and course of ores.

Tinchar — borax.

Trachsas — metal in its own ore.

Truphat — is the hidden virtue of ores, which forces any metal into its own being.

Turbith minerale [Mineral turbith] — is Mercury, that is, precipitated by a corrosive and made sweet.

Vitrum Philosophorum [Glass of the Philosophers] — that is, the alembic.

Urina vini [Urine of wine] — vinegar, or the urine of a man drinking wine.

Xisinum — vinegar.

Xenechton — is hung on the neck against the plague. Its interpretation varies: one understands it as the first menstrual blood of a Virgin, another as something else.

Trcus [?] — stones; *dasypus*, *georychus*, *leberis*: the male rabbit, with whose blood glass and flints are softened, if they are fed [smeared] with diaphoretic substances — which by the ignorant is ascribed to the he-goat.

Zadir — Venus [copper], or green of copper [verdigris].

Ziniat — leaven [ferment].

Decorative woodcut.

[Reading order note — non-linear PDF: the four scanned leaves are out of page-number sequence. Printed running-header page numbers are: PDF-image 1 = p. 327; PDF-image 2 = p. 326; PDF-image 3 = p. 329; PDF-image 4 = p. 328. The text reads in the order 326 → 327 → 328 → 329, i.e. PDF-image 2, then 1, then 4, then 3. Page numbering has NOT restarted for Liber XII — it continues the volume's count (the prior book closed in the low/mid hundreds and this picks up at 326). Translation below follows the reconstructed reading order.]

MUNDI SUBTERRANEI — BOOK TWELVE

ΠΟΛΥΜΗΧΑΝΟΣ [Greek: Polymēchanos, "of many devices / resourceful in countless arts"]

SIVE — SIMIA NATURÆ [or, The Ape of Nature]

**

In which it is taught — and confirmed by experiment — that whatever is produced in the foregoing Books by the sagacity implanted in Nature, anything remarkable, rare, or unusual brought forth by the power and efficacy of the Geocosm, can be made in just the same way by the ingenious industry of Art, provided Nature does not forbid it.

PREFACE

I have not infrequently marveled at the perversity of certain men who, abandoning the true and straight path to higher knowledge, leave no stone unturned to reach — by any means whatever — an acquaintance with unknown arts and the inaccessible riches of Nature's secrets, so that they may seem to know some great thing, something [Greek: ἰξωπικώτερον (ixōpikōteron) — "more deeply hidden / more recondite" (?) — reading of the rare Greek term uncertain] beyond other men. Yet since it is not granted to everyone to reach this Corinth, and since the gates of wonder-working Nature are not opened to all, nor are the keys to the inmost chambers of her treasures granted to all — what do they do? When they find every approach barred to them, in rash daring, breaking the laws of Nature, they take refuge in those workshops of wicked arts. There they not only fail to find what they so eagerly long for and so anxiously seek, but, led astray by a ruinous error and entangled in Satan's snares — from which, unable to extricate themselves — they bring upon themselves the ruin of body and soul, together with the brand of everlasting infamy. Of this kind are those who, whether confused by an insufficiency of native talent and a certain distrust of Nature, or driven sideways by despair of attaining the arts they craved, do not shrink from striking a pact with the enemy of the human race and taking him for their master — though they cannot but know him, even from the sacred oracles themselves, to be the craftsman of all lies and evils.

There are, then, fixed and definite boundaries set for us within the breadth of natural knowledge, which no one may overstep without error and the gravest peril. I know that Nature, in certain matters reserved to herself alone, is so

tenacious, defends her rights with such great effort, and is so inexorable, that it is not granted even to a demon to make use of them unless God and Nature permit; indeed, the World would sooner have to perish than that Nature should yield her rights. Therefore, whoever has a mind to philosophize rightly must in all things look to the one Archetype of Nature, so that in her intricate labyrinth — Ariadne's thread once seized — he may keep himself safe and secure from errors and misleading bypaths. This prototype, just as in the preceding Books we have described it with all the diligence we could, so in this last Book — which we have, not inappropriately, titled *The Ape of Nature* — we shall try to sketch out, as far as is permitted, by the manifold industry of art and ingenuity, so that from these things it may be plainly shown to the curious reader what one can, and what one cannot, do by the power of Nature.

We have divided the whole into seven Sections. Of these the first, as a kind of Introduction [Isagogical], sets the whole majesty of Nature before our eyes [Greek: θεωρηκῶς (theōrēkōs), "contemplatively / by way of theory" (?) — reading uncertain]; it lays open the hidden and secret pathways along which she advances; it shows the nests of her marvelous births throughout the threefold Kingdom of Nature, so that those who follow her tracks—

**

—that following her tracks we may at last, through the production of similar works, attain to that hidden [Greek: ἐγχείρησις (encheirēsis), "undertaking / handiwork" (?) — reading of the Greek uncertain]. These things I have judged worth setting forth deliberately, so that — leaving aside the deceptions of profane and unlawful arts (the more dangerous, the more hidden the ways by which that enemy of the human race is wont, for the most part, to insinuate himself into them) — students of curious matters may pursue only those things which, being lawful and most worthy of praise, likewise have joined to their usefulness and respectability the greatest pleasure of mind that is drawn from them: to the glory of the Divine name, to the benefit of the Christian commonwealth, and also for the relaxation of Princes and great men, whenever they may have some freedom from the press of public affairs. Farewell, and favor my undertaking.

SECTION I

DE PANSPERMIA RERUM [On the Panspermia of Things — the Universal Seed of All Things]

CAPUT I

On the Origin, Nature, and Property of the Seed.

When God, the Best and Greatest, was about to found this visible machine of the World, He did so to this end: that in this most beautiful theater He might display a certain specimen of His ineffable wisdom, goodness, and power — a kind of Archetype of the World, which He Himself was. And He willed that it should subsist not for a momentary but for an everlasting duration. But since He knew that this everlasting duration could in no way persist amid the destruction and utter vicissitude of things that are by their own nature corruptible, in the economy of this sublunary World — lest, as things perished in the course of time, the World itself should perish along with them, and as the species failed, the World should fall away from its perfection — the most wise CREATOR, by His divine and ineffable wisdom, provided against this supreme detriment to Nature in such a way that, by alternating laws, generation should follow upon corruption, and a new generation should take up what corruption had carried off, according to the nature granted to each thing by the World's Maker; and thus the World might persevere in its perfection through this admirable vicissitude of things succeeding one another by turns.

[Margin: The penetrating, unstoppable power and might of the Seed.]

Now this was nothing other than a certain seminal or spermatic power, by whose virtue and efficacy the species of things, through natural propagation, might forestall the destruction of things. And so great is this virtue and property of the seed that in no other thing of this universe does the omnipotence and wisdom of God shine forth so clearly as in this very thing. Concerning its origin the most excellent philosophers of every age have indeed reasoned wisely; yet the more they thought they had drawn nearer to its true wellspring, the more they found themselves removed from its hidden essence and most secret intelligence. As for what, in so great a darkness surrounding this divine work, the Father of lights may have suggested to us concerning this subject, this we shall lay open to the curious Reader in a brief account.

From the sacred Mosaic Oracles, then — which we ought rightly to set, by many parasangs, before all the certainty of human knowledge — it is established that God, the Creator of all things, in the begin—

[The page's right-hand column begins here; marginal notes are keyed within.]

[Margin: God first created a certain Matter, which we not incongruously call Chaotic; from this He afterward drew forth all else.]

—the beginning created a certain Matter of things, which we not incongruously call Chaotic, out of nothing. For the glorious God created all things at once; and within this Matter lay hidden, as in a kind of [Greek: παντοσπερμία (pantospermia), "universal seed / all-seed"] confusedly, whatever of the material of things — mixed bodies and substances — was afterward to be produced in the nature of things, as it were beneath that all-seed. For the divine Architect, besides this matter and the human soul, created nothing anew; this is plain from the text of Sacred Scripture itself. And out of this single chaotic matter — as out of an underlying matter, already made fruitful by the brooding of the Divine Spirit — He afterward brought forth all things, both the heavens and the elements, and from these the composite species both of vegetables and of animals (excepting the rational soul), by the mere command of the Omnipotent voice. Each of these species was drawn from the aforesaid mass of primordial matter, and each single thing, both among vegetables and among animals, was furnished with those endowments of nature which were owed to it by the Creator's intention, and by which they might afterward, through the seminal power granted to them, propagate themselves in perpetual generation.

But the Chaotic matter He did not at once abolish; rather He willed it to endure until the consummation of the World — as in the first beginnings of things, so to this very day, filled full of the panspermia of all things. He willed that what God in the beginning produced out of nothing from the Chaotic matter should not perish — a view which the monuments of nearly all the holy Fathers chiefly uphold, above all St. Basil [Basilius] in his *Hexaemeron*.

Since this is so, it may rightly be asked at this point what that panspermia and seminal power, productive of all things, may have been. I say that it was a certain material spirit, composed of the subtler portion of the heavenly air or of the elements; and that it was a certain spirituous vapor, Mercurio-saline-mercurial [recte: sulphureo-saline-mercurial — see Caput I's later definition and the marginal heading on p. 328; the wording here reads "Mercurio-salino-mercurialem," apparently a compositor's slip], the universal seed of things,

concreated with the Elements by God, the origin of all those corporeal entities that are founded in the World. For this, according to the nature of the matrices in which—

**

—in which it is implanted, produces in inanimate matrices indeed mineral and metallic bodies; in vegetables, plants of every kind; in sensitive nature, animals — each according to the nature suited to it, by a marvelous engrafting. And it is individuated into as many mixed bodies as there are species of things, by a certain ineffable combination known to God alone. And this is openly evident from so great a variety of things, and from the multitude of species, both vegetable and sensitive, which God — who alone is to Himself the idea of the things to be combined — drew forth by the power of this seed.

[Margin: The Elements concur remotely in the composition of things.]

But lest anyone persuade himself that the elements were idle in the composition of things, I say: the elements are the remote matter, while the proximate matter is that universal seed, concentrated and gathered together in the elements from the beginning.

[Margin: A twofold faculty was joined to the Seed — plastic and magnetic.]

Now since the thing produced had to consist, according to the natures of the individuals, of various figures, colors, differing parts, and members, He furnished this seed with two endowments of Nature, the architects of the said things; and these are the plastic and the magnetic powers. The former bestowed on each species its form, figure, and color; the latter gave it the attractive power for like things. But in order that all these matters may be demonstrated in order, it has seemed best to begin the subject somewhat higher up.

For who has wrought gems and precious stones into so many colors, so many figures — round, angular, and polygonal — if not the plastic power of this seed, allied with the magnetic (which we also call *corradiative*), by which alone like parts flow together to parts like themselves, with a certain wondrous appetite?

[Margin: The office of the plastic faculty.]

Who in vegetables distinguished the roots, the stalk, the branches, leaves, flowers, and fruits with such a variety of colors and parts? Surely nothing but the plastic or formative power alone. Who, in the fabric of sensitive bodies, stretched out the nerves, hollowed out the veins and arteries, filled the solidified bones with

marrow? Who bored the channels, made the flesh spongy, furnished the skin with pores? Who, in short, reduced the whole constitution of so many different animals into such figures? The plastic power alone. For there lies hidden in these things the divine Craftsman, who works in the inmost recess of the body without instrument and without commotion, and produces a work worthy of admiration — filled with so great a variety and elegance of dissimilar things, as great as we discover — and this out of rude and formless matter, in which no dissimilarity, no variety, presents itself to the senses.

But to begin our web from the lower grade of Nature, we must now consider what that is which confers upon the fossil offspring of stones, gems, and crystalline bodies so great a variety of figures, so many shapes in their polyhedral and polygonal bodies? which distinguishes them by so many differences of colors? which endows them with so great and so untamable a hardness? Surely no one will deny that the aforesaid seed is the cause, who has looked a little more deeply into these matters—

[The right-hand column begins here.]

—inanimate bodies of themselves and by their own nature require, both for their own increase and for continuing their propagation. For we do not say that metals and mineral things are generated in that manner in which vegetables and sensitive natural mixed bodies are generated from seed properly so called, nor that the account of metallic plants agrees with these; but rather in that manner which properly belongs to the generation of fossils, which is the magnetic motion, by which like bodies are called to their likes, flow together, and are united by a certain wondrous consent.

[Margin: The magnetic [power], in what it consists.]

For with this endowment, as we shall teach in what follows, the seminal power is chiefly furnished. But what this power is, and how it operates, remains to be explained. Therefore let there be:

A DISQUISITION

How the Universal Seed of Nature concurs in the generation of metals and minerals, and how it especially adorns gems with so many colors and figures.

[Margin: What the seed is in the primordial Chaotic mass.]

As we have very often taught in this work, there was a certain seed implanted in the primordial Chaotic mass of things by the Founder of things, constituted out of

the elements and a portion of the etherial fire — which we call the *sulphureo-saline-mercurial spirit* — not that it is actually constituted out of sulphur, mercury, or mineral salt, but that its virtue resides and shines forth chiefly in sulphur, mercury, and salt as in its genuine subjects. For there is nothing in the nature of things that more savors of fire, or of the radical heat, than sulphur and the other bodies born from it, because it suddenly blazes up into flame, possessing a certain desiccative and oily virtue and the other virtues and properties suited to fire. Nothing more nearly resembles the radical moisture in its watery and airy substance than Mercury, or quicksilver, in which the watery is joined to the dry, the subtle to the gross, the light to the heavy, by a wondrous proportion. And what, finally, expresses more exactly the mass of earthy consistency than Salt? — which lends hardness and solidity to all things, and yet so encloses the other two, sulphur and mercury, within itself that they seem unable to be separated from one another by any means. For this substance of salt is in a certain measure clothed with the sulphureous and mercurial virtue, to this end: that, since fire and water of themselves and by their own nature — the one by reason of its lightness, the other by reason of its fluid nature — cannot subsist, they may obtain from the salt of Nature their solidity and consistency. Hence in salt these are so enclosed,

[Margin: The salt of Nature, consisting of three [principles].]

that one thing appears constituted by a threefold virtue, in which the glorious God impressed upon His primordial creature — as the future principle, as it were, of all things — the seal of His Most Holy, ineffable, and adorable Triad.

[Margin: The Spirit of Nature, or the Saline-sulphureo-mercurial vapor, is the seed of all things.]

Hence not undeservedly have we judged that this Spirit ought to be called, as it were, the universal seed of Nature — the Saline-sulphureo-mercurial Spirit, one substance distinguished by a threefold virtue — the proximate principle of all things; to the elements—

**

—to the elements, which are a kind of vehicle of it and its remote matter, implanted from the beginning of things, and destined by God the Best and Greatest for the constitution and composition of all things. For there is nothing in the nature of things that is not constituted out of this threefold virtue contained in the one salt of Nature — as the Spagyric art apodictically demonstrates, and as will be plain from the experiments to be set down a little later.

But let no one suppose that this is common, ordinary salt — that seed we have spoken of; rather, that beneath a certain wrapping, in the chamber of the inmost center, lies hidden that seminal power, the constitutor of all things, as in the first beginnings of things, so now and in future ages, perpetually to endure. And in the Salt of Nature, indeed, this threefold principle lies hidden, in which the earthy element holds predominance; in the Mercurial body these three likewise lie hidden, but under the predominance of the humid; and in Sulphur the same are found, but under the predominance of the hot and dry.

[Margin: The fire of Nature, the entelechy of Aristotle, and the seed of the World are the same thing.]

Hence by the philosophers each of these is not incongruously called the *fire of Nature* by Albertus [Albertus Magnus], the *seed of the World* by Plato, and by Aristotle the [Greek: ἐντελέχεια (entelecheia), "entelechy / actuality"], or the moving power of all things — (a heat indeed, yet not fire, nor any such faculty, but a spirit which is contained in the seed and in the foamy body, such that the nature which is in that spirit corresponds proportionally to the element of the stars; namely, that to which the soul and the plastic virtue are most nearly present is not apprehended by sense, nor is it a moisture of the kind seen in the known sperm, but something spirituous, and of celestial nature, lying hidden in it) — and by the Hermetics the *seed of Nature*, from which all sensible things derive their origin.

[Margin: How the universal seed acquires the grades of nature.]

And in this there occurs something also worthy of admiration. For if it is entrusted to terrestrial matrices, it produces, according to the condition of the matrix, either a mineral — such as a metallic body — or any other inanimate body whatever. This same thing, attracted by vegetables into seed, is converted into that from which it first obtained the first-fruits of its origin. And so in fossils a seed of this kind is inanimate; in vegetables it is endowed with the vegetative soul; in animals, finally, with the vegetative and sensitive virtue — according to the proportion of the mixed body to which it is joined, so it prevails. For any mixed body whatever, if we contemplate it more closely, we shall find to be in itself nothing other than this universal seed, which has reduced itself into an individual and a species within that particular mixed body, with the remote elements cooperating; the form too, inexistent in it, conducts this universal seed to the individual and the species. From the center of the seed, under the varied combination of the disposed matter, it issues forth. But how this can come about will be shown more fully in what follows; for now we briefly set forth how,

through a seed of this kind, minerals, stones, and metals are generated, and how they operate by their plastic power.

CAPUT II

The manner in which Nature proceeds in the generation of minerals is set forth.

[Margin: The seed of metals is not animate.]

Most chemists [Chymici] contend, wrongly, that the seed of minerals and metals is animate. For, as we said a little before, a seed of this kind obtains, according to the condition of the matrix, the grade of nature appropriate to it: if it falls upon a matrix devoid of soul, it produces something inanimate — whether mineral, or stone, or metal; if upon the matrices of plants, something animate; if it falls upon a matrix of the sensitive grade, it produces a mixed body conspicuous in both grades of nature, individuated according to the nature of each.

And the seed, indeed, insofar as it concurs in the generation of minerals, cannot maintain the name of seed properly so called; for metals, minerals, stones, and gems are not properly born from seed, nor can they be nourished by intrinsic nourishment in the manner of proper vital motion — whatever the Alchemists [Alchymistae] may trifle about the seed of gold and silver — but rather by the [Greek: εὐθεϊαν (eutheian) — here in the sense of "a straight drawing / direct tendency" (?) — reading uncertain; the term is used as a near-synonym of the magnetism that follows], that is, a certain magnetism, or by the approach and apposition of like corpuscles to like, through the Saline corpuscles in which the universal seed abounds.

But since we have treated of the manner and reason most fully in several places in the Books of this Tome, we refer the Reader thither, lest we seem to be re-pleading a case already pleaded so many times. Of the plastic virtue too, implanted in the Saline [spirit] of Nature, ample and demonstrative treatment may be seen, copiously set out, in the Eighth Book.

They are therefore greatly deceived who, from the analogy of plants and animals, imagine to themselves that minerals and metals are born from seed properly so called.

[Margin: The metallic efflorescences are not from seed properly so called.]

For those metallic "plants" which are now and then found in the mines are nothing other than efflorescences, or certain exanthemata [eruptions], not arisen from a vegetable nature, but from the evibration, or radiation, of mineral and

saline spirits into certain filaments, distilled after the manner of little twigs. Add to this, that little shrubs of this kind can easily be produced not only by nature but also by art — as will be taught from its own proper Chapter following, on the production of mineral "plants." As for the plastic virtue, which shines forth especially in the polygonal figures of gems, this surely cannot properly be called a plastic power, since the latter properly has its place in the seeds of plants and animals.

Again, that the seed of minerals is not animate is evident from this also: that no mineral or metallic body whatever it may be can nourish us; but it would nourish, if it were endowed with life — since, properly,—

— from Liber XII, Sectio I, *De Panspermia Rerum*, Caput II (continued from printed p. 329) —

[Printed p. 330; running header: LIBER DUODECIMUS, Sect. I]

we are said to be nourished by the very things of which we are composed. But we are not composed of minerals; rather, we sustain our life by the nutriments of the vegetable and the sensitive natures. There is therefore one seminal and plastic power for forming gems, and another for forming the members of vegetable and sensitive beings.

Now some chemists object that salt prepared from nettles sets into triangular crystalline tesserae. I would have you judge that this happens not by the power of common salt, but by the vegetable nettle itself. For that very lye, from which the crystals are gradually gathered as it suddenly freezes solid in the winter cold, presents a wholly different appearance — namely, that of ice itself, not crudely congealed but shaped into crystalline nettles. This is surely a manifest argument and indication of the plastic power residing in the salt of the vegetable nettle. And as for the corpuscles of the different mineral salts — niter, alum, vitriol — coalescing into different figures, this comes about not from any plastic faculty of an animate seed, but from the magnetic flowing-together of like corpuscles toward like. By this magnetic confluence, with the stone-forming power [*vis lapidifica*] accompanying it, the radiative faculty transforms gems now into this, now into another polyhedral figure — as we have amply demonstrated in Book VIII [*Lib. VIII*] and in the *Magnetic Art* [*Ars Magnetica*].

[Margin (left): The sulphur in the salt.]

CAPUT III.

On the seed-bed of plants, or the vegetable seed of Nature. [De Seminio plantarum sive Naturæ vegetabilis.]

[Margin (left): God produced all the genera of plants and animals not immediately, but from the Chaotic mass.]

It is established from the sacred book of *Genesis* that God, the Best and Greatest, created nothing immediately — neither plant, nor animal, nor any other compound thing you may consider — but produced everything from Chaos. From the Chaotic mass, brought forth out of nothing (and into which he had jointly created the panspermia and universal seed of Nature), as from a presupposed subject he produced all things: the heavens, the stars, minerals, plants, and animals. Yet it still remains to be said — so far as the dullness of our wit can grasp it — how, out of a seed of this universal and panspermic, virtual kind, he produced so many and so diverse genera of plants; how he gave them life; and how he furnished them with so many and so great endowments.

After the division of the waters, then, and the separation of the elements out of that void, and the brooding of the Divine Spirit, the mass now being furnished with its panspermia, God said: *Let the earth bring forth the green herb that bears seed, and the fruit-bearing tree producing fruit after its kind, whose seed is in itself upon the earth.* [Genesis 1:11] These words plainly indicate that the herbs and trees were not created immediately, nor produced out of nothing, but were brought forth from the earth already created and furnished with its panspermia — by the command of the Divine word, according to the combination owed to each. For from the firstborn seed he brought forth the whole variety of the vegetable economy; and into these, once produced, he implanted the vegetative power, in which lies hidden a certain potency and a power of multiplying their own kind, a power that was never to fail. And what he had first produced through an invisible and hidden seed, he now likewise constitutes through a manifest seed, which will go on propagating right up to the final consummation of the World.

The production and generation of vegetables in general, therefore, emanated from that elementary moisture — not the simple moisture, but that firstborn salino-sulphureo-mercurial Vapor — inasmuch as it includes within itself the powers and properties of universal nature; and it is individuated and made specific into the particular vegetables, which it nourishes

[Printed p. 331; running header: DE PANSPERMIA RERUM]

[Margin (left): The seed of Nature contains within itself in power and potency a vegetative force, and a sensitive one.]

according to the genus and species of each, and according to the immutable will and intention of the Supreme Founder. For since up to this very day the whole mass of the earth has been imbued with this primigenial seed, and has never failed, hence the vegetables distribute this liquor — drawn in through their roots — into all the members of the plants. These cook it, digest it, and convert it into their own proper substance, by both internal and external heat; and from the purest part of this spermatic liquor, now digested and cooked, they form a certain body, in which there lies hidden above all, and consists, that seed which propagates the like — an invisible seed. As soon as this has fallen into the earth, it at once, as if by a kind of powerful magnetism, draws to itself a new humor, in which lies hidden that power, or architectonic spirit constitutive of all things, the salino-sulphureo-mercurial spirit. Joined to that seminal power in the seed of the now-individuated plant, it at once begins to operate; and it spurs the plant on to receive that form which Nature intends in it, and which is owed to it by the law of nature — and this by a perennial cycling-back [pericyclōsis]. For although that seed of Nature persists in the already-individuated seed of the plant, yet unless it is restored once more to its own soil, it will never bear fruit. But as soon as it is entrusted to the earth, then, with the seed of Nature drawn to it from the earth as from a friend and connatural thing, it will at once be animated, and will perfect the vegetative power according to Nature's intention.

[Margin (right): All things draw the seed of Nature.]

You see, then, how the seed of Nature is first drawn in by the seed of the plant, together with the elementary liquor, from which it cannot be separated. Next, this spermatic nourishment, still impure, passes partly into the trunk and branches, partly into the leaves and flowers, until at last, digested and cooked by the heat both inner and outer of the sun, its purest portion is at last converted once more into seed, for propagating the like. This seed of Nature, therefore, by Divine command and intention,

[Printed p. 332; running header: LIBER DUODECIMUS, Sect. I]

[so that] the decays [putredines] of all things ferment by nothing but salt. Vegetables, in their final dissolution, leave behind nothing but salt; animals, of whatever sort, swell with salt. What else are the feathers of birds but the efflorescence of salt condensed into the covering of plumage?

[Margin (left): The feathers of birds are coagulated.]

Surely human and animal urine, with which they swell, shows well enough that it is something saline — urine that they so greatly delight in, that they feel they can be preserved and made fertile by no other balm of Nature than the saline one. Hence they so eagerly long for it; with such avidity do they suck, lick, and gulp it from the ruins of old walls.

[Margin (left): Animals are preserved by salt.]

Doves and the rest of the birds eagerly dig the cracks and fissures of the ground, seeking it out by their licking. And it is proper to the genus of fish to live and be preserved by salt. This salt, dissolved and insinuated into the roots of plants, produces that variety of herbs which we marvel at — for the nourishment of men and animals, so that we may be nourished by that from which we are composed. And we are nourished by that spermatic salt which is found in the final dissolution of all the foods that are taken. What else is it but the seed and a kind of quintessence and ἐντελέχεια [Greek: entelecheia, "entelechy," actuality/perfection] of all the parts of which we are composed? And on this very score salt may be called an animate seed,

[Margin (left): Seed is animate salt.]

inasmuch as it is extracted, for use in medicines, from all things both vegetable and animal. What is more wonderful than human urine, which by suitable prepara-

[Printed p. 332, right column, continued; running header: LIBER DUODECIMUS, Sect. I]

[Margin (right): Dew is a species of salt.]

-tion is rendered fit not only for medical use, but even for dissolving gold and silver? That it is a vegetable thing is recognized from this: that any plant, once cooked down into salt and set into pure earth, in time reproduces the same plant that had been dissolved into salt. Of this truly marvelous operation of Nature we shall adduce more experiments in what follows.

I will not speak here of dew, which the Spagyric Art [*Ars Spagyrica*] shows to be a vapor congealed into salt — from which it draws out a menstruum of such great efficacy that, no less than from common salt, saltpeter, niter, it dissolves corals and pearls; and it is proper to this menstruum to be dissolved by cold moisture and condensed by heat. The mineral [salt], just as it is divided into diverse

species, so too prides itself with stupendous powers in each, so that there is no genus of salt — whether it be common salt, or alum, or niter — that is not found in each of them. The species of metals derive their hardness from no other source than from an abundance of fixed salt. Take one pound of lead: from it, once calcined, you will extract nearly ten ounces of salt — and so with the rest.

[Margin (right): Experiment.]

This [salt] is found also in the higher regions of the air, as is plain from the wondrous effects of meteors. But since we have treated at length of the four species of salt in Book VI [*VI. Libro*], we refer the Reader thither, where he will find discussed whatever can come up worthy of consideration concerning this argument.

CAPUT V.

How the universal seed concurs in the generation of animals, and on the wondrous efficacy of the plastic power in the seed of animals.

[*Quomodo semen universale ad animalium generationem concurrat, & de mirifica plasticæ virtutis efficacia in semine animalium.*]

We said in the preceding Chapter how, from the universal seed placed in the Chaotic mass, the Founder of all things brought forth plants as from an underlying matter. Now it remains [to show] how, from the same matter, on the fifth and sixth [days] he brought forth animals of every kind. We suppose, then, that God, the most high and glorious, first brought forth from it both plants and animals; whence that universal seed — just as in the already-produced plants it acquired, along with the vegetative grade of Nature, a vital faculty as well — so in the animals brought forth from the same matter on the fifth and sixth day, it shared in the sensitive grade of Nature, according to the good pleasure of the Creator.

[Margin (left): The universal seed is salt.]

And in this manner this seed, through the continual attraction of nourishment — which in each grade of Nature is produced from its final cooking — by which also, by the successive and alternating vicissitude of generation and corruption, the species both of plants and of animals are propagated up to this present day, and will be propagated up to the consummation of the World. But the seminal faculty, by which it accomplishes its operations, since it is too subtle to be grasped lightly, I shall explain a little more fully.

It must be supposed, then, that for the life of living things, and for the right accomplishing of their operations, there is necessarily required a concurrence of heterogeneous parts; since it cannot be that either plant or animal should live, or rightly perform its actions, by homogeneous parts alone. For if all the parts were of the same nature, the operations of all would assuredly be the same, not diverse — according to that maxim: *Idem in quantum idem semper facit idem* [The same, insofar as it is the same, always does the same]. Hence not inappropriately does the Philosopher [Aristotle] define the soul as the act [*actus*] of an organic body — that is, [a body] which has diverse organs and instruments, which it uses as necessary for the diversity of its operations. But just what that is which accomplishes that diversity of parts in animals, I now explain.

We said a little before that God, when he brought forth plants and animals from earth and water chaotically commingled, at that same moment established each of the species of things in its natural being. But in very truth, since they — being [made] from the corruptible mass of the elements — [could] not sustain themselves in

[Printed p. 333; running header: DE PANSPERMIA RERUM]

[Margin (left): The spermatic power that gives propagation to things.]

perpetuity [by themselves], he therefore implanted in each a spermatic power, by which they might propagate themselves, by perennial succession of things and by the alternation of life and death — or, what is the same, by the vicissitude of generation and corruption — right up to the very duration of the World. And in this way each species, whether of vegetables or of animals, would be preserved in its own state and in its natural essence. But how, and from where, the propagative power draws its origin, and from where it comes, I now set forth.

[Margin (left): What is the universal seed of things?]

We said above that the universal seed of things is nothing other than a salino-sulphureo-mercurial, spirituous vapor, by which all things that are in the World are composed. But this vapor, distinguished by a threefold power, I would not say is compounded out of mineral and sensible salt, sulphur, and mercury; rather, [I would say] that there lies hidden in the innermost central chamber of these something that we call the fire of nature — or that which, with the Peripatetic [school], we call the heat innate in all things, which shines forth above all in sulphur, [the heat] of all the things that exist in the nature of things, as we have demonstrated at length in Books Nine and Ten.

In mercury, by contrast, [we said] there lies hidden something most like the radical moisture, which corresponds exactly to the faculties of water and air, without which no corporeal substance can subsist; and it shines forth most of all in mineral mercury. Inasmuch as mineral mercury is the most moist of all things and the driest, the heaviest and the lightest, the hottest and the coldest — which alone Nature was pleased to establish in a perfect degree of contrary qualities — so it most closely emulates the faculties of water and air, as we taught in the chapter on the incomprehensible nature and property of Mercury. Yet I would not have these things understood as if this seed were compounded out of the common Mercury [of the vulgar]; but rather that in the innermost center of this mineral compound there lies hidden a certain admirable power, which the Philosophers call radical moisture, of which Mercury can be called, as it were, an external covering. And this is that power which confers radical moisture on all things, without which nothing could live.

[Margin (left): Sulphur and mercury reside inseparably in salt.]

But since, just as heat cannot subsist without moisture — as being its nourishment — so neither can these [things] be condensed into a corporeal mass without a certain faculty which furnishes consistency and corpulence to all things; and we say that this [faculty] lies hidden in the center of the salt of Nature. Yet since this saline power also cannot subsist without the sulphureous and mercurial [powers], hence most wise Nature has so enclosed both [of these] in the saline body — as in their base and support of all things — that they cannot be separated from one another. And this is the seed of universal Nature, which the most wise Founder first created together in the chaotic mass, so that out of it he might thereafter, by the command of his omnipotent voice, bring forth all the things that are contained within the compass of the World, as from an underlying matter. And this indeed — according to the grade of Nature suited to each, insinuated and individuated into the several species both of vegetables

[Printed p. 333, right column; running header: DE PANSPERMIA RERUM]

and of animals according to the good pleasure of the divine intention — produced that variety of things which we marvel at. And in the vegetables, now established in their species by the glorious Founder, that [seed] is nothing other than that radical moisture, by which all those things that are endowed with the vegetative faculty are, as it were, nourished. And from the final cooking of this [moisture] by the innate heat — that is, by the sulphur made by nature — there is born in plants that seed which, deposited in the earth and animated by a new salino-

sulphureo-mercurial spirit, propagates the species of each thing, lying hidden as a power in its proper seed.

[Margin (right): Of what the seed consists.]

But since an animal cannot live without nourishment, animals therefore have need of nourishment, by which the moisture consumed by heat through attenuation may be restored; and nourishments of this kind are none other than the fruits of the vegetable and sensitive nature, by which we are fed and sustained. But since nourishment of this kind is of a heterogeneous and dissimilar nature, hence, within the stomach, Nature there separates the pure from the impure by digestion and fermentation. The pure it transmits, partly to the liver, partly to the heart, for the elaboration of blood and spirits; the impure, however, it expels like dregs through the two excretory passages [secessus].

[Margin (right): The plastic power innate in the seed.]

But since the seed of Nature is always joined to nourishment in an inseparable bond of partnership, hence too is born that plastic faculty, always connected to the seed, which surpasses all wonder. For by this [faculty] the substance of the body, constituted of so many heterogeneous parts and members, draws its origin. For what is saline in the seed of nature has been deputed by nature for the forming of bones and the other harder portions of the body, without which it could not obtain a solid substance. The moisture of animals — that which lies hidden in the seed — supplies the mercurial [element]; and the nerves, cartilages, and ducts of the veins, being of a more tenacious and viscous nature, accordingly obtain [their being] partly from the mercurial, partly from the saline and sulphureous fatness, by a marvelous combination. The remaining humors: first the blood and phlegm derive their nature from the predominance of mercurial moisture; bile, from the humor burnt by the sulphureous power; black bile [atra bilis], from the separation of the dregs of the blood burnt by heat. But the vapors attenuated out of the mass of the blood by heat — which we call the spirits, both animal and vital — are produced by that fiery power lying hidden in nature in the sulphur. Being the most spirituous and the most subtle, they alone, diffused through all the inmost recesses of the human body, uniquely govern the microcosmic Economy, perpetually urging each thing on to the motions, operations, and actions suited to it.

These things, then, being duly established: since the whole fabric of animate beings is constituted out of the corruptible confluence of the elements, lest the species of things should in time utterly fail, Na-

[Continues onto printed p. 334.]

has appointed another body, surpassingly wise, for whatever results from the final concoction of the nutriment — a body into which all the members of an animal converge, as if upon their own center. Each part transmits whatever has been best concocted within it — whether humor or spirit — into the center of the microcosm, that is, into the vessels Nature has set apart for it. This is that prolific seed by which the species of all living things are propagated. Just as it is constituted from the spermatic spirit of all the members, so too it is rendered, of itself and by its own nature, apt to produce something like the very thing from which it falls away. For once it has been cast into the womb as into a fertile field, the saline, sulphureous-mercurial species at once begin to radiate, each performing the office assigned to it by Nature. Thus the mercurial-sulphureous element in the seed, according to the varying law of combination, flows by a wonderful magnetism toward the members sympathetic to it — that is, toward the principal vessels of the body: the heart, liver, lung, brain, and so on, out of which they came — there to form members like themselves. The saline power latent in the seed, which had been derived from the bones into the seed, undertakes a new fabric of bones; and judge likewise of the rest of the members. Thus whatever lies hidden in the seed, proportioned and sympathetic to some particular member, is at once excited by the native heat and strives to form that very member, by its own radiation, in a like and proportioned place and position.

But so that the manner and reason of this admirable plastic power may be perceived more and more clearly — so far as the weakness of our understanding permits — we shall endeavor to confirm it by experiments. For scarcely anyone has set out its genuine account among the philosophers: most expound these differing accounts of the seminal power through universal and metaphysical concepts, and I have found no one who treats of its proximate causes — except that most learned physician, most distinguished in the experience of things, [Marcus Marci] Marcus Marci, who in his excellent work *On Operative Ideas* [*de operatricibus ideis*] touched the matter, as the saying goes, with a needle's point, and to whom we gladly subscribe. [Margin: In what the radiative power of the seed consists.]

But that the manner and reason may be understood more clearly: it must be known that the nature of Salt — as we have sufficiently shown in the *New Book* [*Liber Novus*] — is endowed with a certain radiative power, by which it forms nitrous, aluminous, and vitriolate bodies, and likewise gems, into various shapes: three-sided, four-sided, five-sided, and so on. This could not happen unless there

were in it a power by which, radiating from some one point of itself into different parts, the saline particles might at last form that polygonal figure in crystalline bodies. This radiation, or ἐκτινοβολισμός [Greek: ektinobolismos, "radiation outward"], by which the saline corpuscles — of themselves, by their own nature, and by an innate appetite, as they flow together toward one another — form a certain definite figure, we say is nothing other than the filaments of the saline corpuscles, in positions differing under a certain proportion implanted in them by Nature, and the thrusting-forth of them within the moist matter under certain limits — which, once the moisture is consumed [recte: dum... — "while it accomplishes the last concoction of the nutriment"; the sentence breaks across the column]...

which accomplishes the last concoction of the nutriment; then, the moisture being consumed, no otherwise than the stony spirits [*spiritus lapidifici*], they coalesce into a polygonal body. And because we have already given a demonstration of this in the cited passage of the *New Book*, we did not wish to repeat it here. For even though such a plastic faculty cannot constitute an organic body in fossils, it nonetheless does what it can: if not a plant or a living animal, it at least imprints something analogous to them, suited to the grade of nature — as was said at length in the cited *Book on the figures occurring in various stones*. In vegetables, however, and in things endowed with sense, this plastic power appears far more wonderful. For what else are the so very diverse figures of plants as to their branches, leaves, and the arrangement of their leaves, flowers, and fruits, but the marvelous effects of this plastic faculty? Surely what Nature attempts in minerals and gems with a crude brush, she does not cease to attempt far more excellently in leaves and flowers: according to the condition of the species, by her radiative power she now distributes them into three leaves, as in the herb trinity [*herba trinitatis*]; now into five, as in cinquefoils [*pentaphylla*]; now into six, seven, eight, nine, ten, and finally into innumerable efflorescences with an innumerable variety of colors — all of which are effects of the plastic power. And this, if God grants life, will be demonstrated in the *Book on the Hidden Characters of Nature* [*Liber de occultis Naturae Characterismis*], where the works of Nature shine forth. But who could sufficiently marvel at what the plastic faculty effects in forming so many and so different parts of the body? Yet, lest we leave so hidden a subject unexpounded, I shall in a few words not so much explain the manner and reason as merely point to it.

It is certain that the plastic faculty, or formative power, does not take its origin from some external agent, but from the begetter of the seed. For that likeness which holds between the one generating and the one generated can be

established on no other ground than the seed of the animal cast into a suitable womb. For if it were produced by some external agent, there would be no reason why, for example, human seed once discharged should degenerate into a dog or a cat rather than into a man. I say, then — to come at last to the point — that this plastic power is diffused equally through the whole mass of the seed; that is, it is in a certain way whole in the whole and whole in each part. The reason for this is that from one seed sometimes single offspring, sometimes several, arise; and a whole offspring is perfected no less from some one part than from the whole; and finally, that no confusion of parts, no disturbance, occurs — except very rarely, as in monsters — which nevertheless would have to happen if [the parts] were related to their subject in a non-uniform way. [Margin: The plastic power diffused through the whole mass of the seed.] Hence I would not have you think that the subject of the plastic power is altogether simple, but rather, as it were, composed of many parts: for that portion of the power which, so to speak, formed the brain, will by no means produce the liver or heart; and that which gave shape to the bones, will by no means [shape the mem-]...

branes, or extend the coils of the intestines; but each tiny portion of the subject contains the whole of what is to be formed — just as is wont to happen in the displaying of the species in a dark place upon a bright object. Let this, then, be the first experiment. [Margin: The plastic power operates in the manner in which species, introduced into a dark place from without, express the object encountered there.]

EXPERIMENT I.

By which the radiative force of the plastic faculty is demonstrated.

Let the figure of a man, with all and each of his members, be painted on some object exposed to the rays of the Sun. This done, in a dark chamber — following the experiment of this book on Chromatic Photism [*Photismus Chromaticus*] — let the species of the image of the man just painted be admitted, through a very small and pointlike aperture, onto a sheet placed in the darkened room; and you will learn by experience that the species of the image is represented within, together with the color of each member. But if you bring the sheet up to the aperture, the whole diffusion of the species will be confounded, and nothing will appear but a bright circle. The farther you move the board from the aperture, the more the species of the image will unfold, until they have reached their natural perfection. Here it is certain that the rays radiate from the individual points of the members of the image through the medium, and are united, unconfused, in the pointlike aperture, where, even though to the senses the radiation of the light

appears simple — yet, once unfolded a little — you will find it stamped not with a simple species but with a certain infinite variety of colors, distinct in its individual parts and divided without any confusion, εὐτάκτως [Greek: eutaktōs, "in good order"]. You will see, with admiration, the individual members radiate together each into its own, and together with the species the colors of the individual members likewise differ; if [you wish to see] that thing in the nature of things which explains that incomprehensible plastic power, this surely explains it.

I say, then, that by precisely the same reasoning the plastic power, or the artificer of form, is contained in the sperm, just as the species of colors are in the air. For the seed, falling away from all and each of the parts by the aphrodisiac motion and by a spermatic ἐκτινοβολισμός [Greek: ektinobolismos, "radiation outward"] into the womb of the woman — as into a place natural for the prolific radiation — there, the matter being indeed simple and homogeneous, involved as regards sense, yet, the natural heat of the vessels promoting it, begins by its radiation to unfold. And through ideas and spermatic reasons of this kind, the parts begin to differ, the members to be distinguished and set apart from one another. Therefore, just as in the single point of the aperture all the visible species are contained virtually, yet once unfolded they distinguish the figure, position, and colors of the individual members, so exactly does the plastic power behave in the sperm.

For some rays, because longer, reach the outermost surface; others end suddenly from their first emergence; others are bounded by a spherical surface, others by a plane, others otherwise — from which all variety redounds into the foetus, as appears in the figure.

Diagram. A camera-obscura schematic illustrating the formative ("plastic") power by analogy to the projection of an image through a pinhole. On the left stands an upright nude human figure (a man), his arm raised toward the center; rays drawn from his outline converge toward a central point. In the center is a circular aperture rendered as a set of concentric circles (the pinhole), at whose middle the point A is marked. On the right, beyond the aperture, the same human figure appears again but inverted (head downward), with rays diverging from A to trace its inverted outline — the projected, unfolded image.

- A (center, within the concentric circles): the pointlike aperture (*foramen punctuale*) through which the species pass, where all visible species are contained virtually and unconfused.

- **B** (left, beside the upright figure): the object — the painted figure of the man, source of the radiating species ("the members of the man B").
- **C** (lower right, beside the inverted figure): the projected image — the species collected and unfolded onto the sheet (the foetus / "the place of the womb A," with members projected from B, C).

[The accompanying text reads: "Where you see the species, collected from all the members of the man B, C, projected to the individual points of the seed at A, the place of the womb, and rolled together from the point A — in which they are indeterminate and exist only potentially and virtually — thence gradually excited by the heat of the womb, first into the principal members, then into the remaining members, distinguished by unequal time and motion."]

Now the order of nature seems to require that the nobler parts, on which the rest as it were depend, should be unfolded first by radiation. And so we see the heart, before the emergence of the others, even then beating manifestly with bloody fibers as the vital instrument of the spirit; then the brain; after this the liver; then the lung and the stomach gradually display their lineaments. Of this matter, take the following experiment. [Margin: An experiment of the plastic faculty from the hatching of an egg.]

EXPERIMENT II.

Setting forth the marvelous force of the plastic Virtue.

Take an egg pierced on the third day from the start of incubation, and opened with the care that is fitting; inspect the yolk diligently with a microscope, and there will appear in it the manifest shape of a heart, congealed like a drop of blood, alive and stirring itself in a certain wonderful manner with bloody fibers — from it, as rays from a torch on every side, and as streams drawn off from a spring, [the fibers issue]. And although the vital motion of the heart and the arteries appears at once after the third day, nevertheless none of the remaining mem-[bers]...

of the members are yet to be found taking shape, until, after four more days, the spinal column appears, drawn down from the brain like a kind of rudiment and a nebulous substance. Then successively the remaining members, according to the perfection of each — in which the individual organs are sculpted suited to their functions, and the colors proper to each are painted on the individual parts, and each is endowed with the savor and odor proper to its own nature — until they grow out into the perfect mass of the fabric. And if anyone were to observe, on

each successive day, one of the eggs broken from the first incubation, he could without doubt easily come to know, in the manner described, the order and the processes of the members in the generation of any creature — as in man, since the reasoning of the members in an animal is the same as in man.

It is therefore plain from these things that the unfolding of the species into the individual members is by no means *ὁμοῦ-γε* [Greek: *homou-ge*, "all-at-once"], that is, simultaneous, but happens — according to the unfolding of the more perfect and less perfect parts — now sooner, now later. All of which is also plain from the displaying of the colored species: unless you display these at a precise distance from the aperture, you will detect nothing else, on either side [too near or too far], but a crude figuring of the species. And just as the species radiate from the center into a circle, each individually with its own rays, unconfused, so too the species of the plastic power [radiate] from the center into the circumference — no otherwise than the mind of the Maker of the world unfolds from the center of the earth all the species of the world-machine into the most disparate members, into the elements and the celestial globes. [Margin: The World was created after the manner of the plastic faculty.] First indeed He globed the Sun, as it were, into a kind of heart of the megacosm; the Firmament into a brain; Saturn into the spleen of the World; Mars into the liver, Mercury into the lung; Jupiter into the spirits and the blood; Venus into the seed of the heaven; and the Moon, finally, into the hypochondria — fashioning all things into a great man by a good covenant. [Margin: Analogy of the members of the human body to the celestial members.] And so, that in the small man too [these things come about] by the unfolding of the species, together with their color, savor, and the rest of their properties, ought to be doubtful to no one.

From this point a single difficulty arises. If the plastic power were to unfold the species of the members latent in the sperm, it would follow with infallible proportion that all men would be alike in the delineation of their bodies and in their other affections. But this is so far from being the case that not even among many thousands of thousands of men are two found alike in all respects. In man, who does not marvel at the variety of faces? Who would not be astonished at the differences of gait and of taste in individuals, amid so great a diversity of natural inclinations? [Margin: The dissimilarity that holds among men.] I say, therefore, that this so great variety of things is not to be ascribed to the plastic power alone, but to the imaginations and effects, and to the perpetual motion of the versatile human wit in the parents, vigorous while they come together. These, as it were touching by their radiation the disposed matter, imprint upon it that variety we have spoken of. And since this wandering motion of the mind ceases in [the

other] animals, it is no wonder that for the most part individuals so alike are found that they can scarcely be distinguished, and are marked off only by spots of color. [Margin: Why there is not as great a dissimilarity among animals as among men.] The manner in which parents imprint on their children the species of things vehemently agitated in the mind, we have set out at length in the *Magnetic Art* [*Ars Magnetica*], in the chapter on the Magnetism of the Imagination, to which we refer the reader.

CHAPTER VI.

On the spontaneous origin of living things, or the hidden seminary of those things that are said to be born from putrid matter.

At no time has the wonderful subtlety of any philosophers' minds whatsoever been so tormented by this subject, full of admiration, that there is scarcely anyone who agrees with another in deciding the cause of such great wonders. Hence, for many years now, I have applied myself wholly to this question with the greatest zeal, that I might come to know whence at last that marvelous seminal power in plants and animals born spontaneously derives its origin. And since I saw, not without reason, that I was rolling the stone of Sisyphus [*Sisyphus saxum*] — that is, laboring uselessly and fruitlessly in this hidden work of nature — if I clung to the scrutiny of remote causes and to metaphysical concepts, I therefore set these aside and turned all my study to exploring the proximate and immediate causes of these effects, partly by observations, partly by [practical] experiments [*experientiis enchareticis*]. What I have found, I have thought worth communicating to the reader.

I suppose, then, first — as I have also intimated in what precedes — that universal seed which is saline-sulphureous-mercurial, and which, according to the grade of its nature, obtains its power either ἄψυχον [Greek: apsychon, "soulless / inanimate"], that is, inanimate, if it be individuated in inanimate things; or vegetable, if in vegetables; or animate, finally, if it be joined to the animal grade — according to the ratio of the seed proper to each species, in keeping with the intention of the Divine Architect implanted at the beginning of things. [Margin: For the ratio of the universal seed individuated in inanimate things.] But between this universal seed and the particular seed implanted in each thing there is so great a consent of nature, that the one cannot be revived into new offspring without the other. Yet as soon as this has been sown in the earth, then at once, by a certain magnetism implanted in nature, those [particular seeds] flow together to it; and in this way they accomplish the effect intended by nature.

I suppose, secondly: since the substantial forms both of plants and of animals (excepting always the rational soul) are drawn out only from the potency of matter, surely those forms are material and divisible — this is necessary; whence it is also necessarily deduced that in all and each of the parts of plants as well as of animals [there is something of that form latent]... [Margin: The substantial forms both of vegetables and of animals are drawn from the potency of matter.]

[there is something] of that form latent in [all] the parts, together with a portion of the seed; and that it remains not only in the bodies of the living, but even in the cadavers of the dead. Which we say is nothing other than the form, clothed with the universal seed now individuated in it. For in the saline-sulphureous-mercurial center of this seed there lies hidden that Spirit which gives life and sense even to those things or matters with which it is mixed, as we shall show more fully hereafter.

I suppose, thirdly: that earth, water, and air are full of seeds of things of this kind, which — as they are certain very minute corpuscles — are likewise easily raised into the air, whether by the Sun together with the vapors and exhalations both from the land and from the sea, rivers, and lakes; and thence, carried by the force of rains, snows, winds, and air into the various regions of lands, mountains, and fields, wherever they find a proportioned matrix — there at once, by the seed's plastic power, not at all sluggish, they begin to weave the web of life for those things with which they are joined, by their own ἀκτινοβολισμός [Greek: aktinobolismos, "radiation"], to be formed in the disposition due to each member. [Margin: All things are full of seeds.]

And so we deny that the proximate spontaneous cause of living things is the heat of putrefying things; we reject the concoction of putrefaction, putrid substance, or putrid corpulence; we do not admit as the sole and immediate cause God's concurrence in producing them, or the concurrence of the Divine archetype, or [that of] the idle nature of God; nor the work of the intelligences; nor the influences of the stars; nor the celestial light; nor the heat of the surrounding [air]. Rather, all these we embrace only as remote causes; but the panspermy [*panspermia*], or that seed cut off from the cadavers of dead plants and animals, and the seeds of all things, we declare to be the proximate cause of these effects — the said causes, as we have said, concurring only remotely. [Margin: The proximate cause of spontaneous living things.] In this opinion we gather that even [Aristotle] Aristotle himself was, from his definition of the origin of spontaneous living things, when he says: *the first participation of the nutritive soul with the warm*. By this he understands nothing else, when he treats of

spontaneously growing things, than that in things that have ceased from life as well — whether vegetables or animals — a certain power lies latent, depending on the last concoction of the nourishment, which it first participated from the vegetable or sentient soul while it was yet among the living; and that from this [power] still latent in cadavers, the generation of spontaneous things is caused. For that a spontaneously living thing can by no means be generated, we have shown above, except from matter which has already in some way previously been living or animate, whether one place it in the series of plants or of animals. [Margin: Something of the soul remains even in dead things.] For since in the second supposition we have already shown to some degree that something of the soul remains in all and each of the living, even after death, together with the seminal power — surely, whether the part of the living thing be wood, leaf, fruit, excrement, cadaver, or anything else — it is always [there] in the disposed matter, in fermented putrefaction; and [from it] either something of the same nature as the prior species, or of another, is produced, even with Hippocrates himself attesting it in his book *On the Use of Members* [*de usu membrorum*], in these words: *From the dead, he says, come nutriments, increases, and seeds.* [Margin: Hippocrates.] By this he beautifully insinuates that the nutriment which we take from vegetable or animal nature contains three things in itself, namely the nutritive, the augmentative, and the generative faculty — which last the final concoction of the nutriment supplies. Such a threefold faculty, therefore, results only from the parts or fruits of the dead, that is, of living things now deprived of life. For nothing can be dead which did not previously in some way live; and although by this seed Hippocrates understood the true and proper seed of things, yet in a secondary sense he is seen to have understood thereby the proximate matter also of the spontaneous generation of living things — as is plain from this, that he says a manifest seed lies hidden within the matter of a thing to be born spontaneously. Therefore the proximate matter of the generation of things born spontaneously is that seed of ours, in which the spirit lies hidden, as a kind of soul cut off from the living thing (as [Fortunius Licetus] Fortunius Licetus knows and teaches) and remaining in the cadaver — not as a form, but as the spirituous corpuscles of that living thing, in which the soul subsists as in a vessel left after the death of the living thing. [Margin: Fortunius Licetus, book *On Spontaneous Origin* [*de Spontaneo neo-vivente ortu*].] [Margin: The soul remains in the seed, not as a form, but as in a vessel.] And of this we have as witness even [Aristotle] Aristotle himself, *On the Generation of Animals*, book 3 [l. 3. *de Gen. Animal.*]. [Margin: The soul not conceived as a form.] ...chapter 11 [*cap. 11*], where he speaks of the spontaneous origin of living things: *Animals and plants are generated*, he says, *from the earth and from moisture, since moisture is in the*

earth, spirit in the moisture, and animal heat in the whole — so that in a certain manner all things are full of soul. Here he plainly understood our seed: by the moisture in the earth, the saline power; by the spirit in the moisture, the mercurial; by the heat, finally, the sulphureous — which, united together in the same seed of Nature (which is salt), contains within its center that spirituous part, as a kind of soul cut off from the cadaver in which it remains. This [soul], implanted at last in matter proportioned to it, the external heat disposing the matter, brings forth either a vegetable or some animal. [Margin: Aristotle, *On the Generation of Animals*, book 3, in the vessel.]

And so living things are truly generated from a cadaver by spontaneous generation; but the same things do not rise again and revive in the same number — neither the soul nor the animated substance — for a twofold cause. [Margin: From a cadaver living things are truly generated.] The first of these is that in the spontaneously generated thing the instruments are not the same in number as those that were present in the cadaver from which it was generated, but others newly produced — lest anyone suppose that a generation of this kind from a cadaver is a giving of a return from privation to habit, since the spontaneously generated thing differs at least in number from the former living thing, as [the offspring] is an origin from a changed cadaver. The other cause is that it most often happens that, in the death of the former living thing, the heat gradually failing, the material nature of the soul is weakened into a worse, more imper-[fect condition]...

[Continues onto the next folio.]

into a worse and more imperfect condition, so that it degenerates utterly in its essence and species — as will become clear afterward from the little animals that arise from the bodies or excrements of living things.

Caput VI.

On the various classes of spontaneously generated things.

You may judge that this spontaneous generation of plants from the earth comes from nothing other than the many corpuscles — whether of plants, or of animals, or of both — driven against the earth by water, by wind, or by the creatures' own cadaver. Joined together into one viscous, sticky body and worked over by the surrounding heat, these acquire a temperament and a degree of heat that make them apt, so that the soul long hidden in them, as in a vessel, may at last bring itself forth into a vital form that constitutes the new plant. [Margin: That the

corpuscles of various plants are sought out from all sources — *Corpuscula variarum stirpium ex omnibus rebus petuntur*.] These corpuscles are everywhere: flitting about in the dusty air, stirred by the force of the spirit; partly steeped in the waters; partly scattered across the surface of the earth on every side. From there they are carried into the bosom and inner parts of the soil through the hidden chinks of open passages, riding the vehicle of the rains. Out of that place, once roots have at last been put forth, they rise up into plants.

These corpuscles, although they do take the place of seeds and correspond proportionally to seed — as we learned earlier from Aristotle — are nevertheless not truly and properly seeds, but rather a kind of wrapper for the seminal principles [*seminalium rationum involucra*]. This too is what Anaxagoras held, by Theophrastus's report, when he maintained that the air contains within itself the seeds of all things. Corpuscles of this kind are of various sorts: each one, derived from things that once lived, retains an enfeebled particle of soul — as both vessel and place retains it — together with a modest heat, with juices and vapors, and with dusts and fragments. In these the seminal force must reside, weakened (though not so far weakened as in those from which we have seen tubers and fungi spring up spontaneously) — I mean those plants which in dignity surpass fungi and tubers.

[Margin: Why fields are made fertile by ashes — *Agri cur foecundentur a cineribus*.] Ashes assuredly make fields fertile for no other reason than that they are the remains, or contain the remains, of bodies once animate. On this principle — as Theophrastus and Pliny report — an olive tree that had been entirely burned up came back to life. Nor do rains and dews make the earth more fertile than rivers do (the Nile alone excepted) for any other reason than that in the rains and dew there are mingled many fragments of cadavers carried along with the exhalation and vapor — as Plutarch too shrewdly noted. The Nile, however, because of the very long and very broad sweep of its course, and because it swells most of all from the rains of Ethiopia, carries far more little portions of cadavers than any other river or any rainwater or dew. This is why it is the most fertile of all waters; and once its impurities have been deposited as sediment, because of its extreme thinness and lightness it is the best and most healthful for drinking.

To this same point belong also the things said by Pliny somewhere about the spontaneous origin of laserwort [*Laserpitium*]. [Margin: The spontaneous origin of laserwort — *Laserpitii ortus prodigiosus*.] "We find," he says, "very clearly stated among the authors of Greece that it sprang up when the ground was suddenly drenched by a pitch-black rain near the gardens of the Hesperides and

the Greater Syrtis, seven years before the town of Cyrene — which was founded in the hundred forty-third year of our City — and that this force coalesced over four thousand stadia of Africa" (Pliny). We have the same from Theophrastus as well: for the rain was thick and black like pitch, because it carried within itself many fragments of dead plants and animals, which, driven into the soil, were able to promote a spontaneous origin of plants over that whole tract.

[Margin: Three kinds of plants from the putrid — 3. *Genera plantarum ex putri nascentium*.] And so it has come about that we may divide this spontaneous origin of plants rising from the earth into three kinds. Let the first have its proximate matter — that of the thing spontaneously born in the earth — already present beforehand, and from no other source than the excrements of plants and animals, or the parts that have flowed off from the bodies of those very living things and become immediately mixed with the soil. Let the second kind have the same matter set into the earth by the floodings of waters, whether rainwater or river water. Let the third and last kind of spontaneously born things have its matter — containing within itself the proximate effective cause of its origin — communicated to the earth by the air, whether by the force of the winds or in any other way.

Theophrastus too once enumerated these modes in the spontaneous generation of an untouched forest. But it is enough for us that plants are born spontaneously from the earth out of the parts of cadavers — whether of plants, or of animals, or of both — parts imperceptible even on account of their smallness, which first come together into a single mass that contains within itself a vegetal soul as if in seminal matter. This same soul, once the mass has been worked over by the surrounding heat and disposed toward life, gives itself over into the form that brings life and constitutes the new plant. Now that the general division has been laid out, let us proceed to the particular partition of these same things.

Under a fourfold class we comprehend the supreme species, as it were, of spontaneously generated things: two of these pertain to plants, the other two to animals. [Margin: From the putrid are born some pertaining to plants, others to animals — *E putri nascentium species duplex, ad vegetabilia, ad animalia pertinens*.] There are certain ones established in the first grade of vegetating nature, which we may not inaptly call *geophyta*, that is, "earth-plants" [*Planto-terrestria*]: such are all the species of tubers and fungi. The second class embraces all the genera and species of plants that are born spontaneously. Likewise two classes are contained among the animals that are born spontaneously: the former of these are a kind of middle thing between plants and animals, lacking

progressive motion — such as all those things the philosophers call ζώοφυτα [Greek: zōophyta, "zoophytes" — plant-animals]. The latter

are all those animals that possess the faculty of motion, and they contain all the genera and species of land insects, of flying creatures, and of aquatic creatures. And just as imperfect earth-plants [*geophyta*] stand to perfect plants, so zoophytes stand to animals — which you may see exhibited in the synoptic table at Sect. 2, c. 1, in what follows.

[Margin: Things born spontaneously always require a presupposed seed — *Spontanascencia semper praesuppositum semen requirunt.*] First, then, I would not have you suppose that spontaneous life arises so spontaneously — without any efficacy of seminal force, but by chance and accident, as many think — by no means. For I do not consider that any spontaneously born thing takes its rise except such as can be assigned no origin other than from elsewhere: either from the cadavers of stocks and plants, or from spermatic corpuscles cut loose in whatever way at last from things that have ceased to live. For since the substances of plants, the powders of roots, trunks, and seeds, and the excrements and juices of stocks and animals are nowhere lacking in the earth — chiefly on its surface — it ought to seem no wonder to anyone if, when many such scrapings and excrements have been collected into some one place, first joined by moisture as by a glue into a soft and workable substance, and then concocted by the heat of the surrounding air, they turn out to be a disposed matter. Its soul — that spirit, whether vegetative or sensitive, existing within the seed of nature as in a vessel — becomes its life-giving form; and by the agency of the surrounding heat and its own, it forms and fashions for itself an underlying body into the shape either of a plant or of an animal. But let us now set forth the origin of each kind.

§. I.

The genesis of earth-tubers and fungi.

Among the spontaneous offspring of vegetable nature, tubers and fungi hold the first imperfect grade of vegetable nature. Since they lack root, branches, leaves, and fruits, they are accordingly established among the plants we call γεώφυτα [Greek: geōphyta, "earth-plants"], or earth-plants, as constituting, so to speak, the grade of fungi in vital nature. [Margin: The various species of tubers and fungi — *Tuberum fungorumque variae species.*] Now there are various species of tubers: for some grow up into bosses, some into caps, certain ones into knobs; some swell up after the manner of pine cones; some are spread out in the fashion of a liver; nor are there lacking those that stretch out into a confused branching like fingers;

and finally some pass over even into the shape of the human male member, or into the shape of a foot or a navel — the reasons for which we shall assign in what follows. No less a variety of colors is observed in them: some are dusky, others blackish, certain ones saffron-colored or of a green color. These arise from the various color of the earthy substance to which the seminal matter is joined; and indeed it is the proximate matter that effects the difference in things, which is not granted to the remote matter. They are all born either from rotten trees and wood, or from earthy slime, or even from rocks.

[Margin: Fungi born from rocks — *Fungi ex saxis nascentes*.] And first, that fungi feed from rocks, daily experience teaches us. Here at Rome, in our own household garden, we have a rock that produces very large and excellent fungi — and we took care to have it brought from a mountain near Tivoli, which they commonly call *monte di Poli*, or *Guadagnuolo*. For on that mountain — as I saw with my own eyes — fungi of such great size grow out even from the driest rocks that they at least equal, if they do not exceed, large gourds. These earthly fruits are held in such great esteem that His Excellency Ioannes Nicolaus Appius de Comitibus [Giovanni Nicola Conti], Duke of Poli, and for the time the most worthy Governor and lawful possessor of these mountains, is accustomed to appoint certain men to that office. As soon as they have seen the traces of the fruit bursting forth on some rock, with particular care they at once fence the rock about with thorns, lest the work of the fungus that has begun be destroyed by the trampling of the herds of goats and sheep and the cattle that pasture on those mountains. Then, once these fungi have attained their full maturity, he offers them both to the Supreme Pontiff and to the other leading men of the Roman Curia as a wondrous, rare, and harmless stimulant to the palate.

Ferrante Imperato, in his *Natural History*, under the name of "fungus-tuber" [*tuber fungarium*], calls the fungi just recounted, and says they have been seen to exceed a hundred pounds in weight. [Margin: Neapolitan fungi — *Fungi Neapolitani*.] They are born — on the testimony of Cardano — when certain broad stones, after the manner of tables, are buried; these they find in the Samnite countryside at a depth of four fingers below the earth, and then, water having been sprinkled on, within four days they abound in the groves and have a swift origin. Mattioli concurs with this: "So great a favor has fungi come to enjoy along with the tables in Italy today that, especially at Naples, there are stones which, dug up and transferred into wine-cellars, covered a little with earth, and then sprinkled with warm water, produce within four days fungi not unpleasing." Porta says that when the old fungi and rocks have been harvested, new ones always spring up beneath; that they reach perfection in seven days; that they are

harvested six times a year, the earth covering the stones again to a depth of nine inches [*dodrante*].

At Naples, from Vesuvius; at Sorrento, from Mount Fageto, the highest mountain of its district; at Avellino, on Mount Parthenius; in Apulia, from Gargano. They report that at Naples, in the gardens of the wealthy, these stones, covered with dung, everywhere produce a numerous offspring of fungi; and that certain stones placed under the drip of a wine-cask produce — even in a single night — fungi not only pleasing to the taste but also harmless.

With these matters set forth, it is now asked: how are these fungi born from earth, wood, and rocks? [Margin: How the fungi are born from rocks — *Fungi qui è saxis oriuntur*.] I reply: from the various outflow of seminal force, whether of stocks or of animals that have died — which outflow is nothing other than spermatic corpuscles. These, insinuated within the inner recesses of the rocks, watered by the moisture of dew, mist, and rains, and roused by the surrounding heat — since, on account of the weakened strength of the seminal force and its variously altered condition, they cannot produce plants or animals — generate, lest they seem like idle things to have produced nothing, a substance of the lowest grade among the vegetables, which are commonly called tubers and fungi. The cause that these same things are born from stones sprinkled with wine is that

a great quantity of seminal force exists in the grape-clusters, which, as it is still present in the wine, so too the wine can produce the said offspring of fungi through the animating power of the vegetating force latent in the seed. And so, among the plants, tubers — the rudiments of stocks — and all the rest of the fungi, of whatever sort they may be, are born: either from the effluvium of seminal corpuscles of plants or animals, both living and dead, conveyed into earthy matrices; or from the juices, excrements, and putrefaction of the parts of herbs and animals, both living and dead; or from the outflow of corpuscles endowed with seminal force, received into pores and hollows as into certain matrices, and cooked by the surrounding heat. At last — since they cannot generate anything more perfect — they produce, according to the condition of the matrix, a fungus or tuber that is good or virulent, harmful or harmless. [Margin: Fungi born in venomous places are venomous — *Fungi in locis venenosis nati venenosi sunt*.] This is clear even from this: that where herbs or animals are venomous, all the fungi springing up spontaneously in that same place are found to possess a deadly force.

[Margin: How the fungi born in venomous places are venomous — *Quantò... fungi in veneno nati*.] For the more the seminal force in the matter cut loose from

cadavers degenerates — through various alterations and mixtures of the most diverse things — the more imperfect an offspring it will always beget, whether in the vegetable or in the sensitive kingdom. So that, with the genuine seed from the stock or animal from which it was cut loose gradually failing, just as this seed cannot maintain the grade of sensitive nature, so too it degenerates into a zoophyte or some plant; and that other seed [degenerates] either into a plant or into a fungus; or, if the vegetative force fails entirely, into some inanimate body — as is plain in fungi and plants turned into stone. But let these things said about the origin of tubers and fungi suffice. It now remains for us to investigate from what source the spontaneous origin of vegetables, plants, and herbs draws its beginnings.

Caput VII.

By which combinations of substrates the plants and animals that are born by spontaneous generation are exhibited.

[Margin: Places apt for producing animals from the putrid — *Loca apta ad animalia ex putri producenda.*] The substrates from which both plants and imperfect animals are born are: first, the earth itself, the fertile producer of all things; second, dung-heaps; third, the porous substance of rocks and cliffs; fourth, the waters and the air — sea waters, lakes, marshes, rivers, the standing ditches of stagnant waters are the substrates from which many things are born spontaneously; fifth, the trees that produce things like themselves; sixth, the trees that generate things unlike themselves; seventh, living animals, which now and then produce both plants and animals; eighth, the cadavers of various living creatures, from which sometimes foreign forms — both plants and animals — arise; ninth, minerals and metals, from which, as the histories relate, plants have grown out; tenth, snowy substance. We shall try to assign the origins of all of these.

[Margin: How they are born from the earth — *Qui ex terra nascantur.*] It is asked, then, first: how are plants and animals born from the earth itself? I reply: in the primordial production of things, all the little plantlets of the more tender substance were brought forth from the universal seed of Nature — that is, by the force and efficacy of the vegetable salt diffused through the innermost depths of the whole earth — distributed into innumerable species according to the intention and good pleasure of the most wise Creator. These then, from the seed-store implanted in them, every year pour forth new seed-beds of herbaceous offspring, in this manner: the herbs which, from the beginning of spring — that

is, from the vernal equinox — sprouted forth into a vast propagation up to the autumnal equinox, those same herbs, when the rains come on and they have rotted, entrust to mother earth a new seed — implanted in their roots, in the leaves of their sprouts, in their seeds, and in the other parts of the herbs — for the renewal of the spring season. [Margin: An example from hay — *Exemplum à foeno.*] When that season returns, behold, the seminal matter, now as if fermented by rains and snows and roused by the heat of the Sun, soon luxuriates into that abundance of sprouts and herbs which we feel with great delight of mind in the spring season; and this by a kind of perennial revolution [*pericyclosi*] that will never perish so long as the world stands. (I speak, however, chiefly of the European climate — lest anyone suppose that this spontaneous genesis of herbs is observed everywhere at the same point of time.)

From the seeds, therefore, implanted in the parts of each herb — first rotted and entrusted to the earth — they revive, at the arrival of the new heat as a guest, as if from some pyre. This is so true that even the driest and most sapless hay, as soon as it has been steeped, rotted, and fermented by frequent rains, grows up in its season — by the force of both external and internal heat — into a rich crop of various herbs, for no other reason than by the virtue and efficacy of the vegetable seed, in which the soul lies hidden and which is present in each part of the herb according to the second supposition.

It is asked, second: how are insects born from the same earth? I reply: there always lie hidden in the earthy substance not only the spirits of vegetables, cut loose from the cadavers, as it were, of rotted plants, herbs, and stocks (as was said just a little before), but also animal, spermatic spirits cut loose from the cadavers of various living creatures. These, set into a proportionate matrix, at once muster

to the work of perfecting their generations. Hence, since from an animated seed — now weakened and degenerate — it cannot generate a perfect animal like the one from which it was cut loose, it at least does what it can: if not a perfect one, then it produces at least an imperfect or "infected" something, all the nobler the less the animated seed cut out from some cadaver has been weakened, and the less it has degenerated from its pristine form — as is plain in insects and mice. [Margin: How they are born from seed — *Qui ex semine nascantur.*] For when a particular seed, cut loose from animals that have died, has been entrusted to the earth, and there at once joined and mixed with the universal saline-sulphureo-mercurial seed, it is animated to a certain degree and is solicited into vital fruits. For unless the seed falling into the earth has died — as our Savior CHRIST testifies — it cannot bear fruit. And so the union of the universal seed of Nature with the

seed brought in from elsewhere, in a fitting and proportionate matrix, produces spontaneous offspring of this kind.

[Margin: How they are born from slime — *Qui ex limo nascantur*.] It is asked, third: how do both herbs and imperfect animals arise from dung? That plants are born spontaneously from dung needs no proof: for since — as the Philosopher [Aristotle] testifies — the matter of generation and of nutrition is one and the same (inasmuch as living things are nourished from the same things of which they all consist, and they consist of that matter from which they were most recently begotten — for the end of generation is both the being and the constitution of the begotten thing), and since plants are everywhere nourished and increased by dung, who would deny that plants are born from it? I reply, then, that plants arise from dung in this way. It is everywhere agreed that in dung there are very many excrements of both plants and animals — juices and parts confounded into one. It therefore comes about that dung-heaps, steeped by rains, winds, and the floodings of waters, and fermented by heat, at last bring forth a great many herbs and animals according to the grade of the animated seed.

But to demonstrate the matter more closely: chiefly a threefold kind of matter can be considered in this dung-born genesis. For it is either a juice coming from plants; or a portion of a plant already putrefied, or its excrement; or — if you attend to the genesis of animals — it is either a juice, or a portion of a cadaver, or an excrement; or it is from the bodies of both, which has flowed off from cadaverous substance. In this matter, spirituous corpuscles, roused by a slight heat while they flow together toward things like themselves, at last fermented, attain the degree and temperament of heat necessary for life. By this the matter at last, according to the degree of heat latent in the seed, rises up either into a plant or into an animal, with partial causes concurring, as it were — both the heaven and the air moistening from above, and the conceived heat working it over. The vital spirit, or soul, dwelling in matter of this kind, as soon as it has perceived the matter placed beneath it duly prepared, at once gives itself over to it as the actuating form. From this, by spontaneous origin, it constitutes new stocks, and by its plastic seminal force implanted in the mass it strives forthwith to fashion it into an organic body.

It is asked, fourth: how are plants and animals born spontaneously from rocks and the cement-like substance of rocks? [Margin: Whence they are born from rocks — *Qui è saxis sponte nascantur*.] That plants spring up from rocks, and grow up from the crannies of walls, daily experience teaches us. That coral is born

from cliffs, we have shown fully above in Book 9, in the chapter "On the genesis of coral." Yet I would not have anyone suppose, when we say that plants grow out from stones, that plants and animals come from the very substance of the stone — for who does not see how far this is from the truth? We therefore say that where stony substance is filled with pores, fissures, and hollows, there too within these — by the force either of rains or of winds — the seeds of various things are carried in. Softened by the moisture of the rains, and then fermented, both by the surrounding heat and by the native force of the vegetal seed or by the heat of the sensitive [seed], and at last according to the grade of nature implanted in the seeds, this produces now these, now those herbs and insects. It also happens occasionally that birds, nesting among the cliffs and the old walls of buildings, bring together there various species of fruits or seeds, which, mixed with the moist soil, at last bring forth those same species of things.

[Margin: The author's observation — *Authoris observatio*.] I myself have observed this matter almost daily in the rubble of ancient structures — as here at Rome, both in the Amphitheater of Titus Vespasian, which they call the Colosseum, and in the aqueducts of the Baths, and in the monuments of the temples — which are so overgrown with dense thickets of wild fig, mastic, fig, ivy, cornel, elder, cypress, and the burgeoning growth of the other plants and herbs, that they could seem to be a forest. Indeed, some of these shrubs grow into so great a mass that with their roots they split apart even the thickest walls, as if with some wedge; and so much so that — as will be seen in our Latium — I judge the aqueducts and the structures of the old temples were destroyed in time not so much by the irruption of the Barbarians as by stocks and shrubs of this kind. For while the roots of the wild figs, mastics, and ivies thicken over time, the framework of the walls too must necessarily gape apart, the continuity dissolving. Hence the so many and so great cadavers of the proudest structures, met with everywhere throughout all Latium, declare well enough that our reasonings are true. But of these things I shall treat expressly in my *Description of Ancient Latium*.

But to return to our purpose: the spirituous corpuscles of animated seed — cut loose either by the wind or by birds, or even from plants and animals that have ceased to live, and raised up into the air together with vapors, and there mingled with the dissolved rains or snows in which they are present — once they have fallen down into the hollow places of rocks, at last bring forth in that same place the variety of spontaneously generated things which we have described. Hence no one ought to wonder if he has read among the historians that — as Pliny relates — a palm tree sprang up at Tralles on the stone base of a statue of Caesar the Dictator; [Margin: A palm born on the base of Caesar's statue — *Palma nata in*

basi statuæ Caesaris.] and that the head of a statue of Lysander of Lacedaemon [Sparta], by Cicero's account, [sprang up] from rough and wild herbs; it is no wonder that on the roof of the Capitol there was once seen a palm,

[Printed page 342 — Liber XII, Sectio I]

[Margin: Palms and figs on the Capitol.] ...and afterward a fig tree too grew there, as Pliny [Pliny the Elder] reports; for such a fig has remained alive on the summits of the Capitol and the palace down to this very day. The same may be observed of figs that grow on statues placed in Roman pleasure-gardens. This happens whenever the fruits of palms and figs are carried there by the wind or by birds and, rotting among the hollows of the stones and bricks, sprout from the seed lodged within. On statues, the seed-bearing particles shed from the surrounding trees fall into the pores of the marble statues and produce plants of this kind.

For the hollows of stones, just as they are filled by the frequent overflow of rains, mists, and dews, so too — together with the scrapings worn away from the rocks — they mostly turn into mud (if moisture is present) or into an earthy clod, once the moist warmth has dissolved them. Within this clod the various particles of seminal portions are received and, as though digested in a genuine womb, cannot fail to be transmuted into a plant or animal, according to the manner in which the seed has been carried there. As for plants that grow from virgin earth in a place where there can be no seeds of things — something experience has not infrequently taught me — I say this comes about from the universal seed implanted in the earth from the beginning of things. By this seed, under a particular combination, now one herb, now another is brought forth, proper to the climate under which such plants usually arise.

[Margin: Herbs born from bronze statues.] If indeed, as the histories relate, herbs have sometimes been born from bronze statues, this is not to be taken to mean that a seed — whether vegetative or sentient — resides in metallic bodies. Rather, it means that within the cracks and hollows of the statue various seeds of things have been carried, either by the wind or by birds, or that they were born there from the droppings of birds.

The Fifth Question. How are herbs and animals born from waters by spontaneous generation? [Margin: How things are born spontaneously from water.] We are not speaking here of herbs that grow spontaneously *in* the water, of which there is no counting, but of those that float on the surface of the waters without roots and propagate themselves in a remarkable way. Of this sort

Theophrastus says the *Mnasias* herb is, and also the herb they call *phyllon* [φύλλον (phyllon, "leaf")], which floats on standing waters without a root. In just this way [Margin: Moss on the surface of standing waters.] we see moss and duckweed [Greek: ἀκρίδας (akridas?) — printed ἀρεῖς, reading uncertain (?)] floating on the surface of pools of stagnant water.

[Margin: Sargasso, an herb on the surface of the Atlantic Ocean.] All who sail the Atlantic Ocean are struck with wonder by that weed which the Portuguese call *sargasso* [sargassum]. With it the Ocean is strewn in certain places — never fixed or determined — so densely that they might be called green meadows. This rootless weed floats on the surface of the sea, drifting here and there as the winds drive it. Of it Léry [Jean de Léry] writes in his account of his voyage: "Moreover," he says, "for fifteen days we passed among weeds floating on the sea, whose density and quantity were so great that, had we not cut through them with axes — our ship being unequal to breaking through — and so made our way, I judge it would have come to pass that we should have run aground. And because that great mass of weeds made the sea somewhat turbid, we believed ourselves to be in muddy marshes, and accordingly judged that certain islands were nearby. Yet when the sounding-lead was cast, to which a line 500 fathoms long had been tied, we neither touched bottom nor caught sight of any islands or mainland."

Christopher Columbus [Christopher Columbus] likewise, when in the year 1492 he set in motion his expedition to discover new regions across the Ocean and had gone a little beyond the Canary Islands, found the sea so weed-choked that it looked like a meadow — the weed approaching in color the pale yellow of hay already dried out, with leaves not unlike those of garden rue, and berries blackening after the fashion of juniper grains.

[Margin: The origin of sargasso weed.] The question therefore arises: from what does this herbaceous progeny derive its origin? I say: if berries of this kind serve in place of seed — as I truly think they do — then the generation of this weed must by no means be reckoned spontaneous; rather, like other herbs, it is propagated by the power of the seed they produce. I have heard from our Fathers that, in place of roots, it sends out from itself certain very long filaments which nonetheless do not touch the bottom; and since they are not anchored, the weeds may not improperly be called floating ones.

[Margin: Cock's-comb weed, poisonous.] This too is worth considering: that some red material grows upon it, shaped like the comb of a rooster, whose touch is so dangerous that hands rashly drawn to it become inflamed and swell to a remarkable degree; and so people abstain from it as from a deadly poison. But if

we are to believe that the origin of these weeds is spontaneous, like the herbs cited above, then we can assign four reasons for this generation. [Margin: A fourfold account of the generation of this weed.] The first is that on the surface of standing water a great mass of dust and scrapings settles, derived from decayed plants or animals; and where this has acquired, through the surrounding warmth, the dispositions necessary for life, the seminal force latent within it at once begins to take shape into some plant.

The second reason may be that this matter — coming from plants whose life has ended, or from animals — arises from living things previously dwelling in the waters, or from their excrements and various fatty effluvia. On account of its rich and oily nature it is borne everywhere to the surface of the water like oil; and there, digested by coction through the surrounding warmth, once it has procured for itself the disposition necessary for life, it at last fixes the soul to itself [animam sibi necat —] into the substantial form that vivifies the new plant.

The third reason may be that from the underlying matter a perpetual exhalation always carries up to the surface of the water some portion of the rich excrement from the carcasses of animals, or of plants that, rotting, cling to the bottom of the water — such as seaweed [alga] and sea-moss [muscus marinus] — from which at last, through faulty dispositions, plants of this kind arise. The fourth reason is a compound of the three already given. That a plant can arise from exhalations of this kind, Aristotle [Aristotle] himself teaches in these words: "Exhalations," he says, "once they have congealed, can grasp the cause by which it comes about that a plant arises." This indeed cannot be said of simple exhalations;

[Printed page 343 — De Panspermia Rerum]

but [it can be said] of those which have some admixture cut off from elsewhere and bearing something of an animate seed. In ditches of standing water — water which, being unmoved, likewise [draws something] from the dusts or rains borne in by the force of the winds, full of animate seed — it draws over itself a kind of muddy skin, which, fermented by warmth, at last produces a plant of the sort we see arising on the surface of standing waters.

[Margin: Those born from stocks of a different species.] **The Sixth Question.** How do spontaneously generated plants arise from stocks of an unlike species and of a heterogeneous nature? We are not dealing here with those that are born on trees and plants of a *similar* species — such as the buds that can blossom on each and every part of a tree, being born from the same seminal power inherent in the whole tree; nor with the fruits proper to each particular tree, as in the case of the

carob, which produces its pods not only on the branches but pushes them out even through the very hardest bark. We do not speak, then, of things of this kind, since none of them is born by spontaneous origin, but is connatural to the plant.

We speak therefore of offspring of a heterogeneous nature that are born of their own accord, from time to time, on trees and herbs — such as mistletoe [viscum], horsetail [hippuris], lichen [licnon — recte lichen [?]], and the moss common to nearly all trees. To herbs, meanwhile, there sometimes cling certain other filaments of a nature heterogeneous to the plant itself, as is evident in dodder [Epithymum], in *epistoebe*, *epithymbron*, *epipolion*, and *epichamaedryon* — herbs so named because such dissimilar-natured things cling onto Thyme, Stoebe, Thymbra, Polion, Chamaedrys, and similar herbs, with their root founded in the very stem of those herbs.

[Margin: Mistletoe — how it is born on trees.] Mistletoe grows on nearly all trees: it occurs on the oak, the apple, the pear, the hardwood-oak, the holm-oak, the terebinth, the pine, the fir. The question therefore arises: how does mistletoe emerge of its own accord, and on trees alone? To untangle this, I say that it can come about in four ways, of which two concern a spontaneous origin and the remaining two a non-spontaneous origin.

For it can happen that the vegetable seed of an old plant, once rotted and degenerating from its former power, produces a more imperfect plant within the bark and within the bark's clefts, filled with a mud-making mold. Secondly, it can happen that the seed of another plant — whether snatched up by a bird or driven by the force of the winds into the cracks of the bark and into the hollows of the branches where they meet — generates a plant of a disparate condition. [Margin: A cherry from an oak.] In this way a cherry tree was seen to come forth from an aged oak — doubtless from cherry-stones brought there by birds. But of these matters there is fuller treatment in the *Art of Grafting* [*Ars Emphyteutica*].

The third manner of herbs and animals being born of their own accord is when dusts filled with a mixture of various seeds slip into the cracks of trees; for these, moistened by the heat [recte: rores, "dews"? — printed "tore"; reading uncertain [?]] and the rains, settle into mud, in which the force of the seed, once fermented, is at last disposed toward producing a plant or animal — according to the grade of nature inherent in the seeds. In this way there is no doubt that moss is generated; and so, without doubt — Pliny being witness — [Margin: A laurel from the stern of a ship.] a laurel grew up from the stern of a ship, when the laurel-berries, lodged within the ship's clefts and cracks filled with mucilaginous matter, blossomed into a laurel once rot and fermentation had run their course. The

same, we say, must be asserted of the parsley [apium] which Pliny relates grew up from the sides of the flagship of Antigonus.

The fourth manner is when the various excrements of an old plant, scattered abroad from the carcasses of stocks and animals into the wrinkled bark of a tree, produce a plant or animal of a nature different from that from which it flowed. [Margin: The origin of mistletoe from the droppings of the thrush.] The origin of mistletoe, indeed, is so well known that it is tiresome to write anything about it. Who does not know that it is born from the dropping of the thrush — so that it has passed into a proverb, "*the thrush sows the evil for itself*" [turdis sibi ipsi malum cacat]? For the thrush produces the very thing by which it is afterward caught. Hidden in this bird's dropping is the seed either of the mistletoe itself, or one compounded from the nourishment of various herbs which the thrush uses; and since for the most part it differs from the older forms, it accordingly produces a degenerate mistletoe plant — and hence mistletoe is found on nearly all trees.

I do not doubt that the droppings of many other birds produce on trees similar herbs — polypody [polypodium], hart's-tongue fern [phyllitis], and other monstrous plants of spontaneous generation, or even insects. But those things which are born spontaneously on other trees and plants are mostly very different herbs. [Margin: Ivy is not to be reckoned among things spontaneously born.] Theophrastus observes that ivy is born on trees, which I would nonetheless by no means think should be placed among the spontaneous origins of living things; since, weighed down by a great swelling of seeds, it can easily grow into ivy from berries carried into the cracks of trees, whether by the snatching of birds or by the wind. [Margin: Laurel on the plane tree; walnut, oak, and cherry on the willow.] Pliny relates that a laurel was once born on a plane tree; Scaliger [Julius Caesar Scaliger] being witness, a walnut, a cherry, and an oak [were born] on a willow. Pausanias, in his *Arcadica*, records that a fig established its birth on a laurel, and an olive [was] the offspring of a holm-oak.

[Margin: How spontaneously born from animals.] **The Seventh Question.** How do plants sometimes arise by spontaneous generation from animals? Many marvels of this kind are read everywhere among the historians. [Margin: Ivy between the horns of a stag.] Theophrastus recounts that ivy was seen growing between the horns of a stag, to which Aristotle subscribes in these words: "A stag has now been caught bearing green ivy grown upon its own horns — which, perhaps inserted into the horn while it was still tender, grew together as upon green wood." The origin of this was none other than that the stag, from rubbing

against trees or even against ivy, received the dislodged berries into the shaggy covering of its head; and these, taken up afterward by sweat, dew, or the nightly damp together with admixed dusts, found as it were a muddy soil, in which the grain, fermented by the surrounding warmth, at last blossomed into ivy. Yet I would not readily place even this among things spontaneously born, since it could have blossomed forth from the true and real seed of the berries, just as if cast into earthen soil. But if we suppose the stag from feeding [on] ivy—

[Printed page 344 — Liber XII, Sectio I]

—on ivy, by the power of the seed lying hidden in that nourishment, [the ivy] arose with the stag's internal warmth as craftsman — then it might rightly be reckoned among things spontaneously born. But the former explanation is the more likely.

[Margin: A barley-stalk found in the bladder.] Plutarch [Plutarch] relates that a certain man, when he had suffered from difficulty of urination, at last expelled a knotted barley-stalk. It may be asked: how could this come about? I say it happened because, since this man for the most part fed on raw barley-grains, it chanced that some portion of the seminal particles flowed, together with the nourishment, into the bladder; there, in the course of time, within the viscous matter of the bladder, the seminal force, stirred up by warmth, grew into an ear of grain from which the seed had flowed. Yet I judge that prodigious births of this kind happen not so much from any seminal power as from some magical enchantment. Who does not know that there have been certain persons who are reported to have cast up by vomiting not only herbaceous matters but even iron nails, tufts of hair, and similar excrements contrary to nature?

[Margin: Ears of grain born from the nose.] Of this same stamp is what Lycosthenes [Conrad Lycosthenes] reports in his book *On Prodigies*: that ears of spelt [farris] grew from the nose of a woman of Arezzo, and that she vomited up the same grains of spelt, in the year after the City was surveyed, 94 years before Christ — at which time Ptolemy, King of Egypt, died at Cyrene and left the Senate and People of Rome his heir. As for such a prodigious birth — if it was not produced by the aid of a demon, then surely no other account of it is available to us than the one we have given concerning the barley-ear born within the bladder. Let me add here something most worthy of wonder.

Leo Allatius [Leo Allatius], in his *Bundle of Letters* sent to learned men by those who had perceived [these things by experience] [Greek: αὐτοψία (autopsiā, "by eyewitness/first-hand observation")], reports an event truly memorable for every

age, concerning a certain Spaniard who, having fallen in autumn from a tree into a thornbush, felt ill for a long time, and said he felt the pain chiefly between his ribs. [Margin: A plant born from a certain man's ribs.] And just as, to one examining him, no trace of swelling or bruise appeared, so too he did not greatly attend to the malady. It happened, however, that in springtime the malady, growing worse, displayed a certain tumor, and within a few weeks grew so much that, along with the swelling, it also put forth some branching thing, and at last the rudiment of a complete plant — with such increase that in summertime it became necessary every year to trim the luxuriant shoot with shears. Often the attempt was made, now by scarifications, now by incisions, to root out the plant's root, but in vain; for the roots had spread not only through the ribs but even through the hip itself all the way into the thigh, until at last, the root being entangled in the muscles and tendons, it brought death upon the man.

The cause of this matter may be asked. I say it came about from the thorn, which, fixed deeper into the flesh and covered over by the skin, from the inflow of a corrupt humor — in which, as in a proportioned womb, the seminal force of the thorn was roused — in the course of time, its roots driven deep, pushed out beneath the skin this truly prodigious shoot. For, as we taught in the preceding [chapters], the seminal force lies hidden not in the seed alone but in the whole substance of the plant; and this, having obtained a suitable humor fermented by native warmth, at last brought forth within the mold of the corrupted flesh this portentous birth.

COROLLARY [COROLLARIUM]

From these things it is evident how on the backs of whales [Margin: Whales.] there sometimes grows so great an abundance not only of moss but also of seaweed and of the other plants of the sea, and of every kind of shellfish, that they can appear to be small islands floating on the sea. This comes about, namely, from the filthy refuse of the carcasses tossing in the sea, which clings to the wrinkled backs of the whales (whose mucous hollows of cracks are filled with it); and also from the excrement expelled from the recesses of the beast's own body, which — cooked both by internal and by surrounding warmth — transmutes the force of the latent seed, however weakened, now into this, now into that plant or shellfish.

[Margin: Dolphins overgrown with coral plants.] It is also written in the history of the Arabs that dolphins, of which there is a vast abundance in the Red Sea [Erythraean Sea], are sometimes found overgrown with coralline plants. The cause of this matter I have given in the Tenth Book, in the chapter on the

generation of coral [De Corallogenesi], where I have also recounted the matter of a human skull preserved in the treasury [Gazophylacium] of the Grand Duke of Tuscany, on which a coralline plant is seen to have grown — see the account there. [Margin: Asparagus.] Concerning ram's horns growing into asparagus, see below, from Pliny and Cardano [Girolamo Cardano]. That plants can arise from the carcasses of animals — and indeed that asparagus is born from ram's horns — experience teaches and reason proves, as was said of certain cases in the preceding [chapters]. But of these matters [there is] more in what follows.

CAPUT IX.

How both Zoophytes and Insects of every kind are born from the bodies of more perfect animals. [Quomodo tum Zoophyta, tum Insecta omnis generis ex perfectorum animantium corporibus enascantur.]

[Margin: The origin of Zoophytes.] Animals that are born by spontaneous generation are of three kinds. First, Zoophytes; second, insects of every kind; third, those which exhibit a complete four-footed form among animals, and, among winged creatures, those that display the form of a feathered being — of which there is a great variety. We shall treat of each in turn.

Zoophytes, or plant-animals [plantanimalia], are those which—

[Printed page 345 — De Panspermia Rerum]

—fixed to rocks by the interposition of what are, as it were, certain roots, hold indeed an immovable position after the manner of plants, yet perceive objects by sense: for they spread themselves out, as it were, toward the things necessary for their life, and are accustomed at once to contract themselves away from things hostile and harmful to them. Of these there are many kinds, such as sea-nettles [urticae marinae], sponges, acorn-barnacles [glandulae], and those which they call sea-*phalli* and sea-*vulvae* from the resemblance — to which some also add the mole [mola] born in the womb of a woman; indeed all things that adhere enclosed in shells, as are the various kinds of shellfish, of which there is no number. All these, since they possess life and sense, are accordingly counted among animals, even though, like plants, they always obtain an immovable state. That life is in them, their growth sufficiently shows; that sense too is in them is shown by the fact that they contract at once when touched.

All these things have no other origin than from the seminal portions of carcasses, in which the sea abounds, driven by the agitation of the waves into the cracks and clefts of rocks; and these portions, according to the diversity of the seminal

particles, having first been fermented by warmth in the mucous hollows of the cracks, at last bring forth either this or that zoophyte. [Margin: The origin of crustaceans, testaceans, and molluscs.] But concerning the origin of shellfish, since I have dealt with it at length in the Fourth, Fifth, and Seventh Books, I refer the reader there.

Those are called *insects* which obtain a status next after the zoophytes, and are of three kinds: *crustaceans*, *testaceans*, and *molluscs*. Crustaceans are beetles of every kind, with wings set into a crusty covering. Testaceans are those covered by a shell — as, among four-footed creatures, tortoises, and among many-footed creatures, the various species of crabs — which arise partly by spontaneous, partly by non-spontaneous generation, but have propagation from their own seed. Thirdly there are the Molluscs, which, among flying creatures, lack a crust — such as all kinds of flies, gnats [cinyphes], wasps, hornets, butterflies; among marine creatures, all the bloodless ones; among land creatures, all the kinds of serpents and worms; and among four-footed creatures, the kinds of mice, frogs, and lizards.

Now the spontaneous origin of all these is manifold, according to the variety of the matter. For some are born from earth, snow, and mud; others from snow itself; of others the begetter is earth, of others air, of some the stocks and trees — and even fungi are their mother; some are generated from the sap of plants; some from the excrements of useful and useless things; others from the carcasses of plants; some are likewise drawn out from animals, both of the same and of a different species; from the excrements of useful and useless animals, and from carcasses whether of the same or even of another species; and finally some are produced even in the very hardest rocks. The reasons for all these we shall try to assign in the following questions.

[Margin: The origin of zoophytes, of crustaceans, testaceans, and molluscs.] **The First Question.** How are zoophytes of this kind — such as limpets [lepades], scallops [pectines], sea-cucumbers [holothuria], and the like — first produced from the waters by spontaneous generation? [Margin: Those produced spontaneously from the waters.] I answer: this comes about from the juices of animals — whether living or devoid of life — driven from the body, in which (as is plain from the suppositions) there are many seminal particles containing, with a slight warmth, a part of the prior soul, though much degenerated and impaired. When these have, through the concocting warmth of the surrounding medium, put on the dispositions necessary for life, they at last, according to the manner of

the seed and the combination of the matter, rise up into this or that insect through the specific form that constitutes animals.

For no one can justly deny that many animals live in the waters, that the carcasses of the dead are dissolved, and that from both a juicy and excrementitious matter, mixed with the waters, arises. [Margin: *Aristotle, Hist. nat.* 5.] For as Aristotle rightly says in Book 5 of the *History of Animals*: "Common to all worms, and to those things that come from worms, is that the principle of generation is furnished either by a spirit or by a seminal account." In this way the kind of worm they call *Tapulae* or *apyae* [ἀπύας?] is born in wells and in ditches filled with putrid water; and their generation is this: From seminal particles carried into the waters from elsewhere and mixed with mud, there first arises a scum, which, rotting, first gleams with a white color, then is foul with black, and finally reddens to a bloody hue. These, little by little having through warmth obtained the due disposition, float on the surface of the water like seaweed and put on a rind; and when this is burst, a gnat [*culex*] emerges — so very troublesome to men and beasts.

[Margin: The origin of frogs, mice, oysters.] **The Second Question.** How are frogs, mice, oyster-shells [*ostreoderma*], and other things born from earth or mud by spontaneous generation? That most animals are produced from earth, mud, or slime no one is unaware: the boundless multitude of earthworms and other worms sufficiently shows it. Of frogs there is no need to speak, since I have already mentioned them often enough. That frogs are born from marsh-mud is a marvel, says Pliny: in the half-year they are dissolved into mud, with no one observing, and again in the spring rains are reborn. [Margin: Oppian.] Oysters [*ostrea* are born] from foamy mud, from the seminal force and efficacy of the sea, as Oppian [Oppian] teaches in these verses:

They do not couple, nor do they bring forth offspring by [sexual] bonds;
They are born of themselves, as oysters [are born] from foul slime. The
light oyster has its scum, never distinct [by sex]; Among these fishes
neither male nor female is known.

[Margin: The origin of sea-nettles, purples.] Sea-nettles [*urticae*], murex-snails [*purpurae*], and razor-clams [*ungues*] are spontaneously begotten — and all things that cling fixed to their own houses, the origin of all of which is the same. [Margin: The origin of the *Tapulae*.] Oyster-shells [*ostreoderma*] are born from mud, Pliny being witness; the origin of the whelks [*buccina*] is the same; the origin of the pond-oysters [*limnostrea*] is from muddy places; mussels, razor-clams, and scallops are formed in sandy places with the mucilage of the sea

coming between. [Margin: All things are born from mud.] In a word, all things are generated from mud, according to the manifold difference of the mud: in muddy [mud], oysters; in sandy [mud], mussels; on rock,— —in the little hollows of rocks, sea-cucumbers [holothuria], barnacles [balani], and limpets [lepadæ] and snails [nēritæ]; in mussels [mytili], purple-shells [purpuræ], and whelks [buccina], the same cradles. That mice are born from mud, Egypt teaches: for when the Nile recedes, little mice are found, the work of generation already begun in the water and earth—already alive in part of their body, while their newest extremity is still earthen clay. This prodigious mode of generation Ovid [Ovid] describes most graphically:

[Margin: Ovid.]

They find, among these, some begun in the very span of their birthing, some half-formed; and often, at the same time, they see one truncated at the shoulders—and at that same moment one part lives, while the other part is raw earth.

I shall say nothing here about certain fish—such as eels and mullets—which, it is agreed, are born spontaneously from the seminal principle [seminium] of their own body. For it has been observed, as we have said elsewhere, that if someone drains off all the water and all the mud, or even digs a new ditch, nevertheless, once water flows again into that place, these are in time refilled with both eels and fish—the eels, at any rate, either from scrapings rubbed off the eels' skin against the rocks, or from algae; the fish, however, from a seminal principle drawn through underground channels from neighboring lakes, whether internal or external, when those places are refilled.

[Margin: The origin of fish, of what kind it is.]

The question is asked, thirdly. How are ducks and geese—which are commonly called barnacle geese [Berniclas]—born in Scotland from the rotten fragments of ships? Almost nothing is better known than the barnacle goose's origin from rotting matter in Scotland, and there is scarcely a historian or natural philosopher who does not mention it. We, briefly setting aside the cited authorities as things already noted and plain to everyone, will lay open what we think about their origin. The subject from which such birds are born is manifold. There are those who say they are born from the leaves of trees; some from the rotten fragments of ships; certain people from the mold of a ship's keel. Nor are there lacking those born after being enclosed in shells and at last released, which then, having taken on wings, begin to swim across the water and fly through the

air. Still others think they are drawn out from the viscous liquid of marine rocks. That all these views may be examined, I say: three things concur in the generation of these birds. First, the subject, that is, the matter. Second, the seed. Third, the disposition of the place. As regards the subject, this can be either the fragments of rotten wood, or the bark and leaves of trees, or the slimy crevices of rocks, or finally the marine shells themselves—of which kind we are accustomed to display specimens in our Museum. Secondly, as regards the seed, I say that it falls from none of the said things. For trees cannot produce a perfect animal, since that is beyond their powers—still less can the slime of the sea, whether embedded in rocks or in rotten wood; nor can shells bring forth a perfect animal, being suited only to producing zoophytes [Zoophyta]. The question therefore is asked: what is that seed which produces so prodigious a brood of ducks and geese?

[Margin: The origin of the Scottish geese.] [Margin: The subject-matter of the Scottish ducks and geese.]

—so that from the seed of broken eggs, dispersed and driven to the shores, ducks and geese must necessarily be generated in suitable wombs [matrices]. Secondly, not only in Scotland but along all the coasts both of Scotland and of Ireland, right up to Belgium itself, such broods are found—everyone everywhere admits it. Indeed, Olaus Magnus [Olaus Magnus] asserts that a similar generation is observed on the shores of Norway and Finmark; in fact, wherever the seed, driven from the Ocean, has found proportioned wombs of a differing condition—provided the soil or salt does not stand in its way—there too such births are accomplished. These things, which seem to us the supreme miracles of Nature, have grown cheap to the natives through almost daily familiarity. Here you have my opinion on the generation of the barnacle geese—so genuine that, with every combination tried, no other than the one stated can be assigned. Since indeed it is impossible that a perfect animal, such as a duck or a goose is, should be born from mere putrefaction, with no prior seminal principle of its own species.

The question is asked, fourthly. How are insects of every kind born from the carcasses of plants and animals—whether living or dead—through spontaneous origin? There is in the whole of nature no plant or animal that does not produce out of itself another insect, of a different species nonetheless, by spontaneous origin—since there is none of either kind that does not undergo putrefaction; and in putrefaction, once it is fermented by heat, there lies hidden that seminal principle, in whatever way it was detached from elsewhere. This I would certainly never have believed, had not frequent experiment, through the use of

the microscope, made me more certain of the truth of the matter. I shall begin with plants.

[Margin: The spontaneous origin of insects from the carcasses of plants and animals, whether living or dead.]

Let no one, while I assert these things, suppose that I believe an animal endowed with a nobler rank than the plant itself can be begotten by the plant's own power, or that a plant can be born by spontaneous origin from a perfect animal like itself. By no means. Rather, I say that the plant always has a seminal principle connected to itself, detached from elsewhere—from the bodies of other animals, whether living, or the carcasses of the dead—all of which will afterward be proven by experiments. Certainly the celebrated Botanist and Physiologist in the City [Rome], Francesco Corvino [Francesco Corvino], long ago getting wind of this, after examining with singular zeal the herbs of the most diverse species, found in each a worm. Having enclosed this worm within a glass vial and fed it on the leaves of that same herb, he at last observed that the said worm, taking on wings, degenerated into a winged insect—and these winged insects, according to the variety of the herbs, counterfeited a different species both by the variety of their shape and of their colors: some bearing only wings like those of flies, certain ones like caterpillars, others with wings enclosed in a crusty sheath, some displaying Spanish flies [cantharides], gold-beetles [chrysocanthari], and the like. The shapes and colors of all of these, together with the plants their mothers, he displays in his house, most elegantly and lifelike. In this way, from various herbs there are produced—

[Margin: No plant produces an animal proper to itself.]

—certain caterpillars by the plant's own power, as being of an inferior nature; and these caterpillars, then taking on wings, he observed to be transmuted into butterflies notable for the variety of their colors. All of which I would have presented here expressed in figures, had the shortness of time permitted. You would see here hundreds of species of herbs, together with the broods they produce—wonderfully different—most beautifully depicted. A most worthy work, indeed, that ought in its own time to see the light. Following his example, I too, after examining most species of herbs, found that not only does each plant as a whole produce its own proper insect, but that there are also different insects in the different members of the plant—such as the root, the leaves, the flowers, and the fruits. In the root, indeed, I found something not unlike earthworms; in the bark, the rudiments of ants; in the leaves, a little caterpillar; in the flowers, a certain winged little animal; and in the fruits, either a worm or something

resembling a spider. In this way the pine [pinus] begets the buprestis-beetle [buprestis]; the mastic-tree [lentiscus], slugs [limaces].

[Margin: From a herb caterpillars are produced; the caterpillars degenerate into butterflies.]

Since these things are so, the question is now asked: since a thing cannot produce an animal [more noble than itself], whence do those creatures come? I answer that this can happen in various ways. First, from the moisture by which the herbs are nourished. Just as this moisture is imbued with the spermatic corpuscles of sensitive nature detached from the various carcasses of animals, so too, once it is implanted in the juices of the herbs, it always produces ever baser and baser insects—according to the differing degeneration of the seed from the prior substance from which it is detached, and the weakening of its power. Secondly, from the spermatic excrements of living animals; the moisture of the earth, imbued with these and drawn up by the plant—together with the seminal principle—into its nourishment, at the slightest fermentation (whether by the internal heat of the plant or the external heat of the surrounding air, according to the combination of concurrent natural causes) hatches out now this, now that insect; which is then likewise fostered and nourished by the very plant from which it is brought forth. Thirdly, from the slimy excrements of some other creature—whether a fly, a butterfly, or a caterpillar—which, gaping after the juices of herbs, always release from themselves a little spermatic excrement, from which afterward arises a new offspring of a different species. In this way I observed on the flowers of leopard's-bane [*Doronicum pardalianches*] a venomous little caterpillar [bruchulus] continually clinging, full of deadly poison, whose origin is from nowhere else than from the seminal principle of a serpent or other deadly animal, dissolved into the earthy moisture. Just as the poisonous herb draws this into its nourishment by a kind of natural magnetism, so too it brings forth a brood not unlike the plant as to its quality. In like manner you will find such little animals arising from the flowers of all poisonous herbs—so that henbane [*hyoscyamus*] produces one, monk's-hood [*Napellus*] another, hemlock [*Cicuta*] another, and finally meadow-saffron [*Colchicum*] yet another, and so on. And what is worthy of wonder: as many as [arise] from the flowers—

[Margin: The origin of the said insects.] [Margin: From the slimy excrements of insects.]

—of the herbs: as from the thinner juice, so too there always comes forth a volatile insect, equipped either with wings buried in a crust, or with unsheathed [wings].

On the Wonders concerning the Signatures of Orchids, or Satyria.

Very many Botanists, when they have contemplated the wonderful signatures of orchids—and these orchids are the plants that are commonly called *Satyria*—cannot sufficiently marvel at the power of Nature in producing them. For if you consider their roots, you will find them in the form of testicles, from which they get their name [*orchis* being Greek for "testicle"]. They are truly rare and elegant species of plants; and in some of them—which are not inappropriately called *Anthropomorphae* ["man-shaped"]—Nature has so sported that there is scarcely a member in the human body which she has not, as far as she could, expressed.

[Margin: *Orchis Anthropomorpha*.]

[Below, on p. 348, an engraved plate occupies the lower two-thirds of the page; its description follows.]

Diagram. An engraved botanical plate showing three orchid specimens, illustrating the "signatures" (resemblances) discussed in the text. On the left stands a tall orchid in flower, captioned *Ornithomorpha sub avis figura* ("bird-shaped, in the form of a bird"), its paired rounded tubers shown at the base. Between and beside the two large plants are small inset vignettes of the resembled creatures. On the right stands a second tall flowering orchid captioned *Orchis anthropomorpha* ("man-shaped orchid"), with finger-like spreading root-tubers at its base. A small lower-central inset is captioned *alia species Orchidis quae cercopithecum refert* ("another species of orchid that resembles a long-tailed monkey [*cercopithecus*]"). Beneath the whole plate runs a two-line reference caption.

- Left plant, flower-spike — labels **G** (repeated four times along the spike, at upper and middle florets): point-letters keying individual florets.
- **A** (lower left, beside an inset figure): keys a small inset vignette (a bird-like / winged figure) to the left of the left plant's stem.
- **B** (lower right of left plant, beside an inset of a small robed/standing figure): keys that inset vignette.
- **E, F** (at the base of the left plant): the paired rounded root-tubers ("testicles").
- Right plant, flower-spike — labels **C** (repeated, upper and middle florets, both sides): point-letters keying individual florets.
- **E, E** (at the base of the right plant): the spreading finger-like root-tubers.

- Lower-central inset — *alia species Orchidis quae cercopithecum refert*: a small figure showing the monkey-resembling orchid form. [No clear point-letter legible on this inset. [?]]
- Bottom caption (two lines): "*Vide de his Fabium Colonniam, de rariorib[us] plantis — Joh[annem] B[aptistam] Portam in phytognomia*" — "On these matters see Fabio Colonna [Fabio Colonna], *On Rarer Plants*; [and] Giambattista della Porta [Giambattista della Porta], in [his] *Phytognomonica*."

[Resuming the text, which continues at the foot of p. 348 in two columns below the plate:]

I found it, so that when I displayed it, it drew everyone into admiration at the work of playful Nature.

But Nature's keen industry did not stop here. You may see, with the greatest admiration, in some the figure of a bird, in others of a long-tailed monkey [cercopithecus] or of a dolphin; nor are there lacking those that present the likeness of a bee—from which it is also called the bee-orchid [Orchis apiformis]—or even of a wasp, a fly, a butterfly, a gnat, a bug, a locust, and the rest of the animals. I myself, certainly not without expense, had such plants brought from the mountains and planted in our home garden, to this end: that I might observe the wonderful properties of this plant. So, having undertaken a dissection, first in one of its species I detected I know not what rudiment of a woman's womb pregnant with a fetus, wholly similar to the natural one; in the bee-orchid too, when the bee-shape was cut away, I found the likeness of a little maiden carrying a small shield [scutella] with both hands, so skillfully expressed that—

[Margin: The various figures of the orchids.] [Margin: See on these matters Fabio Colonna, *On Rarer Plants*; [and] Giambattista della Porta in [his] *Phytognomonica*.] [Margin: See Fig.]

when I displayed it, it drew everyone into admiration. With the microscope, intending to examine in the same way the filaments of the leaves of the anthropomorphic orchid, I found the flowers, throughout, woven of the tiniest little images of the human figure, marked with a C [or: marked "C" — the printed letter is uncertain [?]], so that I could not sufficiently marvel at Nature's admirable industry in things, whether in shaping them or in painting them—whence I thought to add the figures here for the Reader's delight. But, leaving aside such sports of Nature, one might rightly now ask: whence do all these derive their origin? And just as God and Nature do nothing in vain, so here too I

shall lay open to the Reader a new and perhaps unheard-of mystery of Nature, that the Reader may more closely behold the inexhaustible and hidden riches of Nature.

[Margin: In the flower-sheath I also noted by night the figure [...] with eyes, ears, and a hooked beak [—continued from p. 348].]

It was observed by those who have charge of flocks, herds, and horses that, after the animals had been brought together for breeding—once mating had taken place—the following year that field would teem with orchids, that is, *Satyria*, for no other reason than that the surplus spermatic moisture, scattered upon the ground and fermented together with the earthy juice, at last grows up into such herbs. They say the same thing happens from the seed of corpses, both of men and of animals, who in the fields are either killed or die of some sickness. If this is indeed so, what wonder is it that seed buried in the earth—as if within a womb—should there gradually bring forth a plant of exactly the same faculty as the animals from whose seed it was detached? Whence not undeservedly are they called *Satyria* from the power by which they incite to lust—namely, from the lechery of the fabled Satyrs. For since Nature cannot stand idle, she is always contriving and fashioning something, and she shapes it according to the condition of the adopted seed. Since, therefore, in the seed of animals all the members of the animal are present in potency, as we said above, and these are gradually unfolded by the heat of the womb into the perfect structure of the animal—the plastic power [*vis plastica*] being at work to form each individual member—what wonder is it, I say, that the seed, whether of a man or of an animal, once received within a suitable and proportioned moist womb of the earth, should there too contrive and fashion, if not a perfect animal (which is beyond its powers), at least something analogous to the animal or the man, as to its members not unlike the true ones, together with the faculty proper to the seed of arousing to lust? Add to this that herbs of this kind are nearly the first of all to burst forth in springtime—precisely the season in which most animals too are goaded by the heat of desire. Certainly it is so ordered by Nature that she does not work toward fashioning like things except by the aid of that seed which first existed within perfect animals, from which it was detached and conveyed away. But that, besides the members of the human body, it produces in the said *Satyria* many other shapes of various insects—this is to be ascribed to the diversity of the seeds.

[Margin: The *Satyria* are born from the seed of animals poured over the earth at the time of mating.] [Margin: A *Satyrium* is so called because it excites men to lust.]

For if equine seed, falling into the earth, has grown up into the said herb, since Nature cannot produce the perfect figure of a horse beyond her powers, by the power of the seed she will form at least a figure similar to those insects which are accustomed to be born from a living horse—that is, the figure of wasps; but if bovine sperm has produced the orchid, it will delineate not the figure of an ox but of a bee (whose origin is from oxen), as is seen in the bee-shaped orchid [*Orchis apiformis*], and so for the rest. For the fact that in the flowers of different orchids there are seen now the figure of a flea, now of a bug or a louse, now of a fly—this certainly happens only from the spermatic power of those animals from which such insects are born. Yet if anyone examines everything more keenly, he will always also find in them something conformable to the animal from which [the seed] was detached. That bees are born from the bovine kind is plain from the authority of all writers, both ancient and modern. For, as Varro [Varro], Pliny [Pliny], and Virgil [Virgil] testify, bees are born not only from bovine dung but also from the rotting body of the same; and they say that in Egypt there are certain places where, if a bull is buried so that only its horns project above the earth, and these are then cut off with a saw, in time bees fly out. Whence Ovid:

[Margin: Why the bee-shaped orchid is so called.]

[Margin: *Metamorphoses* 15.]

You too bury the slaughtered, chosen bulls (a thing known by sight): from the rotting flesh everywhere are born flower-gathering bees, which, after the manner of their parents, dwell in the countryside, devote themselves to work, and toil toward [their] hope.

And elsewhere, from the Oracle of Proteus:

Bury the body of a slaughtered young bull in the earth— buried, he will give what is enough for us. The shepherd does it: swarms seethe from the rotting [carcass]; from one ox, a thousand lives, once it is slain, are given.

Virgil, *Georgics* 4:

Throughout the dissolved entrails of the cattle they catch sight of bees buzzing all about, and seething out from the burst flanks.

And—to return to where I digressed from—that always something is produced from the seed which is like a living animal, I first understood when I came upon that wonderful history concerning bees of Bernardino Gómez [Bernardino Gómez]. His words are these:

[Margin: The drones display within the figure of a bovine head.]

I shall relate a thing new, unheard-of, and hitherto seen by no one, nor handed down to memory by any writer, so far as I know: when, for the sake of refreshing my spirit, I was lingering by the beehives at Saguntum, and was greatly marveling, among the singular and wonderful works, at the deference and kindness of the drones, and at the seminary of bees enclosed within them—which alone drew me into great admiration: for when, in the meantime, a drone caught by me was being squeezed with fingers and nail, in case it might by chance discharge something in place of a sting—behold, with its viscera and the little skin of its hinder part burst open, a white or saffron-colored ox-head, skillfully formed with spreading and twisting horns and a hooked muzzle, suddenly emerged. The men who were present, marveling at this, and on that account urging me to try it again, I squeezed five drones one after another, and they—

[Margin: Orchis Anthropomorpha. (See Fig.)]

[printed p. 350] LIBER DUODECIMUS, Sectio I — *De Panspermia Rerum* (continued) they brought forth [perunt] — by nature, of course, in which there rightly resides a supreme principle, producing the seminal nature [seminallem rationem] of these creatures, and a certain friendship of theirs with cattle. This is what **Bernardino Gómez** [Bernardino Gómez] reports, things which I too, having tested them, found perfectly true, and which I would wish all investigators of natural things to verify.

[Margin: *Cur Ægyptii inter cornua bovis apim pinxerint* — Why the Egyptians painted the bee between the horns of an ox.]

This matter did not escape the Egyptians, who, wishing to signify royal lineage, painted a bee between the horns of an ox. But about these things I have written

very fully in the *Oedipus* and the *Obeliscus Pamphilius* [Kircher, *Oedipus Aegyptiacus*; *Obeliscus Pamphilius*]. Just as, then, in the insects themselves a certain rudiment of the image of those animals from which they were born is found, so too it happens in the orchids [Orchides]: since these cannot produce a living animal, they at least contrive as far as they can — that is, from the ideal principle implanted in the seed [ex insita seminis ideali ratione] they try to express the figure of that thing from which they spring.

[Margin: *Bombyx ex moro* — The silkworm from the mulberry.]

In the same way one may also observe this in the lofty mulberry [Morus]: when the seed of another insect is discharged into its sap, a silkworm [bombyx] is born — a worm that is then nourished from the very thing from which it was born, and spins for us the silk so prized in the proud furnishing of garments. I will add this too, which is worthy of wonder: that a plant which smells of some animal has taken its origin from that same animal's excrement or seminal fluid. Thus tutsan [Androsemum], which smells exactly like a he-goat and is for that reason also called "goatish" [hircinum], grows only in the mountains where herds of goats graze.

[Margin: *Androsemum hircinum unde* — Whence tutsan is goatish.]

So too the herb which they call κυνὸς ὄρχις [Greek: kynos orchis, "dog's testicle"], from its resemblance to a dog's genitals.

[Margin: *Vulvaria* — Vulvaria (stinking goosefoot).]

It is likewise probable that vulvaria [Vulvaria], whose smell **Giambattista della Porta** [Giambattista della Porta] in his *Physiognomia* and the other botanists report, arises only either from the wantonness of women, or from some hidden recess [scrinio] of those same parts — that is, from the vulva. So that it need not seem fabulous, what **Pliny** [Pliny the Elder] writes about hippomane [hippomanes].

[Margin: *Hippomanes* — Hippomanes.]

I could cite innumerable instances of this sort here, but whoever desires more, let him read on these matters **della Porta** in his *Physiognomia*, **Lobelius** [Matthias de l'Obel], **Mattioli** [Pietro Andrea Mattioli], and countless others; and we ourselves have treated fully of the signatures of plants in the spirit of the Egyptians, both in the *Ars Magnetica*, Book 3, and in the *Oedipus*, Tome 2, Part 2. That asparagus springs from buried rams' horns is well known. One thing I will

add here, about the deer-fungus [fungus cervinus], to make clear how much the seed of animals, when committed to the earth, can accomplish.

De speciali Cervini Tuberis ortu. — On the special origin of the deer-truffle.

[Margin: *Fungi cervini productio* — The production of the deer-fungus.]

The contemplation we have just held concerning the common origin of the truffle is wonderfully confirmed by the experiment and history of the fungus — or rather, the deer-truffle [tuber cervinum] — which grows among the Bohemians, unknown to the ancients. About it **Mattioli** [Pietro Andrea Mattioli] writes the following, word for word, to **Giulio Moderato** [Giulio Moderato]:

Since I know that you take great delight in novelties, I am sending you with this letter of mine a certain subterranean truffle, which the Bohemians call "deer-truffle" [boletum] — for I think you have never heard of it, since no record of this fungus exists among the ancient writers, nor among the more recent ones,

[Margin: *Histor. fungi cervini producto* — The history of the deer-fungus produced.]

[Margin (continued, printed p. 350 foot): *Ortus tuberis cervini* — The origin of the deer-truffle.]

[printed p. 350 left margin running text picks up:] *...and since it cannot be found except in those woods where deer are most numerous; and the hunters who know these secrets of nature [keep them hidden]; but since these things are unheard of among you, I would not wish you to remain henceforth ignorant of the history and powers of the deer-fungus. The hunters affirm, then, that this fungus is born under the earth in the manner of common truffles, where the soil is infected with deer-seed [cervino semine] — which usually happens when something still containing some seed is discharged from the genital vulva, the female fleeing the male's onset. Perhaps no one could find this deer-fungus, were it not that the deer themselves point out the spot at a certain fixed time of year; for by a certain natural instinct, led by their forefeet, they scrape the place where the round fungus lies hidden under the earth — which they perceive by smell, as they affirm; for the fungus breathes out a heavy odor, especially when freshly dug up. Those hunters and countrymen who frequent the woods and know these secrets carefully observe the spots dug apart by the deer's feet, and once the pit has been dug out they take the fungi and sell them to the apothecaries, who cut them up into little pieces, thread them on a string, then dry them in the shade and keep them for medical use. These have nearly the same*

appearance as that which we observe in other truffles, yet rounder than them all and uneven; the outer little skin is somewhat blackish, but the fleshy and itself fungous substance is whitish. There are also those who say that a certain kind is found in the shape of an erect male member, so that on one part the exposed glans, and on the other certain little globes resembling testicles, may be seen. To me, however, it would be said that this truffle imitates the form of a deer's [member] rather than a man's — since Nature everywhere strives to fashion all things like their begetters. This fungus does not come into use for food, nor do the Bohemians eat it, but they use it in medicines that excite venery [venerem movent], since they think it most effective for this, and especially the kind that bears the likeness of a human genital. For which use they administer the dry powder in sweet wine, to the weight of a drachm or a drachm and a half. They say it also brings an abundance of milk, when drunk in barley-water or woman's milk, but that it acts more powerfully if a little long pepper be added. They report that as a fumigation it opens the closed places of women, and drives off the strangulation of the womb [vulvae strangulatus]. There are superstitious little women who misuse them in love-potions, after first muttering whatever incantations. They affirm that the deer-fungus is effective against poisons drunk, and taken in unmixed wine; indeed, against the bite of all venomous creatures, not only drunk but also applied [as a salve]. That it heats, anyone will easily judge from the strongness of its odor. I could wish that so rare a medicine, hitherto unknown to Italy, might be brought over or transplanted, and that among the other rare simples which live in your so celebrated garden under such diligent cultivation, this fungus too might live there; but since Nature forbids this to us, keep this one dried for yourself. I send you, besides it, a few pieces of genuine chalcitis [Chalcitis] and true misy [Mysis], which, being rare among you, I likewise hope will be precious to you.

From these things I plainly conjecture that the origin of the deer-truffle is from a soul — whether merely vegetative or sentient — wondrously disturbed [labefactata], which, in the seed cast into the earth...

[printed p. 351] DE PANSPERMIA RERUM.

whether of a stag, or of a male, or of a female, it is no longer as a form in matter — for the cooled seed dies and becomes infertile — but as something retained in a vessel by some degree of heat, long preserved in that viscid matter. For that the seed is animate we have proved at length elsewhere: namely, when, from the heat of the surrounding environment, the earthy juice committed to that seed is prepared for life, and this same preparation receives the soul latent in the spermatic matter — as in a vessel — into a substantial form, by which it is

constituted in being. This is generally a shapeless tuber, but sometimes one even reproducing the shape of the rod [virgam, i.e. the stalk or member] from which that seed most recently flowed off: so persistent is Nature in the procreation of the like.

And since the nature of seed is both a stimulant of venery [veneris stimulatix] and an opener of the womb [uteri apertiva], as well as most akin to milk —

[Margin: *Usus cervini tuberis* — The use of the deer-truffle.]

— what wonder if the powder of a tuber sprung from seed should both excite venery, promote abundance of milk, open the closed places of women, and drive off the strangulation of the vulva [vulvae strangulatus]? Hence I think it quite clear that the origin of our truffles is from nothing else than the soul latent in the seminal matter — as in a vessel — in the juice flowed off from plants and animals and committed to the earth. This soul, in the underlying matter, cooked [decocta] by the heat of the environment — whether vernal or autumnal — and disposed for life, becomes a substantial form vivifying the underlying matter and constituting the tuber. Most often, indeed, on account of the feebleness of its powers, the hardness of the matter, and the slightness of the heat, the tuber thus constituted is not exactly organized; but sometimes it even forms in itself some likeness of a living member, both in stalk and in leaves. This **Scaliger** [Julius Caesar Scaliger] testifies he saw, in the form of a man's member, which — also found on the shores of Batavia [the Netherlands] — the Dutch call "phallum cum" [*phallus*] from its resemblance to the male organ. **Mattioli** [Pietro Andrea Mattioli] also mentions this here.

Diagram. A woodcut of a "Xylophyte" — a worm-like animated creature with a long segmented body. The figure shows an elongated central stem (the woody twig) from which pairs of curved legs project to either side along its length, with a pair of antennae and a head at the left end.

- Caption (above figure): *I. Zylophytam ex ramulis Liburni in Musæo Authoris.* — "I. A Xylophyte from the twigs of the *Liburnum* shrub, in the Author's Museum."

Diagram. A woodcut of a slender, multi-legged creature: a thin elongated body bearing several pairs of long, splayed legs, generated from a rotted straw or rush-stalk.

- Caption: *II. Ex putrefacta palea aut junci caule.* — "II. From a rotted straw or the stalk of a rush."

Diagram. A woodcut of a densely many-legged, caterpillar- or centipede-like creature, with a long body bearing a great number of short legs along its whole length, like a millipede; generated from rotted horsetail [Equisetum].

- Caption: *III. Ex putrefacto Equiseto.* — "III. From rotted horsetail [Equisetum]."

Diagram. A woodcut of an "animated *Hippuris* (mare's-tail)": an elongated body bearing several pairs of curved, claw-like legs along its length, with feelers at the head end.

- Caption: *IV. Hippuris animata.* — "IV. Mare's-tail [Hippuris], animated."

[Margin: *Mira ex putrido Liburni ramulis productio* — A wonderful production from the rotted twigs of the *Liburnum*.]

I will add this marvel too: that on the twigs of the *Liburnum* — which they call "white twig" [vitem albam] — I have rather often found a zoophyte [zoophytum] consisting of six feet and a very fine body, with the head of a caterpillar [eruca]...

[printed p. 352] LIBER DUODECIMUS, Sectio I.

advancing with the creeping motion of spiders. And when I scrutinized its origin more diligently, I found at last that it was born from the twigs of the said *Liburnum* shrub, infected by a certain rottenness; for I more than once discovered it still attached to a green branch, whence not without reason I called it a "Xylophyte" [Zylophytum, "wood-plant"]. I also found some that on the hinder part had wood, but on the forward part had already taken on a soul [animam], and were stirred this way and that. I saw also some which, in the middle of the body — where the legs were supporting it — were wholly of the same wood as the *Liburnum* twig, but the feet and head, now animated, were moving. Yet as soon as the whole pith of the twig, together with the six sprouting little branches, was informed by the soul, then the animal, as if cut off from a trunk, walked along the ground in the manner of the rest of the insects [ἑξαπόδων, hexapod, six-footed]. When I showed this stupendous metamorphosis to several of our people, it can scarcely be told how greatly they marveled at so rare and monstrous a birth, especially when they saw the forward part, together with its feet, attempting motion while still attached to the hinder stalk. The same happens in rotted mare's-tail [Hippuris] and the others, such as in straws, as is shown in the figures. But lest we seem to have omitted anything to satisfy the reader's curiosity, I have placed the figure above.

CAPUT X. — De Insectorum spontaneo ortu ex aliis animalibus perfectis diversæ speciei. — On the spontaneous origin of insects from other perfect animals of a different species.

A certain philosopher rightly asserts that Nature is never so busy as in the smallest things. For just as the number of imperfect beings is always greater, so too is the number of those born spontaneously greater than of those born by non-spontaneous origin. For we see that there is no animal which does not (as we said also of plants) generate from itself another imperfect animal of a different species — as is evident both in man, and most of all in all living creatures. And to begin from the more imperfect: all brutes generate fleas, lice, bedbugs, ticks, "rendivi" [rendivos, a kind of vermin (?)], or something like these.

[Margin: *Varicæ Zylophytorum species* — Various species of Xylophytes.]

That frogs, toads, serpents, and worms of every kind are born both in the intestines of men and of brutes has long been known by frequent experiment, as a certain philosopher [Aristotle (?)] asserts — about which we have also made ample mention in Book Nine, *On Poisons* [De Venenis] — and that worms are born not only in the intestines, but in all members of the human body, the histories teach by manifold reports.

[Margin: *Ex ocimi odoratu scorpio natus* — A scorpion born from smelling basil.]

For in the human brain a scorpion was born from the frequent smelling of basil [ocimum], as **Liceti** [Fortunio Liceti] [reports]; **Schenck** [Johann Schenck] [reports] worms found in the heart itself; **Paré** [Ambroise Paré] reports [them] in the lungs, liver, kidneys, and bladder; and we, in our *Treatise on the Plague* [De Peste], showed that putrefied blood is worm-ridden — the same which we observed under the microscope in cheese, milk, vinegar, and meats exposed to the Moon. And so all things are full of animals; nor is there any putrid ulcer, any impetigo or elephantiasis, that does not breed its own worm. This the learned man **August Hauptmann** [August Hauptmann] showed in a little book he published long ago on this subject — which he calls "the animated image of death" — and he says that in venereal scab itself he found worms, like little slugs, of such fecundity that within half an hour one had poured forth some 50 others like itself. Their generation, indeed, proceeded from nothing but the virulent putrefaction of corrupted blood and seed. Again, many men suffer from phthiriasis — that is, the lousy disease [pediculari morbo]...

That men extinguished by lice are well known is established — as the historians narrate of **Herod**, **Sulla** [Sulla], **Pherecydes of Syros** [Pherecydes of Syros] the poet, and of countless others. **Lycosthenes** [Conrad Lycosthenes] writes that in Hungary, in the year 1549, up to three thousand men perished from serpents, frogs, and the like that arose within their vitals; of which thing there was no other cause than that the fruits of the earth, infected by a destructive rottenness, and the water, springs, and fountains, had been filled with broods of serpents, frogs, and the like, owing to the humid and pernicious constitution of the year — by the use of which they at last gave birth to those animal-litters.

I pass over here the many women who, as the authors on monsters report, in place of a human fetus have brought forth from the womb serpents, toads, moles, and the like; of which thing the cause may be the same as that of the preceding birth just set out by us. I pass over here too the innumerable animal-brood which is born spontaneously both from the excrements of animals and from corpses.

[Margin: *Ex bovillo stercore mures* — Mice from cattle-dung.]

For **Scaliger** [Julius Caesar Scaliger], on **Theophrastus**, says he observed mice born from cattle-dung; from horse-dung that dung-beetles [scarabaeos pilularios] are born is everywhere established, as **Schenck** [Johann Schenck] [reports]. All these things have no other origin than, first, from the food of the first concoction [primae concoctionis], which, according to the varied condition of the seminal principles by which the nourishment — whether it came from vegetative or sentient things — is imbued: for this, taken up by men and fermented by the heat of the stomach, once it has found a disposed humor there, brings forth now this, now that animal. For the herbs and greens on which men generally feed are infected with the filth of various insects, flies, worms, and caterpillars, in which the seminal principle is vigorous; and so men take up corrupted nourishment...

[printed p. 353] DE INSECTIS.

they take up, which, fermented in a proportioned vessel by heat, at last, by the power of the seed latent in it, hatches out this or that animal.

[Margin: *In corporibus tum hominum tum animantium quomodo, & in lixivio vermes nascantur* — How worms are born in the bodies of both men and animals, and in lye.]

But these things must be set forth more clearly by some examples drawn from men. People wonder why worms are born in putrefying lye [lixivium]. I say this happens in no other way than because under-tunics [indusia] full of a brood of

lice, bedbugs, or fleas have introduced that brood into the lye, where, being disturbed, they have degenerated by their power not into lice and the like, but into little worms of a different species.

[Margin: *Ex lixivio vermes* — Worms from lye.]

[Margin: *Ex defosso anatis cadavere bufones* — Toads from a buried duck's carcass.]

But how toads are born from a buried duck's body — as has become known by the observation of many — I declare the cause to be that this kind of bird willingly feeds on animals of that sort, and consequently, with the toad-seed [semine bufonio] lodged in its food, it comes about that from the rottenness of the buried bird there is born that animal on which toads willingly feed.

[Margin: *Ex cancro scorpio* — A scorpion from a crab.]

By like reasoning, **Pliny** [Pliny the Elder] reports that a crab, buried in the earth as the Sun enters Cancer, in time breeds scorpions. If this is true, it is for no other cause than that the seminal rottenness of the crab, much altered and disturbed, since it cannot produce a like animal, produces another more imperfect one, not unlike it in the figure of its body — namely a scorpion. Of which **Ovid** [Ovid]:

*Concava littoreo si demas brachia cancro, Cetera supponas terrae, de parte sepulta
Scorpius exhibit, caudaque minabitur unca.*

"If you take away the hollow claws from the shore-crab, and lay the rest beneath the earth, from the buried part a scorpion will come forth, and will menace with its hooked tail."

And these are the things which — more fully, perhaps, than I ought — I have thought should be said about the transmutation both of vegetables and of animals into different species: so that the reader might understand that the whole atmosphere, and likewise the air, water, and earth, are filled with seminal principles, which are heaped together nowhere not — and that so too it cannot but be that that innumerable brood of things, which we so greatly admire, should not arise. So that the ancient natural-mystics [Physio-mystae], penetrating the matter more deeply, were not ashamed to assert, not without warrant, that all things are in all. These principles thus laid down, it now remains to be explained whether, emulating Nature, by the application of actives to passives, we can produce by a certain artifice [ἐγχειρήσει, encheirēsei, "hand-craft, operation"] like animals and like plants.

SECTIO II.

DE ANIMALIUM

Quæ à Græcis ἔντομα [Greek: entoma, "insects" — lit. "the segmented ones"], à Latinis Infecta vocantur, varia tum naturali, tum artificiali productione. — On the various production, both natural and artificial, of those animals which by the Greeks are called ἔντομα (entoma), by the Latins Insecta (insects).

PRÆFATIUNCULA. — A Little Preface.

Although in the preceding Section we treated most copiously of the spontaneous origin of living things, nevertheless, because very many matters were there omitted which seemed in any way to pertain to their generation, here we once again call them back to the anvil, so that the vast multitude and abundance of insects of this sort may become known to the reader, and that he may learn whence each obtains its proximate origin; and so that, these things being known, he may understand how at last Art, imitating Nature, may by applying actives to passives be able to produce like things.

CAPUT I. — De variis Insectorum natalibus, eorumque differentiis. — On the various births of insects, and their differences.

There are diverse kinds and species of insects, almost infinite in number, of such great variety that scarcely a region can be assigned in which they do not differ — whether you regard their colors or their bodily constitution — by reason of climate or soil. And first, some [arise] from earthly refuse, some from water, some from air;

[Margin: *Varietas insectorum* — The variety of insects.]

nor are there lacking those said to take their origin from fire itself. Again, some are winged; some are constituted as it were of certain rings [ex annulis], and are therefore called "ringed" [annularia]; others are furnished with four feet, six, or more. But, to comprehend much in few words, it has seemed good to set down here a synoptic Table, so that from it the reader may behold, as in a single glance, the differences of each.

Reading order: This batch's PDF pages are out of folio order. Reconstructed from printed page numbers and catchwords, the reading order is **printed p. 354 → 355 → 356 → 357**, which corresponds to ** → → → **. Page 353 (end of the prior

material) carried the catchword "TA-", which resolves to "TABULA" opening p. 354.

LIBER DUODECIMUS [Book XII], Sectio II, Caput I (continued)

TABULA SYNOPTICA [Synoptic Table]

Of all those things that are born spontaneously, whether of Vegetables or of Animals:

Diagram. This is a large branching (bracketed) taxonomic schema, not a numeric data grid. It classifies all spontaneously-generated insects by a nested series of braces. The root term at the far left is *Insecta* ("Insects"), characterized by a long descriptive clause, and the classification branches successively to the right. Rendered below as a nested outline that preserves every brace level and every terminal label.

Insects are small animals having incisions or rings (annuli), and hence are called *annulosa* by Albertus [Magnus]. Of these, some are either —

- **I. Terrestrial (*Terrestria*), of which some are —**
- **A. Winged, having wings (*Alata, alas habentia*) —**
- **1. Sheathed-winged / beetle-kind (*Detectas, analitra dicta*) [recte: read as the wing-cover group] — having either —**
- **a. Four (wings) (*Quatuor*) —**
- **Membranous (*Membranaceas*), of which some are —**
- **Comb-making (*Favifica*) —**
- Apis [Bee] — Domestica [Domestic], Sylvestris [Wild]
- Fucus [Drone]
- Fur [Robber-bee?]
- Vespa [Wasp]
- Crabro [Hornet]
- **Non-comb-making (*Non Favifica*) —**
- Cicada [Cicada]
- Orfodacna [Orfodacna]
- Perla [Stonefly / Perla]
- Cimex Sylvestris [Wild bug]

- **Mealy (*Farinaceas*), as is the Papilio [Butterfly] —**
- Vulgaris [Common]
- Lucernarius [Lamp-moth / Lucernarius]
- Aliique [And others]
- **b. Two (wings) (*Binas*) —**
- Muscarum genera [Kinds of flies]
- Tabanus [Horsefly]
- Culex [Gnat]
- Ephemerus [Mayfly]
- **2. Covered-winged (*Opertas*), which are called Coleoptera or sheath-winged (*vaginipennia*), as are —**
- Locusta [Locust]
- Gryllus [Cricket]
- Scarabæus [Scarab beetle]
- Cantharis [Blister-beetle / Cantharis]
- Ips [Ips]
- Buprestis [Buprestis]
- Coccus [Coccus / Cochineal]
- Cicindela [Glow-worm / Cicindela]
- Blatta [Cockroach]
- **B. Wingless, or lacking wings (*Aptera, sive alis carentia*), of which some are said to —**
- **1. Have feet (*Pedes habent*), of which again some are, namely —**
- **a. Six (*Sex, ut*) —**
- Formica [Ant]
- Cimex [Bug]
- Pediculus [Louse]
- Ricinus [Tick]
- Pulex [Flea]
- Lens, Coffus [Nit; Coffus-grub]
- Fobricina [Fobricina]
- **2. Have many feet (*Pancipeda habentque pedes*), or —** [recte: *Pancipeda* = polypod; the schema brackets the multi-footed kinds here]
- **a. Eight (*Octo*) —**
- Talpa [Mole-cricket / Talpa]
- Scorpio [Scorpion]

- Araneus [Spider]
- **b. Twelve (*Duodecim*)** —
- Geometra [Geometer / inchworm]
- **c. Fourteen or more (*Quatuordecim aut plura*)** —
- Eruca [Caterpillar]
- **d. Many-footed (*Multipeda*)** —
- Millepeda, sive Centipeda [Millipede, or Centipede]
- Oniscus, sive Asellus [Woodlouse, or Asellus]
- Scolopendra terrestris [Land scolopendra]
- Iulus [Iulus / pill-millipede]
- **3. Lack feet (*Pedibus carent, ut*)** —
- Vermes nascentes vel in [Worms born either in] —
- Hominibus [Humans]
- Animalibus aliisque [Animals and other things]
- Plantis [Plants]
- Lapidibus [Stones]
- Metallis [Metals]
- Teredo [Wood-worm / Teredo]
- Lumbricus terrestris [Earthworm]
- Tinea [Moth / clothes-moth]
- Orips [Orips]
- Limax [Slug]
- **II. Aquatic, and these also are, either** — (*Aquatica atq; hæc quoque sunt, vel*)
- **A. Footed, namely (*Pedata, nempe*)** —
- **1. Many-footed (*Pancipeda, ut*)** —
- Musca fluviatilis [River-fly]
- Cantharis aquatica [Water-cantharis]
- Viola aquatica [Water-violet (insect)]
- Tipula [Crane-fly / water-strider] —
- Alata [Winged]
- Aptera [Wingless]
- Ligniperda, sive Phryganium [Wood-eater, or caddis-fly (*Phryganium*)]
- **2. Many-footed (*Multipeda, ut*)** —
- Scrophula, sive Tinea [Scrophula, or water-moth]

- *Pulex marinus* [Sea-flea]
- *Oestrus*, sive *Asilus marinus* [Sea-gadfly, or sea-asilus]
- *Scolopendra marina* [Sea-scolopendra]
- *Vermes in tabulis delitescentes* [Worms lurking in planks (shipworms)]
- **B. Footless (*Apoda, ut*)** —
- *Vermis Indicus* [Indian worm]
- *Vermis Martymensis* [Martymene worm]
- *Seta aquatica* [Water bristle-worm]
- *Hirudo* [Leech] — *Paludosa* [Marsh], *Marina* [Sea]
- *Lumbricus marinus* [Sea-worm / lugworm]
- *Intestinum aquaticum* [Water "intestine" (gut-worm)]
- *Vermis macrorinchoteros* [Long-snouted worm (*macrorhynchoteros*)]
- *Hyppocampus* [Sea-horse]
- *Uva marina* [Sea-grape]
- *Stellæ marinæ* [Starfish]

We shall divide the whole realm of insects into seven classes, as if into so many separate commonwealths, so that we may proceed with greater method in unraveling each one.

The first is that of those insects which devote themselves to building honeycombs with a certain remarkable industry and ingenuity, fitted to the pattern of a kingdom; these are the bees, drones, wasps, and hornets.

The second is that of the *Analytra*, or insects which cleave the air with an irregular motion on a fourfold oarage of wings — such as butterflies, silkworms, weevils, caterpillars, chrysalises, *Xylophthori* [wood-borers], *Orsodunae*, and cicadas.

The third is that of the two-winged *Analytra*, such as the ordinary flies; the little wine-flies (*vinulae*), which take their origin from wine and vinegar and are commonly called *Moschini* [gnats]; the *Ephemerus*, so named from its single day's life; the *Cyniphes*; gnats; gadflies; and horseflies.

The fourth is that of the *Coleoptera*, or those whose wings are kept concealed within sheaths, and which are therefore called by the Greeks *κολεόπτερα* [Greek: *koleoptera*, "sheath-winged"], and in Latin *vaginipennia* — such as locusts, *Bruchi* [chafers/wingless locusts], crickets, scarabs, blister-beetles (*Cantharides*), *Buprestae*, *Cincindela* [glow-worms], and cockroaches.

The fifth is that of those which the Greeks call ἄπτερα [Greek: aptera, "wingless"], the Latins *sine alis* ["without wings"], and which live their life moving by the manifold use of feet — such as ants, bedbugs, lice, ticks, fleas, nits, scorpions, spiders, and the other kinds and species of many-footed creatures, such as those they call *Onisci* [woodlice], *Iuli*, and *Scolopendrae* [centipedes].

The sixth is that of those equipped with neither wings nor feet, but which scour the earth with a slow motion on a warty belly, and which are divided into countless kinds and species of worms and creeping things — such as earthworms, *Teredines* [wood-worms], moths (*Tineae*), slugs (*Limaces*), and serpents.

The seventh is that of those which receive their birth in the waters. Among these are water-*Tineae*, scolopendras, and sea-fleas, which are equipped with feet; and among the footless ones (*Apoda*) are leeches, sea-worms, sea-horses, the sea-grape, and starfish. To these we add the creatures called ζωόφυτα [Greek: zōophyta, "zoophytes," plant-animals], which are fixed as if in a perpetual place. Of all these, both collectively and individually, we shall say something in order. The sea-horses, conspicuous for their horse-like head and chest, are reckoned among the ringed aquatic insects, and their figure follows below; concerning their remarkable properties we have reasoned elsewhere.

Having thus seen the varied and many-kinded division of terrestrial, aquatic, and winged insects, nothing now remains except for us to investigate the origins of each. With the nests of their manifold proliferation discovered, we may then, imitating Nature, attempt the same thing by art and by the industry of our own ingenuity in producing them — not that any profit should come to us from producing these sordid little creatures, but so that the marriage of Nature with Art, the truth of causes, and the wonderful power of the operation may shine forth from it.

[Margin: *Hippocampa* — The Sea-horse.]

Diagram. A woodcut of a sea-horse (*Hippocampus*), shown upright with its head turned, the characteristic equine head and curved, segmented body with a coiled tail. The body shows the ringed (annular) segmentation that justifies Kircher's classing it among the "ringed" insects. Caption beneath: *Hippocampa*. § 58. That most insects are born from a putrid substance of Earth and Water has already been said abundantly enough in the preceding pages. But it remains to be explained how the same creatures may take their origin from a vegetable and a sentient (sensitive) nature.

[Margin: How the seminal power, implanted in all things, exerts itself.]

We said in the preceding pages, and assumed as certain, that the Elements, as they are constituted in the lowest grade of Nature, likewise cannot produce a plant or an animal of themselves and by their own power — for that would be to act beyond their own strength.

[Margin: The lower grade is proportioned to bringing forth the higher grade.]

Their whole effort would be wholly disproportionate to generating things of this kind. Something else must therefore be added to the matter disposed within the elements, something having the character of a seed, which may produce so wonderful an effect. We say that this is nothing other than a seed detached from elsewhere — whether from a vegetable or from a sentient nature. For this seminal nature has been implanted in all things from the very first beginnings of things, and, diffused throughout the whole mass of the earth and joined within a proportionate matrix (womb), it produces either a plant or an animal.

Now that seed can be shed by countless things. In vegetables, indeed, it can fall from each and every part of the plants — from roots, bark, branches, leaves, flowers, fruits, and seeds; for we taught above that the seminal power of plants resides in each and every part of the plant. Hence, the nearer a part is to the seed properly so called (which lies hidden in the center of the fruit), the more similar the plant it produces to the one from which the seed was detached; but the farther from it — as in what lies hidden in leaves, branches, bark, and roots — the more dissimilar and more degenerate a plant it begets, on account of the weakness of the seminal power.

Since, therefore, the whole surface of the Earth is covered with countless kinds of trees, plants, and grasses, it follows that, by a kind of perennial cycle (*pericyclosis*) following the Sun's motion through the Zodiac each year, the generation of these same things is necessarily followed by their corruption. And from this corruption, the seed — lurking in whatever part — is softened and rotted by rains and snows, and, fermented within the cells of the earth as if in certain wombs, then, when the Sun enters the equinoctial point, soon thrusts itself out and sprouts into a plant according to the character of the detached seed. From this arises that remarkable variety of certain plants — such as the geraniums, spurge (*titimalli*), stonecrops (*sedi*), orchids (*satyrii*), and countless others — the manifold species of which number, in the single case of the geranium, up to 24.

[Margin: Whence so many species of a single plant.]

This is certainly for no other cause than that the plant has acquired its origin not immediately from the seed properly so called, but from the differing seminal

parts of the plant. These parts, however different they may be, are nevertheless recognized — by reason of a great similarity — as belonging to the stock from which they sprang. Yet I would always have this understood: provided that the said spermatic parts of the plant are planted in the same soil, endowed with equal goodness; for otherwise they can also degenerate, by reason either of a rich and fertile,

or of a lean and barren field — as happens in wheat, which, according to the character of the field in which it is sown, degenerates now into spelt, now into oats. In exactly the same way it happens with the spermatic parts of vegetables, which, scattered over the whole surface of the earth and committed to the generative cells, at last produce that variety of plants which we marvel at — so that almost daily new prodigies of plants, not yet known to any botanist, arise spontaneously from that supreme combination of spermatic parts mixed together in diverse ways.

[Margin: Things born spontaneously do not arise from putrefaction alone.]

Let no one therefore think that plants take their origin spontaneously from earthy or watery substance, or from putrefaction alone. Rather, there must be joined to this earthy or watery putrefaction a vegetable seed — committed, by whatever cause, to the earth, the waters, and their putrid materials. For this seed, joined to the putrefaction, produces a plant according to the condition of its own kind and grade.

[Margin: The seeds by which they are sown into their own wombs.]

Now these seeds are committed, **first**, to the proper place of the plant; **second**, they are carried by the blowing of the winds into diverse regions of fields, valleys, and mountains, or committed to rivers, lakes, and marshes; **third**, by the violence of rains and floods, by which uprooted plants are forced to migrate elsewhere, leaving their native places — and as these are mixed with mud and mire and putrefy, so too from this putrefaction there cannot but be produced a new plant, if not similar to the former, yet still not wholly unlike it. **Fourth**, new seed-beds of plants are founded from time to time not only from seeds (which are sometimes carried off by birds into the inaccessible recesses of walls and crags), but also from the very excrements of birds and humans, in which the spermatic power of plants still flourishes.

Therefore, just as no element can produce plants except by the help of the seed of vegetable things, so too it cannot happen that a plant, of itself and by its own proper power and efficacy, should produce some animal, unless the seminal

substance of a sentient nature has been added to it. But how the seeds of things accrue both to inanimate and to animate matter, I have decided to set forth through seven propositions, as briefly as possible.

Lumbricorum Genesis. [The Generation of Earthworms.]

The question is asked, first: How are earthworms, *Teredines* [wood-worms], and slugs generated within the earth? I answer: Earthworms take their origin not from the putrid soil alone, but additionally from a seed which resides either in the rich excrements of animals or in their leavings (*retrimenta*). These excrements and leavings, when entrusted to the earth, come to life as earthworms within a brief span of time.

[Margin: The variety of earthworms.]

The variety of the excrements and leavings is the cause of the variety of the earthworms.

[Margin: Earthworms are born from their own corpses.]

But earthworms corrupted either by their own humor or by excessive dryness found, out of their own corpses, a new proliferation of countless earthworms — which we demonstrate by the following experiment.

EXPERIMENTUM I. [Experiment I.]

Artificialis Lumbricorum productio. [The Artificial Production of Earthworms.]

Take several dried earthworms, reduced to powder, and bury them in an earthen pot filled with rich and sweet soil; then water it repeatedly with rain-water, and within three or four days you will find that whole soil teeming with a new proliferation of earthworms — at first of the size of the worms that are born from cheese, and then, nourished by that rich juice of the soil, you will find them growing into true earthworms. For since the seed does not perish in the incineration of the earthworms, but remains in its power, it comes about that the powder, buried within the soil endowed with rich and sweet juice, thrusts itself forth by the heat of the Sun, and from the latent seed there is hatched out the same animal that it was at first.

The same thing also succeeds, in another way, by a second method: either we mix rainwater with the chopped-up particles of dried earthworms set in the soil — that same rainwater being the very thing that carries with it the seeds of earthworms detached from elsewhere and commits them to the earth. Hence,

immediately after rains and showers, we find rich and sweet soil always teeming with earthworms,

[Margin: Whence, after rains, the great multitude of earthworms.]

and in so great a number that they even fill the very footpaths.

This too is remarkable: that if you expose an earthworm to the burning Sun, it will at once be on the point of dying; and when you examine it the next day, you will see it covered with an innumerable multitude of little worms, which there is no doubt are restored from the seminal parts of the corpse. Hence that vast multitude of earthworms is born in the earth. For just as they hate stony, barren, and sandy soil, and so are not born from it, yet it sometimes happens that, while creeping, they enter such soil; but when they find no food, they die there, and from their own corpses soon send forth an immense worm-brood, which, carried by the rain into richer soil, there grows up into an immense abundance of earthworms.

You see, therefore, even from this experiment, that earthworms are born only either from the seed of their own corpse, or from seed brought from elsewhere by wind or rains — and by no means, as some have supposed, from the putrid juice of rich soil alone.

The question is asked, second: How are the *Tineae* — which, from their boring (*aterebrando*), are called *teredines* — generated?

[Margin: The origin of wood-moths.]

I answer: since for the most part they exercise their tyranny upon books, they arise either from wood spoiled by a seed, or from the hides with which books are bound; whence the differing species of them are found according to the diversity of the material. Those which are born from wood arise, of course, not from its putrefaction alone, but from the seed of other worms (with which the still-green wood was teeming) insinuated more deeply. For since no wood can be so dried that some moisture does not always remain along

with the original seed-stock of the animal, it comes about that the seed, excited either by intrinsic heat or by the surrounding heat, produces those little worms that are the haters and gnawers of books. The same must be said of wood destined for the use of construction, especially under a tepid moon abounding in moisture.

[Margin: Moths from woolen garments.]

It is also agreed by all that this same plague of moths is found in woolen garments. Aristotle says that they are generated from dusty wool — which would be empty talk, did he not also add: if a little of the spider is enclosed along with the dusty wool. That the moths of garments are therefore born not from dust alone, but from the excremental seed of spiders mixed with the wool, is clear even from Aristotle himself. Nonetheless, I, for my part, think that they can be born not only from spiders mixed with dusts, but also from the various worm-seed existing in the wool. Some have asserted — wrongly — that these are also produced from paper, which is made from linen; for neither linen nor linen cloth is ever corrupted by moths, as experience teaches. It is therefore necessary that they be born from wool spoiled by the seed of worms of whatever kind.

[Margin: The origin of slugs.]

Furthermore, little beasts of this sort are also found, not without grave harm to the bees, in the beehives. Columella affirms that these have no other origin than from the excrements of certain butterflies, from which are born those worms which they call moths (*tineae*). "For these," he says, "gnaw away the honeycombs and the wax, and from their own dung generate worms, which they call the moths of the hives."

The question is asked, third: How are slugs (*Limaces*) generated? By "slugs" we here mean those slimy worms, full of a mucous moisture, which are not covered by a shell or snail-house; and they are generated in the manner that follows. When the field-snails have clung to herbs and plants, they emit a certain foamy material, not unlike mucus, which we say is the seed from which slugs are born. The reason they are not covered by a shell is that in them mucous moisture alone holds sway, all dryness being banished. For since the shell in snails arises only from saline corpuscles thrust outward by the animals, whereas slugs consist of scarcely any but very small portions of salt, they remain bare of a shell — having arisen, that is, from the mucous foam of the snail, which is insufficient for forming a shell. Nor is there any difference between the snail and the slug, except that the former is covered by a shell while the latter is left bare.

[Margin: The origin of intestinal earthworms.]

But the earthworms which are born in the intestines of children obtain their origin from nothing other than the copious drinking of milk and the eating of sweet things, in which they delight. For who is ignorant — as the use of the microscope has taught — that milk is full of imperceptible little worms? These, indeed, have their birth from the seed or nourishment taken in from cows, or

from the very portions of seminal nutriments which are channeled, together with the chyle, into the wombs of the cows. And it is clear from cheese, butter, and whey, all of which in time breed worms.

[Margin: How cheese can be made wormy by art.]

Among the Dutch, that cheese is reckoned the better and tastier which teems with a manifold breeding of worms; whence some, in order to make it wormy, pour Spanish wine over it, and in time obtain what they seek. I could produce here more animals of this kind, but, so that we may keep the orders of the several classes, we shall treat of them in what follows.

[Margin: The origin of aquatic insects.]

Further, if you ask how aquatic insects are generated — to dispatch myself in a few words — I say that the generation of aquatic insects does not differ from the generation of those born on land. For all insects draw their origin either from the seed and leavings of fish, or from the seeds of windborne things, carried by the flowing of rains and rivers into the sea, or into lakes and marshes; and there, joined as if to proportionate wombs, they are animated into worms not unlike the terrestrial ones.

CAPUT II.

De Insectorum, quæ favifica vocant, genesi. [On the Generation of the Insects which are called Comb-makers.]

Among all other insects, none can be more worthy of admiration than the comb-makers or bees — whether you regard their industry in building honeycombs or their labors in gathering the honeyed juice. Since countless authors have written about their nature and properties, we shall pass these things by and confine ourselves to what belongs to our own proper undertaking.

[Margin: The origin of bees.]

The question is therefore asked, first: From where do bees, wasps, drones, and hornets draw their origin? As regards the bees, it must be known that, just as the differences among bees are various, so too they have a varying difference of operations. For among them there are those they call kings (the rulers); there are also the drones, deprived of stings; and there are, finally, the worker bees, subjects as it were to the kings — which are indeed as many as there are swarms of bees.

[Margin: The grades of bees, distinguished by their offices.]

Hence various opinions have arisen, even among the foremost Philosophers. Some have held that bees are born from coupling with the kings; others, from the drones — all of which is false; certain ones, from matter transported from elsewhere. We, leaving to each his own opinion, shall set forth what experience has taught us. We say, then, that bees have diverse modes of generation. For, first, we taught in the preceding section, on the testimony of several authors, that they are born from oxen; but not even on this do they agree among themselves, since some hold them to be born from the flesh of the ox, others from the putrefaction innate in oxen, and we, from the very excrements of oxen — as we have learned by this experiment.

[Margin: From cheese, that which can become a worm by art [?]]

(Page 358 — Liber Duodecimus, Sectio II, continued)

EXPERIMENTUM I.

The generation of bees from ox-excrement [Apum ex boum excrementis genesis].

Around the rising of the Pleiades [vergiliae], take fresh ox-excrement — from oxen that have first been fed on the plant called *cerinthe* mixed together with its flowers — and set it out in a shady, sun-warmed place toward midday, taking this precaution: that it not be thinned by the Sun's heat and dissolve into vapor. You will then see, to your great wonder, certain little worms being born in the manner of caterpillars [erucæ], which within a short time, once they have taken on wings, come to life as bees, according to the varying disposition of the material: now as kings [reges], and these are the ones that surpass the rest in size; now as drones [fuci] without a sting. These drones also show this peculiar sign of having sprung from oxen: that when gutted, they display in the hindmost part of the body the perfect form of an ox's head.

[Margin: Quómodo apes artificiose productæ postea similes sibi generent. — How bees, once skilfully produced, afterward generate offspring like themselves.]

If you ask how these insects afterward generate offspring like themselves, I answer that this happens by no copulation, but from the seed-stock [seminium]

placed in them — especially in those kings — by nature itself. If you ask where this seed-stock comes from, I answer: from the flowers of *cerinthe*, or of reed [arundo], or of olive, or finally from the juices of flowers of any kind whatsoever. For it is certain that bees take up the juices of these flowers not only as nourishment but also for the making of honey [mellificium]. Now since the flowers of plants are perpetually sought out by the flies [muscae] proper to each plant on which they were born and by which they are nourished, it comes about that those flowers always have implanted in them some small amount of seed-stock — whether it be the excrement of those flies or something else — which is then sucked out by the bees and carried off together with them as a seed-stock. By this seed-stock they generate not, indeed, an animal like the prior one, but rather, by the power of the honey or of some other liquid that serves them as nourishment, it degenerates into a bee. This happens not from the honey insofar as it is honey, but from the very excrements of the bees — as you will learn from this experiment.

[Margin: Experimentum mirabile. — A remarkable experiment.]

Take from a beehive the excrementitious parts of the bees, and examine them carefully with a microscope [microscopium]. With the greatest delight of mind you will see, frequently, first certain little sacs [folliculi]; then, once these have burst, little worms, of which some now resemble caterpillars while others, having now taken on wings — which by repeated inspection you will find to have already formed into perfect bees. Thus no copulation is necessary in the generation of bees, no union of male with female like that in perfect animate beings, as many have supposed. Rather, the little creature's own spermatic excrement, within a short time — on account of the seed-stock implanted in it, cut off from elsewhere — is shaped into a bee. And from these things it is plainly evident that no other origin of bees is to be found than the one we have now set forth.

[Margin: Fucorum ortus. — The origin of drones.]

But at this point no small doubt arises: where do drones [fuci] come from, and why are they without a sting? To dispatch the matter in a few words, I say that the drone is distinguished from bees by no other respect than that it lacks the sting proper to bees.

(Page 359 — De Insectis) Those who say that bees arise from oxen but drones from horses speak wrongly. For both bees and drones are born from the same excrementitious parts of the ox, though imbued with a different seed-stock. Since oxen, when they take herbs and plants as nourishment, always take up along with them various seed-stocks of flies and worms present in those very plants, these seed-stocks are fermented within the stomach and intestines of the oxen; and finally, once the excrement has been voided, they are hatched out — according to the differing character of the seed-stocks — into different species of bees.

I say, secondly, that the origin of drones consists chiefly in the excrements of bees that have already exhausted themselves [emeritae]; and so, when the spermatic power fails, the drones too are deprived of the very sting in which the strength and vigor of bees lies hidden. The ox's excrement is therefore productive of both bees and drones; and from the same plant-nourishment by which the bees afterward produced are fed by natural instinct, it necessarily follows that from the same dung the same animal afterward emerges — namely either a bee or a drone — as is produced from the dung of oxen, since the seeds of things are the same in both. So here you have the true and genuine generation of bees and drones.

[Margin: Vesparum ortus. — The origin of wasps.]

But as to how wasps [vespae] are born, someone might rightly raise a doubt. The philosophers establish a twofold origin for wasps: some from putrefaction, others

from copulation; and just as the former, they have held, come from the carcass of a horse, so bees come from the bull. So Nicander:

[Greek: Ἴπποι γὰρ σφηκῶν γένεσις, ταυροὶ τέ μελισσῶν. (Hippoī gar sphēkōn genesis, tauroi te melissōn — "For horses are the origin of wasps, and bulls of bees.")] [?]

Equi enim vesparum genesis, & Tauri apum. ("For horses are the generation of wasps, and bulls of bees.")

The Egyptians maintained so fiercely that wasps are born from the carcass of a crocodile that they even held they should be placed among the hieroglyphics. We say that wasps and bees and drones are born not only from a bull, or an ass, or a horse, but also from deer [cervi]. For as Nicander testifies:

[Greek: Σκλήεσι πυθομένοισι λυκόσπαδες ἐξεγένοντο. (Sklēesi pythomenoisi lykospades exegenonto — "From decaying [bodies] there came forth wolf-torn [creatures].") (Σκλήεσι is a corrupt/non-standard form, transcribed as printed.)]

Corpore nam putrido infectum consurgit utrumque. ("For from a putrid body an infected [creature] of either kind rises up.")

Concerning deer, Vincent of Beauvais [Vincentius Belluacensis] testifies that wasps coalesced in the bone beneath the eye of a stag advancing toward ripe old age, once that bone had been bored through; and he supposes that they came forth either from the substance of the brain or of the marrow. We, however, assert that they are born chiefly from the excrement, or else from the very plants on which the said animals are fed — since a plant of this kind is a common nourishment infected with the various seed-stocks of flies and worms, by which not only oxen, horses, asses, and deer, but also wasps are nourished, and from whose excrements wasps afterward rise up. I would not, however, deny that wasps are afterward also generated by copulation, since the excrement of these creatures takes the place of seed: once it has been warmed [fotum] by the wasps, it first passes into a little bladder [vesicula], and when this has burst, as though out of a shell [testa]...

(Page 360 — Liber Duodecimus, Sectio II) ... so that they seem perceptibly to grow before the eye. The colors, moreover, which in the caterpillar were only spots, now display themselves on the wings, painted in a wondrous arrangement of striations, with such variety of figures as we cannot sufficiently marvel at.

[Margin: Folliculus. Tabanus. — The sac. The horse-fly.]

I recall that I once found a chrysalis [chrysalis] that displayed the perfect form of an infant wrapped in swaddling-bands, as is shown in the margin. In a butterfly, too, at another time, I found the image of our Savior so skilfully depicted that it seemed to have been drawn by a painter's hand. But to return to the experiment: if you enclose specimens of this kind in larger glass vessels together with plants, you will soon see them, by a certain natural and wondrous instinct, fly toward one another and together emit a certain excrement not unlike the eggs of fleas [ova pulicum]. If you examine this carefully with a microscope, you will see it come to life, within a short time, as new little worms; and these in turn afterward transform into chrysalises, and finally into new butterflies. And in this way you will recognize, by an infallible experiment, that the caterpillar first brings forth something resembling eggs — which we call its spermatic excrement — and not only within folded leaves of garden herbs, but also among other leaves of plants, folded for this purpose deliberately by the butterflies, lest they be destroyed by rain. If you observe these under the microscope, you will see most plainly that certain little worms are hatched out of them — such as are commonly seen in the little galls [folliculi] of elms and mastic-trees — and that within a short time, among the pastures they meet with, they grow so large as to resemble perfect hairy caterpillars, which are then turned into chrysalises and finally into new butterflies. These last throughout nearly the whole summer season; but when the Sun crosses into Libra they are buried, dead, within the earth. Out of them, afterward, when the Sun enters Aries, they are quickened — both from the spermatic excrement of the eggs and from their own ashes [bustum] — into new worms, then into chrysalises, and at last into butterflies.

Here it is asked whence the *bombylius* or silkworm [bombyx], the spinner of precious silk, draws its origin. I say that it is born from a mulberry-seed-stock [morum seminium] cut off from elsewhere, and that by a threefold transmutation — no differently from the rest of the butterfly kind — it is quickened into a butterfly toward the end intended by Nature, with this one difference: that greater care must be taken of these than of butterflies. I said it is born from the mulberry [morus], because if you examine the texture both of the bark and of the leaves of the mulberry under a microscope, you will find that Nature has so woven it that yellow silk most closely rivals it in its fibers.

[Margin: Bombycum ortus. — The origin of silkworms.]

In this way, then, the generation is accomplished. As soon as the creature is hatched from the spermatic excrement of the eggs, without a sac, it is transformed by an admirable metamorphosis through a brief stage as a zoophyte [zoophyton], devoid of motion and sense. When you have seen it hatched, it at once seeks out — by a hidden instinct of Nature — the foods it requires; and once it has greedily fed on these, struggling as if against drowsiness with frequent raising of its head, it at last falls asleep for three days or two.

[Margin: Observatio mira. — A remarkable observation.]

Meanwhile, having shed its skin, it returns to its accustomed foods; and having fed on these four times, and four times fallen asleep, and four times renewed its skin, it scorns its fodder and seeks the heights. When it has climbed up onto twigs of broom, Spanish broom [spartum], southernwood [abrotonum], and the like — arranged with great industry by women — its belly now duly purged, it practices the rudiments of its wool-working [lanificium] first in hidden mazes among the branches; then, enclosed in a translucent sac, it pushes out from center to circumference the fruit of its tireless labor: a thread, white, green, yellow, of oval shape; and, as if vying with its equals, intent on its work completed in nine days, it dies upon it.

[Margin: Varia Bombycum metamorphosis. — The varied metamorphosis of silkworms.]

From the sac, however — placed in a subterranean spot — after ten days a horned butterfly comes forth, but heedless of wings and of food; destined to repair the loss of its brief life by procreation, it is laid upon soft wool and, coupled with the female in continuous mating for three days (more rarely for four), it dies; and not long after, having left a widow behind it, with a seed-stock after it like grains of millet, it follows the fate of the husband. The

excrementitious seed, deposited in a temperate place and kept through the winter, soon — when the mulberries have begun to bud, with a spirit conceived whether by the Sun's heat or by men's — is quickened into a worm; from which then comes a chrysalis, and at last from this again a butterfly. And so the one that had first been a worm, enclosed in its sac, at last dies in its sac shapeless [informis] — so that for that reason I cannot sufficiently marvel at the infinite wisdom of God, Greatest and Best [Deus Optimus Maximus], in the most abject little creature.

I could say more here about the cultivation of these creatures; but since these matters have already become commonplace through frequent practice and use, I leave them to be set out by the women, and the reader may consult the figures placed here.

[Margin: *Perlarum ortus*. — The origin of the *perla* [mayfly/dragonfly].]

It is asked, secondly: how are the *quadripennia* which they call *perlae* generated? This insect is equipped with four very long, delicate wings, of a crimson, red, and whitish color, and flies chiefly about river waters — truly a beautiful little creature on account of the variety of its colors. Take its generation in a few words, as known to me from experiment. There are found, clinging to rocks at the bottom of rivers, little channels [canaliculi] formed of sand and stalks, in which, as within little tubes, worms are contained. Fishermen use these for catching fish with a hook, fixing them on the point of the hook in place of bait. These worms, now mature, drawn out [educti] by [their] feet...

Diagram. A small woodcut set into the left text column, captioned *Folliculus. Tabanus*. ("The sac. The horse-fly."). It depicts a chrysalis/cocoon (the *folliculus*) shown vertically; per the surrounding text, this is the chrysalis in which Kircher claims to have seen "the perfect form of an infant wrapped in swaddling-bands" and an image of the Savior. The figure shows an oval sac-form with a face-like pattern within. No internal point-labels.

Diagram. A woodcut of three figures in a row at the foot of the right text column, illustrating the silkworm's metamorphosis. Captions over the three figures, left to right:

- (left): *Papilio Bombycinus* — "The silk-moth (silkworm butterfly)." A spread-winged moth with patterned wings.
- (center): *Ex folliculo Bombyx erumpens* — "The silkworm bursting forth from its sac." A cocoon shown with the emerging form.

- (right): [Greek: χρυσάλις (chrysalis — "chrysalis/pupa")]. An oval pupa-form.

No internal point-labels beyond the three captions.

(Page 361 — De Insectis) ... they crawl up, together with their little channel, as far as the surface of the water, to the edge bordering the banks. There, clinging to rocks or to a clod of earth, by the heat of the Sun they degenerate into that little animal which is commonly called the *perla* [mayfly];

[Margin: Natales Perlarum. — The birth of the *perlae*.]

and thus they obtain one and the same origin as the butterflies, with this one difference: that butterflies get their birth in plants, these in waters. [...] from the various refuse of fishes — especially of those they call gudgeons [gobiones] — or from the excrements of other [creatures], a worm is born; from the worm comes a chrysalis; and from the chrysalis at last, together with its channel, there rises up, infected, that animal which we have called the *perla*. And although, so far as I know, this has hitherto been observed by no one, it thus first became known by our observation.

[Margin: Cicadarum ortus. — The origin of cicadas.]

It is asked, thirdly: how are cicadas [cicadae] or crickets [grilli] born? Those who hold that cicadas are born of their own accord are gravely deluded, since they have been observed to propagate both spontaneously and also afterward by copulation, as happens in nearly all insects. Their generation, however, is accomplished in this way. Within the earth, or also in the hollows of trees, a certain seed lies hidden, which Aristotle [Aristoteles] supposes to be deposited by the *tettigometra* [Greek: τεττιγομήτρα (tettigomētra — "cicada-mother," the larval cicada)]; but it is nothing other than a certain animal not unlike a cicada, of the kind that the [Greek: τέττιγες (tettiges — "cicadas")] called *locustae* are. From this seed, then, in the summer season, a worm is hatched, which, afterward wrapped in a little sac, at last — when the sac has burst — comes out as a green cicada.

These are the things that became known to me by experience in observing an insect of this kind. See our *Musurgia* [noted in margin: *Musurgia*], where in the first book we treated very fully of the voice and the structure of the body of this little creature.

[Margin: *Musurgiam, Libro primo* — citation: Kircher, *Musurgia Universalis*, Book I.]

[Margin: Cicada. — The cicada (figure label).]

CAPUT IV.

On the origin of the insects called *analytra*, which they name *bipennia* [De Analytrorum, quae Bipennia vocant, Insectorum origine].

[Margin: Muscarum ortus. — The origin of flies.]

The fly [musca] is an animal known to all, [Greek: ἑξάπους (hexapous — "six-footed")], equipped with six feet and two wings, from which they are called *bipennia* ("two-winged") — about whose net-like eyes [oculi retiformes] we have treated at length elsewhere in our works, detected by the use of the microscope. Just as the species of this insect are innumerable, so too they obtain diverse origins: some take a kind of momentary origin from animals and from the excrements of animals; some from carcasses; some from herbs; some from the carcasses of the flies themselves; certain ones are born from the very excrements of those flies. That all these things are true you will find out as follows.

EXPERIMENTUM I.

The generation of flies [Genesis Muscarum].

Gather the carcasses of flies, and, after first macerating them a little in honeyed water, place them upon a bronze plate; then expose the plate, in the chemists' manner, over ash or sand, with a gentle heat, with coals set beneath it, or else warmed with horse-dung. You will see, first — by the help of the microscope — certain imperceptible little worms being born; then, once they have taken on wings, [you will see them] perceptibly [turn] into little flies [muscillae], and at last, growing until they reach the threshold of the senses, come to life as perfect flies. You will observe the same thing happening from their own excrements — which Aristotle [Aristoteles] himself also...

Diagram. A woodcut of a wasp set into the right text column, captioned *Vespa*. ("Wasp"). It shows a single wasp in dorsal view with two pairs of wings, antennae, and the characteristic constricted waist. No internal point-labels.

Diagram. A woodcut captioned *Perla*. set into the left text column, depicting a dragonfly/mayfly [*perla*] in dorsal view, with the four long delicate wings spread, an elongate segmented abdomen, and the head with large eyes. No internal point-labels.

Diagram. A woodcut captioned *Natales Perlarum*. ("The birth of the *perlae*"), set into the left text column below the *Perla* figure. It shows the underwater larval scene described in the text: the *canaliculi* (sand-and-stalk tube-cases) clinging among rocks at a river bottom, from which the larvae emerge. The image is a clustered rocky/tubular composition. No legible internal point-labels.

Diagram. A woodcut captioned *Cicada*. set into the right text column, depicting a cicada in dorsal view with two pairs of wings folded/spread and six legs. No internal point-labels.

[Reading order: the four PDF pages are non-linear. By printed page number they run 362 → 363 → 364 → 365, which corresponds to PDF-page order 2, 1, 4, 3. Each printed page is set in two columns; I translate left column then right column within each page. Page 362 continues the sentence broken at the catchword "stoteles" ending the prior page (361), completing "[Ari]stoteles observavit."]

as Aristotle himself also observed. "Flies," he says, "are generated when the worms divide into parts; and those who perform this service maintain that one cannot tell the remainder of the dung apart from the seminal matter—they confirm that the dung is itself cooked and digested." Now the beginning of these little worms is the tiniest thing: it first turns red, and then, as though still clinging to the sand by immobile fibers, it begins to stir. Soon the worm becomes motionless; and once it has afterward been born, it again becomes motionless, and finally turns into a fly when stirred by a puff of air or by the action of the Sun. Those, however, who say flies are born from eggs say that the same flies are born from their own filth, in which the seed is contained.

And if flies are sometimes seen to copulate, this happens because of a certain sharpness in the excrement itself, by which, being stimulated, they discharge their excrement more copiously—so that, as though glued together by it, they can scarcely be seen to separate. Wherever this is deposited, little worms rise up out of the already-deposited spermatic matter, and from these comes the winged fly.

[Margin: The variety of flies.]

The first question: From where does so great a variety of flies arise? I answer that it happens either from the dung of animals—which, once they have taken in for nourishment plants steeped with the various seeds of flies, that matter, now fermented within the intestines along with the food, excites the seminal power. Once excreted and still warm, it produces, as though by a kind of impromptu birth, flies of different sorts according to the quality of the seed shed, as is plain to the eye of anyone who observes such things. Hence too the wine-flies that lurk in must and vinegar; hence the mayflies [Ephemera], the gadflies [Oestra], the horseflies [Tabani], the breeze-flies [Asili], and any other kind of fly there may be, all derive their origin. Most of these stink of venom, especially those that draw their origin from poisonous flowers and herbs, or from putrefied serpents.

[Margin: The origin of the gnat [Cynips].]

It now remains to explain the origin of those flies which the Latins commonly call *Zenzalae*, and the Greeks *Cynipes* [Greek: κώνωψ (kōnōps, "gnat" or "mosquito")]. They belong to the genus of gnats [culex], a thoroughly tiresome creature, most troublesome both by its whining and by its bites; about its origin various people have thought variously. I have discovered their origin by the following experiment.

EXPERIMENTUM I.

On the Origin of Gnats [Cyniphes], which they commonly call Zenzalae.

Take rainwater, or even spring water, put it into a glass vial, and set it out in summer in dusty places—just as I had set it out beyond a window that looked onto the public street—and in this way, with the mouth of the vial open, let it stand. You will see that the dust from the street, stirred up by the movement of horses and carriages, within a short time draws a kind of skin over the surface of the water held in the vial; but if you shake it a little, you will see the dust sink to the bottom and there remain in the form of a sediment.

This done, after some days examine the silt carefully, and you will find certain little blisters, which are the wombs of worms; for out of these come little worms, at first perceptible only to the armed eye [i.e., under the microscope]. These, growing steadily, usually swim about in the water in great numbers with a twisting motion; and once they have acquired the proper maturity, then—the water and the side of the vial drawing near—as soon as they touch the air, behold, within a tiny space of time, with legs and wings now taken on, they come

alive as gnats [Cyniphes] or *zenzala*e. And this generation I have discovered by experiment more than once.

If you go on to ask from where they draw their origin, I say they draw it from the dust stuffed with the varied seed of things; and this seed comes either from the carcasses of animals—cats, dogs, birds—with which the streets of Rome are at times crammed; or else from the excrement of horses, asses, oxen, goats, and the like, in which the seeds of various flies and gnats lie hidden. For when this seed has been mixed with the dust, then as soon as it has found moisture and made mud, behold, at once, animated also by the heat of the surrounding air, it turns first into blisters, then into little worms, and finally into those creatures we have called gnats. And what perhaps ought to have become a fly, or a gnat [culex], degenerating through the inadequacy of its matter, is turned into a *cynips*.

Certainly these things agree most fully with the Sacred Text of Exodus, chapter 10 [recte: Exodus 8], where, when the dust was struck by Moses, gnats [Cyniphes] came forth—which was the most troublesome of all the plagues inflicted upon Egypt.

[Margin: The origin of the gnat [culex].]

From this the origin of gnats [culices] too is demonstrated—although I would not deny that gnats and *cyniphes* (which are a smaller species of gnat) may also arise from elsewhere. And to treat first of the origin of gnats: I recall having often observed that in the little pods [folliculi] of the mastic, the elm, the terebinth, and those that grow upon oak leaves, when broken open, there is found some sort of seed-bed of such little beasts—partly under the form of eggs, partly even under the form of little beasts already equipped with wings. For these pods, placed under an inverted glass, hatched out partly gnats [Cyniphes], partly gnats [culices]. All of which I would wish the Reader to observe, for it is a matter full of wonder.

[Margin: The pods are the wombs onto which the flies settle.]

If you ask how seeds of this kind come to be in such pods, I say it is from the settling of various flies upon them at the time when the pods have not yet hardened but are seen under the form of flowers. For various flies, settling upon these, fill the inmost part of the flower with their seed; and this, afterward enclosed as though within a womb, brings forth the little creatures we have described.

CAPUT V.

On the Origin of those Insects which have their Wings Enclosed in Sheaths.

Those insects are so called which have their wings enclosed in sheaths [vaginae]—from the Greeks *Koleoptera* [Greek: κολεόπτερα (koleoptera, "sheath-winged" — beetles)], from the Latins *Vaginipennia*. And they are: the locust [Locusta], the cricket [Grillus], the scarab [Scarabaeus], the chafer [Cantharus], the *Buprestis*, the firefly [Cincindela], the cockroach [blatta], and innumerable others like them.

And to begin with the locusts: their diversity is no less than that of the flies—

Diagram. A woodcut of a locust (grasshopper), shown in left profile with the long hind legs raised, two antennae, and the body and wings detailed.

- Caption (above figure): *Locusta*. — "Locust."

—a diversity which cannot be caused by anything except the degeneration of the diverse seed from which they are born. In the year 1656 this pest infested the fields of Rome with enormous damage; it had drawn its origin from the dryness of the preceding year. Everywhere in the fields nests full of the offspring of this creature were found. For first, as became known to me through the microscope, eggs were seen, then little worms, of which some [were] without wings,

[Margin: The wonderful generation of locusts and grubs.]

while certain ones already seemed to be fashioning wings for themselves. These, exposed to the Sun, within the brief time it would take someone to recite a crown [a chaplet of prayers] to the Blessed Virgin, were shaped into locusts leaping here and there; and once they had arisen, they left nothing in the crops untouched, so that the destructive gluttony of these little creatures could not seem to be sated even by the leaves and buds of trees. And a plague of the following year, attended by great slaughter of men, followed upon them.

If you ask from where so great a swarming of locusts comes, I say they draw their origin from entirely various seeds. **First** I say that most [of them]

[Margin: The cause of their generation is set out.]

arise from blighted grain, whether it be oats, or wheat, or barley—in this way: that, together with venomous subterranean exhalations, the seeds (which for the most part are born from the excrement of other worms and flies settling on the crops) are intermingled; and from this comes the locust, to which the plastic

power of the seed, partly in accordance with the requirements of the insect, gave a sentient body suited to insects, but gave it feet

[Margin: Locusts from the knots of crops.]

not unlike the knots [nodes] of crops. **Secondly** I say that they can be born from the carcasses of men, and this is confirmed by various histories in which it is reported that, when a great slaughter of men had taken place in the fields—whether by war or by those perishing of famine—from their carcasses a vast swarming of locusts soon burst forth; with which the records of all the Historians are full.

If you ask how these are born from the carcasses, whether of men or of animals, I answer that it happens

[Margin: Locusts from carcasses.]

from corrupted grain, on which soldiers and animals for the most part feed in time of famine or shortage of provisions. Since this is stuffed with the seeds just mentioned, hence it comes about that in the carcasses of the locusts that perish [the seed is born again]—the spermatic matter, fermented by heat both external and internal, is at last quickened into locusts.

[Margin: From the very carcass.]

Thirdly I say that this pernicious swarming likewise [arises] from the locusts themselves; in the carcasses of locusts that have perished, [it is born again] at a suitable time of year. For by rains and by the flooding of rivers these carcasses, corrupted and putrefied, are buried in the earth together with clods of soil and mud; and there, by subterranean heat in winter but by external heat in summer, they are animated into locusts by the power of the seed.

It also sometimes happens that a vast army of locusts, driven by the force of the winds into seas, lakes, and rivers, is drowned there; and their carcasses, afterward cast onto the shores, found there a new seed-bed of locusts—on which see more fully, treatise by treatise, in our *Physico-Medical Scrutiny on the Plague* [*Physico-medicum scrutinium de peste*].

[Margin: From the leaves of trees and from grass.]

Fourthly I say that they can also be born from the grasses and the leaves of trees, in this way: since this creature is generated not only out of putrid matter by the power of foreign and alien seed, as we have already said, but also out of the settling of one upon another like itself—which many call copulation [coitus]. For

since most people say that all locusts are female, just as scarabs are male, and that they are distinguished by no sex,

[Margin: By copulation they are produced in a particular way.]

it is certain that they conceive in another way, which I now disclose, as something known by experiment. For when I had fed a locust for a long time, I at length found it impregnated by itself with a manifold brood, which it shortly afterward poured out, fertile. Now in this way copulation is accomplished: the excrement, which serves them in place of seed, since by the power of its innate salt it is exceedingly sharp, hence tickles in a wonderful way the body of the locust onto which it is poured. And do not suppose this excrement to be cast off through the vulva—which the locust does not have—but rather,

[Margin: How they generate.]

the suffering animal, warmed by the tickling, dilates as much as it can its pores and clefts, into which the received [matter] passes into a seed fit for hatching locusts. For at once certain little bubbles appear in the form of eggs, which, when burst, soon rise up into winged worms. So whether the locusts have settled upon one another in the leaves of trees and plants, or on the stalks of crops, or in the very earth, or have deposited the spermatic excrement in the same places—if, as we have said, that excrement has first been fermented by heat,

[Margin: The generation of grubs is the same as that of locusts.]

then, in time, with the external [warmth] of spring arriving at its close, out of their little pods emerge small, blackish worms, without wings and without legs; and at length they are transformed into locusts. For since they must always be born from the same nourishment by which they are fed, with the seed of sentient Nature implanted in it, it is necessary that they be born thus.

[Margin: The generation of grubs.]

What we have said of locusts must be said of the generation of grubs [bruchi], whom they call *Attelabi* [Greek: ἀττέλαβος (attelabos, "wingless locust" or "young locust")]—with this difference, however,

[Margin: The origin of grubs.]

that grubs for the most part take the beginnings of their generation from the mucous sap of plants and shrubs, which the chafers [canthari], or even the locusts, have infected with their filth. These afterward propagate themselves too by promiscuous union, just like the locusts.

[Margin: Why so great a multitude of these insects does not arise in single [individual] years.]

But that so great a multitude of these insects does not arise in single years depends on the now-this, now-that constitution of moister or drier seasons and years. Nothing further remains, then, except to confirm what has been said by experiment.

EXPERIMENTUM [II].

The Generation of Grubs.

If, then, you have a mind to produce grubs, as we have done by experiment, proceed thus: Grind up grubs together with their nests into powder. Then fill any vessel you please with that earth in which oaten stalks have rotted; if into this you mix the powder a little while before prepared, and water it with the mucous sap of a shrub mixed with rainwater, the result will be that, exposed to warm air, within eight days it comes alive into innumerable grubs and locusts. These you will then clearly observe if you fit an inverted glass, open at the top, to the rim of the vessel so that they do not fly away. And this method is exactly the same as that by which Nature proceeds in producing the said insects.

I would by no means wish these things to be referred to evil, but [I say them] so that the power of Nature, joined to art, may become known. For whatever is said in the Sacred Text about the grub, the blight [aerugo], the locusts, is always to be understood of the greatest evil, which God, being just, sends upon men on account of their sins—by which they inflict venomous wounds not upon one or another only, but upon whole nations: death by famine, and from the fetid corruption a deadly and inescapable pestilence.

[Margin: Locusts and grubs, when burned, drive the rest away by their smell.]

Yet there is a thing both wonderful and most worthy of consideration. For if it is true, as Democritus relates, that if you catch and burn locusts or grubs, the result is that the others, soon seized with dizziness, either die, or, shedding their wings, are consumed by the Sun—although I would more truly think that they are afterward revived, as it were, from a kind of funeral pyre. But concerning the other ways of driving off locusts, read the writers on the art of Agriculture.

[Margin: What kind the locusts were on which St. John the Baptist fed.]

Further, as to what kind the locusts were on which John the Baptist, the Forerunner of CHRIST, is recorded by the Sacred Gospel to have been fed in the

desert: read Aldrovandi [Aldromandus], who treated this subject most fully in his *Book on Insects* [*De insectis*], where he also adduces a twofold opinion. Of these, some hold that they were true locusts, which the Greeks call *akrides* [Greek: ἀκρίδες (*akrides*, "locusts")]; but others think it more likely that he took for food only the tips of trees, or even the more tender buds of plants, which the Greeks likewise call *akrides*. But now to other matters.

[Margin: The generation of crickets.]

As to what concerns the generation of crickets [*grylli*], they too are distinguished into many species. There are some that are arboreal and woodland, which all through July and August do not cease to vex the ears day and night with their grating sound; and there are also the hearth-crickets [*focarii*], or domestic ones, which are hatched out of the leavings of meats and of woods stuffed with seeds, when a slight moisture is added, by the heat of the fire. They especially dominate the heated rooms [*hypocausta*] of bakeries, and emerge in vast progeny; and they have their origin from nowhere else than from the seed of sentient nature present in the grain. Since this seed is incorruptible, it likewise clings not only to grain but also to kneaded flour and to moldy bread; and this, afterward raised up by the vapor in the heated rooms and deposited within the cracks of the walls, at length hatches out those crickets which the Italians call *Bargarozzi*—

[Margin: *Bargarozzi*, which [is] in Italian.]

—mute ones, however; the Latins call them *Blattae*. See the First Book of the *Musurgia*, where we have precisely assigned the causes of the sound of crickets.

§. I.

On the Origin of Scarabs [Beetles].

Of scarabs [*scarabaei*], and of those insects we have already examined, not all are of the same species, just as the reason of the seeds from which they have flowed forth is not the same; for they differ in color, in size, in sound, and in the constitution of their limbs. Some are black, yellowish, or ash-colored; some shine with a lustrous golden-green color, which they call *Chrysocantharos* [golden chafers]. There are others remarkable for the branching form of their horns, which from this they also call *Cantharelaphi* or scarab-stags [*Scarabaeo-cervi*]; others resemble unicorns [*monocerotes*]; others *Lucani* without horns; others [have] a horse's or goat's head; and there are some that resemble stags in the head. They differ also in place;

[Greek caption above the figure on this page: ἐλαφοκάνθαρος (elaphokantharos, "stag-chafer").]

Diagram. A woodcut of a stag-beetle (*Lucanus*), viewed from above, showing the broad body, the large branching mandibles ("horns") at the head, and the six legs spread to the sides.

- Caption (above figure): ἐλαφοκάνθαρος [Greek: elaphokantharos, "stag-chafer" / stag-beetle].

Some draw their origin from the dung of animals, like the scarabs they call ball-rollers [pilularii], met with everywhere along every path; others have their birth in trees; some within

the earth, or in latrines, or even within waters are born; yet of all of these the origin is the same—partly from copulation, partly from the seed of sentient nature shed from elsewhere,

[Margin: The origin of scarabs from various living things.]

namely from the herbs that spring up of their own accord. For unfailing experience teaches that they are born not from the excrement of horses alone, but also of oxen and asses. Indeed, I recall having sometimes observed

Diagram. A woodcut of a horned beetle ("unicorn beetle"), viewed from above, with a single long curved horn projecting forward from the head, a rounded thorax and elytra, and the legs spread at the sides.

- Caption (above figure): *Monoceros*. — "Unicorn" [single-horned beetle].

whole scarabs that had hatched out together with the warm dung of horses; and afterward others of them, in great number and by a kind of impromptu birth, were produced out of the underlying matter. If you ask the cause of this generation:

I say there is no other cause than the nourishment of the herbs on which they feed. This [nourishment], being infected with the seed of other insects and of certain worms and flies, and devoured by the beasts of burden, then digested by the heat of the intestines, and at last evolved outward, hatches out scarabs, which have their nests within the earth.

Diagram. A woodcut of a ball-rolling scarab [dung-beetle], viewed from above, with the rounded body, the head shield, and the six legs.

- Caption (above figure): *Scarabæus pilular[ius]*. — "Ball-rolling scarab" [dung-beetle].

In exactly the same way they are born from cattle or horse dung worked into the earth. It is worth consideration, however, that if the beasts of burden eat plants infected with the seed of flies, then from this are produced bees, wasps, and similar little creatures; but if the said plants have been infected with beetle-like or sheath-winged [vaginipenne] little creatures, such as small cantharides, then out of their dung beetle-like animals too, of the kind that scarabs are, are born. For just as such nourishment behaves with respect to producing scarabs in beasts of burden, so does the worm-breeding nourishment of milk behave in infants, with respect to producing roundworms [lumbri] in the intestines of children.

[Margin: Observations on scarabs.]

[Margin: The generation of horned scarabs.]

But as to what concerns the generation of those scarabs they call *Lucani*, which are not unlike stags in their horned head: I say that they are born from rotten woods steeped in deer dung—induced chiefly by this argument, that nowhere is a greater abundance of these insects found than in those places where deer are stabled in herds, as has often been observed by me in Germany. I have also heard from those who have the care of deer that they are sometimes found in their droppings, and now and then are born thus from rotten woods steeped in deer dung—so that at first they appear as worms [resembling] *Zoophyta*, then, becoming detached, they crawl about with the traces of horns gradually opening, and at last emerge as beetles, conspicuous with a horned, stag-like head. And the reason of this matter is no other than that to the excrement is added some little of the deer's seed, which at the time of copulation they scatter even outside the vessel; and thus from differing seed a differing animal arises—that is, a scarab-stag [Scarabæo-cervus]. From the seed present in the food, [there arises] something like the form of a scarab; but from the deer's seed, nature works as much as it can to produce something like a deer. And since it cannot produce a perfect animal—being disposed in an ill-proportioned womb—it at least does this much, that it fashions an *elaphomorphon* [Greek: ἐλαφόμορφον (*elaphomorphon*, "deer-shaped")]—that is, a stag's head conspicuous with branching horns.

[Margin: The unicorn scarab.]

But as to why scarab unicorns [monocerotes] are sometimes found, remarkable for a single horn on the forehead: I say this happens because the animal, either through a defect of the seminal matter, or because the same matter is diffused

into forming other limbs of the body, is now equipped with only one [horn] where it ought to have been equipped with two.

[Margin: The chrysocanthar, or scarab gleaming with golden splendor.]

But how the *Chrysocanthari*—that is, that species of scarab which so greatly delights the sight with its golden-green color—are generated, if you ask: I say they are born in no other way than the rest of the ball-rolling scarabs, nor do they differ in species, but only by accident; yet that color comes to them first in this way, which follows. Within the cavities of the earth there is sometimes a kind of brassy [aerosa] clod arising from veins of marcasite, which tinges not only the surrounding places, but also certain plants—while they draw in moisture—with that color which the brassy earth confers on them, as appears in the sap of celandine [chelidonia] and turmeric [curcuma]. And so the scarabs, at first tinted with a black color, as soon as they have insinuated themselves into places of this kind,

[Margin: An experiment on the origin of the golden color in scarabs.]

are at once excited by the saline and vitriolic little spirits which exist in the brassy clod, stirred up by the force of heat; and this, acting upon the body of the scarab, tinges it with the said color. This first became known to me when I had moistened a scarab enclosed in glass with spirit of vitriol mixed together with verdigris, and it was at once, with its color changed, transmuted into a translucent golden-green. And since this is a most beautiful experiment, I would wish all natural philosophers of a more curious doctrine to try it.

You see, then, with how many differing seeds even this single animal is constituted: the minerals give the color; the deer's seed [gives] the horned head; and the seed shed from other sheath-winged creatures not unlike the scarab gives the scarab itself.

[Margin: The generation of cantharides.]

It now remains to unfold the generation of the cantharides [blister-beetles]. The cantharides are little beetle-like worms, which I would not inappropriately call little scarabs [Scarabaeunculi]. These Aristotle, on the testimony

[Reading order used: PDF pages were out of sequence. Reconstructed from printed folio numbers and catchwords as 366 → 367 → 368 → 369. Page 366 continues the cantharides passage broken off at the end of the prior folio (p. 365, catchword "teste"); its catchword "porem" leads into p. 367; p. 367 ("redeamus") continues to p. 368 only after the figure of the scorpion and the body text resumes

— but by folio sequence 366→367 is the recto/verso pair, and 368→369 the next. Catchword chain: 366→"porem"→367; 368→(habita-)→369→"de-".]

[Continuation of §. I, "On the origin of beetles" — the generation of cantharides (blister-beetles).]

as Aristotle reports, on the testimony of Aelian [Aelianus], they are born among grasses and standing crops, and on the branches of poplars. "From the prunings," he says, "of the fig and the pine there also arise κράμβης [Greek: krambēs, "of cabbage" — i.e., cabbage-caterpillars], that is, 'dog-caterpillars' [eruca caninal]; and there are likewise worms in all of them; for this kind of animal seeks out foul matter, since it is itself constituted out of such matter." Pliny [the Elder] holds that they are born from the sponge-like gall of the dog-rose [Cynorrhodon], and from the ash and from roses. And these authors are right — provided they had also learned the more immediate cause of the seed-stock [seminium] from which the creatures are born.

[Margin: The origin of cantharides from the toad's filth.]

For my part, I judge that most of these little creatures — the more venomous cantharides especially — are born partly from the excremental filth of the toad [rubeta], partly from spiders. This is clear to us from the fact that plants nearest a toad's nest are for the most part found thick with cantharides, and the ferocity of the toad's venom, manifesting itself in entirely similar symptoms, shows plainly enough that the nesting of cantharides in this or that tree or plant is to be reckoned a clear sign of the matter — since, once hatched out of the underlying material, they immediately make for whatever tree comes nearest.

[Margin: Cantharides born from venomous plants.]

I would not, however, deny that they can sometimes also be born from plants stocked with the seed of spiders — especially from hemlock [cicuta], monkshood [napellus], and leopard's-bane [doronicum Pardalianches], deadly plants, in whose flowers, at their flowering season, I remember having observed a great abundance of them.

[Margin: From spiders.]

Nor should you wonder that cantharides can by nature be born from the seed-stock of spiders, since some of the cantharides are so similar to spiders in their bodily constitution that, if you set aside the color, it is at once apparent that what is expressed by so close a resemblance is not foreign to them. But as for the nature of the venom with which cantharides are equipped by nature, let the

reader consult Book Ten [Libro Decimo], where all these things are discussed in detail.

§. II.

On glow-worms, or fireflies [De Lampyridibus sive cincindelīs].

Among the beetle-winged insects [Coleoptera] are also counted those which the Greeks call λαμπυρίδες [Greek: lampyrides, "glow-worms"] and the Latins *cicindela*e. For — on the testimony of Hesychius — the firefly [Lampyris], "ἡ πυρολαμπομένη ταῖς νυξὶ λαμπυρίς" [Greek: hē pyrolampomenē tais nyxi lampyris, "the firefly that shines with fire in the nights"], "shining by night," might perhaps better be called λαμπρουρίς [Greek: lamprouris, "bright-tail"] or πυγολαμπίς [Greek: pygolampis, "rump-shiner"], because its hindmost part — that is, its uropygium [tail-end] — shines perpetually by night. Concerning their generation there is doubt, and much dispute and contention among the natural philosophers; and since I have been an inquisitive observer of a great number of captured animals of this kind, I shall set out in a few words what I have learned.

[Margin: Description of the firefly.]

The λαμπυρίς [Greek: lampyris, firefly], *nitedula*, or *cicindela* is a beetle-winged worm whose hindmost part, or uropygium, emits a most brilliant flame; its wing is black, its belly of a reddish warmth [color], and its body consists of a ringed expanse marked with alternating black-and-white circles. About its original generation the question is raised. Most people think, on the testimony of [Giambattista della] Porta, that besides mating it is also born from dew.

[Margin: The generation of the firefly.]

We do indeed admit their propagation by mating — yet in the same manner that we set out above for cicadas, locusts, and beetles. But we also assert that this creature is born spontaneously from rotten wood or from a plant already infected with the seed-stock. For you will scarcely find rotten wood in the fields on which, at the season when they are wont to be born, fireflies are not seated.

[Margin: An experiment.]

For if you observe wood of this sort under a microscope [microscopium] at the right time, you will see first certain imperceptible little sacs, like eggs; when these burst, a worm comes out, which after a brief interval, having taken on wings, is transformed into a beetle-winged firefly that shines by night with intense light. And as to how it has acquired this property of nocturnal-glowing light beyond

other insects, I shall explain in a few words. It is known to everyone that rotten wood has this peculiar property above all: that by night it shines no differently than a flame.

[Margin: The origin of light in the firefly.]

Since, then, the firefly arises directly from rotten wood, it comes about that it derives that native light of the wood, together with the seed-stock, in part into itself. And this I take to be the explanation of the light in the firefly: that, just as it is intrinsic and innate to the little creature no less than to rotten wood, so too it is not extinguished when water is poured over it — as we have often proved — namely on account of the thin and dull heat in the viscous moisture, which the moisture does not easily overcome. This is also evident in certain fish, as in acorn-shells [balani], that is, date-shells [dactyli], in putrefied crabs, and the like, whose luminous humor emits in the dark a light, innate to them, that is quite intense. But the firefly's light is not diffused through the whole body; rather it is gathered in the outermost part of the uropygium, which by day shows a white spot. See, reader, what we have treated at length concerning the firefly's light in Book One of the *Great Art of Light and Shadow* [Ars Magna Lucis et Umbrae], where you will find set out whatever can be desired about this subject; and below we shall add a few things suited to this argument.

Caput VI.

On the insects which are indeed deprived of wings, yet equipped with many feet [De Insectis, quae alis quidem destituta, multis tamen pedibus instructa sunt].

These insects are called by the Greeks ἄπτερα πολύποδα [Greek: aptera polypoda, "wingless many-footed (creatures)"]: deprived of wings indeed, but furnished with a manifold variety of feet — of which kind are ants, scorpions, spiders, fleas, lice, bedbugs, and innumerable similar creatures, whose origin we now undertake to investigate. And let me begin with the ants.

[Margin: Description of the ant.]

The ant [Formica] is an animal known to everyone — diligent, industrious, and unwearied in labor — whose dogged and tireless toil is such that it strikes nearly everyone with amazement.

that it should drag [its burden] — the most dutiful and busiest of all insects. For who would not marvel at such robust strength in so tiny a little creature?

[Margin: The observation of St. Jerome.]

By the labors of these creatures the holy Jerome [Divus Hieronymus], once roused in the desert, used to lament his own negligence in his divine exercises, when he saw himself surpassed even by the most worthless little animal in steadfastness for enduring toil. His words are these: "I behold," he says, "a swarm of ants along a narrow track keeping up loads almost greater than their own bodies — some were dragging certain seeds of plants with the shears of their mouths; others were carrying out earth from their pits and shutting off the channels of water with embankments; those creatures, mindful of the coming winter, lest the damp earth should turn their stores into a green shoot, were nibbling off the seeds they had brought in; in a famous funeral procession they were bearing away the bodies of the dead; and — what is more wonderful — going forth in so great a column, one did not block another coming in, but rather, if they saw any one fall beneath its load and burden, they put their shoulders underneath and helped it. Why say more? That day afforded me a beautiful spectacle, from which, recalling Solomon, who sends [us] to the ant for its skill, and who rouses sluggish minds by such an example," and so on. Rightly and wisely!

[Margin: The author's observation.]

And I myself have more than once hung astonished in contemplation of toils of this kind, nor could I grasp how they carry bodies far larger than themselves, push them, and roll them every which way — now superior in weight, now pressed down by the mass of the weight, lower, taking up afresh the rolling of the burden with new labor; with what great effort, with the whole little body, with all their shoulders, with all their strength, they strain against the weights; and that what at one attempt they cannot do, owing to the feebleness of their strength, by serious and steadfast application again and again they at last move forward — the mass [of food], summoned by their hind feet and thighs stretched out before them, into the appointed place — so that the ant is deservedly an example to us of great labor. I have marveled not a little at the industry and foresight with which they store provisions within their granaries at the opportune time.

[Margin: The observation of Aelian.]

Aelian [Aelianus] says: "When the harvests are made, the ants, busying themselves about the threshing-floors, gather for the threshing — leaving their dwellings and accustomed roofs either singly, or in pairs, or in threes; they gather wheat or barley, and all make the same journey: some go to gather the grains, others return carrying the burden, and with the greatest courtesy and modesty

some yield the road to others — above all to those who, unencumbered, are carrying a burden. But when they go out to forage, certain larger ones lead the rest, like the generals of an army; and when they have reached the standing crops, the younger ones stand beneath the stubble, while the leaders climb up and, cutting off the ears of grain, throw them down to those below; these in turn, standing around, tear them apart and one by one unfold the grains enclosed in their husks and sheaths. They need no instrument for shaking out the grain, nor a winnowing-fan for ventilating it, nor winds for cleansing the grain from the filth in the wheat — labors which men perform; and they store up provisions for themselves, contriving them by enormous toils." And how skillfully they arrange their dwellings according to the exact rule of the architectural art, and how thoroughly they perform all the parts of the political art in the distribution of offices —

[Margin: The dwellings of the ants.]

— let him read who wishes, in Simone Maioli [Simonis Maioli], *Dies Caniculares*, Colloquy 7. But having pursued these matters at greater length than I intended, let us now return to where we digressed from.

[Margin: The origin of ants.]

Concerning the origin of ants there is great contention among the authorities. Most assert that they are born from mating — which we do not deny; but it is also most certain that they are also born from putrid matter. As to *how*, exactly — here is Rhodes, here is the leap [*hic Rhodus, hic saltus*!] We ourselves, by diligent investigation, have observed that they draw their birth partly from the urine of animals, partly from old lime infected with seed-stock taken up from elsewhere, and partly also from the corrupted sloughs of serpents. For I do not remember ever to have seen a greater abundance of them than in those places where there was a multitude of rubble, or among the standing crops, where there had been an abundance of animal dung the year before. For the urine of animals — whether of wholesome or of venomous creatures — once joined there to the earth, carries along with itself a seed-stock fit for generating ants, as is evident from the sharp pain which they inflict on people, whether by stinging or by biting. Indeed, if it is true that animals are nourished by the same things of which they consist, then certainly they must be born from the standing crops of grain (which is their ordinary nourishment, infected with various seed-stocks). But they are also so eager for toads that a toad [*bufo*] thrown into an ant-heap is wholly consumed by them within a short time —

[Margin: A toad thrown into an ant-heap is consumed by them.]

— which is said to happen also with serpents cast onto the heap. The hidden reason for this is that the ant is said to be born from the urine of a toad or from the sloughs of a serpent; whence they crave the very thing out of which they are made. Again, we have observed that from the carcass of a single ant innumerable others are born, so that the whole carcass of the ant seems to be resolved into ants —

[Margin: From the carcass of an ant others are born.]

— which happens also with beetles and other insects. But having now set out enough of these matters, let us proceed to the generation of the scorpion.

The Generation of Scorpions [Scorpionum Genesis].

[Margin: The scorpion.]

The scorpion is an eight-footed animal, with a tail of six or seven joints, from which in some there emerges one, in certain others two, stings — which are the chamber of a hidden venom, and by which it is animated to inflict a deadly wound.

Diagram. A woodcut of a scorpion, viewed from above. The body shows the two large anterior pincers (chelae) extended forward, a segmented thorax and abdomen, four pairs of walking legs splayed to the sides, and the segmented tail curving up and over the back, terminating in the sting. The single printed caption above the figure reads:

- (caption, above figure): "Scorpio." ["Scorpion."]

Some are so similar to the *pagurus* or river-crab that, if you remove the tail, they appear exactly the same.

[Margin: Nine kinds of scorpion.]

Aelian [Aelianus] recounts nine kinds of scorpion, whose origin, as it is diverse, so too they differ variously in color, size, and shape. In the northern regions they are scarcely to be found, and if they are found, they are nonetheless harmless and lacking venom; a great multitude of these is born in the Noric Alps. They are reckoned to be the more venomous the more they have been hatched under a more torrid climate. In Egypt, Africa, and the other places subject to India's torrid zone, they are utterly deadly, and scarcely anyone who has been stung by their sting easily escapes.

[Margin: Where scorpions are found at Rome.]

At Rome, in the rubble of the old buildings, and especially in the Doliolum, that is, on Monte Testaccio, a vast abundance of them is found; and although these are potent in venom, it is not so dreadful that one cannot at once remedy it — even with the body of the scorpion itself, ground up and rubbed into the wound. Concerning these matters see our fuller treatment in Book IX, *On the Origin of Venoms* [*de venenorum origine*]. But to return to our purpose: according to the varied disposition of places, varied differences of scorpions are born. In some places they are the largest, as in India; in others winged, as in Mauretania; in certain places without a tail; in most they are imbued with a red, ash-gray, dusky, green, or black color. In Egypt, Aelian relates that they are born from the seed-stock of the crocodile.

[Margin: Winged ants.]

In Mauretania huge winged ants are transformed into winged scorpions. And although it has been observed that they propagate themselves by mating, yet that they are also born from their own body I have found to be true by this experiment.

EXPERIMENT — The Generation of Scorpions [*Genesis Scorpionum*].

Store the ground-up carcasses of scorpions inside a glass; if you pour over them water steeped in basil [*ocimum*], and expose it to the summer sun for a day, then — if you inspect it with a keen and aided eye [i.e., under magnification] — you will find this whole mixture to have degenerated into an innumerable brood of scorpions. You will find the same thing happens both in a living and in a dead-but-unground [scorpion], since from the body a certain excrement is cast out which is wholly turned into scorpions like itself. I should like another to test this — for he will find it true.

[Margin: Why scorpions are born from basil.]

But why a scorpion should be said to be born from basil [*Ocimum*] above all, someone might rightly ask, since it is found to have I-know-not-what sympathy with basil. Zollerius [*Zollerus*] relates that a scorpion was found in the brain of an Italian man, born there from the excessive use and odor of basil, and Ambroise Paré [*Ambrosius Pareus*] depicted it exactly. They say too that basil, ground up and placed between two bricks, when they have been exposed to the sun for the space of 24 hours, generates scorpions — which Pliny too testifies to be true. Indeed, Aristotle [*Aristoteles*] himself, in his collection of marvelous narrations,

asserts that scorpions are hatched also from putrefied σίσυμβρια [sisymbria]. Now sisymbrium [water-mint / a kind of cress] is a certain species of basil. Again, Pliny proposes an experiment of this kind: "If you wish to summon together into one place all the scorpions lurking anywhere, you will accomplish it in this way: a handful of basil bound together with ten river-crabs you shall set down in that place, and you will have your aim."

[Margin: The artificial production of scorpions.]

Avicenna [Avicenna] writes that he had a friend who, when he wished to produce scorpions from certain putrefied pieces of wood (which I judge to have been nothing other than putrefied stalks of basil), brought them forth; moreover he relates that basil reduced to powder, worked together with the ashes of scorpions, heals the sting. All of which are manifest indications of a mutual friendship between basil and the scorpion.

[Margin: The true cause of the sympathy of basil with the scorpion.]

But how an animal of this kind can be generated from basil without a sensitive nature and seed-stock, I do not see. Therefore, when I rather anxiously inquired into this matter with Francesco Corvino [Franciscus Corvinus], a thoroughly noble botanist and a most skillful investigator of natural things, he replied that it was no wonder: for the root has, native to it, a certain worm not unlike a scorpion, which Theophrastus [Theophrastus] calls *spondylus*. For this worm, once it has infected the plant with its seed-stock, from it scorpions are at last born — partly of themselves and by their own nature, partly by art, through the application of actives to passives. And this is the true and genuine explanation of the generation of scorpions from basil. As for the fact that they are also sometimes born from river-crabs, the reason is the resemblance of the crab or *pagurus* to the scorpion, by which the former is easily turned and transformed into the latter. By what art this is to be set up, Ovid [Ovidius] teaches in the following verses:

If you take away the hollow arms [pincers] from a shore-crab, and lay the rest beneath the earth, with that part buried, a scorpion will come forth, and will threaten with its curved tail.

But let this suffice concerning the generation of scorpions. Now let us proceed to explore the origin of spiders.

On the Generation of Spiders [De Genesi Araneorum].

[Margin: Caterpillars in plants are the offspring of spiders.]

The spider [Araneus] is an eight-footed and ἄπτερον [Greek: apteron, "wingless"] animal — that is, a wingless creature — infecting [its prey] not with a sting but with the venom diffused from its mouth; and just as it is divided into innumerable species, so too the authors hold varied opinions about their origin. That spiders are procreated from animals of their own kind by mating, but that from the φαλάγγια [phalangia, "venomous spiders"] and spiders come Ἀττάλαβοι [Attalaboi, a kind of locust], locusts, and cicadas, and that caterpillars too are the offspring of spiders — this Aristotle says in *On Animals* Book 9, chapter 14 [Animal. l. 9, c. 14]. These statements are not at variance with our own observations. For the seed-stock of any other animal whatsoever, which exists in its leavings and excrements, can be sufficient to generate a spider — just as the Philosopher [Aristotle] says that the caterpillars in plants are nothing other than the offspring of spiders. But in desert places, as in houses not [inhabited]...

inhabited, in towers, gardens — indeed even in meadows, fields, subterranean caverns, and in the fruits of certain plants, and in the little pods of the mastic, terebinth, and elm, and even in oak-galls and nuts — it has become known by frequent experience that they are found born from nothing other than dusts stocked with various seed, within the earth and above the water.

[Margin: Spiders born from dusts stocked with various seeds.]

That the spider-webs are procreated from these same seedbeds stocked with various seeds, experience — as I said — establishes; so it is no wonder that everywhere, in all places, they are born by an extemporaneous birth, that is, from dusts joined to moisture. For first, within the said little chambers, there burst forth certain eggs, as it were, enclosed in little sacs; when these burst, there comes out a certain imperceptible worm, or little spider, already constituted with all its limbs, which, scarcely yet hatched out, is at once set to the work of weaving and begins to weave the most delicate threads, perceptible only to an armed [magnified] eye. Indeed I have seen from a single sac of this kind sometimes 20, 30, or even 40 offspring bursting forth, so that I could not but marvel sufficiently at the fecundity of the little creature.

[Margin: A portent observed on the leaves of sage.]

On the leaves of sage [Salvia] especially I remember having observed a natural portent of this kind, which, beset with innumerable webs together with eggs and the tiniest spiders, anyone who has a mind to observe these things under a microscope will discover. The eggs are white and so fine that they might seem to be atoms; yet when compressed — being surrounded by little sacs — they emit a

certain crackling sound; and these too, warmed by a moderate heat, at once hatch out the multitude of little spiders I have described.

[Margin: How spiders mate.]

As for what pertains to their mating, it cannot properly be called mating, since they lack generative organs; but they seem, as it were, to mate, when, joining their uropygia together one to another, they impart to one another a viscous matter, from which there first arises an itching and tickling, then a heat in the little creatures, by which the seminal force, stirred up and lurking in the viscous excrement, swells into certain little bubbles; when these at last burst, those vigorous spiders, weavers of webs, are produced. And this is the true and sole generation of spiders.

[Margin: The spider acts as an astronomer.]

If you regard the nature of this little creature, it truly surpasses all admiration — so much so that it seems to yield in cleverness and industry not even to the bees and ants. For it fulfills all the roles of a good geometer and astronomer in weaving its webs. For what else is the web it weaves than the figure of an astrolabe, in which both the vertical and the horizontal circles — which they call *azimuths* and *almucantarats* [Almicantarath], as the Figure shows — are displayed, with so great and so equal a distance of the threads from one another that it seems to have been drawn with a compass; and this not without a purpose, which it directs above all toward catching flies. For it weaves itself a net, fragile indeed, but exceedingly proportioned to sustaining its own little body —

[Margin: The spider, in the figure of the astrolabe, adapts its web.]

— while at one and the same time it plays the weaver, the astronomer, the geometer, the rope-dancer, and the hunter. With what great sagacity it weaves its nets, who does not know? — with threads taken from nowhere else but drawn out from the subtle and, as it were, imperceptible gum of its own body, hither and thither,

Diagram. An uncaptioned schematic woodcut of a spider's web, drawn as a circular orb-web in the manner of an astrolabe net. The figure shows a central hub with the spider's body at the center; from the hub, straight radial threads ("vertical circles" / radii) run outward to the rim like the spokes of a wheel; concentric, roughly polygonal cross-threads (the "horizontal circles," the *azimuths* and *almucantarats* of the text) connect the radii at regular intervals, giving the

geometric, compass-drawn appearance the text describes. No printed labels appear within or beside the figure.

drawn out from this point and that, with such tenacity of glue that it fastens and glues that [thread] to whatever object it wishes, when it comes in its way. That it also plays the tailor, who does not know? — when, the webs being broken by the agitation of the air, or by the falling of debris, or by the impact of flies, it at once repairs them with a certain admirable industry, so that no trace of the rupture appears.

[Margin: The spider acts as a geometer.]

Certainly that it fulfills all the parts of an astronomer, its net — as we said above — clearly shows; whence the astronomers have thought that the net of the astrolabe should be named from nothing other than the spider's webs [i.e., the "rete" of the astrolabe], so that I cannot sufficiently marvel at the divine wisdom in the laborious and ingenious works of this animal. For with a wondrous equality of intervals it first draws lines, as it were, from the circumference to the center, in which — as in the center of its power — it has set the seat of its authority; these it then, by the parallelism of the subtended lines, demarcates with so great an equality of distance from one another, for the firmer structure of the whole fabric, that it may seem furnished with both compass and rule.

[Margin: The spider.]

Yet [it does this] by no other means than by the application of its own body and feet, which serve it in place of compass and rule, with which it measures all the distinctions of the intervals; and while it does this, it represents a perfect rope-dancer, with the mass of its body so applied to the line of direction that it advances itself along the threads in a certain perfect equilibrium. But when it has seen an opportune place for fastening its threads to some object, it lets out from itself a greater abundance of gum, which — at once split into several filaments and, as it were, scattered by the agitation of the air — wherever they have run upon an object, are there fastened, fixed as though by glue. The spider, perceiving this, by running here and there along those [threads], completes the web already begun by weaving; and when this is finished, it prepares for itself a nest, fenced about with filaments of denser material. From this, going forth to the hunt, it stations itself in the center of the net, so that from every part of the circumference, if any fly or gnat falls into the viscous net, it may feel it by the motion of the threads drawn from the circumference to the center. And it is a pleasant thing to see that, as soon as the said animals have fallen into the gluey

mass, the spider at once, from the center, by that radius which it feels to be moving, with hasty speed at last [seizes] its prey...

[the spider], once it has caught [its prey], attacks it and does not let go until it has sucked it entirely dry. And so the nourishment that it had already used up out of its own innards in weaving its web, by this skill and industry it now replenishes for the spinning of new webs, as all that nourishment drawn from the flies degenerates back into fresh silk [viscus]. These, then, are the things I judged worth saying about the marvelous nature and reproduction of the spider.

CAPUT VII.

On the worms that are generated in animals, and chiefly in human beings.

In a marvelous way the philosophers tear themselves apart over the manifold breeding of worms that is sometimes found in human beings. Hardly any of them assigns its true and proximate cause; they are all stretched thin around the corruption of the four humors. I will set out in a few words what I myself think. It is certain from experience that in human beings earthworms [lumbrici] arise not only in the intestines, but that there is no part of a human being, whether internal or external, that does not produce worms and other animals. [Margin: Worms are produced in every part of the body, both internal and external.] To say nothing of the verminous broods that a person voids in his stool, in the brain itself there have been found — according to the observations of Schenck, Mercurialis, Paré, Cardano [Cardanus], and others — not only worms but also bedbugs [cimices], scorpions, millipedes [iuli], and so on. They have been observed in various cases in the ears, on the tongue, in the eyes, in the skull, and in the nose. [Margin: Phthiriasis.] In phthiriasis too — that is, the lousy disease — the whole substance of the body dissolves into worms; in the hands, the feet, the hips, and the private parts, ticks [ricini] now and then deposit their brood. All diseases, whether external or internal, are subject to worms. In our *Scrutinium physico-medicum de peste* we showed by various experiments that worms are generated in the blood, and that every gangrene, leprosy, scabies, elephantiasis, venereal disease, and plague is nothing other than a kind of imperceptible worm-breeding, by which the little creatures, gnawing continuously, reduce the neighboring living flesh to rottenness. Indeed, the above-cited authors confirm by various instances that worms have been found in the deepest vital organs — the stomach, liver, heart, kidneys, lungs, brain, bladder, and spleen. We have even

shown in the preceding pages that frogs, serpents, and the like have been both born within the skin and thrown up by vomiting.

[Margin: The cause of worm-generation.] Since this is so, the question arises: where does this verminous brood take its origin? I say that the cause is the food by which human beings are nourished. To make this understood, note first that a person is fed in two ways: either by the nourishment of animals, or by that of herbs and plants, or by whatever can in any way be referred back to these — such as milk products and fruits of every kind. Note secondly that animals generally take in food of a vegetable nature, infected with the various differing seeds of flies and worms; and this food, passing afterward into a human being's nourishment, carries those said seeds along with it. The food, once turned into the substance of the one nourished, wherever it meets a humor proportionate to it, is fermented there by the internal heat, and at last [Margin: Worms — and serpents — whence they come by vomiting.] expels a worm according to the quality of the seed, either like the original or degenerate. For — as we showed in the preceding section — some people have vomited up frogs and serpents, and I judge this can have happened from no other cause than that they had drawn in the spawn of frogs or serpents with their drinking water. In this way, children who are fed by the frequent use of milk (which, as has been found by experiment, teems with worms) are for the most part filled with worms and earthworms. For milk is the first chyle of animals; in milk, as in the chyle of animals, various seeds of herbs are first transmitted, and these — once taken up especially by people of more tender age and endowed with a gentle warmth — are easily quickened into worms. This also happens in adults, when they too unwisely consume the verminous brood imperceptibly lurking in herbs, or when they take as food the flesh of animals that is no longer fresh but already rancid, infected, and teeming with hidden worms. These seeds, according to the disposition of the limb to which the nourishment is distributed and according to the coagulation [systasis] of the humors, at once exert themselves and expel a worm; and this worm, depending on the malignity of the worm from which it was cut off, or depending on the property of a poison lurking in the worms, inflicts a greater or lesser, noticeable harm on the person. [Margin: The harms that worms inflict.] For some are carried off into malignant and putrid fevers, some into internal corrosions of the limbs, and some by a kind of sympathetic magnetism toward attacking now this limb, now that. Hence it comes about that those who incautiously consume the seed of cantharides [cantharidum seminium] suffer ulcerations of the bladder, pass blood, and are swollen with priapism; [Margin: The symptoms of cantharides.] and by the same reasoning, those who consume the excrement of the buprestis suffer palpitation of the heart and are afflicted with fainting

[lipothymia]; other things cause nausea, vomiting, vertigo, and dimness of sight [scotomia]; nor are there lacking those which, when their internal heat is driven to the exterior, induce mortification [sphacelus], gangrene, and similar symptoms. We may therefore infer from this that there is scarcely any disease of a malignant and putrid nature that does not draw its origin from these. See *Liber X, De Venenorum origine*, where we have pursued these matters more fully.

Having set out these matters in general, let us now explain the generation of lice, fleas, and bedbugs. [Margin: The louse [φθεῖρ] of the Greeks, and its origin.] The question, then, is first asked: where do lice arise in human beings? I say in a few words: not from human flesh, nor from corrupted blood, nor from putrefaction. Not from human flesh, as —

— as Aristotle [Aristoteles] held, because it would follow that all men — the highest, the middling, the lowest — always generate lice from their own flesh; yet we do not see this happen. Rather, we observe that lice are generated only by those who, oppressed by poverty, collect much filth on their bodies, or who use coarse, foul, and contaminated nourishment, such as the poor; and by those who sweat a great deal without any change of clothing, such as farmers and soldiers — in the same way we said happens in the other insects. Daily experience teaches us about the nits of fleas, so that I marvel all the more at Aristotle, who in *Historia animalium* V.31 [printed "l. 5. hist. c. 31"] says that fleas are indeed generated from the coupling of both sexes, but produce something from which nothing further can be born. "From lice," he says, "are bred the maggots of flies; the flea is a kind of maggot resembling the form of an egg, from which neither the things that generated them come forth, nor any other animal, but only nits."

[Margin: From eggs lice are produced. Aristotle's experience teaches.] Nor can lice be said to be born from corrupted blood, since experience establishes that the sick and those lying ill with malignant fevers, who were previously burdened with a verminous louse-brood, are at once freed from it — as the hospitals teach by experience. I say, then, that lice are born from the seminal spirits lurking in the food; for it is established that from a human being, as from the other animals, animal spirits breathe out, [Margin: The true origin of lice.] and these — sensitive [spirits] — produce them through the continuous transpiration of the bodies. While these spirits exhale in this manner, it is certain that they carry off with them some coarser and filthier parts as well. If, then, it happens that those coarser impurities, driven together by sweat, cling between the flesh and the skin, or to the hairs — such impurities, being something cut off from the animal, are likewise by their own nature suited to receive again those animal spirits as they breathe out from the body. And in this way the power lurking in the spirits

forms — according to the coarseness or fineness of the matter — either a louse [Margin: The generation of fleas and bedbugs.] from foul phlegm, or a flea from a finer little portion of putrescent blood drawn from the capillary veins turned into sweat, or a bedbug — which the Greeks call κόρις [Greek: kóris, "bug"] — which it produces by the exhalation of that same coarser, contaminated blood that is mixed with the phlegm.

But because the frequent eating of figs is commonly said to generate lice, [Margin: Why the frequent eating of figs generates lice.] this is not to be understood as though it produced them immediately and from its own nature, but in the same way we said happens in the other insects. Daily experience teaches us about the nits of fleas. They also propagate themselves by coupling, in this way: at first they are white, but scarcely hatched, they are soon clothed in a black covering — and the same must be said of lice and bedbugs. A louse, therefore, is born by the agency of putrescent phlegm, in which the power of the seed of the animal spirits resides; [Margin:... the microscope teaches.] the microscope teaches this, for when inspected it appears wholly transparent, like the white of an egg, with a dark spot conceived in the middle, which occupies the place of a heart; and eggs too appear heaped up around the hinder parts. The flea is sustained by the blood by which it is nourished, which it sucks out by piercing and boring through the skin with its proboscis until the swelling of its little body — exhibiting in a tiny frame the perfect form of a locust, except that it lacks wings; in other respects it has the same leap. [Margin: The chained flea.] I have sometimes seen a flea fastened to a little chain, which the craftsman had scarcely set, starving, upon his hand, when behold — with its proboscis driven in — it swelled up astonishingly with a most greedy suck of blood, and so, glutted, it was put back inside its little box: a troublesome pest indeed, scarcely granting rest day or night.

The bedbug, κόρις to the Greeks, is foul and abominable in both form and stench. [Margin: The origin of the bedbug.] It mostly gains its nest in the cots of beds and in their cracks and crannies, and in the holes of walls near the beds; and bedbugs arise from human filth, as we said above, and from the exhalation of corrupted blood mixed with vicious phlegm — which is easily indicated by the abominable stench they give off, which smells of I know not what carrion, a foul reek not unlike that of fetid asafoetida. But lest it stir up further nausea in us by its abominable stench, let us leave these things and pass on to others.

CAPUT VIII.

An experimental recapitulation of what has been said.

There are in the nature of things certain spirituous little bodies which, in the dissolution of bodies, are separated from other parts that are not homogeneous, that is, not of the same nature. Some of these are mineral, others vegetable, others sensitive [sensitiva], so that — united with matter — they constitute the one a vegetable thing, the others a sensitive thing. These were implanted in the primordial chaotic mass, by the wondrous wisdom of the Divine Architect, through the power of the spirit brooding above the moisture. For whenever these vegetable spirits, together with —

— a proportionate matter, are united, at once a living thing arises; and whenever the animal spirits are united with a disposed matter, then some animal must come forth. Yet not just any conjunction of these spirits suffices for generating either a vegetable or an animal; rather, by their very selves and their own nature they require that such-and-such spirits be joined, in such great quantity and in such a manner. [Margin: How animals are generated from seminal spirits.] For when some living thing or animal is dissolved, this happens: those spirits which, joined with that fixed [body], formed such a living thing, are separated and fly away once the moisture has been thinned out — but they do not fly away conjoined. Let me explain myself: when a horse is corrupted, the soul of the horse or of the dog cannot be said to fly away; rather, the seminal spirits, torn apart, fly off and are scattered and dispersed this way and that. Hence it comes about that this single mass of spirits is never again joined with that same or a similar mass; but those spirits, in which some portion of seminal power still lurks, are swiftly mingled with the air and combined with others. If, then, it happens that these are joined, in such a quantity, with some proportionate fixed [body], such that from those spirits and from that fixed [body] an animal can be constituted, at once — by the plastic power [virtus plastica] which is both in the spirits and in the fixed [body] itself (that is, in the matter informed congruously to those spirits) — that body is organized and formed, and an animal arises: degenerate from the first seed (whence the spermatic spirits had been cut off) and of another species. And in this way are generated all those animals that are said to draw their origin from putrefaction. For the spirits, separated from some animal substance that has been broken down and dissolved, fly through the air, and are carried back again by clouds, rains, winds, and the like to plants and trees, and are forced into the pores of the earth. From there, according to the quality of the substrates, new seeds of an animal economy are sown — since the plastic force of the seed, hidden in the

spirits, forms that matter with the aid of moisture, and at once a frog, a fly, a locust, or a similar insect is born. But the smaller the supply of such spirits dispersed throughout all things, the more imperfect must be the plants, as well as the animals, that are born. To make all this clearer, I have thought it best to unravel it through a series of questions.

[Margin: How worms fall together with rain.] It is asked, then, first: how is it that little animals are seen to fall down together with the rain? I answer that there are in the air and the clouds the exhalations of all things, and the seeds of all mixtures, and consequently very many animal exhalations; and these, when dissolved, if they are joined with some congruous and proportionate matter — by the plastic power existing within them — will soon form animals according to the proportion of the seed cut off from the exhalations and raised into the air out of the dissolved bodies of animals and plants, whether living or dead. And this is the reason why rainwater so readily generates worms, whereas springwater does not: because rainwater swells with the spirits of the seeds, which springwater lacks. [Margin: The extemporaneous origin of frogs.] And this is plain from frogs, which sometimes arise by a spontaneous birth together with the dewy rain — not because they are hatched in the air, but because the water, made pregnant by the spawn βατραχογόνον [Greek: batrachogónon, "frog-producing"], that is, by the frog-making [substance], drawn up through exhalations together with the dust of marshy mud, as soon as it falls upon the warm dust, the plastic force there at once forms a little frog. And although I have often observed these little animals in various places, I have never been able to perceive them, as the common crowd supposes, falling already in perfect form from the clouds. Hence the marvelous power of the seed is plain, which, when the matter is already disposed, in so brief a span of time expels animals of this kind. So the dispute of certain natural philosophers about the generation of the frog is frivolous, when they wrongly suppose that frogs are produced by I-know-not-what vague or immediate concurrence of GOD, since by the proximate reasons and causes of the seeds the said generation can be explained with almost no difficulty. But that what we have said may be seen to be true, we shall establish it by experiment.

EXPERIMENTUM

Βατραχογένεσις [Greek: Batrachogenesis, "frog-generation"], The origin of frogs.

When frogs, having shed their abundant spawn at the beginning of March, fill all the ditches, it happens that, once the ditches dry out, the mud is again dissolved into dust together with the frogs already hatched from it. If, then, you have a mind to produce a new generation of frogs, proceed thus: Take the dust of

marshy mud, or of ditches where you know frogs have nested; soak it with rainwater and set it out in an earthen vessel under a moderately warm sun in the morning during summertime, and sprinkle it repeatedly with the said water, lest the matter be dried out by the sun. You will find first certain little bubbles, out of which first come white little frogs without hind feet, equipped only with their two front limbs, which are called *graminulae*; then, gradually divided into two hind feet by way of the tail, they will rise up into perfect frogs in enormous quantity — which I remember to have exhibited before many spectators, not without their wonder, and I would wish everyone to verify it. These things clearly teach that there lurks in the said mud that seed which, when joined with moisture and aided by concurrent heat, at last, according to the proportion of the seed, expels new frogs.

[Margin: Question 2. How serpents are generated.] It is asked, secondly: how are serpents and reptiles generated? I answer that serpents are generated in exactly the same way as the rest of the insects — namely, from the seed of serpentine cadavers. Many wonder why, after great floods, immediately a vast multitude of serpents sprouts again throughout the fields and lands. The cause is none other than that serpents nesting in the lairs of the mountains, driven out by the deluges of waters, are rolled down together with the water onto the plain below; there, lightly buried in mud and gravel, and with the heat afterward brooding over them, out of the seed-bed of their own cadavers —

— they are restored to a fresh stock. For just as even the smallest part of a serpent consists of seminal power, so too from that same part a serpent can be born — no one can doubt it — so that from a single serpent a thousand others can be generated. [Margin: From the cadaver of a serpent new ones arise.] To make this still more luminously clear, the following experiment will teach it.

EXPERIMENTUM

Ὀφιογενετικόν [Greek: Ophiogenetikón, "serpent-producing"], the production of serpents.

Take whatever serpents you wish; first roast them and then cut them into the finest pieces. Commit these pieces to oozy earth, which you will irrigate again and again with rainwater through a vessel made in the form of a sieve, and in this way you will leave the irrigated earth exposed to the spring sun. Within eight days the whole mass of earth will rise up first into little worms, which then — fattened by milk mixed with water and poured over the earth — at last grow into perfect serpents, which can thereafter also propagate by coupling to infinity. The cadaver of a serpent first taught me this: when I had carefully observed one I

came upon in a field, I found it surrounded with countless little worms, of which some were small, others larger, and others again had already acquired the manifest form of a serpent. Yet it is remarkable that now and then certain species of flies were mixed in among serpentlings of this kind, which I for my part judged to come from no other source than the seed of the food that serpents are accustomed to enjoy.

It is asked, thirdly: how is it that, now and then, from cadavers and their leavings such diverse species of insects are born? I say that this comes about from the diverse seeds of the food on which they feed. For the herbs on which they feed, being filled with flies, caterpillars, and the other worms, scatter — once taken in together with the food — various seed-stocks both in the substance of the one nourished and in the excremental filth. For since some are born from flesh, from blood, and from sweat, and others from the very dilutions of the body and its excrements, it is necessary that a diversity of insects too should come from there. But let us show the matter by experiment.

EXPERIMENTUM

Μυογενετικόν [Greek: Myogenetikón, "fly-producing"], displaying a mixed offspring of insects.

If you should wish to see the effect of this matter, proceed thus: Take of the dung of horses, oxen, and asses, one part of each; commit this mixture to a rather broad shell-vessel, and irrigate it daily with a sprinkling of that water which is contaminated with the seed of various worms from the herbs on which the said animals feed, together with the flowers and calyxes [of those herbs]. Then let it be left exposed to a temperate sun, yet covered, lest it be dried out by the sun's heat. You will see arise from this mixture, at once, certain little bubbles as it were, resulting from the fermentation of the combined matter; and when these burst, in successive hours you will see come forth a reddish and hairy worm. [Margin: The medlar [Mespilus] produces various worms; the vines (Vites), gnawing through, produce Butyri and...] The medlar, various worms; the vines, gnawing, butyros and ipes; [Margin: The marvelous generation of worms.] wasps, beetles, wild bedbugs, and also worms — that is, caterpillars equipped with many feet — and similar insects of differing species, which assuredly have their origin from nowhere else than from the diverse seeds of animals: both those that lurk in the excremental parts of the foods, and those that lurk in the plants themselves. For these, mixed together and warmed by due irrigation, tempered and digested by the moderate heat of the sun, stirred by an internal motion, at last rise up, according to the laws of nature, into little creatures of this kind — such as the

principle of the diverse seed demands. But now let us give an experiment about marine insects as well.

EXPERIMENTUM

Κογχυλιογενετικόν [Greek: Konchyliogenetikón, "shellfish-producing"], practiced in Apulia and Sicily.

Not without wonder did I see this experiment, first in Sicily, near the Pharos [the lighthouse], twelve miles distant from Messina. So that they may have a multiplication of the shellfish [Conchyilia] which they call *Tellinae* [tellins], they proceed thus. They grind tellins and shellfish into minute pieces, and then, at the shore of a salt lake about sixty paces distant from the strait, they scatter the little shell-fragments — just as a farmer [scatters] his grain — and so leave them, until the water of the lake, stirred either by the force of the winds or by a subterranean swell, pours over the shore. There the little fragments, mingled together with the sand, bring forth so great a sprouting of new tellins that anyone who has not seen it could scarcely believe it. I have learned that the same happens at Taranto, but by means of stakes made of a certain wood, which, once fixed within the seafloor, at once have I-know-not-what matter clinging to them, which in time brings forth an innumerable supply of shellfish. Martini [P. Martinius] teaches in his *Atlas* [Atlas Sinensis] that a similar generation of shellfish and oysters is carried out by art in China. [Margin: Chinese.]

COROLLARIUM.

From these things it is manifestly plain that all the kinds and species of insects — if it has been established for us whence they draw their origin, or to which plant they especially cling by a certain natural sympathy — can be produced by skillful application. For there is no plant nor animal that does not produce something out of itself and its own substance, as we have shown above. For very great trees produce in their trunks the cossi [grubs], the moths, the wood-borers [teredines]; the fig, the ceraste; [Margin: Each plant produces its own animal.] the pine, the buprestis; the olive, the Rauca; the service-tree [Sorbus], a reddish and hairy worm; the medlar, various worms; the vines, gnawing, the Butyri and Ipes; the tendrils of the same [vine], the Volucra, that is, the convolvulus [coil-worm]; while wine produces the Volucella, that is, the wine-fly, the Musciliones [gnats], and the Vinulae — this is well known. The spindle-tree [Evonymus shrub] begets an ephemeral worm, which, once the leaves are consumed, soon —

Reading order used: printed pages 374 → 375 → 376 → 377, reconstructed from the printed page numbers and verified by catchwords (p.373 "moritur," → p.374

"moritur."; p.374 "motus" → p.375 "motus"; p.375 "micarum" → p.376 "micarum"; p.376 "vel" → p.377 "vel comburi").

— dies.

The cases [folliculi] of the elm, the terebinth, and the mastic tree produce the worms called *psenes* [Greek: ψήνες, psēnes — fig-wasps]; these are either caterpillars, or spiders, or something of the kind. Grass produces ticks [crotones]. Nightshade produces a green worm tinged with a saffron color. The leek produces *prasocuris* [Greek: προσοκουρίς(?) (?), the "leek-cutter"], that is, a moth [blattam]. Cabbage, lettuce, and olives of every kind produce caterpillars. The asphodel begets winged worms in the form of little flowers. The mallow produces wild bugs [cimices agrestes], as may be seen in all flowering plants. Indeed, even the most wholesome plants — rue, sage, fennel — generate altogether deadly worms. Wheat produces weevils [curculiones]. In short, it is unknown to no one that all legumes and fruits produce worms peculiar to themselves.

How worms are born inside nuts. [Margin: *Quomodo vermes intra nucleos nascantur.*] Yet one might well wonder how the seeds of these creatures, from which they are born, come to be lodged inside nuts above all, and inside the closed cases of the elm, mastic, and terebinth, when these are sealed shut. I say that this happens in the following way. When the said plants first begin to flower, then — drawn to them, or rather to the tenderer substance of the plant — various flies fly up and work their way deep within the calyxes of the flowers. Shut in there at last, and gradually fermented by the hotter sun, they are revived as if from a funeral pyre. In this same way gourds too nourish worms: if you examine their flowers more carefully, you will see within them a packed swarm of certain flies, which are then trapped by the sticky sap; and when they cannot extricate themselves, at last, as the moisture swells up, they are driven deeper into the substance of the gourd, and are the cause of those worms found within it.

And so in all cases of this kind one may behold and admire a certain marvelous **circular play of Nature** [Greek: ἀνακύκλωσις, anakyklōsin — recirculation, cyclical return]. [Margin: *Pericyclosis naturae in genesi animalium.* — The cycling of Nature in the generation of animals.] From the various excrements of animals — terrestrial, winged, or aquatic — insects of every kind arise. Greedy for this nourishment, they stream each to the herbs most suited to them. The herbs, contaminated by the seeds of the insects, pass in turn into the food of animals; and from this, through the filth they discharge, new insects of a different species are at last born; and these are restored once more to the plants from which they

had come — and this in a perennial revolution, so long as the world shall stand in this fashion.

CAPUT IX.

Why Nature willed to produce so many and so great a variety of kinds of insects.

[Body heading, p. 374: *Caput IX. Cur tot & tanta Insectorum differentia genera Natura producere voluerit.*]

The Peripatetics say that Nature produced so many insects for no other cause than the adornment of the universe. The theologians [Margin: *Theologi peccati originalis effectus asserunt.* — The theologians declare them effects of original sin] assert that they were sent upon men, and upon their descendants, because of the transgression of the first-formed man [Protoplast], since nearly all of them are found to be harmful, with few exceptions.

For our part [Margin: *Mundus carere infectis non potest.* — The world cannot do without insects], although insects of their own nature — apart from bees and silkworms — confer no benefit on man, owing to the venom with which they generally teem, and although they seem superfluous to Nature, we nonetheless say that they were produced not merely for the adornment of the universe, but also to furnish men with very great advantages and benefits. Indeed, I say that the world could not be without them save to the greatest detriment of Nature. And lest we seem to have spoken a paradox, we have decided to set out their benefits here.

[Margin: *Ratio cur natura tot insecta produci voluerit.* — The reason why Nature willed so many insects to be produced.] In the Ninth Book, on poisons, we showed at sufficient length that the Earth, Water, and Air — and whatever is composed of these mixed bodies — are subject to countless forms of putrefaction. Lest these, by their virulent power, should infect the threefold kingdom of Nature even to its final destruction, Divine Wisdom most wisely willed that diverse species of insects be produced through Nature, its handmaid; so that in the threefold kingdom of Nature, by a kind of tripartite division of offices, whatever in each individual region had been contaminated by the diffusion of a deleterious quality, these creatures should draw it into themselves — as into so many living purses — and consume it.

Hence the terrestrial insects, duly performing their office, by some unknown magnetism implanted in each, would draw to themselves whatever in the earth is

virulent, pernicious, and deadly — lest the whole mass of the earth, infected with defilements of this kind, should also infect the foods produced for man's sustenance, to the truly great harm of the human race and of the animals. In like manner those that have their birth in watery and airy chambers obtained this office from Nature: that whatever is harmful from pernicious exhalations, and has the power of infecting water and air, they should draw into themselves by magnetic attraction, and in this way, the waters and air being purged, confer health upon them.

But lest the vast and pernicious brood of insects should bring destruction upon animals and men, Nature entered upon a new plan of counsel: namely, that they should pass into the food and nourishment of birds. For since most birds sustain their life on nothing but worms, caterpillars, butterflies, beetles, locusts, flies, and the like — however venomous these may be — it was truly beautifully provided that the venom, which had been drawn from the foods by the insects, should afterward, in order to check their excessive multiplication, pass in turn into the nourishment of the other needy living creatures; and thus a new cycle of Nature [pericyclosis] was established.

[Margin: *Pericyclosis naturae in genesi infectorum*. — The cycling of Nature in the generation of insects.] For just as the excrements of animals, while living, supply a new seed-stock, so too from their own corpses they lay the foundation of a new seed-bed from the very things they had taken as food. Thus at no time shall there ever be lacking new insects arising to purge the earth, water, and air; nor, when these have multiplied, shall there be lacking to the other perfected animals the material on which they may feed. —

— [the motion] of Nature, if it were not perpetual, as it is in the elements, then through the infection of earth, water, and air all things would be thrown into utter confusion; and so too most flying creatures, together with men, would of necessity perish from want and lack of nourishment.

The **second benefit** is that most insects, even though they seem troublesome, loathsome, and grievously harmful to animals, nonetheless always have their own attendant uses and advantages. What flies, wasps, hornets, ticks, and worms do upon beasts of burden and the other animals, that same office fleas, lice, and bedbugs perform upon men: namely, by drawing out the putrid blood, lest it pollute the neighboring parts with its own foulness — and in this way man is freed from his superfluous putrefaction.

The **third benefit** is this: that there is scarcely any insect so worthless that it does not have its own use in medicine. For — to pass over the profit they yield, as regards the honey-making bees, the silkworms in the spinning of silk, and the vipers in the compounding of theriac, on which we discoursed at length in the preceding pages — surely no insect, however potent its poison, can be named that does not have manifold uses in driving off even desperate diseases.

The Use of Insects in Medicine.

[Body heading, p. 375: *Usus Insectorum in Medicina.*]

That God and Nature do nothing in vain is made known above all from the marvelous powers and properties of insects; and nothing is so slight and worthless that it does not, by the gift of the Creator's most kindly goodness, have its own use, necessary for driving off men's infirmities.

[Margin: *1. Apum utilitas.* — 1. The usefulness of bees.] And to begin with bees: who does not know how varied and manifold is the use of honey, when scarcely any medicine, plaster, or the like is compounded by the apothecaries [Seplasarii] into which honey does not enter? What is more excellent, more worthy, or more useful than the wax that the bees' honeycombs supply to us? So that, accordingly, Divine mercy has drawn from the smallest little worm a benefit so great, so universal, and so altogether necessary. To this succeeds —

[Margin: *2. Bombycum.* — 2. Of silkworms.] the **silkworm** [bombyx], which is by no means unequal to the bee in usefulness; since the gift of these creatures (in spinning for us the most precious silk) extends to clothing the very Pontiffs, Emperors, Kings, and Princes, all the way down to men of the lowest plebeian rank. By their labors the ornaments of the Church, the furnishings of the sacred vestments, and the splendor of houses both public and private grow so great that nothing magnificent and precious in men's esteem is reckoned that is not woven from silk. The cocoons too, in which they are enclosed, are held at so great a price that, among the other ingredients of which theriac is compounded, these too have been allotted their place.

But let us now proceed to describe the other uses of insects.

[Margin: *Cicadae.* — Cicadas.] **Cicadas** help open obstructed veins; they remedy the bladder, difficulty of urination, and colic afflictions. On these, see Dioscorides, Galen, and the rest.

[Margin: *Cantharides.* — Spanish flies / blister-beetles.] As for the **cantharides** [blister-beetles], who does not know what a remedy they are in hopeless and

desperate diseases? For when all other remedies have been applied with fruitless labor in malignant fevers, physicians take refuge in these as in a sacred anchor. For first reduced to a powder, then made up with suitable oils into the form of an ointment, and applied to the legs and arms, daily experience teaches how many they snatch from the jaws of death.

[Margin: *Blattæ*. — Cockroaches.] The **blatta** [cockroach], which is a species of beetle or cricket and is chiefly born in mills — the Italians call them *bargarozzi* — is a singular secret for curing infirmities of the ears, if you boil them in oil and insert them into the ears on cotton wool. Galen also says it remedies jaundice, when they are worn fastened about the neck.

[Margin: *Culices*. — Gnats.] **Gnats** [culices], besides aiding the maturing of *phlysides* [Greek: φλυκτίδων(?) [?], blisters/pustules], also serve as food for very many animals — such as bats, swallows, the green woodpecker (which they call *titinellus*), and countless others.

[Margin: *Scarabæi*. — Beetles.] I learned from an outstanding swimmer that **beetles** [scarabaei] are wonderfully effective against spasm and convulsions of the nerves; for he, whenever he was about to give a demonstration of his art, never used to trust himself to the water unless he had first anointed the sinewy parts with oil of beetles. The horns of the *Lucani* [stag-beetles], worn at the neck, are also said to have power to drive off quartan fevers. Pliny [Plinius] relates too that earth dug from a place where there has been a nest of beetles wonderfully soothes the gout. Aldrovandi [Aldrovandus] says that oil in which a beetle has been boiled remedies pain and deafness of the ears. Moreover, Pliny says that the *Helicantharus*, or the green-shading-to-golden translucent beetle, so strengthens the sight that gem-engravers used to keep it set before them, gazing at it frequently as a remedy fit for refreshing the eyes.

[Margin: *Locustæ*. — Locusts.] A **fumigation of locusts** wonderfully remedies difficulty of urination. A locust, beaten up with goat-suet and laid on in the form of a plaster, greatly helps scabies, ringworm [impetigo], and leprosy; it heals the bites of serpents. [Margin: *Experimentum de Locusta*. — An experiment concerning the locust.] It has also been found by experience that a locust placed in a cup of purer wine does not sink but floats; whereas if the wine has been spoiled by water, it sinks at once.

[Margin: *Lampyrides*. — Fireflies.] **Fireflies**, or glow-worms [cincindela], are of great use in catching fish; for if a great quantity of them, enclosed in a glass

sphere, is brought to a river by night, the fish, rushing at once to the light poured out by the glow-worms, are as if stupefied, surrounded by the net, and caught.

[Margin: *Formicæ*. — Ants.] **Ants**, especially the winged ones, are of the greatest use in medicine; for ground up with a little salt they remedy all cases of scabies, and cooked they avail against the bites of *phalangia* [venomous spiders]. The bear too heals its own ailments by the sole medicine of swallowed ants; for when it is afflicted by its accustomed malady, then it makes for the ants' —

— [the] ants' heap, thrusts out its tongue and inserts it, and when it has felt it filled with ants, it draws back the tongue caught by their stickiness and immediately devours them, and by that medicine heals itself. No hair grows any longer wherever the blood of a bat, or of a larger shrew, worked up together with ants into the form of a plaster, has been applied to the hairy part.

[Margin: *Muscæ*. — Flies.] **Flies of the napellus** [aconite-flies] — which others wrongly, on the resemblance of the Greek word *μῦς* and *μηνύς*, interpret as "mouse" [?] — are, on Galen's testimony, a specific remedy against all kinds of poisons; they are also given with great benefit against alopecia [loss of hair], leprosy, and boils.

[Margin: *Cimices*. — Bedbugs.] **Bedbugs** [*Cimices Lectularii*] are a potent remedy against the quartan fever, if they are drunk by the unwitting patient in a suitable vehicle. They remedy women's diseases, and by their smell alone restore a prolapsed womb to its place. Applied to the bite in the form of a plaster, they heal those struck by the asp; and to those who have incautiously swallowed leeches or drunk [tainted] water, they are said, mixed with vinegar, to be a remedy.

[Margin: *Scorpiones*. — Scorpions.] How great is the importance of **oil of scorpions** against the bites of serpents and the other venomous animals, no physician is ignorant. Read what Matthiolus treats of it at length, in the chapter on the scorpion [*De Scorpione*].

[Margin: *Aranei*. — Spiders.] **Spiders' webs**, laid over fresh wounds — how easily they stanch the blood, how quickly, by suppressing putrefaction, they heal — almost daily experience teaches; ground up too, and worked with oil and put into the ears, they calm pains and remove deafness. Cantharides wrapped and bound up in spiders' webs collect and dry out all venomous humor in the human body.

[Margin: *Lumbrici terrestres*. — Earthworms.] How much **earthworm oil** avails to allay the pains of any disease whatever, physicians know; indeed earthworms dried and ground to powder, worked up with oil, and applied in the form of a

plaster to the stomach, instantly kill the worms lodged in the intestines. I add that flies, born from as many different plants, are remedies for as many different kinds of diseases.

[Margin: *Limaces*. — Slugs/snails.] From **slugs** [snails] there is first made a potent cosmetic, suited to the beauty of the body; it wonderfully soothes the sharpness of pain lurking in any part of the body whatever.

[Margin: *Sanguisuga*. — Leech.] As for the **leech** [*Sanguisuga* or *Hirudo*], how much it can do in drawing out blood, nothing is better known — when, applied where there is need, it draws off harmful blood not only from the hemorrhoidal veins but from the neck, back, belly, head, and the other members; and it draws it so copiously that it sometimes bursts. I myself knew a man who had entered a pool in summertime to wash his body, and who, while he sat wholly submerged within the sand, suddenly felt himself surrounded by so great a multitude of leeches that he could not tear them from his body. Having returned home, then, while he summons the surgeon, meanwhile, the leeches being —

— [the leeches being] half torn off and continuing to suck, from the abundance of blood poured out he fell into such weakness that within three days thereafter he died, every effort to restore the blood being vain.

The **hippocampus** [seahorse] is said by Galen to be a specific remedy against *hydrophobia* [Greek: ὑδροφοβία, hydrophobian — rabies], that is, the bite of a mad dog.

I could adduce countless things here; but because you will find all these things more fully described in Galen, Hippocrates, Dioscorides, Theophrastus, Pliny, Avicenna, Rhazes [Rasis], and the other Arabs, I did not wish to dwell on them. For in adducing these matters our whole intention has been only to show that insects were created not only for the adornment of the universe, but by Divine providence for innumerable uses utterly necessary to the human race; and that there is in the nature of things no animalcule so worthless, so slight, so virulent and deadly that it does not have immense benefits attached to it — so that, just as we showed in the Book on Poisons, there is no animal so venomous that it is not the destroyer of its own poison, if at any time they should have introduced it into the human body by their bite, especially if they are either thickened into oils, or resolved into salt, or prepared in the other ways already suggested in the passage cited, duly and according to the precepts of the Chymical Art.

On the Antipathy of Insects toward certain things, and how they may be driven off, if at any time they should have grown into a vast multitude.

[Body heading, p. 376: *De Antipathia Insectorum cum certis rebus, & quomodo fugari queant, si quandoque in ingentem multitudinem excreverint.*]

Lest anything should seem to be lacking to this subject, I shall set out here in a few words by what means pernicious insects may be driven off and destroyed. They are of four kinds, which — as the histories teach — have from time to time, under unlucky influences of the heavens, grown into so vast a multitude that they have devastated whole regions, compelled men to abandon their cities and migrate elsewhere, and brought on plague. They are: first, the armies of **Locusts**; second, of **Mice**; third, of **Ants**; fourth, of **Caterpillars** [Bruchi]. To these we shall add something concerning the household worms — that is, the extermination of lice, bedbugs, and fleas.

The Extermination of Locusts.

[Body heading, p. 376: *Locustarum Exterminatio.*]

Just as Nature willed that the various and innumerable kinds of locusts be generated in different ways, so too she established diverse remedies by which we may either exterminate or drive them off — so that where there is an evil or a disease, there too is a remedy at hand. [Margin: *Fugatio Locustarum.* — The driving-off of locusts.] This plague, however, does not break out every year, but at certain seasons of a malignant airy constitution, from the malignant influx of the stars. First, then, locusts are exterminated if you burn up locusts collected in great number; for, seized by a dizziness from the smoke of their own kind, they are deprived of their wings, and while they sit motionless on the ground, they are easily —

— easily either burned, or carried off elsewhere. In this way the **Ethiopians** free themselves from this plague. Larks [Galeritae] and jackdaws [Graculi] also pursue locusts and their eggs for food; hence, where there is a multitude of these birds, that region is for the most part wont to be immune, on account of the inexplicable voracity that they exercise upon the locusts. This plague can also be removed by a multitude of men. Thus one reads that in the year 1542, when the locusts were laying waste everything in the territory of Milan, the prefect of the city, having set a reward for those who collected them, in a short time filled twelve thousand sacks — to say nothing meanwhile of the supernatural aids: through processions,

exorcisms, and the other ceremonies of the Church, by which (through the intercession of the Saints) the destruction of the locusts was removed, as the histories of the Saints teach.

[Margin: *Locustæ in bruchum conversio*. — The conversion of the locust into the caterpillar.] The same is to be determined concerning the extermination of caterpillars [bruchii]. For these animals are so like one another that either the caterpillar generates the locust, or the locust is at last converted into the caterpillar — since they are stirred up from the same seed, and differ as the perfect from the imperfect within one species. For the cicada without wings, when winged, is the caterpillar; whence they are removed by the same means as the locust.

[Margin: *Murium propulsatio*. — The repulsion of mice.] Another devastating plague is the multiplication of **mice**, which have at times increased into so vast a swarming that — when the roots of grain and plants had been gnawed away — histories relate they brought famine and pestilence upon cities, with such persistence in certain years that men were forced to abandon their cities and dwell elsewhere. Against them the one remedy is arsenic scattered through the fields, by whose mere odor they are put to flight, or else, when even the smallest particle is taken, they are made to burst. By this remedy the **Egyptians** are accustomed to fortify themselves yearly against the swarming of mice that rises up from the rot after the flooding of the Nile; whence the Venetians make a great profit from the arsenic that they bring from Carinthia [Carneolia], by selling it to the Egyptians. Several other means present themselves, but I think none better or more suitable than arsenic can be found, and it has been confirmed by my own experience that mice are so exterminated by arsenic that scarcely any more are produced, or can stay, in a place infected with arsenic.

[Margin: *Serpentium fugatio*. — The driving-off of serpents.] **Serpents** in some regions breed again so abundantly that they scarcely allow [the inhabitants] to dwell there; whence divine providence has appointed certain birds, such as ibises and storks, which at the fixed times when they [the serpents] are wont to come forth, consume them all. In this way the ibises consume all kinds of serpents born in Egypt after the flooding of the Nile; just as in Germany and the other Northern regions the storks are wont to do in springtime, when these regions abound in frogs and serpents. Art too, however, has found a remedy for this bane: with ashes of the ash-tree [Fraxinus] — with which the serpents are at variance by a natural antipathy — scattered through the houses and gardens where they nest,

they are wont to do away with them. In this way one of our colleges in Italy freed itself, on my advice, from a troublesome multitude of serpents in past years.

Now let us proceed to eliminate the annoyances of household worms, gnats, bedbugs, lice, and fleas.

[Margin: *Cimicum fugatio*. — The driving-off of bedbugs.] **Bedbugs** [Cimices], most foul little creatures: Varro says they are driven off by spelt [farro] steeped in snake-cucumber water; Didymus, by liquid pitch and the juice of the wild cucumber sprinkled on the sleeping-places. Others use squill [scilla] steeped in vinegar; likewise some would have the walls sprinkled with ox- or goat-gall mixed with vinegar. Some think they are driven off by isinglass — that is, fish-glue. The water in which lupines are steeped is also a potent remedy for driving off bedbugs. There is nothing that lice and bedbugs so greatly dread as sulphur and quicksilver, which they generally use mixed with axle-grease. Wormwood, rue, fern, lavender steeped in vinegar, and likewise broom [genista] placed under the pillow, are said to drive them off.

Against **lice**, various authors have prescribed various remedies; I think none more potent than quicksilver [hydrargyron] amalgamated with oil of stavesacre [stuphisagria] or of henbane [hyoscyamus]; for this, smeared on the seams of the garments, permits no louse to remain anywhere.

Fleas are killed first by a decoction of *melanchium* or nigella [black cumin], dwarf-elder [ebulum], rue, fleawort [psyllium], or wild cucumber, sprinkled over the floor of the bedchamber. Nothing puts fleas to flight so much as strong-smelling plants — garlic, mint, hops; horse-urine; wormwood; and the dregs of oil [amurca] too, scattered over the floor. Fresh pennyroyal [pulegium], when burned; but fleabane [pulicaria] and goat's blood gather fleas together — and countless other remedies, of which the books of the physicians are full.

[Reading order note: The PDF pages are out of sequence. Reconstructed from printed page numbers and catchwords, the reading order is printed p. 378 (PDF image 2) → p. 379 (PDF image 1) → p. 380 (PDF image 4). LIBER DUODECIMUS, Sect. III.

SECTIO III.

SECUNDUM NATURÆ REGNUM explorat.

Which is the Philosophy of Plants [Philosophia Botanica], concerning the marvelous effects that the Subterranean World produces in the generation of plants and growing things [Vegetabilium plantarumque genesi], and the wonderful art by which they may be derived from it.

PRÆFATIO.

Now that the generation of insects [entomogenesis] is complete — that is, the marvelous origin of spontaneously generated insect-animals, which hold the first and highest place in the threefold Kingdom of Nature — it remains for us to advance to the second grade of Nature's Kingdom. Here the curious reader will learn, from its effects, how astonishing and wonderful God, the Best and Greatest, has shown himself to be in its operations, through the agency of Nature, his handmaid. From these effects the reader will plainly see that Divine Wisdom has founded all things according to a certain analogy, so that there is nothing in one thing which does not, by some analogy, shine forth as similar in another. For whoever has mastered the rules of the analogical art, I am fully convinced, will find that nothing in the nature of things can lie hidden from him, so far as human ingenuity is permitted to reach — not indeed according to the inmost perfection of things, but according to the capacity proportioned to the human intellect. This shines out most of all when Art, probing more deeply into Nature's hidden paths and emulating her operations, produces so many and such marvelous effects. These are the effects I have undertaken to set out for the reader in this Section, together with a great store of the most secret experiments to be shared with him.

CAPUT I.

De mirifica seminis in Vegetantibus vi & efficacia.

(On the marvelous power and efficacy of seed in growing things.)

[Woodcut initial "I"] That a spermatic spirit [spiritus spermaticus] was implanted by God, the Best and Greatest, the Author of Nature, in the original constitution of the Chaotic mass — not only for the propagation of animals but also of plants — was shown in the preceding [discussions] from the sacred text of Genesis. For God brought forth no animal and no plant immediately, but by means of an

underlying matter, as it were drawn forth from potency into act. For the glorious God created all things at once, to this end: that, once produced, they should thereafter propagate themselves by the efficacy of their own seed, in a continuation never to fail at any time — at least as regards the state of the present age. This seed, innate in growing things, is the proximate and immediate cause of the generation and production of all things that come to be.

Now, since no plant can live without nourishment, plants draw it to themselves by a kind of twofold magnetism, as it were. The first of these is grounded in the moist, earthy [medium] already imbued with the universal seed; the second is grounded in the air. By this [second magnetism] the plant propagates the nourishment — which it has extracted from the earth through its roots, out of the grosser moisture of the soil — up through the trunk, branches, and leaves, refining it by external heat, all the way to the place destined for the seed. Again, since there is no part of a plant that does not contain within itself certain spermatic principles [rationes] proper to the plant, from this source too arise those seed-grains [seminia] of the vegetable Nature. Just as these exert their power in the various parts of plants, so too, once detached from them, they produce in spontaneously generated things differing forms. I said "detached," because seed-grains joined to plants always produce the same thing — as is clear in trees, where the buds produced from the very trunk and bark always yield the same as the whole [parent]; but the plant-parts rotted within the earth, just as they degenerate from the original vegetable seed, so too, because of the weakness of their powers, produce another bud of a more imperfect plant, which we say is born spontaneously from putrefaction. Since we have treated of these matters at length in the preceding sections, we refer the reader there. If you should ask how the universal seed

[Margin: How the universal seed is attracted.]

[Margin: The spermatic spirits — what they are.]

[continuation of Caput I, from p. 379]

is attracted: I say that this comes about by the attraction of nourishment. For as soon as moisture has been drawn in by the plant, it is at once joined to the seed proper to it (which resides in each of the plant's individual parts) and converted into a sap connatural to the plant — so that if [the moisture] is drawn in by a pear tree, a pear is what grows; if by wormwood, wormwood; if by a rose, a rose is produced; and so for the rest. This is because the nourishment in which the universal seed resides, once drawn in by the differing plants, is at once

individuated within them according to the condition of each; and from this the diversity of forms necessarily arises, together with the properties and powers owed to each one.

If you ask what those spermatic spirits are — the Architects of such great marvels as are beheld in plants — I say that it is the most subtle part of the nourishment, that primal light latent in the chaotic seed. As soon as it is individuated within plants, it at once also conveys the powers and faculties of the vegetative soul throughout its whole body, and together, by its plastic faculty, transforms the leaves into different forms according to the endowment each one's Nature requires; it arranges the flowers into their due forms, tints them with an appropriate color, and now clothes the seeds with a husk [cortex], now covers them with a follicle, now arms them with a thorny integument against all external injuries.

[Margin: The true part of the seed — what fraction it is, in regard to the whole.]

We said in the preceding [discussions] that the seed of Nature resides in all things, and that as it is drawn in by plants and individuated, it always produces ever-new plant forms according to the condition of the seed with which it is mingled. And we affirmed that this seed is nothing other than a saline–sulphureous–mercurial spirit congenital to the elements, by whose benefit, through the varied combination of the mixture, the forms of differing plants — endowed with diverse properties — are educed. And sulphur indeed is the most subtle and tenuous fiery spirit, the first principle and origin of all actions, powers, and properties in growing things. If it predominates in some vegetable compound, then that compound too will be found to be of an utterly fiery nature — as

experience teaches in pepper, ginger, cloves [caryophylli], and the like. But since this fiery sulphureous spirit cannot subsist without moisture, a Mercurial liquor must necessarily be joined to it — a portion, that is, of the radical moisture. Wherever this predominates in some plant, we conjecture that it is surely of nothing but an aerial or watery nature; and it is defined by the Spagyrist [Spagyrici] as the nourishment of all things. But since neither the fiery nor the watery spirit can hold together [on its own], some support [fulcimentum] was necessary to them, by which they might obtain a solid consistency; and this salt we call the Condensative [Condensativum] of all things, for by its aid plants acquire the solid consistency of a body.

[Margin: in the growing things, while they are stirred by heat both internal and from the surrounding air — heat which, just as [the growing things] draw their first origin from the now-individuated hylean [hylæo] nourishment, so too gradually grow coarser and pass from invisible substance to become visible. For from their grosser parts is made the body of the growing plant; from these finer parts, which persist in the coarser nourishment, are made the leaves and flowers, and from these the fruits; and from the finer parts of the fruits is made the seed. In the center of the seed lies hidden that most subtle part of [the seed], that is, of the chaotic moisture mingled with elementary moisture, which composes the whole body of growing things — from which thereafter come germination and sprouting. But if this seed is committed to the earth, it is once more dissolved by the chaotic spermatic moisture, digested and fermented through putrefaction, and so disposed toward a new germination. In this seed resides the soul of the growing thing — not indeed in the whole body except through certain ideal principles, but in the smallest little spark [scintillula] of the now-perfected seed, which by certain chemists is reckoned to be the 8200th part. And so we cannot sufficiently admire and praise the wisdom of the Creator, who was pleased to bring forth from so tiny a little body such great masses, even of the loftiest trees.]

[The two columns of p. 379 alternate between a marginal-set fine-print continuation and the main text; I have placed the fine-print continuation in a Margin bracket where it intrudes, as it is set as an extended marginal note keyed to the discussion of the seed's animating spark.]

No one, however, should suppose that we here assert the sulphureous–saline–mercurial spermatic spirit to be composed of mineral sulphur, salt, and mercury — by no means. Rather, we affirm it to be something analogous in common to salt, sulphur, and Mercury, and, as to its powers and properties, not unlike them; joined to the elements by an indissoluble bond; and also imperceptible, since the sulphur of Nature, in spagyric resolution, shines out only under the form of a fatty oil

[continuation of Caput II text, from p. 380]

[At the head of p. 380 the running text completes the sentence broken at the foot of p. 379:]...and an inflammable [oil]; Mercury under the form of a liquor; Salt shines out under the salts and ashes. Yet that these three proximate principles of things are conjoined in a single saline corpuscle by an inseparable knot is sufficiently — more than sufficiently — taught both by the fiery acidity and by the moisture (into which [the corpuscle], when stored in a cold place, resolves itself) and, finally, by the proper corpulence of the salt itself.

And although there are several differences of salt — as we showed in the Sixth Book — we have nevertheless judged that this kind of salt may conveniently be divided into two classes, so that the first class is that of *fixed salt* [sal fixum], the second that of *volatile salt* [sal volatile]. These salts are found and gathered abundantly by the Chemists both in all things and, most of all, in all species of plants: the fixed [salt] in the ashes, the volatile separated from the soot of burned vegetables — yet each one preserves the powers and properties of the growing thing from which it was extracted.

This too is most worthy of admiration: that the salt of animals is much lighter in weight than the salt of growing things, and this lighter than mineral salt. This comes about from no other cause than that mineral salt, being mixed with earthy refuse, is necessarily heavier; whereas the salt of growing things is lighter, because it has been purged of the admixture of earthy refuse — or, with the coarser earthy parts left behind in the final resolution, remains pure of all admixture. But the salt extracted from sentient creatures is the lightest of all, because, through the many purifications effected by the agency of the native heat, it at last attains to the utmost limit of its subtlety. For example: if in the composition of a vegetable salt there were four parts [pondera] of water, three of earth, two of air, and one of fire, there will be in the composition of an animal salt nearly the contrary proportions — namely, four of fire, three of air, two of water, and one of earth; whereas in mineral salt

there will be four parts of earth, three of water, two of air, and one of fire. Hence animal salt is found by the spagyric art to differ from mineral by the whole heaven [toto cælo], as follows:

	4	3	2	1
In Mineral salt	earth	water	air	fire
In Vegetable salt	water	earth	air	fire
In Animal salt	fire	air	water	earth

Although these too differ among the various species of animals and growing things — namely, according to the difference of temperaments — we shall treat of these matters in a special chapter further on.

As for the weight and degrees of the elements: even if discovering it by art may perhaps seem to the Peripatetics [Peripatetici] a thing impossible [Greek: ἀδύνατον (adynaton, "impossible")], to the Spagyrist it is not so very difficult — as many might persuade themselves. For when some vegetable compound is

burned and calcined by fire, if its weight was one pound, the ash that remains from the combustion will for the most part be about four drachms in weight; the remainder of the earth, which during the calcination was carried upward together with the other elements, cannot be of greater weight than the very earth left fixed and surviving in the ashes. Hence we can gather how much earth is in the composition of plants — since it has been found by skilled Spagyrist that, of sixteen parts, one is earth, four water, eight air, and three fire, once the distillation has been carried out. For in succulent plants we have found that water always holds the middle weight: in which, since there are two parts of air, one of earth, and one of fire, these being subtracted, four parts of water will remain. But of these matters fuller material for discussion will be given expressly further on; it suffices in this place merely to have indicated the threefold weight of the salts.

CAPUT III.

DE DIFFERENTIIS PLANTARUM.

(On the differences of plants.)

Quæ necessaria sint ad plantarum vires cognoscendas, & quomodo ex diversitate vires explorandæ.

(What things are necessary for knowing the powers of plants, and how their powers are to be investigated from their diversity.)

[Woodcut initial "D"] The genus of plants, then, is divided first into Trees, shrubs [frutices], under-shrubs [suffrutices], and herbs. Of trees, some are acorn-bearing [glandiferæ] or nut-bearing [nuciferæ], cone-bearing [coniferæ], resin-bearing [resiniferæ], or apple/fruit-bearing [pomiferæ], or berry-bearing [bacciferæ], or finally Sterile, Poisonous, evergreen, or of marvelous power. Shrubs are either greater or lesser; these are followed by the lesser under-shrubs, such as butcher's-broom [bruscus], knee-holly [ruscus], and sea-holly [eringium]. Of herbs the differences are innumerable: such as the various species of grasses [gramina] and reeds [arundines]; others are bulbous, tuberous, garland-flowered [coronariæ], flower-bearing [floriferæ], leguminous, fragrant, oleaceous; others leguminous, fragrant — [the source repeats these adjectives] — others broad-leaved [latifolia], sinewy-leaved [nervosolia], sharp-leaved [acutifolia]; and there are creeping and climbing kinds. Others are downy [tomentosæ],

thick-leaved [pinguifolia], milky [lactariæ]. Nor are there lacking umbel-bearing [umbelliferæ], corymb-bearing [corymbiferæ], head-flowered [capitatæ], apple-bearing [pomiferæ], and finally [the] miraculous. But, so that the reader may

grasp the whole in a single synopsis, we have appended here an Analytical Table of them all.

In this Table we have set out a certain universal synopsis of plants. If we wished to examine their individual further species, we would find in each of the species an incredible diversity of things — since almost nothing in a plant can be considered that does not consist of its own peculiar and differing powers. Plants have one power in the root, another in the bark, another [in] the leaves, flowers, fruit, [and] seed; another [power belongs to] the saps pressed out of them and thickened, as

ANALYTICAL TABLE [Tabula Analytica], General, setting out the form and differences of all plants

This is a single large two-leaf taxonomic table. Its left leaf (fol. 380) carries the bracketed division-labels at the far left and the beginning of each species list; its right leaf carries the continuation of each species list and a column of right-margin category words (Actions, Passions, When, Where, Situation, Disposition) keyed to the prose discussion that follows on fol. 381. The table is rendered below as a structured list: each italic division-label is followed by its complete species list (left-leaf start joined to right-leaf continuation).

A. Trees [Arbores]

- **Acorn-bearing [Glandiferæ]:** Cerrus (Turkey oak), Ilex (holm oak), Quercus (oak), esculus, fagus (beech), Phyllodrys, Robur (hardwood oak), smilax, suber (cork oak).
- **Nut-bearing [Nuciferæ]:** Amygdalus (almond), Anacardus, Avellana (hazel), Ben, Castanea (chestnut), siliqua (carob), ebenus (ebony), fraxinus (ash), Guajacum, Juglans (walnut), Myristica (nutmeg), Miricolanus [recte: Myrobalanus?][?], Pistachia (pistachio).
- **Cone-bearing, or Resin-bearing [Coniferæ, seu Resiniferæ]:** Abies (silver fir), arbor vitæ (tree of life / thuja), Caphur (camphor), Cedrus (cedar), Cupressus (cypress), Larix (larch), Lentiscus (mastic), Myrrha (myrrh), Pinus (pine), Styrax (storax), Thimiama [thus / frankincense-tree], Terebintus (terebinth), Ulmus (elm).
- **Apple/Pome-bearing [Pomiferæ]:** all the species of pomes, Arbutus, the species of Aurantia (orange), Citria (citron), and Limones (lemon), Ficus (fig), Granata or Punica (pomegranate), Musa (banana/plantain), Nuciprunus, Palma (palm), Persica (peach), Prunus (plum), Pyrus (pear), Cerasus (cherry), ebasten [sebesten], sorbus (service-tree).

- **Berry-bearing [Bacciferæ]:** Acer (maple), agallochus (aloeswood), alnus (alder), laurus (laurel), lotus, mespilus (medlar), morus (mulberry), olea (olive), platanus (plane), populus (poplar), sandalum (sandalwood), Taxus (yew), Tilia (lime).
- **Wool-bearing [Laniferæ]:** Glossipium (cotton), Malabathrum.
- **Barren [Steriles]:** Aleternus, or Physia, Salix (willow).
- **Poisonous [Venenatæ]:** Napellus arborescens (tree-monkshood), Taxus (yew), and various trees in India.
- **Wonders [Admiranda]:** trees that act against the stings of lust, such as the chaste-tree (vitex); the water-distilling tree [aqua stillans — the rain-tree]; the tree whose falling leaves at once come to life — the barnacle-tree [arbor anatifera].
- **Evergreen [Sempervivæ]:** Pinus (pine), abies (fir), Ilex (holm oak), laurus (laurel), viticella, Laurus Imperialis (imperial laurel), Juniperus (juniper), Cypressus (cypress).
- **Deciduous of leaf [Deciduæ foliis]:** all the rest are stripped of their leaves in the winter season.

B. Shrubs [Frutices]

Larger shrubs [Frutices Majores]:

- **Fertile, fruit-bearing [Fecundi, bacciferi]:** Aspalathus, berberis (barberry), Ribes (currant), capparis (caper), Cerasus marina (sea-cherry), Amomum, cardamomum (cardamom), chamelæa [chamaelea], smilax, storax, Timelea [Thymelaea], viburnum, Paliurus (Christ's-thorn), vitis (vine), Cassia.
- **Barren, without fruit [Steriles sine fructibus]:** Buxus (box), salix (willow), salicunca, Tamariscus (tamarisk), Genista (broom), Titimallus arborescens (tree-spurge), acacia, Glycyrriza (licorice), Gellistum[?] — these are woody plants furnished with a thorny stem.

Smaller shrubs, or under-shrubs [Frutices minores, seu Suffrutices]: Ruscus (butcher's-broom), Myacantha, Halimus, portulaca marina (sea-purslane), myrtillus (bilberry), genista (broom), spartum (esparto), spinosa, and innumerable others.

C. Herbs [Herbæ]

Those that go by the name of grass [Quæ graminis nomine gaudent], divided into 3 classes, of which the first contains:

1. **Grasses [Gramina]**, of which there are 25 species, whose manifold difference lies in the ear and in their other parts.
2. **Reed-like herbs [Arundinaceæ herbæ]**, such as all the kinds and species of reeds and rushes, of which some are:
 - **Of knotted stem [Caule nodoso]**, like the reeds, horsetail (equisetum), knotgrass (plygonum [polygonum]), Zinziber (ginger), Zedoaria (zedoary), Acorus (sweet-flag), Costus, Curcuma (turmeric).
 - **Of stem without knots and smooth [Caule enodi & levi]**, all the species of rushes.
3. **Edibles [Edu lia]**, and these are either:
 - **Grain-bearing [Frumentacea]**, which consist of an ear and seed, such as wheat (triticum), barley (hordeum), oats (avena), legumes (legumina), beans (fabæ), kidney-beans (phaseoli), peas (pisa), rice (oriza), and the like.
 - **Without grains [Sine granis]**, such as all the species of lettuce (lactuca), Intybus (endive), endivia, chicory (chorium [cichorium]), beet (beta), atriplex (orache), oxalis (sorrel), and those that serve for salads.
 - **Bulbous [Bulbosæ]**: the species of garlic and onion, all the species of Tulips, Narcissus, Hyacinth, and Anemone[?]; the ten species of lilies.
 - **Tuberous [Tuberosæ], they have 14 species:** Arum, Arisarum, Asphodelus (asphodel), Cyperus liliaceus, Cyclamea (cyclamen), glans Malacensis [Malacca-acorn], Nucula terrestris [earth-nut], the species of demons[?] [daemonum species 67][?], Cyclaminus, Peucedanum (hog-fennel), all the species of orchids; the S. gladioli [sword-lilies] are reckoned 69.
 - **Conspicuous in flower [Floribus conspicuæ]**: Tulips, Anemones, Hyacinths, Narcissi, Ranunculi, Doronicum, Pardalianches (leopard's-bane), Heliotropia (heliotrope), Heliocabus Peruvianus, Lychnides, Bellides (daisies), Aquilegiæ (columbine), Chrysanthemum, and innumerable others.
 - **Outstanding in scent [Odoribus eximiæ]**: satureia (savory), mentha (mint), salvia (sage), melissa (balm), betonica (betony), lilium convallium (lily-of-the-valley), Nardus (nard).
 - **Leguminous [Leguminosæ]**: those that consist of a pod and bear fruits fit to eat.

- **Pot-herbs [Holeraceæ]:** ones [olera], orache, chicory (cichoreæ), purslane (portulaca).
- **Of manifold leaf-differences [Foliorum differentiæ multiplices]:** monophyllum (one-leaved), millefolium (yarrow), and others differing in the multitude of their leaves, such as tormentilla, ruta (rue), fumaria (fumitory), Aparine (cleavers), [?]ium, and innumerable others.
- **Sinewy/veined [Nervosæ]:** bistorta (bistort), farfara (coltsfoot), Lappa (burdock), Isatis (woad), Polygonatum (Solomon's-seal), Nicosiana [Nicotiana, tobacco].
- **Sharp- and thorny-leaved [Acutifoliæ spinosæ]:** all the species of [?], ficus Indica (prickly-pear), and whatever have the power of burning and pricking.
- **Hair-like / fern-leaved [Capillares]:** lingua cervina (hart's-tongue), scolopendria, nummularia (moneywort), ruta muraria (wall-rue), and innumerable others.
- **Creeping on the ground, or propped on other plants, or climbing [Repentes in terra, seu aliis suffultæ, seu scandentes]:** [convolvul]us[?], Clematites (clematis), Saxifragia (saxifrage), cucurbita (gourd), salsa perillia [recte: salsaparilla / sarsaparilla][?], polygonum (knotgrass), Nasturtium Indicum (Indian cress / nasturtium), Aristolochia (birthwort), Hedera terrestris (ground-ivy), wall- and tree-ivy [muraria, & arborea], cuscuta (dodder), convolvulus (bindweed), Smilax, Periclymenon (honeysuckle), Lupulus[?] (hops), Chelidonium (celandine), Herniaria (rupturewort), Kerta Turca[?], Paronychia (whitlow-grass).
- **Downy, or woolly [Tomentosæ, seu lanuginosæ]:** Gossipium (cotton), Verbascum (mullein), Pilosella (mouse-ear), Gnaphalium (cudweed), Leontopodium (edelweiss / lion's-foot), Borago (borage), hyosciamus (henbane), blattaria (moth-mullein).
- **Fat-leaved, or always-living [Pinguifolia, seu sempervivæ]:** all the kinds of houseleek (sedum), Portulaca (purslane), perfoliata (thoroughwax), hyrphita[?], cotiledon, or umbilicus Veneris (navelwort).
- **Milky [Lactariæ]:** all the species of spurge (Titimalli), Esula, Latiris [Lathyris], peplus (petty spurge), chamesicæ [chamaesyce], hippoloës [hippophæes], bestalzar[?].

- **Umbel-bearing [Umbelliferæ]:** sanicula (sanicle), althæa (marshmallow), pulmonaria (lungwort), helenium (elecampane), horminum (clary), malva (mallow), Telophium, Critamum (samphire), levisticum (lovage), Angelica, Pimpinella (burnet), imperatoria (masterwort), Apium (celery), petroselinum (parsley), pastinaca (parsnip), cærifolium (chervil), cicuta (hemlock); Foeniculum (fennel), Anisum (anise), Ammi, Anethum (dill), Cuminum (cumin), Coriandrum (coriander), Menni [Meum], Daucus (carrot), Branca ursina [bear's-breech], Chelidonium majus (greater celandine).
- **Corymb-bearing [Corymbiferæ]:** Oenanthe, filipendula (dropwort), laserpitium, sesilis [seseli], siler montanum, ligusticum (lovage), ulmaria (meadowsweet), succisa (devil's-bit), Coreula[?].
- **Capitate and apple/poppy-bearing [Capitata & Pomiferæ]:** Papaver (poppy), Artemisia (mugwort), Millefolium (yarrow), Tanacetum (tansy), Matricaria (feverfew), Abrotanum (southernwood), Absynthium (wormwood), Cotula, Nigella, betula[?], Cerasus[?].
- **Dripping, or tear-yielding [Guttantes, sive Lachrymosæ]:** hyosciamus (henbane), heliocacabus, stramonium (thorn-apple), Mandragora (mandrake), scabiosa (scabious), lacca, scorzonera, Galbanum, Acacia, Oppoponax, Storax, Mastyx (mastic), Camphora (camphor), Lentiscus (mastic-tree), Myrrha (myrrh), Bdellium, [?].
- **Resin-bearing [Resiniferæ]:** all that exude balsam, pitch, resin, and gum.
- **Wonders [Admiranda]:** the sensitive plant [Herba mima — mimosa], lunaria (moonwort), a certain kind of heliotrope, hæmanthes [haemanthus], aras, Boniza.

[Right-margin category words, keyed to the prose on fol. 381 and printed down the outer edge of the right leaf:] Actions [Actiones], Passions [Passiones], When [Quando], Where [Ubi], Situation [Situs], Disposition [Habitus].

PHILOSOPHIA BOTANICA [Botanical Philosophy] — continued

[Fol. 381. Running header: "PHILOSOPHIA BOTANICA. 381".]

such as Aloe, opium, acacia, manna; another kind, which is the gum that exudes from the plants themselves, such as Galbanum, Opopanax, Sagapenum,

Euphorbium, and the like; another, the resinous gums, such as frankincense (thus), mastic, myrrh, and Bdellium; and those that have taken on a liquid natural substance, such as Balsam, terebinth-resin, cedar-resin, liquid storax, and countless others. Of the same kind too are the dry resins, such as pitch, fir-pitch, and pine-pitch. Let this suffice as far as the *substance* of plants is concerned.

There remain the various other *accidents* of plants to be examined, which we are accustomed to investigate in this way, following the series of the nine Predicaments [Praedicamenta — the Aristotelian categories], according to various rules of combination.

[Margin: Quantity of herbs (Quantitas herbarum).]

1. If we consider the **Quantity** of herbs, we shall find in each of them a differing length, breadth, and solidity in the roots, trunk, leaves, flowers, fruits, and seeds. If we consider their *duration*, we shall see that each has a different lifespan, and is allotted varying conditions of age, of rising, of ripening and of decline, and finally of gathering — since some are winter plants, some spring, some summer, and some autumn; some, in the end, come up, decline, ripen, and are gathered [at their own seasons].

[Margin: Qualities of herbs (Qualitates herbarum).]

2. If we go on to investigate the **Qualities** of the individual herbs, we shall find them so varied that one can scarcely see where to begin. For here first come the colors, odors, savors, and softness, and the like — which the philosophers call the first and second qualities, born from the tempering of the elements. To these are added the *specific* qualities, which flow from the likeness of the whole substance and are endowed with a manifold difference of powers and properties. To these in turn are added the *sympathetic* qualities, struggling wonderfully against the *antipathetic* ones. Nor shall I here pass over what pertains to *geometric figures*, which the plants display most of all in their leaves and flowers. Among these are some furnished with leaves of 3, 4, 5, 6, 7, 8, and more, which are called *Polyphylla* [many-leaved]. In the umbel-bearing and cone-bearing plants too the wonderful geometric craftsmanship of Nature is plain; in others the radiating outgrowth of the herb shines out most of all, as in the heliotropes.

Here too belongs the *characteristic signature* of plants [signatura], for there is almost nothing in the natural world that the plants do not exhibit by their leaves, flowers, fruits, or seeds. In the peony the human head shows most clearly; in the poppy a crowned head; in the toothwort (dentaria) teeth; and so with the rest — matters I have treated at fullest length in Book III of the *Ars Magnetica*, and in the

Oedipus, under "On the Egyptian Characteristic Medicine" [*de Medicina Ægyptiorum Characteristica*]. There I refer the reader.

[Margin: Relation of herbs (Relatio herbarum).]

3. In investigating the **powers** of herbs, one must pay the closest attention to the condition of each sex, and to the analogies as regards their likenesses and unlikenesses, both among themselves and as related to animals. The palm, being a plant of both sexes, so pines away that the one must necessarily perish without the other; and one robbed of its spouse has been observed to grow barren as a widow. Indeed, the male's flowers, plucked from the trunk and set about the head of its beloved, not only gladden the loving tree with this pledge of love, but also make it fruitful with abundant offspring.

[Margin: Actions (Actiones).]

4. To the **Actions** of plants are referred chiefly those herbs that are at variance with one another in strife and friendship — as the cabbage with the vine, the fern with the reed, and countless others. From these, marvelous and scarcely credible things can be done by art, as we shall disclose in what follows.

[Margin: Passions (Passiones).]

5. The **Passions** of plants concern chiefly the modes of gathering, drying, and storing plants; and besides this, their violent degeneration, the diseases inflicted by insects, their long or short life — and, in short, whatever pertains to the cultivation of plants, as will be seen later.

[Margin: When (Quando).]

6. By **When** [Quando], we investigate the duration of plants, asking when they ought to be gathered at the right time. For plants are more effective and better when gathered in this or that month — not only as regards the whole substance of the plant, but as regards the roots, flowers, fruits, and seeds. Some too are short-lived, others long-lived; and all these things furnish us with great indications for medical use.

[Margin: Where (Ubi).]

7. **Where** [Ubi] considers the place of plants. For some are woodland, some garden plants; some love the mountains, others the valleys and the plains; certain ones delight in waters, springs, lakes, rivers, and the sea; others seek a rocky, others a rich soil — for "not every land bears all things." Hence, as many as are the differing intervals of climates, so many different plants must necessarily

spring up, so bound to their native soil that, if they are transplanted from one climate to another, they either perish outright or degenerate so far that they can scarcely be recognized. The reasons for this we shall give in what follows. The substance of the earth too, of differing virtue, must be considered.

[Margin: Situation (Situs).]

8. The Situation [Situs] proper to each plant is shown by its erectness, its bending, its leaning, its creeping, its climbing, and the natural position of its parts — of roots, seeds, and so on. All of these things have deep-hidden ends in physical Botany.

[Margin: Disposition (Habitus).]

9. The Disposition [Habitus] of a plant shows it to be healthy or diseased, together with its ornaments and coverings, which are observed in the stalk, leaves, and flowers.

Now, since it is a most celebrated Axiom of the Cabalists that "*there is no herb on earth to which some star in heaven does not correspond, which says to it: Grow*" — surely it is of great moment in Botany to consider this correspondence, or harmony, of the Sun, the Moon, the other planets, and the fixed stars. Hence, not without reason, the Initiates [Mystæ] of the more hidden nature have arranged every kind of plant according to the analogy of the seven planets, so that some are shown to be of Saturnine, Jovial, or Martial nature, others of Solar, Venereal, Mercurial, or Lunar nature, drawn from the nature and properties of the planets by a certain analogy. The season, too, the constitution of the air, and the quality of the earth must especially be considered, so that at last you may conclude something about the inmost powers and properties of the plant. But this inner...

[The following leaf is blank.]

[Printed page 382 — top of left column resumes mid-sentence from the previous page.]

the disposition of the earth derives its origin from the exhalations and vapors of the Subterranean World. In the same way, the outer celestial disposition draws forth that variety of plants from the earth, once it has been made ready and supplied with seeds suited to it — the variety we set out in the Synoptic Table.

Now that these matters are well understood, nothing further remains for the Initiate of Nature to do than this: relying on the help of the spagyric art, and

following the recognized prototype of Nature, to set himself to producing those astonishing growths that mortals so admire.

CAPUT IV.

On the Art of Grafting, that is, of Engrafting [De Arte Emphyteutica, seu Insititia].

Among the other ingenious accomplishments of the human mind, the grafting craft — the art of engrafting [Emphyteutica facultas, seu Insititia] — shines out especially. Following the pattern of Nature, it has found, aptly and elegantly, the way to engraft plants of different species onto the substance [hypostasis] of a single tree, in accordance with these lines of Palladius:

Beneath the bridal canopy to join glad woods, that on either side a fair offshoot may grow up; to clothe the linked grove with kindred shade, and bring the foliage to a double nobility of birth; in gentle bonds to wed the sweet saps together, and feed a joyful fruit of twofold flavor.

For just as different animals, mingled in a single coupling, bring forth something that resembles neither one entirely, so too the grafting or engrafting art — which in plants is nothing other than a kind of coupling, by which different species of plants are forced together into a single host [suppositum] — gives rise to those marvels of Nature that we sometimes observe in one and the same tree. Exactly how this comes about we shall now explain with physiological precision.

Columella enumerates the three kinds of grafting [Emphyteusis, or Insitio] handed down by the ancients, and Palladius follows him. The first is done under the bark: the cut shoot, set between the bark and the inner trunk, takes up the seminal power there. The second is done in the trunk itself: the tree is cut and split, and so receives the inserted shoots; both of these are best done in springtime. The third is done by a patch — they also call it patch-grafting [emplastratio] — because the trunk takes into a part of itself the very buds, together with a small piece of bark. This is carried out chiefly in summer. To these three we add two others, as will soon appear.

Now this coalescence of two species into one comes about only through a certain marvelous magnetism, by which two different things, drawn by a certain likeness of Nature, mutually seek one another, attract one another, and share their powers with one another. For just as we set out in the foregoing, nothing exists in the natural world that does not agree with something else by likeness or

unlikeness — or, what is the same, by attraction or repulsion, friendship or hatred, consonance or dissonance. Hence like things, by their own nature, flow together toward like for mutual nourishment, while unlike things flee one another by a certain blind discord of Nature.

Rules of the Grafting Art [*Regulæ Emphyteuticæ Artis*].

1. In the grafting art, then, you must above all attend to choosing plants that are friendly to one another — the plants you are seeking to wed in this marriage. For if things are dissimilar, or antipathetic, that of themselves and by their own nature flee from one another, then once grafted they will either perish outright or grow barren by fruitless labor. [Margin: The grafted shoots must be sympathetic.]
2. The shoots should have a certain kinship with the tree onto which they are to be grafted, such that they bud or flower at the same time as the tree. Otherwise your labor will be in vain, since the proportion of nourishment drawn will be unequal, and it will not easily coalesce given the unlike constitution of the sap. [Margin: The shoots to be grafted should flower at the same time.]
3. The right time must be chosen, for the moist nourishment does not have the same constitution at every season. Most therefore choose springtime as the time for grafting, since the sap is then vigorous in both, mild, and most fit for coalescing. Others, according to the condition of the shoots and the trees, take now spring, now summer or autumn. [Margin: Choice of time in grafting.]
4. Moreover, the shoots are not to be grafted at once, as soon as they have been cut from the trees. Rather, they should be taken as the Moon is waning, about ten days before the grafting, and laid away in a covered and well-protected vessel.
5. The coalescence should be made in the cleanest part — never in a part that is ulcerous, knobby, or twisted — once the suckers and buds round about have been cut away. Hence you should know it to be of great importance that the shoots to be grafted be cut from a well-suited place on the trees. This will be so if the buds have faced the summer quarter of the rising Sun, and if the shoots are swelling with leaves and sap; and even if they have not yet borne fruit, they should give promise of abundant fruit in the years to follow. [Margin: The place of cutting in the shoots to be grafted.]

6. Columella points out the qualities of the shoots: "When you are about to take shoots for grafting," he says, "see to it that the tree is tender and fertile and frequently branched. And as soon as the buds begin to swell, choose them from the year-old twigs that face the rising of the Sun and are sound, the thickness of the smallest finger, forked or three-forked." Palladius takes the same from Columella. Pliny adds some points; Virgil forbids grafting from the topmost tip, and it is certain that the shoots are to be sought from the shoulders of the trees that face the summer East. [Margin: The qualities of the shoots.]

[Printed page 383.]

PHILOSOPHIA BOTANICA. 383

and from a new sprout, unless they are grafted onto an old tree; for these need to be more robust.

7. You should select shoots that are pregnant — that is, swelling with the urge to germinate, the ones that give hope of budding that same year — at least two years old and certainly no slenderer than the smallest finger. The sap, moreover, lies differently in different plants and in different parts of each. In vines and figs the middle is drier, and the sap gathers in the upper part, so the shoots should be sought from there; in olives the sap is around the middle, and so the shoots there reach upward toward their tips. [Margin: The shoots of figs and vines, and their saps.]
8. The shoots that are grafted should be glossy, fertile, knotty, cut with sharp pruning-hooks from the part of the tree that faces North, smooth, pregnant with frequent buds, forked or three-forked, simple from the lowest part of the stem, the thickness of the smaller finger, and two years old. Year-old shoots indeed shoot up readily, but are barren. [Margin: The glossiness of the shoots.]
9. By Theophrastus' teaching, a cultivated tree will bear much fruit if you graft it onto wild trees of its own species, since the trunk then supplies more nourishment. This is why, before all else, they graft olives onto wild olives; for the trees join their strength, and the root, drawing more nourishment, makes the tree more fruitful. But on the other hand, if you graft a wild scion onto a cultivated tree, even though you may find a certain difference, it will never be a tree of good fruit. And although Varro may seem to have contradicted Theophrastus, the two can easily be

reconciled: Theophrastus was speaking of fruitful germination, whereas Varro was speaking of the sweetness of the fruits that comes from grafting one cultivated tree onto another cultivated one. [Margin: Cultivated trees are to be grafted onto wild ones.]

10. By Pliny's testimony, those trees coalesce most easily that have the same nature of bark, and that likewise have their flowering at the same time as their germination, and a shared society of saps. For it is a sluggish business whenever dry things resist moist, and the hardness of the bark resists soft things. [Margin: The agreement of germination.]
11. As to the grafting itself, take care that the cleft is not made at a knot, for the inhospitable hardness there rejects the newcomer. Let it be made instead in the glossiest part, and let the cleft be not much longer than three fingers, neither slanting nor letting the light through. The shoots are also grafted inverted, to this end: that the lesser height may spread out into width. They should be grafted near the ground, if the condition of the knots and trunk allows; and the reeds should stand out no more than six fingers in length. [Margin: The cleft is to be made in the shoots to be grafted.]
12. But if the apple-reeds are brought from farther off, some hold that the sap is best preserved by fixing them into a turnip, and that they may be kept between two roof-tiles beside streams or fishponds, stopped up with earth on either side; or even fixed in mud, carefully smeared over in a vessel, so that they may not feel the wind. Yet Porta says that the inverted method of carrying shoots set down by Pliny — meant to keep the tree from growing tall — he found to be false. For having tested it on a vine and on a plum, the tree reached the same height as the rest. "This method," he says, "seems to me safer: that we graft on top two- or three-year-old shoots, not old ones, taken from above; for then they spread out into width, and in this way we have made dwarf cherries and figs." [Margin: How the apple-reeds, when carried from far off, are to be preserved.]
13. Plants that are ἐλαιώδεις [Greek: elaiōdeis, "oily," of an oily nature] — that is, oily by nature — can in no way admit grafting. For farmers report that the pine cone, the cypress, the pine, and pitch-trees generally will neither tolerate nor nourish anything foreign. The proof of this is that if you anoint any plant with oil, it dies at once. And that the trees just mentioned are very fatty and oily can be shown by this: the outflow of pitch or resin refuses to mix with other substances, just as oil itself does. [Margin: Oily trees are not to be grafted.]

Among students of Agriculture the question is often raised whether it is better to sow plants in seedbeds, then graft them, and afterward transplant them into the orchard — since we read in the Ancients that a tree transplanted in this way is made milder — or whether it is wiser to graft them out in the woods and afterward transplant them into the orchard. On this point probable reasons are brought forward on both sides. But experience has shown us that it is better to sow wild plants in the orchard and, once they have grown up excellently, to graft them there, rather than to transplant ones already grafted. For when we transplant these, we often see them, as if unaccustomed to a foreign place, grow sickly, and many times wither away entirely.

14. Furthermore, if we wish grafted trees to bear fruit in the same year in which we graft them, this will be the method: graft an old shoot, especially one swelling with flowers and buds and about to bear fruit the following year, so that it may conceive in its own tree the offspring which here it shall bring forth — the very fruit it was going to bear on its own tree.
[Margin: How a grafted tree bears fruit in the year it is grafted.]

These, then, are the Rules you should apply in the happy business of grafting. So nothing remains except to demonstrate the manner of proceeding by experiments.

EXPERIMENT I.

Cleft-grafting [Emphyteuticum].

Which shows how grafting under the bark is to be done — what they also call leaf-grafting [insoliationem].

The tree you wish to graft, first cut into with a saw — carefully, and chiefly in the part that is most glossy and free of any swellings, sores, or scars. Use this precaution: do not damage the inner bark or rind. This done, drive an iron wedge — or better, a bone one — into the wound, that is, between the bark and the trunk, and gently penetrate not less than three fingers' depth, so that the bark does not break. Then take the shoots you wish to graft and, into the wound now opened, work them in as deeply as you drove the wedge — gently, so that you do not wound the bark or the pith — once the wedge is withdrawn. Fit the shoots in so that three fingers' depth is buried within the wound, while about six fingers stand out. In one tree you can graft several shoots by the said practice, provided they keep a proportionate distance from one another, so that one shoot does not, by robbing its neighbor of moisture...

384 — LIBER DUODECIMUS, SECT. III.

bring upon the rest the loss of growth. When all this is done at last, smear the whole wound and the space round about with mud, and over the mud lay moss plucked from trees, fastened so that it is not scattered by the violence of winds and rains.

EXPERIMENT II.

Which demonstrates how grafting is to be set up in the trunk of a tree.

Bind the cut trunk of the tree with rather tight cords, and split it moderately with a chisel, so that the cleft has a width of three fingers. This done, take the shoots you have selected, shaved on both sides into the shape of a wedge — but with the pith whole and uncorrupted — and, first inserting a little wedge to open the cleft, sink them in. When this wedge is withdrawn, the sides of the cut trunk return upon the wound, and the shoot will be held fast. At last smear the wound with mud and moss, exactly in the way done in the preceding cases, and you will have the work of grafting accomplished. Trunk A, wound C, the trunk from side B, the shoots to be grafted D, D.

EXPERIMENT III.

Which shows the kind of grafting they call patch-grafting [emplastratio] or budding [inoculatio].

This third kind of grafting is the most delicate. It does not suit all trees, but only those that have been allotted a moist, sappy, and strong bark or rind — such as the fig, for it swells with a milky juice and has a strong, robust bark. Proceed thus. Take shoots of any well-suited tree you please, ones that have glossy, young, and fruitful branches, and observe especially in them a bud or eye [gemma seu oculus]. Cut around it with the care that follows. Let the bud be of a leaf, that is, the wrapping of the eye [involucrum oculi].

Diagram. A small geometric figure illustrating the budding technique, in two parts side by side. *Left figure:* a square frame within which a leafy eye-wrapping (involucrum) is to be cut into a quadrangular shape. The square's corners and edges are lettered: **a** (top-left corner), **e** (top edge, center), **b** (top-right corner), **h** (left side), **c** (bottom-left corner), **d** (bottom-right corner), with **f** and **g** at the bottom (the leaf-tail of the involucrum); at the center is **I** (the bud/eye, "Oculus I"). *Right figure:* a smaller, star-like figure showing the bud detached and ready,

lettered **b** (top-left), **c** (top-right), **a** (center, the eye itself, drawn as a rounded mark), **d** (bottom-left), **e** (bottom-right).

[Text resumes:] ...efgh — into the shape of the square abcd you shall cut, with this caution, that you do not damage the eye. This done, choose the glossiest branch of any well-suited tree you please, which you shall cut with such skill that it can conveniently receive the bud or eye in the cut you have made. When this too is done, fit the patch in — with the eye unharmed, the bud inserted — so that it answers exactly to the cut both of the tree and of the bud's wrapping. Then bind the patch round with great care, lest it harm the eye...

bind it; then surround the joins and bindings with mud, yet in such a way that the bud's eye has free room to germinate. When this is done, leave the muddied patch about twenty-one days; then, the patch loosened, leave the bud — now grown together with the tree's branch — to be perfected by Nature.

Proceed another way thus: bore through the tree with an auger as far as the pith, with the wound gently inclined inward; then, all the borings drawn out, push a fruitful and moist vine or branch tightly into the hole, with this skill: that two or more buds project outside. This done, carefully smear the place with clay and moss, and you will have your aim.

COROLLARY I [CONSECTARIUM I].

In this way the apple can be grafted onto the willow and poplar; the vine onto the elm and mulberry; the almond onto the peach; and they can be grafted onto the plum. If they are united by their own buds and grafted onto the plum according to Experiment III, the flesh will be of a peach, but the kernel will taste of an almond. Again, by this art the olive is grafted onto the wild olive, the fig onto the mulberry, and the mulberry in turn onto the fig, the ash, and the chestnut. The cherry loves to be united to the laurel, plane, plum, and poplar. The garden pear seeks to be incorporated into the wild pear, the apple, the ash, the almond, the rowan, the chestnut, the medlar, and the pomegranate-apple. The walnut is grafted onto the plum, whence the fruit "walnut-plums"; the walnut again onto the peach, whence "walnut-peaches"; and the almond can be grafted onto the fig. [Margin: On which trees can be grafted onto which.]

The apple is of such wantonness that it does not refuse to prostitute itself to ten different trees — the pear, wild apples, the plum, the service-tree, the willow, the plane, the peach, the poplar, the medlar, and the chestnut. The quince-apple alone abhors the company of all the rest — so some think; yet we have found this to be false, nor does that line of the poet about the quince stand in the way: "For,

opening kindred chambers on its own branches, / it stands content to ennoble its own house."

The trees that most enjoy a friendly grafting-partnership are, first: the quince-apple, which some assert delights in grafting only with its own species. But experience has taught us otherwise; for even as we write, our farm-steward showed me a quince-apple onto which a hawthorn had been grafted, displaying on one side fruits commonly called "Lazeroli" [the azarole, fruit of *Crataegus azarolus*], and on the other side an apple-tree loaded with quinces — a truly handsome sight to behold. The medlar, in turn, rejoices in the oak and the pear; the citron-apple in the mulberry; the plum in itself and in the chestnut. For just as a magnet brought near to iron at once flows together with it, so these rightly applied, friendly and sympathetic species of trees, draw one another marvelously together. But whoever desires to know more of this sort should consult, not books, but countrymen, by whose long and frequent experience countless things of this kind first became known to us. It is our task to assign the true and genuine cause of all these things, which we hope to do in the following Inquiry [Disquisitio].

[Printed page 385.]

PHILOSOPHIA BOTANICA. 385

Diagram. An engraved plate occupying the upper part of the page, set within an open landscape. A gardener — a bearded man in a hat, jacket, and breeches — stands at center, grafting a tall, leafless scion into a thick cut tree-stump or trunk before him. To his lower left, a smaller cut stump marked **B** has shoots being set into it. At his feet to the right lies a bundle of cut rods (shoots/scions) tied together, with a billhook or pruning tool beside it. Mature leafy trees fill the background to either side. In the upper-right corner of the plate is the engraver's volume/page reference "**Tom. II. 384**" [Volume II, p. 384]. The only diagram-letter label legible is **B** (the smaller stump at lower left). [The single point-letter "B" corresponds to the "Truncus è latere B" of Experiment II; no other point-letters are inscribed on the plate.] ...repulsion, in strife and friendship, in consonant and dissonant — as we taught at length in our *Musurgia* [Kircher, *Musurgia Universalis*] — the Ancients held this should be assigned.

The innermost kernel of operations of this kind consists in the inmost bridal-chambers [thalami] of the Geocosm. For since we have already shown, in various places of this work, that all things contained within the compass of the Subterranean World draw the first beginnings of their composition from the

offspring of the Subterranean World — that is, from the saline-sulphureous-mercurial vapor and exhalation, as from the primordial seed of Nature, implanted in the chaotic mass by the most wise Architect of the World to endure forever — it now remains for us to exhibit Nature's process in producing plants, step by step, just as was set forth in the genesis of insects and the other animals. This we shall expound as briefly as may be. [Margin: All things have their nearest origin from the Subterranean World.]

No one is ignorant that the nourishment of plants is a moist substance present within the earthy matter, in whose inmost center lie hidden those three nearest principles of things: Salt, Sulphur, Mercury — clothed, as it were, in a garment, by the elements. But where that spermatic moisture differs according to the differing nature of the earthy parts, it likewise produces differing effects in the nourishment of things, once it has been converted into the substance of the things nourished. For this universal seed, as soon as it has been joined to the seed of each particular plant, is at once individuated in that same plant, and produces its various... [Margin: The elements are the nearest garment of the principles.]

Nor should the Reader persuade himself that degrees of this kind are confined and constrained, so as to admit no latitude. By no means! Rather, just as in numbers, between one whole number and another, infinite fractional numbers — which they call "minutes" — can be interposed, all of which vary essentially, so too between the first degree of hot or moist, cold or dry, and the second degree, innumerable other intermediate degrees can be set, which will perceptibly vary the constitution of the mixture. For as the Philosopher rightly says (*Metaphysics* VIII): since the species of things behave like numbers, it is easily clear that there is an inexhaustible diversity, marvelous in every kind of mixed things — just as we taught concerning the variety of colors (Book VIII) and, in the *Physiognomy*, concerning the marvelous diversity of temperaments in men. For you will scarcely find a man who is entirely like another, whether you look at his face, his voice, his gait, or finally the whole carriage of his body and the inclination of his mind. In the same way, you will scarcely find a species of plant that entirely agrees with another, since each differs either in root, or stem, branches, leaves, fruits, seeds, wood, sap — or finally in the color of its flowers and the flavor of its fruits. Whatever therefore is said of the elementary degrees, understand the same of the degrees of predominance in the saline-sulphureous-mercurial seed, from which the generations of natural things derive their composition. [Margin: The marvelous power of combination in the nature of things.]

PHILOSOPHIA BOTANICA

DISQUISITIO PHYSICA

By which this wondrous Marriage of differing Trees, arranged by Nature acting as their match-maker [Paranympa Natura], is set forth through the manifold demonstration of Experiments.

The ancients had a celebrated refrain [epiphonema] concerning this mystery of Nature:

[Greek: Ἡ φύσις τῇ φύσει τέρπεται. / ἡ φύσις τὴν φύσιν νικᾷ. / ἡ φύσις τὴν φύσιν κρατεῖ. ("Nature delights in nature; nature conquers nature; nature masters nature.")]

That is:

Nature is undone by nature. Nature conquers nature. Nature masters nature.

And rightly so. For there are some things so attuned to one another by a certain natural likeness that, the moment one is placed beside the other, they rush into mutual fellowship, embracing each other by wondrous laws of friendship.

[Margin: The sympathy and antipathy of things.] This is evident in every class of worldly bodies, but most of all in Nature's work of grafting [emphyteutica operatio]. Other things, by contrast, are so at odds in the blind discords of their natures that they can scarcely seem able to coexist — indeed, they would sooner perish than be joined one to the other. Truly remarkable is the magnetism of Nature, by which on the one side she strives to attract whatever is friendly to her, and on the other to repel by every possible means whatever is hostile. It is therefore not unfitting that the ancients held the universal working of Nature to consist in attraction and repulsion, in strife and friendship, in concord and discord — as we taught at length in our *Musurgia* [Kircher, *Musurgia Universalis*].

[Margin: All things have their origin and nearest source from the subterranean World.] Now the inmost kernel of operations of this kind lies in the innermost chambers [thalami] of the Geocosm. For since we have already shown, in various places throughout this work, that everything contained within the bounds of the subterranean World draws the first beginnings of its composition from the womb of the subterranean World — that is, from the saline-sulphureous-mercurial vapour and exhalation, as though from the firstborn seed of Nature implanted in the chaotic mass by the most wise Architect of the World, destined to endure

forever — it now remains for us to set out Nature's process in producing plants, step by step in the same way as was done in the generation of insects and other animals. This we shall expound with what brevity we can.

No one is unaware that the nourishment of plants is the moisture residing within the earthy substance, in whose inmost centre lie hidden those three proximate principles of things: Salt, Sulphur, and Mercury. [Margin: The seed of the proximate principles of things.] These are clothed, as it were, in a garment of the Elements. But since that spermatic moisture differs according to the differing nature of the earthly parts, it accordingly yields differing effects in nourishment, once converted into the substance of the things nourished. For this universal seed, as soon as it is joined to the seed of any particular plant, is at once individuated within it, and draws out differing forms according to the differing nature of the plants. These forms cannot live without nourishment, and so they too are continually preserved, by a kind of marvellous circulation [pericyclosi], from the sap and attraction of this spermatic moisture. For whatever sulphureous matter lies hidden in the moisture produces — at differing degrees of concoction — the differing species of colours (as we have shown elsewhere) in the leaves, flowers, and fruits of plants. What is mercurial yields the juices and liquids; what is saline confers, besides solid consistency, together with the rest, the odours and savours suited to the constitution of the combined plants, and enriches the plants with still further virtues, both manifest and specific — the ones they call "occult." Hence, where the sulphureous predominates, plants for the most part acquire a hot and parched temperament with sharpness; where the mercurial, a moist and airy one (for Mercury gives both); where the saline, there plants take on an earthy, dry, and coarse character.

Now just as the mixture of these things can be extended through countless intermediate degrees, so too the countless variety of plants results from nothing other than the varied combination of these saline-sulphureous-mercurial degrees. All the differences of vegetable nature arise from the excess or deficiency of the predominance or subordination of these. For if we combine the said composition of plants according to the rules of the combinatory Art [Ars combinatoria], through the four degrees most commonly used by natural philosophers, we shall find a multitude of plants beyond reckoning. [Margin: The wondrous power of combination in the nature of things.] And let not the reader persuade himself that degrees of this kind are confined and constricted, allowing no latitude — by no means. Rather, just as in numbers, between one whole number and the next, infinitely many fractions (which they call "minutiae") can be interposed, all of them essentially varying, so too between the first degree of

hot or moist, of cold or dry, and the second degree, innumerable other intermediate degrees can be set, which will perceptibly vary the constitution of the mixture. For as the Philosopher rightly says (*Metaphysics* [l. 7]), since the species of things behave like numbers, it is easily seen that there is a marvellous, inexhaustible diversity in every class of mixed things — just as we taught concerning the variety of colours in Book VIII [Lib. VIII], and in the *Physiognomia* concerning the marvellous diversity of temperaments in human beings. For you will scarcely find a person who is exactly like another, whether you regard his face, his voice, his gait, or finally the whole disposition of his body and the inclination of his mind. In just the same way, you will scarcely find a plant species that exactly matches another, since each differs in root, or stalk, branches, leaves, fruits, seeds, wood, sap, or finally in the colour of its flowers and the savour of its fruits. Therefore, whatever is said of the elementary degrees, I would have understood as applying likewise to the degrees of predominance in the saline-sulphureous-mercurial seed, from which the generations of natural things derive their composition.

But let us now return to the subject we proposed.

The work of grafting, as we said above, requires a suitable time. Here in our vineyards at Rome we usually begin the work of inoculation around the start of March, when the earth is by then gradually growing warm and the shoots of the trees are swelling with abundant moisture; budding [inoculationis], however, we begin around the start of the dog-days, when the Moon is in the last quarter of its age. But no fixed rule for this can be prescribed; it must be left partly to the constitution of the different climates and horizons, and partly to the practice and custom of the regions. Here at Rome it meets with most successful outcome [Greek: ἐμφύτευσις (emphyteusis, "implanting/grafting")] at the times mentioned. In our vineyards you will scarcely find a tree that does not display sports of this conjugal nature. A shoot grafted onto a plum is made so fruitful that within a year it triumphs with an abundant yield of fruit. Likewise a peach, grafted in a wondrous way onto plum and pear, thrives as an apple-tree whose fruits are called *Pericoccoli*. But since these matters are commonly known, I shall not dwell on them. Let us instead proceed to investigate the causes of so wonderful a marriage of nature.

[Margin: The universal seed and its power and capacity.] Since the universal chaotic seed, existing everywhere throughout the world, is wanting in no part, it comes about that, when in the art of grafting two, three, four, or even more shoots of differing plants are grafted onto the trunk of some one tree, those

shoots — once coalescence has taken place — become one thing together with the tree, and so live by one and the same nourishment drawn in. But the saline-sulphureous-mercurial nourishment thus drawn in, as soon as it encounters the manifold seed-principles [seminis rationes] in the trunk, is at once individuated according to the diversity of the seeds that lie hidden both in the tree and in the shoots grafted onto it; and by its plastic virtue [plastica virtus] it strives to produce, on one and the same trunk of the tree, branches of differing nature, and then it sets about forming differing buds into leaves, flowers, fruits, and seeds, each suited to its own kind.

Hence the bud of a citron, grafted onto a tree of golden apples [oranges], soon brings forth differing fruits on one and the same tree — specimens of which may be seen, not without the admiration of visitors, in the domestic garden of the Roman College. For the said seed of each tree, joined to the seed-principles, gives to each what is its own according to the intention of nature. [Margin: From the diverse seed-principles diverse species of things are begotten.] It is no different from the way that, from the mating of differing species of animals, there arises either a *tragelaphus* — that is, a goat-stag [hippocervus] — or a mule, or a *tigricanis* [tiger-dog], or something intermediate compounded of diverse parents; such things also emerge as monstrosities from the generation of insects, as we have sufficiently shown in the preceding [section]. For example: the spermatic nourishment described above, while it is drawn in through the roots of the tree and carried up through the fibres of the tree's trunk, as soon as it encounters a citron branch, is there joined to the seed-principles lying hidden in the citron branch or bud, and being individuated, soon by its plastic virtue produces not a golden apple but a citron fruit — just as on the branches of the orange-tree it produces not citron fruit but golden apples. Each fruit is composed of sulphur, salt, and mercury: and in the citron fruit the sulphur indeed lies hidden temperately in the rind, while in the white moist pulp something mercurial lies hidden; the sour juice lying within, whether you regard its whole savour or its sharpness, comes from the salt. But the golden apple [orange] counterfeits more burnt sulphur in its most bitter rind, mercury in its interior, and in its whole substance salt; and the spagyric Art [Ars spagyrica] teaches that it will resolve the rind into oil, and the remainder into a spirituous liquor, with the salt left behind in the *caput mortuum*. Thus from the varied composition of sulphur, mercury, and salt, by the concurrence of the elementary portions, the temperament of mixed things emanates according to the unequal degrees of their powers; and that these things hold no otherwise than as we have said, we shall make manifest by experimental demonstration.

Experimental demonstration of what has been said thus far.

Now that Nature's operation in the Art of Grafting [Ars Emphyteutica] has been set out, nothing remains but to add certain other methods, supported by which Nature's Initiate [Natura Mysta] may deservedly accomplish things that in the universal opinion may seem paradoxes and, so to speak, miracles in Botanical Philosophy. And concerning the grafting of one tree into another, enough has now been said; but how, and what admirable specimens of art, can be exhibited in fruits, flowers, and seeds — this it remains for us to teach.

The metamorphosis of fruits.

Theophrastus, in his book *On Plants*, reports the ingenuity of certain men who, by grafting pomegranate fruits onto various trees, produced differing fruits; and how this is done, we teach by the following experiment.

EXPERIMENT I.

Let shoots be bruised with an ivory mallet [?], to this end: that the bruised parts may more readily cohere with one another; then, tightly bound together, let them be grafted. And behold — coalescence having taken place — the pomegranate tree, from this new union of the compounded shoots wedded by Nature acting as match-maker, will be loaded with manifold offspring; and each of the several shoots keeps its own kind and draws and concocts its nourishment by itself. The reason is that the bruised shoots of the different trees, since they swell with the seed of the whole, when grafted into one trunk of a tree will most easily coalesce by their own saps; and from the spermatic nourishment drawn in by each, individuated according to the seed-principles of the differing shoots, they will bear differing fruits too — pomegranate-peaches [granato-perficos].

Columella, Pliny [Plinius], and Didymus, where they treat of Agriculture, in like manner prepare a vine to bear both a red and a white grape on one branch; and this is how they proceed.

EXPERIMENT II.

Let buds of differing kinds be taken, which are to be split through the middle with such care that the cleft reaches into the buds [oculos, "eyes"] without injury, however. And in this way one must join the one to the other so that they nearly touch, and the bud [oculus] precisely matches the bud by apposition. This done, let them be most tightly pressed together, and — earth having been placed in them — let them be buried whole within a squill [squilla, sea-onion], or in earth

rich with a glutinous sap, and finally let them be moistened by three or five days' watering, so long until the bud puts forth a sprout and gemmae, that is, eyes.

[Margin: To produce on one vine grapes both black and white.] And in due time, in the manner shown in the second experiment, you will obtain on a single vine both black and white grapes, to the extent intended — the portion you decided to cover with earth being as much as you proposed. In this way Leontius, a very ancient writer, used to produce figs white on one side and red on the other.

[Margin: A fig that produces white fruit on one side and red on the other.] He would lay synchronous, that is, coeval, branches or shoots of the vines [recte: of the figs?] in a trench and water them with manure heaped on; and when they had sprouted, he again bound together the eyes of each shoot into one, and after about two years, coalescence having been made, he would transplant them, and produced a fig with fruit black on one side and white on the other. For such is the difference of the fruits as is the conjunction of the differing gemmae which are planted together — yet in such a way that they only touch, and are by no means commingled or confounded.

Nor can fruits of differing colour only, but also of differing savour, be produced by the art of grafting. [Margin: Acid and sweet apples on a single tree.] Thus Porta [Giambattista della Porta] relates from the ancients that two shoots were grafted onto a golden apple [orange], one of which bore sweet fruit and the other sour; but when, the two shoots having coalesced, they wished to transplant the tree, they first cut it after the usual rustic manner — not so much by deliberate care as by chance — and when the cut had reached the place of the grafting, it came about that the tree, once it had brought forth fruit, bore each fruit sweet on one half and sour on the other.

COROLLARY.

From this it is also evident how, from the varied commingling of seeds bound together by the ingenuity of a shrewd mind and committed to the earth, a tree laden with various fruits can spring up. [Margin: A mixture of diverse seeds produces diverse fruits.] For the seed-principles, just as they operate unconfusedly, so too, the gemmae of the shoots being joined into one — in which the seminal power lies hidden — will unconfusedly produce, each one, differing fruits. For nature rejoices: like is readily joined to like by a certain friendly appetite of Nature — nature with nature, the living with the living.

It is wonderful and most worthy of consideration what Diophanes teaches about the *oleostaphylon* (which is an olive commingled with a grape), which is described as having the savour of both at once. Florentinus, in his *On the Country*

Estate [in sua villa], holds that this can be done in the manner that follows: [Margin: How an olive can be grafted onto a vine.] the vine is to be bored in its lower part near the root, and then an olive-sucker is to be grafted into it, and so drawn out beyond. And these things are so in accordance with Nature that the very trees sometimes produce similar results of their own accord; for, as we showed in the preceding, it sometimes happens that diverse seeds of fruits are carried by birds into trees, which seeds, then falling among the barks or junctions and mixed there with rains, dew, and dust, finally grow into cherries, olives, figs, nuts, peaches, and the like. [Margin: One tree sometimes by chance produces various fruits.] And thus the same thing may happen by chance in any trees whatever which Art accomplishes by grafting. In this way I myself have often observed wild figs [caprificos], cherries, mastic-shrubs [lentiscos], and like plants spring up on one and the same tree, which it is certain grew there for no other reason than the one stated.

But those who wish to imbue fruits with differing colours generally obtain this by grafting. [Margin: To imbue fruits with diverse colours.] Well known is the grafting of peach onto mulberry: for the peach-shoot gives the form of the peach-fruit, while the mulberry imparts its blood-red juice to the peach. You may see such spectacles of grafting everywhere in the Roman gardens, and nothing can be more delightful than such fruits. But this matter of producing roses of differing kinds from a single stem is also wonderful.

These corollaries arise from the fact that the said olive [?] and the savour of both — but the meaning is not as Diophanes [?] supposes: for the sense is not that an olive is set under in the vine, so that, as the vine bears grapes, this should bear olives; rather, Diophanes' intention was to produce [Greek: ἑλαῖος ἄφυλον (elaïos aphyton)] — that is, an olive that should at the same time reproduce the savour of a grape. I myself judge that this can be done better, if the gemmae of each plant, as was said in the preceding, are brought together into one, or the berries [acini] of each are fused into one. Innumerable experiments of this kind can be verified, if anyone has the leisure and time for the practice of the art prescribed here.

EXPERIMENT III.

Chromatic.

[Margin: To imbue roses with various colours.] Onto the growing heads [capitula] of Roses, having pierced the branches or stalks beneath the heads with an awl, into these holes inject the juices of various kinds of colours — not mineral but vegetable, such as those of lake [lacca], heliotrope, bramble [rubus], alkanet [anchusa]. This done, smear the holes with cow-dung and clay, and you will

obtain as many differently coloured roses — though for one year only — as the differing colours you apply.

Whoever desire that a grape be produced without seeds [vinacea] proceed thus.

EXPERIMENT IV.

From Porta and the records of other Authors.

A grape without seeds they make thus. They split lengthwise, as far as is fitting, the cutting [sarmentum] which they intend to plant, and with a tooth-pick [aurifcalpium] remove all the pith; then they lay down the cutting wrapped in moist paper. It will be more effective, however, if you set down the whole part of the cutting that is to be placed in the earth grafted into a squill: for the squill conduces both to taking root and to uniting. Others cut the fruit-bearing vines themselves, and with a tooth-pick [remove] the pith of the fruit-bearing cutting—

—as far as can be done, drawing it out from above through the cutting (which is not split, as was indicated, but left whole); and they pour in the sap of Cyrenaic juice [laser] dissolved in water, or often boiled to a thickness, and they tie the cuttings upright at the roots, so that, namely, the sap may not flow out; and then every eighth day they pour the same sap onto the cutting, until it puts forth a sprout. The same you may do with the pomegranate and the cherry, if indeed you wish the fruits of these also to be born without seeds and kernels. [Margin: The author's opinion concerning this kind of grafting.] And this is the practice of certain men who suppose that, the pith being removed, grapes and the other similar fruits can be generated without kernels. This opinion is an open imposture, since, the essential pith being removed, an essential part of the plant is destroyed, and so the whole must necessarily be destroyed; and what the juice of laser, being utterly disproportionate to generation, can give when infused into the pith, cannot be made out. I would therefore advise no one to waste his time on trifles of this kind.

But whether a medical or cathartic power can be induced by art into the fruits and flowers of plants, one might rightly doubt. I say that it can; and this is the method by which grafters proceed.

EXPERIMENT V.

To impart a medical power to plants.

[Margin: To induce a medical power into fruits.] Of the offshoot or shoot of a vine which they wish to plant, they split the lower part to the measure of three or four

fingers, and into the cleft of the very shoot they put theriacal water [aqua theriacalis]; then they plant the cleft part wrapped in paper. Those who wish to be reckoned more diligent in preparing this also pour the said water over the roots. A purgative power too they introduce into plants in the same way: into the cleft roots they put the juice of rhubarb [Reubarbarum], colocynth [Colocynthis], spurge [Tithymallus], scammony [Scammonea], the milky spurge [Cataputia mercurialis], and the like, and daily they water the earth surrounding them with the same; and in this way the alimentary moisture, imbued with the powers of the purgatives, imbues the fruit together with them. [Margin: To acquire the virtue of herbs from the soil.] Experience has taught this: that wine from a plot of ground stocked with similar herbs, or even with antimony, and the fruits of the vines — that is, the grapes and the wine drawn from them — are wont to purge wonderfully. It must be noted, however, that virtues of this kind introduced by art scarcely last beyond the course of a year, but rather, the virtue languishing with time, expires — the natural power of the plant driving it out, as illegitimate, from an improper possession — unless you repeat the artifice every year; and the same can be accomplished in the fig, peach, gourd, and the like.

Experiments on inducing Savour and Odour into fruits and flowers.

In like manner, if you wish that the Radish [Raphanus] should grow sweet, you must proceed thus. [Margin: Sweet radishes.] If you desire to have sweet radishes, [you must steep] the seeds—

[Resuming the right column of p. 388, which continues this radish recipe:] —in honey-wine [mulsum], or in the juice of raisins, or in water imbued with sugar, you should pre-macerate for two days, and, dried, commit to the earth; and you will have your aim: for the sweetening power of the sugar, drawn in together with the nourishment, is communicated to the fruits — yet it does not persist beyond a year, for the reason stated a little before.

[Margin: A leek of prodigious size.] If again you wish the Leek [Porrum] to grow to a prodigious size, do thus: if you pierce the head of the leek with a sharp reed, or with a fiery stylus, and conceal the seed of turnips or cucumbers in the hole, the head of the leek swells so much that it may seem a prodigy. [Margin: The reason.] The reason is that the cucumber-seed grafted into the leek is of itself and by its own nature most desirous of amplitude and dilation; hence it comes about that, placed into the leek, gradually swelling, while it exerts its powers, it extends along with itself the leek's moisture, with which it is mingled, to that magnitude which it is able to bear.

In like manner, that Lettuce [Lactuca] may become fragrant, one must proceed by this ingenious device.

EXPERIMENT VI.

[Margin: Fragrant lettuce.] Fragrant lettuces will spring up, if their seed be placed within a citron seed and so committed to the earth; which the same will also accomplish if the lettuce-seed be macerated for some days in fragrant water. The reason is the same as for the preceding. We read in Columella, Pliny, and others that Asparagus springs up in great abundance if the horns of wild rams, very finely bruised, be put into the furrows and watered. [Margin: Asparagus springs up from rams' horns.] If this is true, we can assign no other cause for it than that rams feed willingly on asparagus and pursue it most eagerly for food; whence it may come about that the seed-essence [seminium] of asparagus, latent in the food and raised into vapour, is found not unlike rams' horns — as I recall having often observed myself. [Margin: Asparagus presses out a ram's horn.] For if you twist asparagus, it will perfectly press out [the shape of] a ram's horn.

EXPERIMENT VII.

On Roses, from Porta.

[Margin: How to preserve flowers and fruits uncorrupted.] That Roses may be kept fresh up to a year. You will keep roses fresh in this way: Take wine and salt, as much as suffices, which pour into a pot; then fill it with the roses you wish to preserve (you must, however, gather the roses while still closed); stop the pot with a lid, and set it away in a cellar. When you wish to use them, take them out with the vessel uncovered, and expose them to the Sun or to a furnace, so that they may open; and you will have roses as beautiful and fragrant as if they had been freshly plucked. But we ourselves preserve uncorrupted not only Roses and flowers, but fruits of every kind. We prepare a round-bellied glass phial, fitted with a very long and wide neck, which we fill to the half with water, and within we place whatever flowers or fruits we please, so that they do not [touch?] one another—

Reading order used: = printed p. 389; = printed p. 390; = the engraved distillation plate (caption "Tomus 2di f. 391"); = blank verso of the plate. The pages run in natural sequence; printed page numbers and the catchword "Non" at the foot of p. 389 (matching the opening word of p. 390) confirm the order.

[Continued from the previous folio: the long-necked glass phial, with the fruits arranged] so that they do not touch one another. We then close the mouth of the

neck with a hermetic seal over a lamp-flame. By this means they will enjoy the perpetual gift of incorruption, as we demonstrate by experience in our Museum. We have likewise learned, by an experiment carried out over the course of a single year, that fresh eggs submerged in oil also remain forever uncorrupted.

Some think that roses become more fragrant if you plant garlic beside them, since those that grow languid from cold are usually quickened by heat.

[Margin: To make fruits more fragrant.] If you wish to make fruits sweeter and more fragrant, proceed as follows. The seeds or grains must be steeped for three days in mead, in ewe's milk, or in water in which you have dissolved sugar—a method the ancients held in esteem—and then set out in the sun; the fruit will take on greater sweetness. [Margin: Fragrant fruits.] If you seek fruits that are more fragrant, dissolve the seeds in oil of spikenard, in the juice or in distilled liquor of roses, [steeping them] in moss or in musk where you have moistened them a little; for once dried, you sow them. The fragrant fruits that arise will be steeped in the wonderful fragrance of that scent whose [essence] the seeds have absorbed. But if you crush the tips of the seeds, the fragrance will linger only a short time.

EXPERIMENT VIII.

To dye roses, gillyflowers [Caryophylli], or tulips in various colors in a short time.

Take as much of the richest soil as you wish, well dried in the sun until it can be reduced to the finest powder. Then set the gillyflowers, roses, or tulips, each in its proper season, into large earthenware pots filled with this soil. But take care that the soil be moistened with no water other than what follows.

[Margin: To dye the flower with color.] So, if you wish to make red flowers out of white ones, take as much finely chopped brazilwood [lignum Brasili] as will suffice, and boil it in water until a third or a fourth part is consumed; let the water turn red, and with it let the soil be moistened gradually twice a day, namely morning and evening. This must be done until the little plant begins to grow—that is, for fifteen or twenty days. If you want green flowers, take, instead of brazilwood, the ripe berries of buckthorn [spina cervina]; if yellow, the unripe berries of buckthorn; if black, oak-galls and vitriol [gallas & vitriolum]; and let these be boiled in the same water with which the soil, as already said, is watered.

But take care not to leave it out in the open at night, on account of the dew, which it readily absorbs. The flowers, however, are dyed with color not throughout, but partly with their natural color and partly with the color by which they are tinted,

so that they appear immersed in two or three colors, as one sees in "Turkish paper" [Charta Turcica, i.e. marbled paper]. And if you wish to dye them in three colors, in the morning let one part of the soil be moistened with water tinted with some color; in the evening, another part; and the next morning, again let yet another part of the soil be moistened with water tinted with some other color. Or else by another method, with this device: morning and evening let the soil be moistened with two colors, but in such a way that the place in the soil is varied—which will happen if you do not set the tinted water that was placed in the morning in the same spot in the evening, but in another. Thus the plant, together with its own color, will acquire three colors, from which many others can then be propagated. The reason for this is clear from what precedes.

But those who, in order to make red lilies, pour cinnabar [cinnabaris] within the bark should not hope for success in the operation, since cinnabar by its corrosive force destroys the lily sooner than it can imbue it with a red color. If, however, you smear it with some other, non-mineral color, the lilies will be produced of whatever color you wish.

[Margin: That apples may bear whatever image you please.]

EXPERIMENT IX.

Choose any impressed image you wish, in gypsum or in potter's clay, and—just as statuaries make the molds of a statue, which they call forms or matrices, destined for casting figures—cut it into two parts with a suitable instrument and with such care that the two can again be duly joined and fitted together. [Margin: How shapes may be induced in fruits.] Then bake the form in a potter's furnace. And when an apple, or a cucumber, or some similar swelling fruit has reached half of its growth, enclose it in these little molds and bind it firmly with strong ties, lest the clay molds, wrapped around it, be torn apart by the growth of the apple. As soon as it has filled their capacity, it will reproduce such figures of animals as you saw fit to counterfeit there in their bearing and image. This will have a place not only in shaping apples, but also in pears, quinces, peaches, citrons, pomegranates, oranges, and the rest of the kinds of fruit—but most of all in gourds.

That apples may be made sweet.

If you wish them to be made sweet, pour about the roots goat's dung dissolved in human urine, together with the lees of old wine.

That apples may be made red.

Let the tree be watered with urine, and the fruit will redden. [Margin: That apples may be made red.] Certain men, however, make the fruits of apple-trees ruddy in this way: they drive stakes into the ground, and tie to the stakes the curved branches that bear the fruit—without shaking it—and they fill ditches near the branches, or other vessels, with water, the calculation being made so that at midday the splendor of the Sun, falling into the water and sending back a warm vapor, and striking the fruit by refraction, may produce excellence of color and ruddiness. Some sow roses beneath the plants, and in this way make the fruits ruddy. But this too has been found to be false.

[Margin: There are, finally, those who think peaches and plums can be made to be born without stones, by grafting them in such a way.] [continuation:]...turned to its own juice from predominance.

They tell you: "You will procure a tender tree of two feet in height; you will split it down to the root, cut away, and with a knife scoop out the pith of each of the two parts; the separated parts you will at once bind together with a tie, and you will coat the upper part and the joins of the sides with dung, or with clay, or with wax, and protect them with moist paper; and when after a year the scar has firmly closed, you will see that everything has grown together." [Margin: That peaches and plums may be without stones.] Then you will graft into this tree shoots of willow, of chaste-tree [vitex], and of similar trees that bear no fruit, and it will bring forth fruits without stones—whether they be plums, cherries, peaches, medlars, dates, or stony cornel-berries. But these things are contrary to experience, for the reasons stated a little before.

The mulberry [Mora], however, if you wish to make it white, will attain that effect if the mulberry-tree is grafted into a white poplar, or budded onto it, and it will give white fruit; for as the poplar is most filled with sap, so it will [...] the sap of the mulberry naturally [...].

EXPERIMENT X.

Peaches, that they may grow to wondrous size.

To procure peaches of wondrous size for yourself, as well as almonds, nuts, and the like, you will take three or four kernels from those [fruits], and fit them together in such a way that they seem to constitute a single body. These, joined—and, if need be, tied—you will put into some vessel filled with earth worked with dung; you will plant and bury them, but in such a way that the vessel has a hole in its lid, through which the sprout of the kernels is forced to come out. Thus it

will come about that those kernels coalesce into a single tree, which in its season will yield and bring forth fruit of remarkable size and beauty.

There are those who put the kernels not into a vessel, but into a pipe or small tube packed with earth. But this will come to you much more easily and readily if you take care to procure those peaches that appear small and feeble; for in this way the nourishment that the weak fruits draw feebly is converted, to the great increase of the fruits, into the nutriment of the rest.

SECTIO IV.

DE ARTE STALACTICA

SIVE

DISTILLATORIA.

PRÆFATIO.

That the Art of Distillation is an imitator of Nature, which in her subterranean workshop or laboratory accomplishes all things by distillation.

If we look more deeply into the industry of operating Nature, we shall find that she carries out all things by means of distillation—not only within her subterranean womb, but also outside the earth in the sublunary Macrocosm, and even in Man himself, the Microcosm, and in the other animals. For the Geocosm has its inner laboratories and Vulcanian workshops, so filled with the panspermia of things, that whatever was said in the preceding Books up to this point seems to have drawn its origin from their sublimation. But since we have set these matters forth at various points in the course of this work, here it only remains to say in what manner the natural philosophers of keen wit—catching the scent of the hidden contrivances of Nature, which seemed to lie concealed in that manifold array of chemical vessels in her subterranean laboratories—attempted to imitate by art what they had learned from Nature their Mistress.

[Margin: The Subterranean World is nothing if not a distillatory furnace.] For they observed that manifold multitude of minerals and concreted juices, which the earth supplies to us from no other source than from the unequal sublimation of vapors—vapors which that Archeus Vulcan could produce from the pots and

cauldrons of the subterranean fire of Nature's furnace. For (as was shown at length in the first volume) the Subterranean World has its own chemical vessels: pots, cooking-pans, kettles, basins, and bellied receptacles, channels and siphons furnished with long necks, to which its small heads [capitella], alembics, cupels, and capped receptacles are applied by the wondrous ingenuity of Nature. Nor are these vessels lacking to it...

Diagram. A full-page engraved plate of distillation apparatus, captioned "Tomus 2di f. 391." [Tome 2, facing p. 391]. It comprises nine numbered distillation set-ups (n. 1 through n. 9), plus an unnumbered pair of funnels and a small head/alembic at the right. The figures illustrate the four modes of distillation named in the prose: by descent (*per descensum*), by inclination (*per inclinationem*), by ascent (*per ascensum*), and by the Sun's rays (*per radios Solis*). Reading the engraved labels:

- **Top right — n. 1:** captioned *Vas distillatorium per descensum* ("Distilling vessel by descent"). A cylindrical furnace-vessel with a retort-neck curving downward into a base; an I marks the lower receiving chamber.
- **Top center — n. 2:** captioned *Vas distillatorium per inclinationem* ("Distilling vessel by inclination"). A masonry furnace with a flaming alembic on top and a globular receiver set off to the right on a stand; a grate is shown at the firebox.
- **Top left — n. 3:** captioned *Vasa distillatoria per radios Solis* ("Distilling vessels by the Sun's rays"). A radiant sun-face at upper left directs rays onto two large globular flasks set on a slatted bench/table, with two further flasks beneath.
- **Middle left — n. 5:** captioned *Fornax balnei sicci ad aquas et olea per ascensum extrahenda opportuna* ("Furnace of a dry bath, suitable for drawing off waters and oils by ascent"). A masonry furnace with internal vessel; lettered labels at left, keyed in an adjacent legend:
 - **D.** *Vesica* ("the bladder/cucurbit")
 - **G.** *Alemb[icus]* ("Alembic")
 - **F.** *Collum* ("Neck")
 - **H.** *Refrigeratorium* ("Cooling vessel")
 - **C.** *Canalis per quem carbones ingeruntur supra locum foci* ("Channel through which coals are fed in above the hearth-place")
 - **A.** *Conisterium* ("ash-pit")
 - **nn.** *Spiracula* ("vent-holes")

- **Middle center (between n.5 and the legend) — lettered key for n. 4:** headed *OLXZ* and listing:
 - *Vas cup[ellatorium]: aqua plenum* ("Cupelling vessel: full of water")
 - **B.** *Cucurbita* ("Cucurbit")
 - **C.** *Porta per quam Lucerna imponitur* ("Door through which the lamp is set in")
 - **D.** *Lucerna quatuor elychniis [ellyphniis] instructa* ("Lamp fitted with four wicks")
 - **e.e.** *Spiracula* ("vent-holes")
 - **ff.** *Canales fumum exonerantes* ("Channels discharging the smoke")
- **Middle right — n. 4:** captioned *Vas distillatorium per ascensum* ("Distilling vessel by ascent"). A large bell-shaped furnace lettered **L, O, B, Z, A, X, e, c, C, D**; at its foot the note *Locus lucernæ* ("Place of the lamp"); at lower left, an engraved cross-potent within a circle enclosing the letter **I** — a deliberate device, not an alphabetic key.
- **Lower left — n. 7:** captioned *Fornax pro arena* ("Furnace for [a bath of] sand"). A masonry furnace with curved retort-neck; lettered **A, B, C, D, E, F, V, O, S, Q, G, H** and the key at bottom left:
 - **A.** *Cucurbita materiam distillandam continens* ("Cucurbit containing the matter to be distilled")
 - **B.** *Capitellum, Alembic* ("Small head, alembic")
 - **C.** *Rostrum* ("Beak/spout")
 - **D.** *Canalis per vas ligneum transiens* ("Channel passing through a wooden vessel")
 - **E.** *Vas aqua frigida plenum* ("Vessel full of cold water")
 - **F.** *Recipiens* ("Receiver")
 - **Q.V.** *Fornax* ("Furnace")
 - **G.** *Pyristerium* ("Fire-chamber")
 - **H.** *Conisterium* ("Ash-pit")
 - **S.O.** *Patella cineribus aut arena referta* ("Pan filled with ashes or sand")
- **Center bottom — n. 6:** captioned *Vas distillatorium per ascensum* ("Distilling vessel by ascent"). A two-bodied apparatus lettered **H, G, F, I, D**, with a key:
 - **D.** *Vesica cuprea quæ materiam distillandam continet* ("Copper bladder which contains the matter to be distilled")
 - **F.** *Collum stanno obductum* ("Neck coated with tin")
 - **G.** *Alembicum* ("Alembic")

- **H.** *Vas aqua frigida plenum* ("Vessel full of cold water")
- **Right (unnumbered):** captioned *Infundibula* ("Funnels") above two funnel/flask shapes, and *Capitellum* ("Small head") below a small head-and-spout vessel.
- **Lower center — n. 9:** captioned *Vas distillatorium per descensum igne supraposito* ("Distilling vessel by descent, with fire set above"). A flaming brazier above a globular flask.
- **Lower right — n. 8:** captioned *Vas distillator[ium] per inclinationem* ("Distilling vessel by inclination"). A boxy furnace with a retort inclined into a receiver.

[The verso of the plate is blank.]

[Reading order used: = printed p. 391 (end of the Sectio IV Praefatio + opening of Caput I)]

vessels for receiving the vapors that have been condensed in the vaulted upper chambers, once they have dissolved and settled, so that they may take them up in the form either of water or of oil — as may be seen in the drippings of caverns, some of which distill pure water, some salt, others niter, alum, or vitriol. Nor are there lacking caverns that pour out oils, bitumens, and the other resinous materials — all of which surely come about only through the agency of chemical distillation, the very process that Nature follows in everything.

[Margin: The exterior face of the geocosm compared with the distillatory operations.]

Now, if we turn our eyes to Nature's external operation, we shall see that the whole meteorological region of the air is nothing other than the work of distillation. For what are lakes, rivers, seas, and even the outer substance of the earth itself, but a kind of receptacle filled with distillable moist material? As soon as this material has been struck by the burning heat of the Sun, it at once sublimates the rarefied moisture into vapors. These vaporous fumes, once they have entered the cold alembic of the higher air, are condensed there and resolved back into whatever they had been — whether that moisture was pure, or concreted, or charged with fiery exhalations.

[Margin: Man, the microcosm, the furnace of distillation.]

Who would deny that in man, the microcosm, the most perfect work of distillation is found? In him you can see as many chemical vessels as there are vital membranes. What else is the stomach but a kind of chemical cucurbit, in

which the food taken in — its moisture rarefied by the force of innate heat — at once seeks the cold alembic of the head and brain? There, resolved, it rushes out by whatever opening it finds, discharging itself through the mouth, nostrils, ears, and eyes. From there, descending, it lubricates the nerves, cartilages, tendons, and muscles by its moistening, so that they can produce movement, and thus preserves the whole body in its state of integrity.

But if the moist food has been imbued with the corrupt qualities of salts, sulphur, and mercury, then the moisture, raised into the brain and there resolved into salty, tartareous, sulphureous, and mercurial catarrhs, causes — should it fall upon the lungs — consumption [phthisis]; in the hands, gout of the hand [chiragra]; in the feet, gout of the foot [podagra]; in the knees, gout of the knee [gonatagra]; sciatica in the hips; and arthritis throughout the whole body. The sulphureous vapor, when resolved, kindles the blood and brings on fevers, producing every kind of disease that arises from heat. The mercurial moisture, when resolved, attacks chiefly the class of nerves; from this arise paralysis, apoplexy, and similar monstrous diseases.

[Margin: Nature the distiller.]

From all this it shines clearly that Nature, in everything, takes upon herself all the roles of a good distiller, and that consequently the stalactic, or distillatory, art has been drawn from nothing other than the workshops [ergasteria] of Nature, and was established by the chemical philosophers to her own exact rule and prototype.

[Margin: The worth of the distillatory art.]

Its excellence and dignity can scarcely be described in worthy enough terms — both because of the manifold benefit it brings to the human race, and because of the hidden secrets to which it grants us access. It is truly the unique key-bearer of Nature, by which the gate stands open to a perfect knowledge of natural things, to the constitutions of mixed bodies, and to their hidden principles — as we shall show in this brief treatise.

Since this is so, let us now at last proceed, under favorable auspices, to the subject we have proposed.

Caput I.

Definition and the manifold varieties of Distillation.

[Margin: What distillation is.]

Distillation, then, is nothing other than the resolution of the parts of a body into vapor by the force of heat — a resolution established by the chemists according to the prototype of Nature. When these parts meet the cold head of the alembic, they are raised there and, condensed, are converted into a liquid. For a vapor, once raised up into the cap or alembic, cannot be dissolved into a liquid unless it is first multiplied and packed together there by condensation. This condensation is at times so violent that the vessels must necessarily burst; and when this happens, such a great quantity of fumes pours out at once — as we have carefully observed — that it fills a whole house.

[Margin: The varied differences of the kinds of distillation.]

Distillation is, moreover, of many kinds, established by the chemists according to the prototype of Nature, and we subdivide it in this way. One distillation is partly by fire, partly by earth, upward. Another is by fire, earth, air, and water, downward. Another is by inclination, through fire, air, water, and earth. Another is by the reflected rays of the Sun and other sources of heat. There are therefore three genera of distillations, according to the distinctions of the natural motions — upward, downward, and laterally; and each of these distinctions is in turn divided into four, according to the number of the elements; and in this way — in this way the twelve varieties of distillation arise.

[Margin: Distillation by fire.]

Distillation by fire is set up when the humors or spirits residing more deeply within the earthy parts are sublimed by the great force of fire, in order to extract both oils and waters. The figure of its furnace is marked with the Number 7.

[Margin: By earth, sand, ashes, dung.]

Ascending distillation by earth — or what is the same thing, by sand, ashes, lees, or dung — is set up when the finer parts we are seeking do not cling so stubbornly to the material being distilled; as at Number 5.

[Margin: Distillation by water.]

Distillation by water is properly carried out by a bath [balneum] — what they call the bath "of Mary," or "of the Sea," or "of dew" [Mariae, seu Maris, aut roris] — and it is set up in countless ways: Number 4, 5.

[Margin: Distillation by air.]

Distillation by air is properly carried out by a vapor-bath, that is, by vapor of water rarefied by heat.

[Margin: Distillation by descent.]

Distillation by descent is in turn set up either directly by fire, or by water, or by earth — that is, by ashes, lees, or dung — as may be seen in vessels 9.

[Margin: By inclination.]

Distillation by inclination is so called when distillation is set up sideways, by a middle route, by means of what they call a retort — as appears in vessels 2 and 5.

Countless other vessels are everywhere in use; I set down those that we commonly use in the pharmacy [pharmacopoeum] of the Roman College. But having now dealt with these common ones, let us proceed in the same way to describe the furnaces that they call philosophical.

Furnaces and Instruments, or the Philosophical (Hermetic) vessels.

[Margin: What a philosophical furnace is.]

A furnace is properly called philosophical when, by its ingenious structure made after the model of Nature, it brings a mixed body to the highest perfection and resolves it, by a certain marvelous skill, into its elementary parts — or also when (as others hold) by a manifold repeated distillation, which they call cohobation, it completes the philosophical contrivance [technasma] all at once.

Description of the Philosophical, or Spagyric, Furnace of the Roman College of the Society of JESUS, which is called the vapor-bath.

[Margin (Greek labels keyed to the figure): Κωνιστήριον; πυριστήριον.]

This furnace consists of six principal parts. The lower part, marked with the letter H, is the Conisterium [Κωνιστήριον, "ash-chamber"], and represents the place of the ashes. The second part presents the Pyristerion [πυριστήριον, "fire-place"], that is, the place of the hearth. The third presents the inner seat of the kettle [Cacabus], extended to the breadth B C. The fourth, the outer one, L M B C, contains a copper cupola fitted with 66 alembics. The fifth is the copper vessel A, set upon the cupola, which serves for calcining horns and bones. The sixth is the Register [Registrum], placed at the back, which serves to give the fire a determined degree of heat.

The alembics are filled individually, either with different herbs, or all and each with one and the same material — both to avoid the tedium of evacuating the water at different times, and because, just as the different species of herbs possess different qualities and degrees, so too their distillation cannot be completed in one and the same time by one and the same degree of heat.

Those about to begin the work therefore first fill the kettle [cacabus] through the stopcock [epistomium] with running water; then they furnish the pyristerion with live fire. The water of the kettle, feeling the fire, at once boils and fills the hollow of the cupola with vapors; from their effervescence the cucurbits likewise grow hot, and the herbs that they hold within their bellies are resolved into vapors. These, raised into the little caps of the alembics, are there condensed by the encounter with the surrounding cold air, and, resolved, flow down through a nose-shaped siphon [syphon] into the receiving vessels — in such quantity that within the space of a natural day they gather a hundred pounds and more of distilled water.

[Margin: How the bones, horn, etc., are calcined in this furnace.]

In the copper vessel marked with the letter A, by a truly remarkable mastery, they place the things they wish to be calcined — bones of every kind from horns, bones, and teeth: stag's horn, ivory, whatever pleases them — for calcining in a little basket woven of iron wire; and in this way they leave them suspended within the vessel on a little net. From this it comes about that the hot vapor, penetrating through the narrows of the said vessel, not only confers upon them a most brilliant white color, but in time also renders them so friable that by the pressure of the fingers they can be reduced to powders without any trouble. And this method of calcining bones and horns is truly the most beautiful and easiest. For those who are accustomed to calcine in this way by fire lose much of the inherent virtue, since the vehemence of the fire makes it evaporate; and besides, they easily acquire a burnt smell [ἄπόπνευσίς] from the fire — which, as it is harmful, must be avoided by every means. All these harms are removed by the bath alone, by the benefit of the vapor.

[Margin: The equalizing register of heat.]

It now remains to explain the register, for giving to each plant the distillation-heats proportioned to it. For since not all plants require the same degree of heat — because some are of easier, some of more difficult resolution, as we said a little earlier — the register has therefore been set up at whatever degree you wish, so that, by pushing the register in or back, the force of the internal heat is either

increased or relaxed. It is truly a beautiful invention, expressing as it were a type [Greek: ἐν τῷ τύπῳ (en tō typō, "in the type / model")] of Nature's subterranean furnace.

[Margin: Etna a furnace.]

I myself have observed the truly marvelous nature of many mountains, and among the rest of Etna. For in it you may find diverse springs and streams, of which some carry off saline, some nitrous, some aluminous, and some vitriolated water. Certain caverns too, in different places, distill naphtha, bitumen, and petroleum — which surely come from nowhere else than from the volcanic furnace; for in the subterranean cauldrons with which they are filled, the humors, raised through hidden channels and little conduits of the earth and resolved in the cold caverns of the mountains, evolve into those different waters and liquids. The figure of the furnace follows.

Diagram. A full-page engraved plate of the Spagyric (philosophical) vapor-bath furnace of the Roman College of the Society of Jesus. Engraved at the upper right: "Tomus II. f. 392."

The structure is a cylindrical masonry furnace (the drum). Its front face is open to show the fire-chamber. At the top a great dome-shaped copper cupola is densely packed with rows of bulbous alembics (cucurbit-and-cap pairs, each with a downward drip-spout), arranged in tiers — the engraver shows roughly forty to fifty visible (the text specifies 66). Surmounting the cupola at its apex is a small domed vessel (A) holding the bones/horns to be calcined. Below the dome, on the cylindrical drum, the fire burns on a grate within the open hearth; beneath the hearth is a square ash-pit opening at the base.

At the top of the plate, two engraved banners flank the central calcining vessel:

- Left banner: **FORNAX / COLL. ROMANI** ("Furnace of the Roman College")
- Right banner: **SPAGYRICA / SOC: JESU** ("Spagyric, of the Society of Jesus")

Above, in a decorative cartouche, an engraved verse-motto (two lines): "*Pratorum hic manant lachrymæ per vitra cadentes / Herbarum in tumulo, dum parit ignis Aquas.*" ("Here the tears of the meadows trickle down, falling through the glass vessels — over the tomb of the herbs, while the fire gives birth to Waters.")

Letter labels on the figure:

- A (apex, atop the cupola): the copper calcining vessel set on the cupola.
- M (upper left of the cupola): edge of the alembic-array / cupola.

- L (upper right of the cupola): edge of the alembic-array / cupola.
- C (lower left of the cupola rim): left limit of the cupola breadth.
- B (lower right of the cupola rim): right limit of the cupola breadth.
- E (upper left, within the fire-chamber opening): upper-left corner of the hearth opening.
- D (upper right, within the fire-chamber opening): upper-right corner of the hearth opening.
- F (center of the fire-chamber): the kettle/cacabus seat above the fire.
- G (in the flames): the grate (craticula) on which the fire is kindled — the pyristerion. Labeled in the engraving "Pyristerium."
- O (lower left of the hearth opening): lower-left corner of the hearth opening.
- N (lower right of the hearth opening): lower-right corner of the hearth opening.
- K (lower left of the drum base): left foot of the furnace drum.
- I (lower right of the drum base): right foot of the furnace drum.
- H (the square pit below the hearth): the ash-chamber, labeled in the engraving "Conisterium."

Engraved key panel at the foot of the plate (two columns):

Letters	Description
A L M / B C I K	Fornax distillatoria. (The distillation furnace.)
A	Vas in quo cornua et ossa Philosophico magisterio calcinantur. (The vessel in which horns and bones are calcined by the philosophical mastery.)
D E N O	Focus quo Lebes G calefit igne succenso. (The hearth, where the kettle G is heated by the kindled fire.)
L M B C	Alembicorum 72 distillatio, quæ vapore balnei stillant liquorem. (The distillation of 72 alembics, which distill liquid by the vapor of the bath.)
B C / I K	Murus seu Tympanum Fornacis. (The wall or drum of the furnace.)
G	Craticula supra quam ignis accenditur, et

Letters	Description
	dicitur pyristerium. Πυριστήριον. (The grate over which the fire is kindled, called the pyristerion.)
H	Locus est in quo cineres colliguntur et dicitur Κονισήριον [?] (engraver's irregular Greek for Κωνιστήριον), signatum litera. (The place in which the ashes are collected, called the conisterium, marked with the letter.)
A F	Canalis per quem fumus se exonerat. (The channel through which the smoke discharges itself.)

Reading order used: The text folios run in printed-page sequence — fol. 393, then fol. 394 — followed by the engraved plate keyed to fol. 394 and its blank verso. Catchwords confirm the order: fol. 393 ends with the catchword "quod," picked up at the head of fol. 394; fol. 394 ends with the catchword "His." [Plate caption: *Tomus 2 die fol. 394* — i.e., the plate belongs at fol. 394 of the second volume.]

Vessel II: a philosophical distillation apparatus, by which the quintessences are extracted from plants and liquids.

The chemists, in order to bring their liquids to the highest degree of subtlety, hold that this must be achieved by what they call repeated *cohobation*. Here I shall teach the construction of certain vessels by whose aid you may accomplish in one and the same operation what the distillers do, with so much labor and expense, through five, six, or seven sublimations.

[Margin: A newly devised distillation apparatus for sublimating liquids.]

The furnace A B, divided into two parts, is called *Althanor* by the chemists — a word which in the Arabic tongue means, by way of excellence, "the Furnace": الطَّنُور [Arabic: al-ṭannūr, "the oven, furnace"]. On this, see what I have set out more fully in Book XI.

The device C serves to sublime liquids by means of a reflected ray of the Sun. I have given a better method of constructing this elsewhere, so let us proceed to the other vessels.

Let six glass vessels, or alembics, be made under a proportional diminution [i.e., each smaller than the last], together with their beaks and the receivers fixed to each beak, as Figure D shows. This done, let the first vessel be filled with the liquid you have decided to sublime, and set above the small furnace X, surrounded with ashes or sand. Once this too is arranged, the liquid placed in the first vessel, raised into vapor, will be somewhat resolved in the second vessel and descend into receiver A. The vapor, carried further, will be resolved in the third vessel and descend into receptacle B; carried still higher, it will be resolved in the fourth vessel and descend into receiver C. In this fashion it is raised up to the last vessel, marked with the number 6, where, having slipped down into receptacle D, it attains the final term of its subtlety and perfection. This you will then collect separately and store in a crystal vessel, very tightly sealed. Here you see that in each successive vessel the resolved vapor is always found, as if by certain degrees, purer and purer in the receivers — until in the last vessel, 6, the liquid, freed from all dregs, acquires a kind of celestial subtlety.

This technique we have learned from the works of Nature; for experience teaches that the higher earthly vapors ascend, the subtler they always become, until — borne up into the highest region of the air — they degenerate into some other substance. The same thing, and indeed far more perfectly, is taught by the following device.

[Margin: A second philosophical device for purifying liquids and bringing them to the ultimate degree.]

Let glass vessels be made in the manner that Figure E shows. First two retorts, which I have marked with the numbers 2 and 9; into both of these let there be inserted the channel marked with the number 3, furnished in its lower part with five small channels [canaliculi], to which correspond just as many receivers marked with the numbers 4, 5, 6, 7, 8. Into the retort marked number 2 place the liquid to be distilled and subtilized. This done, the joints of both retort 2 and of the receiving vessels with their little channels having been bound and luted together so that nothing may exhale — only retort 9 being left free of lute, so that it does not impede the progress of the vapor — let this whole apparatus, firmly fitted together, be set up: on one side, with its retort 2, place it above the small furnace 1, and the other side above the support 10. When the fire is lit, the liquid, gently raised into vapor, is first resolved within receptacle 4; then, carried further, within receiver 5; and so on in turn up to the final degree of perfection, within retort 9, into which it will work its way. In this manner, with a single instrument and without labor or expense, you will attain your end. But if you

have a mind to bring to the ultimate purity those liquids collected in the five receivers which have not yet attained their due purity, gather them together and pour them once more into retort 2, and continue the operation as before.

[Margin: A third device.]

The third device, marked with the letter F, serves for substances of more difficult dissolution. Let there be made a glass vessel N, fitted with two little channels G P on its side and one, L, in its belly. To the lateral channels are set opposite two retorts: the one marked with the letter O, filled with the material to be sublimated, is set above the furnace P, strewn with ashes; the other, M, is set above the support L. Into the lower channel let there be inserted a bladder [vesica] R; and the joints having been bound together, fire is applied beneath the furnace P. The sublimated portion of the more stubborn material, resolved first, will discharge itself by descent into the bladder R, while the subtler and purer portion will work its way into the vessel M.

[Margin: Circulatory vessels.]

There now follow the *pericyclic* or circulatory vessels, of which there is great use in chemistry, because no magistry, no elixir, nor *aqua vitae* can attain its highest degree of perfection without them. Their working consists in this: that in them, by a gentle and mild heat, the raised vapor continually goes round in a circle; and from the continuation of this circulation the liquid is exalted to such subtlety that it puts on a kind of celestial nature. But the circulation of the liquid differs from the foregoing sublimation in this, that this circulation must be continued for at least four months, to be accomplished by a fire of ashes, or sand, or dung; whereas the former [sublimation] is for the most part completed in one natural day. The figures G, H, I, K, L, M, N, O exhibit the shape of such vessels. Of these, the first, G, sublimates liquids by the heat of a bath of water [*balneum maris*, water-bath]; H by the heat of pressed grape-skins [*vinacea*]; I by the heat of ashes; K by dung; L by the heat of vapor; M by the heat of sand; N, finally, either by the heat of dung, or of sand, or of ashes. For a modest fire — of a lamp, or of coals placed in the furnaces — warms the sand, dung, and ashes always with the same tempered heat; and just so the liquids, exalted in the circulatory vessels, ascend through one arm and return through the other, whence they always shed off something impure, until, the circulation of many days being completed, nature refuses to purify them any further. But the circulatory vessel most used by the chemists is the one

which you see expressed first in the figure marked with the letter O, and then in the figures marked with the letters M and L. The remaining vessels G, H, I, K, being without arms, are called "blind" [*caeca*], even though they accomplish circulation; the true method of circulation, however, is achieved by those handled [arm-fitted] vessels of which we spoke a little before.

RULES to be observed in the Stalactic Art.

[Margin: The quality of the chemists' vessels.]

1. Let no vessels of this kind be made of lead, since by their malignant quality they infect the humors — so that water even drawn through leaden channels does not yield springs as wholesome as those made of wood or baked earth. Yet it is a remarkable thing that sour liquids [vinegar], distilled through leaden channels, grow sweet.

[Margin: Sour liquids grow sweet when drawn off through leaden channels.]

Neither are substances to be distilled to be placed in iron vessels, since they are corroded by the moisture; nor are copper vessels to be used in the distillation of minerals and salts, because they dissolve the vessels into verdigris. Hence, in magisteries, extracts, quintessences, and similar works of the subtler art, only those attentive to glass vessels achieve what they seek in chemistry.

[Margin: Precautions in distillation.]

2. In distilling spirituous materials, let the glass vessels be long — at least two cubits — for the taller they are, the better the effect they obtain, so that such vessels accomplish more than the rectification carried out with low vessels (which, however, are suitable for extracting oil, wax, and other fixed substances).

3. In every distillation the vessels are not to be filled too full; you will work more safely if you fill cucurbits to a quarter, retorts to a half, and the brass bladder to three parts with the material to be distilled. Flatulent substances — such as wax, resin, and those that easily boil over — should be put in smaller quantity into very large vessels; and since such things do not easily ascend, in order to repress the flatulence and the dislocation of the parts, the desired effect will be obtained by adding sand, bole, brick-flour, calcined pumice, clay, or the like.

4. Distillation by water-bath [*balneum*] is properly suited to things of lighter composition, such as those of a temperate complexion. In things extremely hot, however — such as wormwood and rosemary and the like — you will avoid too much heat, lest you extract not so much the essence as the useless phlegm.

5. Distillation by ashes or sand is properly suited to things of more solid substance, such as seeds, woods, roots. By the bladder, not only thin substances but also others of firmer texture will be dissolved — provided, however, that they have first been macerated in their appropriate menstruum or water; the reason being that by maceration the materials are prepared for easier extraction.

6. Distillation by retort elicits not only the heavier spirits from minerals, but also waters and oils from thinner substances — such as woods, seeds, roots, gums, resins; the reason being that retorts, by their lateral inclination, more easily draw out the more stubborn liquids than [is done] by straight ascent.

7. Herbs dried by any method whatever should not be distilled unless first sprinkled with water, or May-dew, or wine, if the distillation is set up in a brass bladder; there must be added at least two or three pounds of water to each pound: the reason being that there is greater danger of the herbs being scorched in the bladder than in the glass vessels of the bath.

8. By the bladder too a more intense degree of heat can be applied; whence from any plant-parts whatever not only water but also oils are extracted.

[Margin: A remarkable account occurring in the distillation of acids.]

9. The distillation of acids, such as of vinegar and of salts, has this peculiarity: that the baser part always comes out first, the nobler last. The reason is that vinegar by nature has much fixed salt; and although it draws its origin from wine — so that it may not unfitly be called "the corpse of wine" — yet in distillation it behaves the opposite way. For just as in vinegar the baser part comes out first and the nobler last, so, by contrast, in wine the more precious water comes out first and the baser phlegm last. For in wine there is much volatile salt, and so it is of easier dissolution; but in vinegar there is much fixed salt, in which the spirit of wine chiefly nests. Hence it is necessary that the nobler liquid come out last.

[Margin: The luting of vessels.]

10. In coating chemical vessels with lute, singular care must be taken. In constructing furnaces first: fat earth mixed with sand, horse-dung, and salt water is very suitable, because lute mixed with sand gives body; horse-dung, by the manifold intermixture of its fibers, holds it together so it does not crack; and the salt water hardens and consolidates the whole mass. For luting retorts, potter's clay, horse-dung, the powder of crushed bricks, iron filings — all mixed together and worked up with water — is of the greatest help.

[Margin: The lute of wisdom.]

The lute they call "of wisdom" [*lutum sapientiae*] is made from quicklime and egg-white reduced to a liquid — which, however, must be applied at once, lest it dry out.

[Margin: How broken glass is glued together.]

For gluing together broken glass, let a glue be made from Armenian bole, minium, and ceruse in equal portions, which, reduced to a fine powder, are to be worked up with linseed oil or liquid varnish. But for casing an alembic with its receiver, melt wax, resin, and colophony in an earthen pot, mix in with a stick a modest quantity of olive oil, then pour cold over it and knead it again with your hands as well, and you will have a glue ready prepared.

[Margin: A remarkable method.]

But the retorts in which the distillation of sharp spirits is carried out require a lute of salt water, or even of bovine blood tempered together — joined with beasts' [draft animals'] hairs and a portion of *calcotar* [copperas/vitriol residue]; for this serves most of all for the retention of the spirits, that they may not exhale.

Diagram. A full-page engraved plate of distillation apparatus, keyed to the text of fol. 393–394. The upper-right caption reads "Tomus 2 die fol. 394." Twelve to fifteen distinct apparatus are arranged in roughly five rows; each is keyed to a capital or lowercase letter or numeral matching the letters discussed in the text (A–O). The plate is well inked on the recto; the verso is blank apart from offset show-through.

- **C** (top left): a single alembic on an ornate scrolled pedestal, with a flask/cucurbit below and its head directed toward a mirror or burning-glass panel at upper left, above which is engraved a radiant Sun-face. This is the device that "sublimates liquids by a reflected ray of the Sun."
- **B** (top center): a low circular furnace-table seen from above, its top bearing a grid/lattice and small flasks; tubing runs from it across to the right toward apparatus A. The furnace is shown with arched stoke-holes around its base.
- **A** (top right): the two-part *Althamor* furnace, a battlemented circular structure with arched openings around the base and several flasks/towers rising from the top.
- **F** (second row, left): the third device. A central round-bellied glass vessel **R** flanked by two retorts; labels read **P**, **G** across the top, **o** at far left, **L** and **M** on the body, with **R** on the central vessel. Two furnace-bases support the assembly. (Some small peripheral letters are faint — see review note.)

- **E** (second row, center): the second philosophical device — an arched train of vessels. Two retorts at the ends marked **9** (left) and **2** (right); a row of five pendant receivers hangs from the central arched channel, labeled **8 7 6 5 4** (left → right), with **3** marking the crown of the arch; furnace-base **1** at right and support **10** at left.
- **D** (second row, right): the first apparatus — six alembics of diminishing size mounted in a stepped/inclined row over a tall furnace, with receivers attached. Lowercase labels **d, c, a** (top → bottom) run down the left side, and the stepped alembic bodies are numbered **5 4 3 2 1** descending, with **1** seated at the foot on the furnace mouth; the small "+"-like marks beside the upper alembics are the beaks/receiver-spout junctions rather than letters.
- **I** (third row, left): three arm-less ("blind") circulatory flasks set in a wooden tub, labeled **I**.
- **H** (third row, center): a single tall circulatory flask standing in a wooden barrel/tub, labeled **H** (the barrel for the grape-skin / *vinacea* heat).
- **G** (third row, right): a pair of circulatory flasks on a square pedestal-base with a paneled front; labeled **G**, with a small hanging vessel/lamp above. (The water-bath, *balneum maris*.)
- **M** (fourth row, left): an arm-fitted ("handled") circulatory apparatus on an ornate square pedestal with paneled, inset sides; top labels **c** and **b** flank a small finialed vessel; the body is labeled **M**.
- **L** (fourth row, center): a cabinet/cupboard with open doors revealing several circulatory flasks ranged on shelves within, flanked by two furnace-bases at the foot; labeled **L** (the vapor-heat enclosure).
- **K** (fourth row, right): three arm-less circulatory flasks set in a wooden tub, labeled **K** (dung-heat).
- **O** (bottom left): an arm-fitted circulatory vessel on a square paneled pedestal, shown emitting vapor/flames from two side vents; labeled **O**. This is the form "most used by the chemists."
- **N** (bottom right): a furnace of brick courses surmounted by a cluster of pendant gourd-shaped vessels, with a retort and round vessel attached at the right side; labeled **N** [?] (the multi-mode vessel — dung, sand, or ashes).

ARS DISTILLATORIA [The Art of Distillation]

Now that these matters have been set out, certain points of great importance in chemical work remain to be explained. These are the chemical operations, which, although I treated them very fully in Book II, I have nonetheless decided to

explain here more amply as well — as I promised there — this being the suitable place. They are chiefly **Digestion, Putrefaction, Circulation, and Fermentation**, without an accurate knowledge of which nothing exact can be accomplished in chemical operations.

On the Kinds of Digestion, and on Putrefaction, Circulation, and Fermentation.

§ I. — DIGESTION.

[Margin: What digestion is.]

Digestion is a simple ripening, by which substances that are not yet fully prepared are worked up in a digestive heat — much as the stomach, by its own moderate warmth, digests the raw foods it has taken in and, by concocting them, transforms them into chyle. The purpose is that, once the dregs have been set aside, an attraction of the more benign and purer substance may be made by the liver out of what remains. In the same way digestion separates the fine from the coarse, cuts up and thins out what is thick, cooks what is raw, and softens and sweetens what is harsh — so working over everything that from what has been digested an ever more abundant harvest of essence may be hoped for.

This is how digestion is carried out. Let the vessel containing the materials to be digested be placed in a digesting furnace of suitable warmth, whether the heat be ash, or sand, or dung, or iron filings; it makes no difference. Let it be left there until the intended end, which varies according to the manifold use of digestion. For example:

[Margin: The way to proceed in digestion.]

Fresh herbs, moist with their own juice, are macerated for three days; herbs dried out and sprinkled with wine, for seven days; seeds and aromatics, for a two-month span; dry roots, for a month; minerals, for a Philosophical month, that is, forty days. Some things are macerated twice, sprinkled with Greek wine — as are the aromatics, which, once moistened, are digested until dry, then shortly afterward are pounded, sprinkled afresh, and macerated again.

§ II. — PUTREFACTION.

Putrefaction is the digestion and dissolution of a concrete body through a natural rotting, in a moist heat that corrupts the very substance and opens up its innermost parts — so that, just as digestion regards the generation of a

compound, so putrefaction regards its corruption. It is called *natural* rotting because, although properly a native heat resides in all things to be putrefied, that heat can be roused only by an external heat. For thus the native heat, made more robust,

[Margin: The rationale of putrefaction.]

[The column continues at the head of the right-hand column of the same page:]

brings about the dissolution of all the parts; and finally, when the adjacent moisture comes to exceed the dry body, it completes the putrefaction by continued degrees. For it is known that every material to be putrefied abounds in moisture, and hence — the external heat cooperating — it is necessary that it should overcome the dry; from which the innate heat, together with its own substantial moisture, is separated from the mixed bodies and, preserving its own homogeneous nature, stands apart by itself. Once these things have been accomplished, the separation is afterward more easily completed by the Spagyric [Spagyric, i.e. alchemical] art.

Now although all putrefaction consists in the separation of the internal moisture implanted in the things themselves, yet because this cannot act unless it is urged on by an external agent, it has been necessary for it to have a ζύμη [Greek: *zymē*, "leaven" — i.e. a ferment] or vehicle — or, as they call it, a *menstruum*, named from the *month* (*mensis*) of its putrefaction. And this is the moisture of each particular thing, whether its own or analogous to it — as the water poured over it, so that by its excess it may take away the dryness of the mixed body, may bear off the mixture, may draw to itself the emerging essence, and may keep that essence whole and uncorrupted right up to the extraction. And lest the heat with its moisture should expire, the vessel must be sealed hermetically and afterward placed in a horse's belly — that is, in dung, or ashes, or sand, or the like — for the predetermined time.

In the putrefaction of herbs and flowers, to elicit oil, some add salt or vitriol, alum or tartar. The reason for this is that, with these added, putrefaction is completed more quickly because of the sharpness of the salts, by which the more stubborn parts of the mixture are dissolved; and the mixing, furnished with these aids of [the salts], is also accomplished more quickly, and the material is thereby protected from foul and harmful putrefaction.

[Margin: The effect of putrefaction.]

It is the property of putrefaction to change the savors, odors, and colors, and, having destroyed their old nature, to produce a new one. But what the proximate causes of this kind of transformation may be is taught a little later, in the material on fermentation.

§ III. — CIRCULATION.

Chemical circulation is nothing else than the conversion and exaltation, into a more excellent degree, of a liquor that has already been purified — as far as is possible — from its elementary refuse, this being accomplished through various windings about and rotations in the Pelican, or in the *dyota*, into that more excellent grade.

[Margin: How circulation is carried out.]

There are, moreover, various circulatory or hermetic vessels of this kind, which you may see marked in the Schematism with the letters L, M, O. In L, indeed, [is shown] the middle δυοβάρχιον [Greek: dyobarchion — a two-necked circulatory vessel] [?]; likewise in figure M [are shown] vessels marked with the letters b, a, c, whose function is supplied by the vessels called *blind alembics* (*alembica caeca*), of the kind seen in figures G, H, I, K, N, L. These must be hermetically sealed — that is, at the lamp, by the art known to glassworkers. And the Chemists, under a certain riddle, see vessels of this kind now twisting themselves up into heaven and returning to earth by a circuit. Hence, if a liquor of this kind

is in this way circulated, it at last — having shed all its dregs and impurities — takes on a kind of celestial nature, almost devoid of the qualities of the elements, as the Chemists put it. In this way is made that celestial elixir which Lull [Ramon Llull] calls *heaven*, on which see at length in Book III of his *Art of Magnetism* [*Ars Magnetis*] [recte: this attribution to Llull's work; the text reads "in Libro III. Art. Magnet."]; consult the matter there.

[Margin: A new apparatus invented by the author.]

We have devised another instrument far more excellent than those just mentioned, by which circulation is achieved not only with greater excellence, but is also completed in a shorter time. It is a glass machine, constructed — by the device you see below — through the courses of helical lines, where you should note that the vapor, ascending through the helices on either side, rises to the head A, and from there returns into the belly V.

Diagram. A glass circulatory vessel ("Figura I"). The central body is a rounded flask (the *venter* or belly) with a short neck rising to a small head at the top. From

the two sides of the vessel rise tall, ornate spiral (helical) tubes that curl over symmetrically toward the top, so that vapor ascending through the helices on each side reaches the head and returns into the belly.

- A (top, at the head/neck of the vessel): the head, to which the ascending vapor rises
- V (body of the vessel): the *venter* (belly), into which the condensed liquor returns

It can scarcely be told how great and in how short a time the work of circulation is completed. For, ascending through the helices, in each coil [the liquor] acquires some degree of purer nature: while what is subtle is repeatedly driven upward, the coarser portions of the moisture fall back from one coil into another and again into the belly; and finally the most subtle part, having glided down into the head A and been dissolved by the cold, is again committed to the belly to be circulated. In this way, within eight days, you will accomplish the same — and indeed far more excellently — than what the Chemists have not managed in a space of forty days with the aforesaid hermetic vessels: a truly enormous saving in circulation.

Circulation will obtain a still better effect in Figure II,

Diagram. A glass circulatory apparatus ("Figura II"), a double vessel. Below is a large rounded flask (the *venter*, marked T). Set upon its mouth is a smaller funnel-shaped cup or little vessel (the *vasculum* O, marked S at its top opening). From the two sides of the apparatus rise long, wavy (serpentine/helical) tubes that arch over symmetrically toward the top. The purified liquor does not fall back into the belly T but is collected within the little vessel O set above T.

- S (top, the opening of the upper little vessel): the mouth/opening of the *vasculum* O
- T (lower large flask): the *venter* (belly), the main vessel

where the purified liquor does not fall into the belly of vessel T, but within the little vessel O, set above vessel T. The procedure is as follows.

[Margin: Description of the machine.]

The liquor to be exalted is enclosed in this helical vessel [ἑλικοειδῆ, Greek: *helikoeidē*, "helix-shaped"] — or also in the other circulatory vessels — leaving the vessels empty up to three-quarters [*ad ¾*]; and in this way the hermetically [sealed] vessel is placed in dung or in a bath up to the height of the liquor that is to be thinned, so that a small part of the vessel stands out, cooler, in the air. The

purpose is that by the heat of the dung and of the sides the thinning of the liquor takes place, while by the coldness of the top there is condensation; and the said vessel is kept in a moderate and continuous heat until the artist has attained his end, with the dregs settling at the bottom of the vessel. And let this suffice concerning Circulation. Let us now proceed to Fermentation.

§ IV. — On FERMENTATION, the Cause of the generation and corruption of all things.

Fermentation, in this place, is nothing else than a certain internal motion of the particles or principles of any body existing in the threefold kingdom of Nature; and it is the same as a certain effervescing or fermenting of matter disposed for generation — as Thomas Willis [Thomas Willis] rightly teaches — by which Nature aims at a change into something else, since there is a tendency toward the perfection of some compound.

[Margin: How fermentation comes about.]

Fermentation occurs in this manner: the elementary particles — saline-sulphureous-mercurial — either spontaneously by nature or occasionally being roused into motion, marvelously agitate one another; and, set in motion by a reciprocal motion, they draw one another apart and entangle one another. The subtle and active ones strive to fly off, but are held back, entangled by the coarser ones; the coarser ones, however, always resist, until — subdued, thinned out, and raised to exaltation by the more subtle ones — they either acquire the due perfection or complete the alterations assigned by nature.

It is also called a *swelling*, which arises in a natural body from the spermatic particles of that body when variously agitated; for, stirred up by heat, whether external or internal, they excite wondrous tumults. All things are full of fermentations, and in this way, the pure being separated from the impure, the mixture attains its own perfection. Now apt for fermentation are all heterogeneous bodies: thin and thick, liquid and solid, animate and inanimate, natural and artificial. In heterogeneous mixtures the corpuscles are highly spirituous, agile, and volatile, and are of two kinds — as I have said elsewhere — volatile and fixed; the fixed so contain the volatile that they do not entirely fly off, as is evident in spirit of wine and in distilled waters, in which the burning spirits, oils, and fixed salts persist by [their] implanting. But the juice and blood of vegetables and animals, and all concrete fluids, and the various compounds of mixed bodies, quickly ferment and undergo various turns of change. The experiments of this are as follows.

EXPERIMENTS.

[Margin: 1st Experiment.]

Spirit of wine enclosed in a phial gives no signs of effervescence; but if you add to it a little oil of turpentine,

the particles of the liquor are so agitated that it bursts the phial itself, especially when it has been tightly closed. The reason is that the sulphureous corpuscles of the oil of turpentine, poured over the corpuscles of the spirit of wine — which have obtained a contrary nature — at once effervesce with violent agitation; and from this the rarefied liquor, when it finds no room, seeks room for itself by bursting the vessel.

[Margin: 2nd Experiment.]

Again, distilled water of any herb whatever is kept a long time in a closed phial; but if you add to it some sugar or syrup, it will at once turn sour and be corrupted. The reason is that the saline corpuscles, as soon as they have been joined with the saline corpuscles latent in the distilled water, being subdued into their own nature and the sweetness laid aside, are converted into a sour liquor — as Thomas Willis finely teaches in his little book *On Fermentation* [*De Fermentatione*].

[Margin: Requirements for fermentation.]

Concerning artificial fermentation, the following must be noted. First, there must be a looseness and disjunction of the parts, with a tendency toward perfection; for otherwise the fermentative particles cannot expand and be moved from place to place. This is why in things compact, harder, viscous, and boiled down to thickness, or dried out by evaporation, fermentation does not succeed. But liquids easily swell with their juices; next to these are things that, though soft, are nonetheless endowed with a thicker consistency — as bread, and all effervescing things and medical compounds are. Second, there must be a heterogeneity of the parts, or a mingling together of all the principles at once — namely, that some particles drive out, dislodge, and stir others into motion. For simpler bodies, such as water, on account of the likeness of their homogeneous particles, are unfit for fermenting; whereas in dissimilar mixtures of bodies, from the ambition for predominance, strife and discord at once arise, whereby some provoke others into motion. Third, in bodies to be fermented there must not be too great a rawness of the parts, since in that case the active and subtle particles are not easily torn away from the coarser ones, nor are they released into motion. This is

evident in those juices that are pressed out of unripe fruits; for in these the particles, too volatile, are not held by the bond of mixture, but fly off at once, evaporated, and dispose the substrate to rottenness — as is known from over-ripe fruits. Blood too, once shed outside the vessels, milk, and meal do not ferment, but quickly undergo rottenness.

[Margin: Whence the stench.]

From this it is clear how corruption is brought upon things. For, as the spirit abounds and there is a supply of sulphur and salt, the particles, loosed from their bonds, at once break out; and so thereupon the mixture putrefies with a stench, even though it consists of a dense mass. For the stench proceeds from the exhalation of sulphur with sharp salt; rottenness follows because the external moisture enters in place of the particles flying off; and heat is produced by the sulphureous particles or corpuscles at once set in motion and shut up within the subject, so that they may gather together at once and act more strongly in unison. But if in the subject there is a smaller proportion of salt and sulphur — so that, when the mixture is dissolved, the particles are stirred more sluggishly and gradually evaporate without notable stench, rottenness, or heat — then the body dries up and falls into decay.

All things, therefore, are full of fermentation — not only in the disparate bodies of minerals, vegetables, and animals, but the whole sublunary world seems as it were one mass set up and pregnant with fermentative corpuscles throughout, which are perpetually engaged in motion and agitation. They flit hither and thither (as I also said above concerning the seeds of things), now snatched upward, now downward; they variously meet one another, associate, and again depart; in a continual alternation they now enter into diverse unions, now suffer separations, on which the origin and decay of things depend. For these [corpuscles] are not only in the Subterranean World, where they properly hold sway, but also in the Ocean and all lakes, rivers, springs, and ditches — indeed, through the whole Atmosphere they are spread out in a dense throng — just as I also said above concerning the seeds of things, which are indeed nothing else than certain fermentative corpuscles cut off from elsewhere, whether from the vegetable or the sensitive nature, agitated with a view to generation, until they attain the end intended by Nature.

[Margin: The opinion of Democritus concerning the corpuscles that constitute all things is refuted.]

But in asserting these things, I would not have anyone persuade himself that I here hold the opinion of Democritus [Democritus] concerning atoms — from which I have always been averse, as will be abundantly clear to the reader from various places in my works. For it is impossible to frame a true norm of physical science out of the polymorphous corpuscles of the Democriteans, from which he taught that all things consist, since they are repugnant to the senses and are nothing else than the idle figments of ill-occupied men. Something different must be determined concerning our particles or corpuscles, for these the Spagyric art makes manifest in the very dissolution of bodies, so that it cannot be denied — what is so obvious to the senses. There is added, too, the Microscope [*Smicroscopium*], by whose aid alone the things that before lay imperceptible are now brought forth into open light, obvious to the senses, and demonstrated; so that truly the very same things that were first in the composition of things are found again in the resolution of mixed bodies. But since I have treated of these matters more fully elsewhere, I have not wished to dwell on them longer.

CAPUT II. [Chapter II]

On the Kinds of the Elements and of the Mixed bodies, and on their use and benefit in the nature of things, arranged according to the Rule of [our] Art.

So that the things we have said in the preceding pages κατὰ τὴν θεωρίαν [Greek: kata tēn theōrian, "according to theory / by way of speculation"] may afford us some benefit in medical use, we shall subjoin practice to speculation, so that it may become known to the reader how one is to proceed in resolving each thing into its elements, and what use each may have in driving off the infirmities of the human body. But since the chemical operations set forth a little before regard not only plants but also minerals and animals, we shall first reason about each separately — how the elements too may be brought to the dissolutions of individual things through the stalactic art — as follows.

Therefore, the properties of the Elements being first set down and examined, you will proceed further according to the rules of our Art, by seeing first what each and every thing contributes to the preservation of the human race — for which they were created by the Author of Nature. And this you will achieve in the following way; and first, indeed, concerning Fire, you will reason thus.

§ I. — On FIRE.

Fire is twofold: either with a consuming flame, or without flame. Fire with flame consumes every combustible thing — such as are wax-comb [*favum*], oil, butter, fat, and all the kinds of woods, trees, shrubs, and plants; whose excrements are either ash, or lime, or soot. Fire without flame is preserved in coals, metals, stones, [and things] set on fire. From this you may deduce a universal Axiom:

[Margin: There are as many fires of differing quality as there are differences among the combustible things themselves.]

Each fire is of the property of which the combustible thing is. If this be good, wholesome, profitable to health, such too will be the flame of the thing that is consumed; but if the combustible thing has harmful qualities, the flame will likewise contain such within itself. Thus, according to the variety of combustible materials — which are countless — a variety of flames of fire will be constituted. All of which have been proved by induction in our *Combinatory Art* [*Ars Combinatoria*], from the principles of the Art. For example: Concerning the Communication of the properties of the flame; concerning its Extension to the individual members of the body; concerning its Duration; concerning the Power and efficacy that it imprints on the members of men; concerning natural Appetite, Sympathy; concerning the Virtues, etc. All of which are likewise to be understood concerning ashes, lime, soots, [and] smoke.

§ II. — On AIR.

Air is most necessary both for preserving life and for driving off evils. From this you will deduce a universal Axiom.

[The text continues at the head of the right-hand column:]

It is either Natural or Artificial. Natural air acts either by a primary or by a secondary quality.

[Margin: The differences of air.]

Of the primary quality: one [air] is temperate, and this is either Eastern or Western; another is Northern or Southern. Another is Intemperate, as the Southern and the Northern, which nevertheless is diverse according to the diverse nature of regions and lands. Of the secondary quality, air rarefies and dissolves, as the Southern; it condenses and binds, as the Boreal [Northern].

The substance of the air acts insofar as it is pure, clear, subtle — or impure, or thick, or misty. Hence you will form this Axiom: *Such is the air as is the constitution of the place or climate that dominates the air*. If therefore a place abounds in wholesome breathings-out and exhalations, it will assuredly produce wholesome air, as in places mountainous, dry, and not exposed to pernicious blasts of winds. On the contrary, that air is harmful and unhealthy which arises in places liable to putrid exhalations — such as marshlands, and subterranean places exposed to the blasts of winds,

[Margin: The quality of the air follows the nature of the place.]

and places infested with the spirits of metallic exhalations, which [air] follows the nature of the plants and animals [of the place].

From the theory of this arises artificial air, which is either cold, for tempering heat, or hot, for provoking sweat, [and] is opportune in every kind of infirmity.

§ III. — On WATER.

Water is either superior or inferior.

[Margin: The differences of waters.]

The superior is rainwater; the inferior is either endowed with a medicinal faculty or not — of which kind are spring water, well water, lake water, [and] rainwater; which again are either wholesome or unwholesome, according to the proportion of the places in which they are housed.

[Margin: Medicinal waters.]

To medicated water are referred all the kinds of thermal [waters], which are taken either from metals or from places. Waters taken from metals are salty, nitrous, aluminous, sulphureous, bituminous, ferruginous, coppery [*aereae*] [?], cupreous, golden, gypseous, antimonial, vitriolated; there are also poisonous ones, such as the Arsenical, Mercurial, etc., from which is given the rationale of the most hidden nature of all prodigious effects.

[Margin: The differences of waters according to the constitution of places.]

Waters are also taken from the constitutions of the places in which they gush forth, as the Baths [Thermae] of Germany, France, Italy, Spain, Hungary, Sicily, England, [and] Switzerland; all of which take their differences from the nature of the places through which they pass — concerning which see the treatment given most fully elsewhere in this work.

§ IV.

Diagram — Synoptic table (*Pinax*). A single large landscape fold-out branching table ("Pinax") spanning the opening, printed sideways across two leaves. and 884 are the blank backs of the leaf (only mirror-image bleed-through of the print is visible); the printed table occupies (left half) and 883 (right half), which together form one continuous tree. Running header (top of the printed side, rotated): "Tom. II. Fol. 398." Reading order used: the table is read as one continuous left-to-right brace-tree, with carrying the IGNIS and AËR branches and the head of the AQUA branch, and carrying the remainder of AQUA and the whole TERRA branch. The structural root ("The four elements are potent each in its own medical faculties") is printed at the far left of the lower register of p. 883.

Title (centered, large caps): **PINAX MEDICO-PHYSICUS QUATUOR ELEMENTORUM** — "A Medico-Physical Synoptic Table of the Four Elements."

The tree is organized from a single root statement that fans out into the four elements, each subdivided by its medical use. Transcription of the full brace-structure, branch by branch:

Root (far left, lower register): Quatuor Elementa medicis suis Facultatibus pollentia sunt: — "The four elements are potent, each in its own medical faculties:"

I. IGNIS medicus ("medical Fire") — *sumitur vel ab* ("is taken either from"):

- **Ignе ipso & est vel** ("the fire itself, and this is either"):
- **Cum Flamma depascente** ("with a consuming flame"):
- Ligna — wood
- Sevum, Oleum, Butyrum, Adipem — tallow, oil, butter, fat
- **Sine Flamma, uti ab ignitis** ("without flame, as from glowing/heated things"):
- Carbonibus — coals
- Metallis — metals
- Lapidibus — stones
- **Recrementis ipsius, uti à** ("from its own residues, as from"):
- Fuligine — soot
- Cinere — ash
- Calce — lime [quicklime]

II. AËR medicus ("medical Air") — *est vel* ("is either"):

- **Naturalis, agit vel suâ** ("natural, and acts either by its own"):
- **Qualitate, vel** ("quality, [being] either"):
- **Prima, & sic alius est** ("primary, and thus is of one kind or another"):
- Temperatus — temperate
- Intemperatus — intemperate; *each subdivided by direction*:
- Orientalis — eastern
- Occidentalis — western
- Meridionalis — southern
- Septentrionalis — northern
- } **Pro conditione locorum** — "according to the condition of the places"
- **Secunda, & sic alius** ("secondary, and thus of one kind or another"):
- Rarefacit, ut Meridionalis — rarefies, like the southern [air]
- Condensat, ut Septentrionalis — condenses, like the northern [air]
- **Substantiâ, ut** ("by [its] substance, being"):
- Purus, clarus, subtilis — pure, clear, fine
- Impurus, crassus, nebulosus — impure, thick, foggy
- **Artificialis, sic arte conficitur aër** ("artificial — thus air is produced by art"):
- **Frigidus — Contemperandum** ("cold — for tempering")
- **Calidus tum ad — Ad sudorem eliciendum, ut Laconicum** ("hot, then — for drawing out sweat, as in a Laconicum [sweating-room/sauna]")

III. **AQUA medicata est vel** ("medicated Water is either"):

- **Superior, ut aqua** ("higher [atmospheric] water, such as"):
- Supercoelestis — supercelestial
- Pluvialis — rain[water]
- **Non medicata, ut aqua** ("non-medicated water, such as"):
- Fontana — spring water
- Putealis — well water
- Lacustris — lake water
- Fluminea — river water
- Maritima — sea water
- **Inferior** ("lower [terrestrial] water"):
- **Medicata, quarum differentiae sumuntur vel à mineralibus, uti** ("medicated, whose differences are taken either from minerals, such as"):
- Salsae, nitrosae — salty, nitrous

- Aluminosae, sulphureae — aluminous, sulphurous
- Bituminosae, ferreae — bituminous, ferruginous [iron-bearing]
- Aeneae, cupreae — brazen [copper], cupreous
- Aureae — golden
- Gypseae — gypseous
- Venenosa qualitate praeditae, ut arsenicales, mercuriales — endowed with a venomous quality, such as arsenical, mercurial [waters]
- **A locis in quibus scaturiunt, eorumque non est numerus, in** ("from the places in which they gush forth — and these are without number — in"):
- Italia — Italy
- Gallia — France
- Hispania — Spain
- Germania — Germany
- Anglia — England
- Polonia — Poland
- Asia — Asia
- Africa — Africa
- America — America
- } **Quae exhibent diversas proprietates thermarum** — "which display the various properties of [their] thermal waters."

IV. **TERRA medica vel** ("medical Earth, [acting] either"):

- **Astringit, ut** ("astringes, such as"):
- **Venenis resistit, uti** ("resists poisons, such as"):
- Terra Armenia — Armenian earth [bole]
- Terra Lemnia — Lemnian earth
- Ochra — ochre
- Rubrica Synopica — Sinopic red [ruddle]
- Rubrica fabrilis — workmen's red ochre
- Terra omnis — every [common] earth
- Erethria, Samia — Eretrian, Samian [earth]
- Chia — Chian [earth]
- Selenusia — Selenusian [earth]
- **Discutit, ut** ("dissolves/disperses, such as"):
- Terra cimolia — Cimolian earth [fuller's earth]
- Terra Ampelitis — ampelite [a bituminous earth]

- Terra fornacea — furnace earth
- **Abstergit, uti** ("cleanses, such as"):
- Terra melia — Melian earth
- & innumerae aliae — and countless others
- **Deleteria** ("deleterious/destructive [earths]"):
- Arsenicalis — arsenical
- Antimonialis — antimonial
- Auripigmenti — of orpiment

Stones formed from Earth and Water — a cross-branch at the right of the table:

- **Ex Terra & Aqua lapides coalescunt, suntque vel** ("From Earth and Water stones coalesce, and they are either"):
- **Pretiosi** ("precious"):
- **Terrestres sunt:** ("[those] of the land are:")
- Rubinus — ruby
- Carbunculus — carbuncle
- Saphyrus — sapphire
- Amethystus — amethyst
- Topazius — topaz
- Smaragdus — emerald
- Corniola — carnelian
- Achates — agate
- Iaspis — jasper
- Magnes — lodestone [magnet]
- Marmorum complures species — many kinds of marble
- **Maritimae** ("[those] of the sea"):
- Uniones — pearls
- Gemmae, Perlae, seu Margaritae — gems, pearls, or margarites
- Succinum, Ambra — amber, ambergris
- **Non pretiosi** ("not precious"):
- Omnis generis lapides fabricis apti — stones of every kind suitable for building.

` flag. The directional sub-bracket "Orientalis / Occidentalis / Meridionalis / Septentrionalis → Pro conditione locorum" attaches to the "Intemperatus" (intemperate primary-quality air) node. The geographic list under medicated

waters and the "Quae exhibent diversas proprietates thermarum" closing brace span the page seam between 882 and 883 but belong to one continuous bracket.]

Reading order used: map directly to printed pages 399, 400, 401, 402 in sequence — no non-linear reordering was required for this batch. The catchword chain confirms it: p.399 ends "dura-" → p.400 begins "duratione"; p.400 ends "tan-" → p.401 begins "tantum"; p.401 ends "Sal" → p.402 begins "Sal vero." (p.398, the fold-out Pinax, immediately precedes p.399.)

§ IV.

DE TERRA.

[On Earth.]

[Margin: Differences among the kinds of earth (*Terrarum differentia*).]

Earth comes into human use no less than the elements just discussed. There are: Armenian earth, called *bolus*; sealed earth [*terra sigillata*]; Melitensian earth, which resist poisons and have an astringent effect; ochre earth, Sinopic earth, the workman's red ochre [*rubrica fabrilis*], Samian, Chian, Selinusian; Cimolian earth, *ampelitis*, and furnace-clay [*testa fornacea*]. Irish earth too, along with wood, the leaves of trees, and so on, act against poisons — though this happens more by a kind of miracle than by nature. From this you may argue as follows:

[Margin: They draw their qualities from the nature of the place (*A loci conditione trahunt qualitates suas*).]

Every earth has the property belonging to the constitution of the place from which it is dug.

§ V.

DE MINERALIBUS ET METALLIS.

[On Minerals and Metals.]

[Margin: The difference among minerals and metals (*Mineralium Metallorumque differentia*).]

Some minerals and metals alter the body, while others preserve it, doing so either by a manifest or by an occult quality. Those that preserve do so either by a primary or by a secondary quality. Of the first quality, some are temperate,

others intemperate. Temperate, like gold; intemperate, in that they are either hot, or cold, or moist, or dry.

Hot and dry in the second degree are iron, crocus of Mars [*crocus Martis*], and cinnabar.

In the third degree: flowers of copper [*flos aeris*], burnt copper [*aes ustum*], copper scale [*squama aeris*], native verdigris [*aerugo fossilis*], *diphryges*, alum, salt, niter, sulphur, and *chalcitis* — all of which we have treated more fully in Book VII.

In the fourth degree, such as *calcanthum* [blue vitriol], orpiment [*auripigmentum*], *sandaraca* [realgar], *chrysocolla*, *misy*, and *melanteria*. On these, see Book X.

Cold in the first degree, like antimony [*stimmi*]. In the second degree, like filings of silver [*argenti scobs*], litharge [*spuma argenti*], quicksilver, lead, plumbago, burnt lead, and white lead [*cerussa*]. Or, by a secondary quality, they are astringent, like *cadmia*, *pompholyx*, *spodium*, *antispodium*, alum, verdigris, *calcanthum*, cinnabar. Some bind and induce a scar [i.e. promote healing], like lead, gypsum, antimony. Or they alter by corrupting: like poisons, mercury, litharge [*lithargyrium*], litharge of silver [*argenti spuma*], orpiment, arsenic, white lead, lime, gypsum, *sandaraca*.

§ VI.

DE LAPIDIBUS.

[On Stones.]

[Margin: The difference among stones (*Lapidum differentia*).]

Stones are either precious or non-precious.

The precious ones alter by either a manifest or an occult quality. Those that act by a manifest quality are of either the first or the second quality. The first-quality ones are either cold in the first degree, like the hyacinth [*Hyacinthus*], the sapphire, and the emerald; or in the second degree, like the ruby, the carbuncle, the garnet, and the sardonyx; or in the fourth degree, like the diamond [*Adamas*].

Or they act by a secondary quality, like the hyacinth, the sapphire, the emerald, the carbuncle, the garnet, the sardonyx, the amethyst, and lapis lazuli.

Or they act by an occult, that is, a specific quality: like the bezoar stone [*lapis Bezoarticus*], the topaz, the *colubrinus*, the toadstone [*bufonitis*], the emerald, the *alectorius*, the chalcedony, the amethyst, jasper, the kidney-stone [*lapis nephriticus*], and every stone found in the viscera of animals. On these see Book VII.

The non-precious stones, again, alter by either a manifest or an occult quality. They alter by a manifest quality through heat, or cold, or dryness. By heat, like the hematite, the pyrite, the Asian stone [*lapis Asius*], the *thyites*, the emery [*smiris*], and the *schistus*.

By cold: crystal, the Phrygian stone [*lapis Phrygius*], the Samian stone [*lapis Samius*].

By dryness, like sand and brick-dust [*laterum pulvis*].

[Margin: The qualities of stones (*Qualitates Lapidum*).]

Or they alter by a secondary quality — by astringing, softening, numbing, cleansing, gluing, inducing a scar, grinding down the stone [*calculus*], or retaining the fetus.

By astringing, like the Asian stone, the Naxian stone [*Naxias*], the *geodes*, and pumice.

By softening, like the *alabastrites*, jet [*Gagates*], and the Thracian stone [*lapis Thracius*].

By numbing, like the *memphytis*, jasper, and the *ophites*.

By cleansing, like the Arabian stone [*Arabicus*].

By gluing, like the *galactites* and the Melitensian stone.

By inducing a scar, like the *morochtus*.

By breaking up the stone [*calculus*], like the *lapis Lynceus*, the Jewish stone [*lapis Judaicus*], and the sponge-stone [*lapis Spongiae*].

Or they act by an occult, that is, specific quality: like the sponge-stone, the swallow-stone [*Chelidonium*], the magnet [*Magnes*], the fish-stone [*lapis Piscium*], snail-stones [*Limacum lapilli*], the vulture-stone [*lapis Vulturis*], coral, the *lyncurius*, jet, the eagle-stone [*Aetites*], the crab-stone [*lapis Cancrorum*], amber [*Succinum*], and crystal.

Or they purge the gross humors, like the magnet; or melancholy, like the Armenian stone [*Armenus*], the *Cianeus* [blue] stone, or lapis lazuli.

De iis, qui ex Mari proveniunt lapidibus liquoribusque.

[On the stones and liquids that come from the sea.]

The stone-bearing offspring of the sea act by either a manifest or an occult quality. The manifest ones are either hot, like the *alcyonium*, sperm of the whale [*sperma Coeti*, spermaceti], ambergris [*Ambra*], and the fragrant *unguis odoratus*. Or cold, like coral and the pearl [*Margarita*], that is, *uniones*.

Of the second quality, the marine substances either astringe, like amber [*succinum*], that is, *electrum*;

or they soften, like bitumen, asphalt, naphtha, and *pissasphaltum*.

Or they cleanse, like the shells of purple-fish [*purpurae*], whelks [*buccinae*], mussels [*mytili*], *tellinae*, *chamae*, *conchilia*, sea-snails [*cochleae*], crabs [*cancrī*], and cuttlefish-bone [*os sepiae*].

By an occult quality act the pearls [*uniones*] and bitumens.

Here, reader, you have in summary whatever can be said about earthy things. If you draw these out through the precepts of our Art, they will give you so vast a material for philosophizing that you could not encompass it even in many volumes. And first, indeed, concerning the communication

[Margin: The opinion of the later authors on the degrees of things (*Posteriorum Authorum de gradibus rerum sententia*).]

of individual properties; concerning duration; concerning their powers and efficacy in acting, and so on. And through the Rules of Questions: what the powers of the individual species are, why they were implanted by nature, where, when, with what, of what kind, of what magnitude, and so forth. But on these matters see more fully what was treated in our *Ars Combinatoria*.

CAPUT III.

IATPIKON.

[Greek: ἱατρικόν (iatrikon, "medical" — the medical part / matters pertaining to the art of healing).]

De Qualitatibus primis & manifestis, occultis seu specificis Plantarum, singularumque partium, uti sunt, folia, radices, flores, fructus, semina, ligna; oleis, gummi, eorumque viribus & proprietatibus in usu Medico, ex Veterum, Recentiorumque Medicorum melioris notae monumentis extracta, & in Tabulas Synopticas reducta.

[On the primary and manifest, and the occult or specific, qualities of plants and of their individual parts — such as leaves, roots, flowers, fruits, seeds, woods, oils, and gums — together with their powers and properties in medical use, drawn from the records of the better physicians, both ancient and modern, and reduced into synoptic tables.]

Before we proceed any further, I have thought it right to set out here first a certain universal synopsis of all plants, so that we may not seem to have omitted anything that could in any way contribute to a complete knowledge of plants.

That the physicians have been occupied solely with investigating the manifest qualities of vegetables is clear from their writings. Now since the manifest, or (as they call them) elementary, qualities are four — dryness, moisture, coldness, and heat — they stretched each of these across a range of four degrees, so that some things were hot in the first degree, others cold in the first degree, others dry in the first degree, others moist in the first degree. But since they saw that degrees of this kind were too few to suit the nature of things — which is supremely eager for variety — they devised a further distinction, so that some things were moist, cold, hot, or dry in the second degree; others moist, cold, hot, or dry in the third degree; and finally others in the fourth and highest degree, hot, cold, dry, or moist. By this division of degrees they reckoned that they had encompassed the whole nature of vegetables.

When the later authorities saw that this division established in four degrees could not stand, they amplified degrees of this kind and assigned them a greater range by a sixteen-fold distribution, so that between degree and degree — between the first and the second, the second and the third, the third and the fourth — they placed other, smaller degrees, which some call "points" [*puncta*]. But anyone who weighs this matter more deeply on the more exact balance of reason will find, clearer than daylight, that this distribution of degrees is too difficult to be grasped by the human mind, on account of the immense and inextricable difficulties that can confront natural philosophers in investigating them. Let us, however, unfold a few of them. The first of these is the very

uncertainty of the degrees; second, the fallibility of the senses by which they have tried to track them down; third are those which we shall review a little later.

[Margin: The distribution of degrees is fallacious and lacks a sure mark (*Graduum fallax & incerta notitia*).]

First. The uncertainty of the distribution of degrees consists in this: that no degree can be reached precisely, and — as we also taught above — there is as great a diversity between one degree and another as the broken numbers, or fractions, that can be placed between 1 and 2. Since this brings in a kind of infinity, it likewise seems to exceed the condition of the human intellect to reach the precise degree of a quality in any given mixed body whatever. And so the differing temperaments of vegetables may rightly be compared with the diversity of human faces: just as that diversity arises from a certain infinite variety of temperaments, so too I would have you understand the same of the various parts of plants — roots, leaves, flowers, fruits, seeds — which, even within one and the same tree or herb, are imbued with the most diverse qualities.

[Margin: The fallibility of the sensible qualities (*Sensibilium qualitatum fallax experimentum*).]

Second. How fallacious is the test made by way of colors, tastes, smells, and tactile qualities, only the man knows who has frequently made trial of such qualities. Plant-experts [*Phytoptae*] for the most part form their judgment about the hidden powers of plants, flowers, fruits, and seeds from the colors white, green, leek-green, blue, saffron, yellow, red, purple, ash-gray, and black. But anyone who has read what we taught about colors in Book VIII will openly admit that to want to determine precisely the variety of all the colors in plants is something ἀδύνατον [Greek: ἀδύνατον (adynaton, "impossible")]. Add to this that it is utterly false that everything white is of a moist temperament, everything red of a hot, everything green of an undigested one, and so on for the rest — as we could amply demonstrate in this place, had we not already done so in the cited book of this work a little earlier. It appears plainly in the white oleander flower, than which nothing can be more caustic, and in the red rose, which is endowed with a certain moderate moisture entirely free of fiery heat. Color, therefore, can give us no firm and certain indication of the quality of plants.

[Margin: The fallibility of the test from tastes and smells (*Saporum, odorum fallax bonitatis aut...*).]

If we examine exactly the tastes and smells of plants, we shall find that nothing about the powers of plants can be established for us, except in general —

— that is to say, that a good smell is for the most part an indication of heat, a foul one of coldness and excrementitious moisture, an odorless one a sign of pure moisture (as in spring water); whereas in taste the botanists hold that the Sharp [*Acer*] is an indication of vehement heat, the Acute [*Acutum*] of extreme heat, the Acerbic [*Acerbum*] of cold, dry, and earthy, the Acid [*Acidum*] of an excess of the moist over the cold, the Bitter [*Amarum*] of dryness, heat, and earthy dryness, the Austere [*Austerum*] of cold over moist, the Sweet [*Dulcem*] of temperate heat and moisture, the Salty [*Salsum*] of cleansing heat, and finally the Greasy [*Pinguem*] an indication of an airy temper. So judge the more skilled of both the ancients and the moderns, the followers of Galen, Dioscorides, and Theophrastus. In all these matters it is as easy to err as to speak, since the senses cannot be a faithful judge for forming a precise verdict about the elementary qualities. Add to this that tastes of this kind for the most part take their origin from something other than the elements, as will appear later.

Yet, lest we seem in this place to condemn the venerable tradition of the ancient physicians, I say: even if the ancients did not reach the precise degrees of qualities in vegetable nature, their effort was nonetheless praiseworthy. By continual study and experience they arrived at the point of establishing a dogmatic doctrine concerning the degrees — confirmed by the experiences of countless centuries, accepted and confirmed by the unanimous agreement of physicians, and not so much discovered by human ingenuity as divinely inspired — which to this very day the best-reputed Doctors of both branches of Medicine have safely followed.

[Margin: The praiseworthy effort of the ancients in assigning the degrees of individual things (*Laudabilis veterum conatus in gradibus singulorum indagandis*).]

We do not dispute in this place whether smells, tastes, and colors flow immediately from the elementary qualities — for we have shown this to be false in several passages of the preceding Books, since the elements concur in the composition of mixed bodies only as a remote cause. Nor can it happen that those simplest bodies should generate in plants those various differences of colors, smells, and tastes; for, besides the fact that — so far as concerns the simplicity of their nature — they are devoid of all color, no other reason can be assigned by which sensible qualities of this kind should be introduced into them.

[Margin: The proximate cause of the qualities that emerge in plants (*Proxima causa qualitatum in plantis elucescentium*).]

The proximate cause of these qualities is therefore sought. We say that all the variety of colors, tastes, and smells in plants and their parts — leaves, flowers, fruits, seeds — comes from nowhere else but from those things of which each is composed, that is, from sulphur, salt, and mercury. From sulphur, indeed (as we taught in Book VIII), we showed by various experiments there that all the differences of colors arise; from salt and mercury, that all the tastes in plants derive their origin.

[Margin: From what the colors and tastes come (*Unde colores & sapor*es).]

They do not, therefore, arise immediately from the elementary qualities, but proximately from sulphur, from the fourfold kind of salt, and from the mercurial moisture. The colors all depend on the greater or lesser decoction of sulphur in plants. As for tastes and smells: that the Bitter taste consists of salt and niter, its cleansing, purgative power sufficiently shows. In this way the Acerbic resides in nature through the astringent virtue of alum; the Acid savors of the nature of sal ammoniac, and is therefore highly valued by physicians because of a certain incisive power, and for the same reason it dissolves bodies and coagulates spirits; the Austere savors of vitriol, and so possesses a styptic, astringent, and fermentative quality; the Salty, as it arises immediately from salt, so too displays the nature of salt in all things. Yet not even from these does the precise account of the said sensible qualities stand clear to us. For how many things, I ask, are bitter in taste which nevertheless, by the rules of the ancients, are by no means hot? Such are opium, chicory, and many others. Again, how many acid things exist which, even by the ancients' own judgment, are most hot — like the spirits of vinegar, of niter, and of sulphur — while that same rule of the ancients meanwhile determines acids to be most cold? How many things are sweet on the surface which, in their inner substance, indicate not, I will not say a temperate state, but the very greatest δυσκρασία [Greek: δυσκρασία (dyskrasia, "bad mixture / distemper")]?]

[Margin: From honey and sugar a caustic water is nevertheless drawn out (*Ex melle & saccharo aqua tamen caustica extrahitur*).]

Such are honey, cassia, and sugar — as is plainly shown by the fact that from them, sweetest though they are, a water is nevertheless extracted endowed with so great a caustic power that it yields to no aqua fortis: a most potent menstruum for dissolving gold, silver, and the other metals.

[Margin: Lead is said to be sweet (*Plumbum dulce dicitur*).]

Lead imprints no taste on the tongue, although its inner substance — to speak with Quercetanus [Joseph Duchesne] — is nothing other than a kind of insipid, sugary sweetness. By such and innumerable similar examples, if there were need, we could demonstrate it. From this we infer that one must not rashly trust and rely on the tastes, qualities, and outward temperaments of things. Noting this, the more recent investigators, guarding against the danger of falsehood, took another path for exploring the hidden qualities of mixed bodies — namely, through the spagyric art [*ars Spagyrica*], by which a perfect separation of the three principles of nature is made from mixed bodies. This is the one true and legitimate way by which the difference of colors, tastes, and smells is brought out; for one and the same substance can hold within itself distinct colors, smells, and tastes, which indeed you will not easily recognize without an exact knowledge of the spagyric art.

[Margin: Another method of arriving at the hidden powers of things (*Alius modus vires rerum ingrediendi/veniendi*). [?]]

[Margin: The various powers of the wood of guaiac (*Ligni Quajaci variae vires*).]

We give an example in the wood of guaiac [*Quajacum*], whose differing properties you will not easily distinguish by taste, nor will you easily find the cause of the diaphoretic [sweat-inducing] virtue it possesses; but once it is resolved into its principles, it will at once disclose the causes of the latent virtues. For, as Quercetanus rightly says, you will find that diaphoretic, that is, sudorific power placed in its mercurial acidity and its oily sulphur and finer substance — the same power that has been found to exist also in the ash-tree, and indeed in nearly all woods and trees, such as cinnamon.

[Margin: The diversity of properties and powers in herbs comes from the difference of the things that concur in their composition (*proprietas viriumque in herbis differentia diversitas a compositione rerum concurrentium*). [?]]

But the salt extracted from guaiac — how much it contributes to evacuation and to the purging of the humors — is not hidden from physicians. Opium too, which is bitter, and the other more bitter herbs, like gentian and centaury, arise from a salt separated from its own oil, that is, from its narcotic sulphur, and hence it rises into a most excellent cathartic. Just as, therefore, the diversity is great, so too there arises from it a varied range of natures: for some salts are bitter, others sweet, others sharp, acerbic, austere, salty, and purgative — and their particular faculty is more rightly attributed to the proper substance of that same salt than to some other, namely (as we said a little earlier) to an elementary quality.

[Margin: The method of the ancient Egyptians in discovering the powers of things (*Veterum Aegyptiorum modus in viribus rerum inveniendis*).]

To this spagyric art there has accrued another never-sufficiently-praised method of exploring the hidden qualities that lie concealed beneath the coverings of vegetable nature — a method drawn from the hieroglyphic school of the ancient Egyptians, and in modern times revived anew by men preeminent for sharpness of intellect. On this see the treatment we have given most fully in the second volume of our *Oedipus Aegyptiacus*, in the *Syntagma on the Medicine of the ancient Egyptians*. For by means of the signatures, that is, the external characters, impressed by God most good and great upon each individual thing, the plant-expert [*Phytopta*] will recognize what is especially health-giving to each member of the human body and fit for its preservation. Since we have dealt with these matters in the *Ars Magnetica*, the *Musurgia*, and the cited part of the *Oedipus*, I have not wished to dwell on them. Here I shall add only a figure, from which you may grasp in a single synopsis the whole — namely which plant corresponds to each member of the body and is suited to healing it, should it ever be impaired by a distemper [*dyscrasia*] of the humors. *There follows the use of this figure.*

But to proceed now to the matter we have proposed. So that the reader may derive some usefulness from what has been said thus far, it seemed good in this place to set before the eyes of the curious reader, through four synoptic and combinatory tables — or epilogisms — the whole doctrine of simple medicaments, so that what was comprehended by various authors in whole volumes might be obtained by the reader, set out on four leaves, to the great relief of the labor of reading books. Now, since it is first necessary to know which and how many medicaments and compositions can be made from the individual simples, here we first place a resolutive table displaying them all. See Table I, that is, the Epilogism.

I know that the followers of the more curious Doctrine desire this one thing: to have ready at hand a certain synopsis of the individual simple medicaments, by which they may come to know — without such great labor — the qualities of plants and of their individual parts, such as leaves, flowers, fruits, seeds, roots, barks, woods, liquors, juices, gums, resins, and finally in what degree of coldness, moisture, dryness, and heat each one is strong. Here, therefore, [we place] Table II, which will stand in the reader's stead for many books, extracted from the records of the better-reputed physicians, both ancient and modern. (Opium indeed, which stands in place of the bitter, [is included].) See Table II.

USUS TABULAE.

[The Use of the Table.]

The table is divided into ten columns. In the first column are contained the degrees of the primary qualities. In the second, the plant and its leaves. In the third, the flowers of the plants. In the fourth, the fruits, and so on, as appears from the table. If, therefore, anyone wishes to know which herb and its parts are moist in the fourth degree, let him look in the first column of the table for the fourth degree of moisture; and having found this, he will find in the [second] column the herbs — opium, hemlock, mandrake, and so on. In the third column, among the flowers, the flowers of those same plants. In the fourth column, of fruits, in the common angle, the apples of mandrake, and so on. In the fifth column, of seeds, the seeds of the said plants, and so for the rest. And in this way you will proceed in finding the qualities of the remaining herbs. As for how all these are to be reduced into their waters, oils, quintessences, and salts — this was stated a little earlier, and will be taught more fully in what follows.

§ II.

De Virtutibus Vegetabilium materialium, comparatione facta ad singula humani corporis membra.

[On the Virtues of vegetable materials, by comparison made with the individual members of the human body.]

The most wise Creator of Nature bound together whatever exists in the threefold Kingdom of Nature with bonds so tight that there is nothing in one which is not found in another according to a certain analogy. He bound evils to goods with such ineffable wisdom that even the evils themselves might turn to the good of the human race, for whose sake all things were created.

[Margin: The wonderful providence of God (*Divina providentia mirabilis*).]

He bestowed nourishments suited to feeding, and good indeed for preserving man in a perfect state of health; yet because he foresaw that man — whether through an excess of nourishments, or through a defect of them — could not always remain in an exact state of εὐκράσια [Greek: εὐκράσια (eukrasia, "good mixture / good temperament")], he produced medicaments, so that by their power and efficacy a defect might be supplied or an excess diminished, and thus by their aid man might be brought back to the balanced poise of health. But lest from the mixing together of so many powers of different medicaments a confusion should

arise, and so that all things might be carried out with the right order of reason, he willed each and every one of them to be imbued with a certain magnetic virtue — so that, taken up within the stomach as into a kind of center, and thence diffused into the whole economy of the microcosm, each should seek out its own, and above all those members, those humors and juices, toward which, by a certain sympathetic appetite implanted in them by nature, they are borne of their own accord as if by a kind of weight. And since both the nourishments and the *alexipharmaca* [antidotes]

EPILOGISMUS I.

A summary of the medicinal virtues implanted in herbs, and into how many classes medicaments can be resolved.

The following synoptic table sets out the classification. Its branches read from left to right: the broadest category stands at the left, and each bracket opens into its subdivisions toward the right.

Simple medicaments are considered according to:

I. Their matter — which is either:

- **Natural**, which is either:
 - **Animate**, which is either:
 - **Sensate** — as animals and their parts;
 - **Insensate** — as plants and their parts.
 - **Inanimate** — as are minerals and metals.
- **Artificial**, which is either:
 - **Fluid**, which is either:
 - **Non-fatty**: Waters [Aquæ]; Syrups [Syrupi]; Decoctions [Decocta]; Infusions [Infusa]; Preserves [Conservæ]; Candied preparations [Condita]; Electuaries [Electuaria]; Linctuses [Loch]; Clysters (enemas) [Clysteres]; Gargles [Gargarismata]; Fomentations [Fomenta]; Head-purges [Caputpurgia]; Sitz-baths [Infessus]; Baths [Balnea]; Washes [Lotiones].
 - **Fatty** — as are all Oils [Olea].
 - **Non-fluid**, which is:
 - **Extracted** [Extirpata]: Powders [Pulveres]; Species (powdered compounds); Sweetmeats [Tragemata].
 - **Compacted** [Coacta], which is either:

- **Moist:** Electuaries; Preserves; Opiates; Extracts, etc.
- **Dry:** Tablets and Morsels for the chest [Tabulæ, Morselli pro pectore]; Eye-salves, for the eyes [Collyria, pro oculis]; Nasal preparations, or Errhines — ἔρρινα καὶ φάρμακα [Greek: errhina kai pharmaka, "nasal medicines"] — for the nostrils; Aromatics, etc., for the brain [Odoramenta, pro cerebro].

II. The form by which they alter quality — which is either:

- **Common** [Communiter], which is either:
- **Manifest** [Manifesta], being either:
 - (1.) Hot [Cal(ida)]; Cold [Frig(ida)]; Moist [Hum(ida)]; Dry [Sicc(a)].
 - (2.) Astringent [Astringentia]; Emollient [Mollientia]; Laxative [Laxantia], etc.
- **Occult** [Occulta]:
 - (3.) Those that promote sweat [Quæ movent sudorem]; provoke urine [Urinas cient]; break up the stone [Calculus frangunt]; ward off poison [Venenum arcent], etc.
- **Proper** — that is, with respect to a member of the human body [Propriè quoad respectum ad membrum humani corporis], and these are:

Faculty	for the
Cephalic [Cephalica]	Head [Capite]
Pectoral [Pectoralia]	Chest [Pectore]
Cardiac [Cardiaca]	Heart [Corde]
Stomachic [Stomachica]	Stomach [Stomacho]
Hepatic [Hepatica]	Liver [Hepate]
Splenetic [Splenetica]	Spleen [Splene]
Nephritic [Nephritica]	Kidneys [Renibus]
Hysteric, that is, Uterine [Hysterica, id est Uterina]	Womb [Utero]
Arthritic [Arthontica]	Joints/limbs [Artubus]

[The prose below continues directly from the close of the preceding pages: God has given each medicament a magnetic virtue, so that by a sympathetic appetite it seeks out its own member and humor — "and since both the nourishments and the antidotes consist, each of them, of..."]

their own salt, sulphur, and mercury — that is, of native heat, radical moisture, and earthy dryness — the nourishments drawn from herbs, fruits, and animals

are at once roused by the heat of the stomach. The saline parts that lie hidden in those nourishments then flow together to the saline parts of the body, the sulphurous to the sulphurous, and the mercurial to the mercurial. So long as these subsist in their just measure and weight, a man remains in good health. But if the sulphurous spirits are kindled — whether through exertion, sleeplessness, and toil, or through a corrupted diet, or through intemperance and surfeit — then the salt and the microcosmic tartar are fixed, and the mercurial liquor floods everything with its inundation. At that point, as though by a sudden onslaught, the whole body is assaulted by them, and various monstrous kinds of disease arise. Against these no remedy can be fitting except those that share a certain proportion and likeness with one another. For it is by the inflowing of such remedies that the members are freed from their troublesome enemy: the medicament that has been taken in, being like that which dwells within the members, draws to itself by excess the matter that is at fault, and so discharges it.

I have treated deleterious diseases more fully in Book IX. [Margin: *Analogia rerum denominationes ad humani corporis membra* — "The analogy by which the names of things are matched to the members of the human body."]

From this it came about that physicians, by diligent inquiry, sought out these faculties down to the individual members of the human body, and once they had found them, marked them aptly with their own names. Thus we have: **Cephalica**, those that concern the head; **Ophthalmica**, those that concern the eyes; **Otica**, those for the ears; those that benefit the teeth, **Odontica**; those that cleanse the nose, φθάρμικα [Greek: phtharmika — for *nasal/sneeze-provoking remedies*], ἑρρῖνα [Greek: errhina, "errhines, nasal medicines"]. Again, those that concern the chest, **Pectoralia**; those for the lungs, **Pulmonaria**; those for the stomach, **Stomachica**; those for the liver, **Hepatica**; those for the heart, **Cardiaca**; those for the kidneys, **Nephritica**; those for the spleen, **Splenetica**; those for the bladder and urine, **Diuretica**. Physicians named them all from a certain occult mark impressed upon them by nature.

[Margin: *Effectus mirabilis medicinalium* — "The wonderful effect of medicines."]

And so that nothing might be lacking, they arranged in fine order — according to the primary, secondary, and tertiary qualities, and those they call specific — exactly what each of the simple medicaments can do, as appears from what follows. For with these they cool the sinning hot humors and warm the cold; they moisten what is dry and dry what is moist; they open what is obstructed; they soften what is hard; they purge what is depraved and corrupted among the vitiated humors; they bind together what is dissolved; they suppurate the unripe;

they constrict the slack; they expel what is virulent and poisonous; they disperse what is flatulent. But since physicians render all matters of this kind by Greek names, I have thought it right to set down here an explanation of each one, lest the reader be left at a loss over their meaning.

Explicatio terminorum Medicinalium. (*Explanation of the medical terms.*)

Astringent, στυπτικόν [Greek: styptikon] [Margin: στυπτικόν] — that is, *closing the mouths of the vessels*. Such things are cold, of thick substance, harsh, austere, and so on. It is opposed to the aperients.

Adurent (caustic), πυρωτικόν [Greek: pyrotikon] [Margin: πυρωτικόν] — that which burns. These are, first, **Vesicants** [Vesicantia]; second, **Escharotics** [Escharotica]; third, **Caustics** [Caustica].

Anodyne [Greek: ἀνωδυνόν, *anōdynon*] [Margin: ἀνωδυνόν] — that is, *relieving pain*, whether it be narcotic [Greek: ναρκωτικόν, *narkōtikon*] [Margin: ναρκωτικόν] or paregoric; though it is more often said of the paregorics.

Aperient, ἀναστομωτικόν [Greek: anastomōtikon] [Margin: ἀναστομωτικόν] — that is, *opening the vessels*. Such things are warm, but not beyond the second degree, and of thin substance. It is opposed to the **Astringents** [στυπτικοῖς, *styptikois*].

Apophlegmatizant [Greek: ἀποφλεγματικόν, *apophlegmatikon*] [Margin: ἀποφλεγματικόν, ἔρρῖνον] — that which draws the excrements down from the brain into the palate and mouth, whether it be chewed, used as a gargle, or smeared on the palate. Such things are warm, sharp, or acting by their whole substance; and they are also called ἔρρῖνα [*errhina*].

Attrahent (drawing), ἐλκτικόν [Greek: helktikon] [Margin: ἐλκτικόν] — that is, *enticing the humors and spirits from the body to the surface*.

καταγματικόν [Greek: katagmatikon] [Margin: καταγματικόν] — that which is suitable for knitting together broken bones.

Cathaeretic [Greek: καθαιρετικόν, *kathairetikon*] [Margin: καθαιρετικόν] — that which consumes superfluous flesh, applied to it.

Cathartic, καθαρτικόν [Greek: kathartikon] [Margin: καθαρτικόν] — that is, *Purging*, whether upward (ἀνω, *anō*) or downward (κάτω, *katō*); though it is said chiefly of the downward-purging (evacuant) sort.

Cicatrizant, ἐπουλωτικόν [Greek: epoulōtikon] [Margin: ἐπουλωτικόν] — *inducing a scar*: it consumes not only what flows in, but also the humor contained within the flesh itself, so that by this means the flesh is turned into skin. It is vehemently drying and astringent.

Eccoprotic, ἐκκοπρωτικόν [Greek: ekkoprōtikon] [Margin: ἐκκοπρωτικόν] — that is, *loosening the belly*, and merely expelling the faeces.

Emetic [Greek: ἐμετικόν, *emetikon*] [Margin: ἐμετικόν] — that is, *a vomitory*. As antimony.

ἐμμηναγωγόν [Greek: emmēnagōgon] [Margin: ἐμμηναγωγόν] — *provoking the menses*.

Emollient, μαλακτικόν [Greek: malaktikon] [Margin: μαλακτικόν] — that which dissolves the concreted and congealed humors, being somewhat dry and plaster-like.

Emplastic, ἐμπλαστικόν [Greek: emplastikon] [Margin: ἐμπλαστικόν] — that is, *Gluey*, which, smeared on some part, sticks to it tenaciously and fills the pores. Such things are dry and earthy, without sharpness.

ἐναιμόν [Greek: enaimon] is κολλητικόν [Greek: kollētikon] [Margin: κολλητικόν] — that which is applied to bloody wounds for the sake of staunching the blood.

Epulotic, or **Synoulotic** — that which induces a scar upon an ulcer.

Extergent (cleansing), ἐκφρακτικόν [Greek: ekphraktikon] [Margin: ἐκφρακτικόν] — that is, freeing one from obstruction by washing away the sticky and gluey humors that cling to the skin. Of this kind are the drying agents — of thin substance, nitrous, and bitter.

Glutinant, glutinatory, κολλητικόν [Greek: kollētikon] [Margin: κολλητικόν] — that which glues together and joins the separated parts. It dries more than the sarcotic (flesh-forming) agent; it cleanses nothing, but rather astringes.

Indurant, σκληρωτικόν [Greek: sklērōtikon] [Margin: σκληρωτικόν] — that which, as it were, congeals and distends.

Laxant (relaxing), χαλαστικόν [Greek: chalastikon] — that is, attenuating and dispersing the matter which, when inflated, slackens and causes tension; mildly warming, more freely moistening, of thinner substance.

Lithontriptic [Greek: λιθοθρυπτικόν, *lithothryptikon*] [Margin: λιθοθρυπτικόν] — that which grinds down and ejects the stone.

Maturant, πεπτικόν [Greek: peptikon], ἐκπυπτικόν [Greek: ekpyytikon] [Margin: πεπτικόν] — that is, [a producer] of pus...

(The terminology list continues on the following page.)

[The following is a fold-out synoptic plate. Header: *Tom. II. Fol. 404.*]

TABULA II.

A table exhibiting the degrees of the primary qualities of philosophy in plants.

This plate is a large grid. The left-hand stub column gives the quality and its degree (1–4); the body columns classify plants by their parts: **FOLIA** (Leaves), **FLORES** (Flowers), **FRUCTUS** (Fruits), and **SEMINA** (Seeds). The four column-headings carry descriptive sub-captions:

- **FOLIA** (Leaves): *"They are the broader and finer parts of the plant."*
- **FLORES** (Flowers): *"They are the subtler outgrowths of plants, distinguished from the rest of the plant by their property and color."*
- **FRUCTUS** (Fruits): *"That which the plant brings forth last, for the conservation and propagation of the species; they consist for the most part of a husk, a skin, flesh, and a seed."*
- **SEMINA** (Seeds): *"The seed is that part [which the plant produces to be cast] into the earth..."* (heading partly cropped at the plate's outer edge).

Quality / Degree	FOLIA (Leaves)	FLORES (Flowers)	FRUCTUS (Fruits)	SEMINA (Seeds) — <i>partly cropped</i>
Calida in gradu 1 (Hot, degree 1)	Absynthium, Althea, Borago, Buglossum, Beta, Brassica, Camomilla, Cassutha, Eupathorium, Melilotus, Linaria, Spica Nardi, Scolopendriu m,	Flores boraginis, buglossæ, betonicæ, buphtalmi, crispini, meliloti, camomillæ, stæchados.	Amigdala dulcia, Jujube, Nux Cypressi, Nux viridis, Uva matura.	Coriandrum, [?]cum, Lithosp[ermu m?], [?]ni, Oryza, [?]

Quality / Degree	FOLIA (Leaves)	FLORES (Flowers)	FRUCTUS (Fruits)	SEMINA (Seeds) — <i>partly cropped</i>
	Symphitum, Tussilago, Malabathrum.			
Calida in gradu 2 (Hot, degree 2)	Anetum, Angelica, Apium, Arthemisia, Betonica, Camæphytis, Hypericum, Hedera, Lupulus, Melissa, Marabium, Mirrhis, Ocimum, Pimpinella, Peucedanum, Rosmarinus, Salvia, Scabiosa, Scordium, Stæchas, Parthenium.	Amoni, croci, cariophylloru m, Ericæ, melissæ, Spicæ nardi, Gelsamini, Lavendulæ, Junciodorati, Rosmarini.	Been, ficus, capparis, Nux moschata, Myristica, Nuces siccæ, Bistacia.	Anethi, Apii, [?], Ocimi, Urtic[æ], [?]
Calida in gradu 3 (Hot, degree 3)	Abrotanum, Asarum, Vitex, Amomum, Ammi, Pictamnus, Caryophyllata , Sabina, Serpillum, Thymus, Sisymbrium,	Agni casti, Epythymi, Leucoii, Schenanthæ, Periclymeni. Liber XII — ΠΟΛΥΜΗΧΑΝΟΣ / SIMIA NATURÆ

Sectio IV — De Arte Stalactica, sive Distillatoria

Caput III — ΙΑΤΡΙΚΟΝ

This opening of the book carries two large fold-out synoptic medical tables. The first PDF page shows the **right-hand half of Tabula II** (the *materia medica* classified by plant part: Seeds, Roots, Barks, Woods, Liquors, Juices, Gums/Resins). The two following PDF pages are the blank/show-through versos of the fold-out

plate. The final s **Tabula III** (folio 405), classifying medicinal plants, flowers, and fruits by the body part they treat and by their therapeutic action.

[Reading order used: the four PDF pages are read in file order. = right half of Tabula II (folio continues from the SEMINA-cropped left half ending the prior folio)]

Tabula II (continued) — the medicinal substances classified by plant part

[Source: this is the right-hand continuation of the synoptic table whose left columns (Plant, Flower, Fruit, and the start of SEMINA) appeared on the preceding folio. The **leftmost SEMINA column is cropped at the inner plate edge**, so only fragments of its entries are legible here; these are transcribed as far as the ink survives and flagged.]

The italic definitions in the first (header) row read:

- **SEMINA (Seeds).** "[It is] that part of the plant which, cast upon the earth, [?] produces a similar [plant]." [The full definition is cut at the plate edge.]
- **RADICES (Roots).** "The root is the base of the plant, by which it stands fast, lives, and is nourished with nutriment."
- **CORTICES (Barks).** "The bark of trees, fruits, and roots is the wrapper or skin of the plant, by which it is defended against all the injuries of the air."
- **LIGNA (Woods).** "These are in plants what the bones are in animals: a hard and firm substance, by which they stand [supported]."
- **LIQUORES (Liquors).** "A liquor is that which, when some part is cut, scarified, or bored, drips out or flows forth."
- **SUCCI (Juices).** "The juice of herbs, fruits, and seeds: it is that which is pressed out by crushing and pounding."
- **GUMMI, RESINÆ (Gums, Resins).** "A gum is a watery exudation; a resin, by contrast, is oily and inflammable."

[The two following plate sides are the blank versos of the folded engraving — show-through staining only, no text.]

Tabula III (folio 405) — medicinal plants, flowers, and fruits by body part and action

Table. Running head/caption across the top: *Tom. II. Fol. 405. | TABULA III Philosophicæ; Quâ fructus medicinalis ad omnes humani corporis infirmitates* — "Tom. II, fol. 405. Philosophical Table III, in which the medicinal produce [to be applied] to all the infirmities of the human body [is set out]."

The table is read in columns: an index number; the **member or action** treated (in *italic*); **PLANTÆ & FOLIA** (Plants & Leaves — "which look to the various members by a quality of the 1st, 2nd, or 3rd [degree], or a specific one"); **FLORES** (Flowers); **FRUCTUS** (Fruits); and a rightmost **SEMINA** (Seeds) column cropped at the plate edge.

Within the FLORES and FRUCTUS cells, the abbreviations **C.** (= *Calefacientes*, warming) and **F.** (= *Frige facientes*, cooling) sort each cell into a warming and a cooling sub-list, following the heading of row 1.

#	Member / Action	PLANTÆ & FOLIA	FLORES	FRUCTUS	SEMINA (cropped)
1	Cephalica — those that look to the head	<i>Calefaciunt</i> (they warm): Betonica, Calamintha, Foeniculum, Majorana, Ruta, Salvia, Pulegium, Pæonia, Serpellum. <i>Frige faciunt</i> (they cool): Fumus terræ, Lactuca, Lupulus, Rosa, Portulaca, Plant[ago]	<i>Cal.</i> Anthos, Prunellæ, Camomillæ, Betonicæ, Lavendul[æ], Meliloti. <i>Fri.</i> Pæoniæ, Salviæ, Nenuphar, Violæ	C. Reading order used: The o not run in linear order. is the *right-hand half* of the large fold-out synoptic plate (Tabula III), continuing the table whose left half (the body-part/action index column plus FOLIA, FLORES, FRUCTUS) was carried in the preceding folio (book p. 405); its right-hand columns are SEMINA, RADICES, LIQUORES/SUCCI/OLEA, LIGNA/CORTICES, GUMMI/RESINÆ, and a final *Usus & Applicatio* column. is the blank verso of that plate. is letterpress book page 405 (running head *ARS DISTILLATORIA*, signature *Eee 3*). is letterpress book page 406 (running head *LIBER DUODECIMUS, Sect. IV*), which carries the heading and opening of Tabula IV. Reading sequence: (book 405) → (book 406), with the fold-out plate belonging to the Tabula III material that the page-405 text refers back to.

Tabula III (Synoptic), continued — right-hand columns

[The fold-out plate carries the right-hand six columns of the synoptic materia-medica table whose left-hand index column (the affected body part / therapeutic action) appears on the preceding folio. The running headline across the top reads:] "...[infirm]itates curandas exhibetur juxta Plantarum unicuique

appropriatam Naturam & Proprietatem." — "...is set out for curing illnesses according to the Nature and Property proper to each Plant." The final column is headed "**Usus & Applicatio:**" ("Use & Application:"), and the rows of that column run continuously down the whole table rather than aligning one-to-one with the medicinal rows.

The plate has **no row labels of its own** (those are the index column on the left half). The 26 rows below are given in printed top-to-bottom order so the collation step can align them with the index column from the preceding folio. The leftmost column here (SEMINA) is fully present; the columns are not cropped at the plate edge on this half.

Semina (Seeds)	Radices (Roots)	Liquores, Succi, Olea (Liquids, Juices, Oils)	Ligna, Cortices (Woods, Barks)	Gummi, Resinæ (Gums, Resins)	Usus & Applicatio (Use & Application)
C. Foeniculi, Majoranæ. F. Lactucæ, Papaveris.	C. Foeniculi, Pœoniæ. F. Sonchus.	C. Apii, Agrestæ, Calaminth æ, Ehymenth æ [recte: Thymenth æ?][?], Rutæ, Scordii. F. Acetosæ, Lactucæ, Portulacæ.	Agallochu m, Xylaloes, Aspalathi, Guajaci, Juniper. Viscum Quercinum .	Laccæ, Tragacanth i, Thus, Mastix, Myrrha, Galbanum.	<i>Sumuntur hæc omnia vel — Decocto simplici,</i> ("These are all taken either — as a simple decoction,")
Hyoscyami semen cum farina imposita.	Anemonis radix emplastrat a, Radix Aconiti, Pardalianc his.	Hierasii [Hieracii] succus, Euphrasiæ, aqua Betonicæ, anisi, chelidoniæ .	Guajacum, Santalum.	Aqua rosacea in qua Thus vigesies accensum fuerit extinctum .	<i>Composito.</i> ("as a compound.")

Of fumigation s.")
Anethi [?], Foenugræc i, Lini, Dauci, Gith [?], Sesami.	Apii, acori, foeniculi, Dauci, Galangæ, Spicæ celticæ, Nardi, Peucedani.	Liquores & Succi omnium herbarum discutienti um.	Nephriticu m.	Thus, Mastix.	[No further <i>Usus</i> entry printed in this final row of the column.]

ARS DISTILLATORIA. [Book p. 405]

[Running head: *ARS DISTILLATORIA* ("The Art of Distillation"). The left margin carries Greek technical terms keyed to each medicinal-virtue heading.]

[a remedy] that aids generation. Temperately warm, moist, and emplastic [softening/plaster-like].

[Margin: Μελαναγωγόν.] **Melanagogue** — that is, a medicine drawing off black bile.

[Margin: Νεφριτικόν.] **Nephritic** — what is suited to the kidneys.

[Margin: σηπτικόν.] **Putrefacient** — Greek σηπτικόν (*sēptikon*, "septic, putrefying"): what is most hostile to sharpness [acrimony] and to the native heat, and which either drives that heat off or destroys its balance. Such are the biting and acrid remedies.

[Margin: σαρκωτικόν.] **Sarcotic** — Greek σαρκωτικόν (*sarkōtikon*, "flesh-forming"): that is, flesh-generating, which beyond the bite [of the wound] cleanses away the filth of wounds so that it may not hinder their healing.

[Margin: ύπνωτικόν.] **Soporific** — that is, Greek ύπνωτικόν (*hypnōtikon*, "hypnotic, sleep-inducing"); such as opium, a species of nightshade [*solanum*].

[Margin: πταρμικόν.] **Sternutatory** — Greek πταρμικόν (*ptarmikon*, "causing sneezing"): which provokes sneezing, and expels the excrements of the head — both those that lodge in the brain and those that cling about the meninges.

[Margin: διουρητικόν.] **Uretic** — the same as **diuretic**: which opens the passages for urine and clears away other obstructions.

[Margin: θεραπευτικόν.] **Vulnerary** — Greek θεραπευτικόν (*therapeutikon*, "healing"): which, taken internally, aids the consolidation [healing-together] of wounds.

An **anodyne** is a medicine that calms and soothes pains.

With these preliminaries set down, it seemed good to lay before the reader's eyes — in the Synoptic Table that follows — which plants, leaves, flowers, fruits, seeds, roots, oils, juices, woods, and so forth bring a remedy to each of the diseased members, and with what virtues they are endowed. This material has been collected here from the better medical authorities. The use of the table is self-evident. Suppose, for instance, you wish to know which medicines purge bile: look in the first column (*bile-purging*); then, proceeding along the lateral and transverse series, you will find in each column — under leaves, flowers, fruits, juices, and the rest — the medicines suited to your purpose. As was said above, these medicines can, by the Spagyric art, be resolved into salts, waters, oils, and spirits, or else be administered both internally and externally in the form of decoctions, conserves, juleps, syrups, and the other modes we taught in the first Table. See **Table I**.

§ III.

An account of the fourth Table. [Tabulæ quartæ expositio.]

By what art the ancients and their successors came to know the virtues of herbs, we set out in the preceding Books together with a Synoptic Table of all the simple medicines. Now, however, we shall present in this place another Table, which we have drawn from the German books of the Chymists Tannhauser [Tannhäuser], Tabernæmontanus [Tabernaemontanus], and Carichter [Carrichter]. These authors took a different road: by the aid of the Spagyric art they arrived, with a truly happy success, at a knowledge of the true and genuine virtue and efficacy of plants. They did so in the following manner, through long and difficult experiment.

First, they investigated the proper time at which each plant ought to be gathered, and when — as the saying goes — the virtue of each several plant is at its height [*in auge*]. For they knew that plants are by no means to be gathered all at the same time, plants which differ so greatly in virtue and quality. For just as all plants are composed of diverse parts — that is, roots, flowers, fruits, seeds, and so on — so too they vary among themselves; and accordingly one must await the opportune time for gathering each part. Hence, with singular diligence, they observed by astronomical knowledge the course of the Sun and Moon as they pass through the twelve signs [*dodecamoria*] of the Zodiac, together with the motion of the planets and their mutual aspects to one another — aspects which do not hold themselves the same everywhere, but according to the constitution of the horizon proper to each Region.

[Book p. 406] [Running head: *LIBER DUODECIMUS, Sect. IV.* ("Book Twelve, Section IV.")]

These things, then, being duly and lawfully observed, they selected the plants of more powerful virtue. When each of these had been resolved, with truly the highest skill, into its three principles, the virtues of salt, sulphur, and mercury inherent in each plant — discovered by the benefit of the Spagyric art — they resolved into certain analogous oils, essences, and salts; and by what method and on what principle, this will appear in what follows. Having obtained the saline-sulphureous-mercurial grades of each plant, they turned to investigating the hidden powers and properties of each plant; and this study accomplished, they at last founded a new Botanical doctrine — one more certain than all the others already related above, and confirmed by manifold experience, and most apt for medical uses, inasmuch as in them the astral virtue and influence corresponded

exactly with the planetary stars set under them. For just how much the astronomical reckoning of time contributes to the opportune gathering of herbs, learn from the following experiment.

EXPERIMENT. [*Experimentum.*]

[Margin: A matter of great moment in things subject to the constitution of the time.]

Cut from a tree, while it is still fixed in the earth, a little piece, at the time when the plant's power most exerts itself; and another little piece from the same tree, exactly equal and matching the first, but at a time contrary and opposed to the time at which you cut the first. Weigh these two pieces in an exact balance, and you will find the first far lighter, on account of its having been cut at a drier season; the second heavier, on account of the moister constitution of its season — as experience teaches in all woods. Indeed, if you cut one little portion of the same plant from its southern side and another from its northern side, you will see the one outweigh the other, even though equal in size and thickness — the northern outweighing the southern; the reason for which we shall assign later. The same you will find in digging up mud, clay, and the other earthy clods. For vessels (as I have learned from potters) are much more durable in the fire when made from clay dug up at the opportune time than from clay dug at the wrong, or wholly contrary, time. And it is likewise plain in the felling of timber for building: when the Moon is set in an unfavourable place, all of it lies open to worms, as long experience has taught; which does not happen when the Moon is set in a favourable place.

The Table is divided into five columns. [Margin column-key:] The first contains the names of the plants; the second, the time of gathering; the third, the grades of the three principles; the fourth, the analogues of the quintessences and salts to the three principles; the fifth sets out the knowledge of the medicinal powers — as follows.

TABULA IV. SYNOPTICA.

Plantarum in sua tria principia resolutarum. ("Of Plants resolved into their three principles.")

Nom. Plant. (Name of Plant)	Collectio (Gathering)	Compositio (Composition)	Resolutio (Resolution)	Vires (Powers)

Diagram. Full-page engraved plate (folio marked *Tom. 2. Fol. 406.* at upper right). The plate is titled, on a banner held by two flying putti across the top: "**The Sympathetic Type of the Microcosm with the Macrocosm**, that is, expressing the *signatures* of plants together with the several members of the human body." At the center stands a nude male figure, arms outstretched, the torso opened to show the internal organs (heart, stomach, intestines). The figure is enclosed in a great oval. An inner circular zodiac band surrounds the body, its twelve signs marked by their glyphs; a set of radial lines runs from the body outward to a ring of oval cartouches around the rim, each cartouche naming the plants whose signature corresponds to a particular bodily part. Each radial line is labelled with the bodily destination it points to (*ad Caput* = "to the head," *ad Oculos* = "to the eyes," etc.).

Below the navel, a horizontal row of planetary/metal glyphs is engraved across the abdomen: ♄ ♃ ☉ [or the symbols for the seven planets] ♀ ... flanked by ♂ on either side (the alchemical planet-metal series across the belly). These are small

and partly worn; rendered here as the planetary series but several individual glyphs are indistinct [?].

Radial destination labels (reading clockwise from the top), each with the plants assigned to it:

- **ad Caput** ("to the head") — top center.
- Cartouche (top center): *Pæonia, Iuglandes, Squilla* — "Peony, Walnuts, Squill."
- Cartouche (upper right of head): *Hyssopus, Melanthium, Tussilago* — "Hyssop, Black-cumin [*Melanthium*], Coltsfoot [*Tussilago*]."
- Cartouche (upper left of head): *Flos Euphrasiæ, Moracinum, Flos Potentillæ* — "Flower of eyebright [*Euphrasia*], [mulberry?] [?], flower of cinquefoil [*Potentilla*]."
- **ad Oculos** ("to the eyes") — upper, between head and left arm.
- Cartouche: *Dentaria, Hyoscyamus, [semen?] Acini, mali punica* — "Toothwort [*Dentaria*], henbane [*Hyoscyamus*], [seed of] grape-stones, pomegranate" [several words abraded] [?].

Zodiac glyphs around the inner band (clockwise from top): ♈ [Aries], ♉ [Taurus], ♊ [Gemini], ♋ [Cancer], ♌ [Leo], ♍ [Virgo], ♎ [Libra], ♏ [Scorpio], ♐ [Sagittarius], ♑ [Capricorn], ♒ [Aquarius], ♓ [Pisces].

Caption beneath the figure, **The use of this figure:**

In the circuit of the figure, plants are arranged to correspond to each member of the human body; these are indicated by lines drawn to the said members. For example: should you wish to know which plants suit ailments of the head, follow the line drawn from the crown of the head, and it will point you, in the circuit, to *Peony*, *Walnut*, and *Squill* — which, since they express the signature of the head, are likewise judged by physicians to be the most potent remedies against diseases of the head. Proceed in the same way with the rest. Since these are perfectly straightforward, I did not think they needed any further exposition.

[Many of the peripheral cartouche labels are engraved in very small type and are abraded at this scan resolution; the plant lists above are transcribed as far as legible, with [?] on uncertain readings.]

[The verso of the plate is blank.]

ARS DISTILLATORIA. [The Art of Distillation.] — 407

[Continuation of the *Tabula IV Synoptica*: each plant is given with the date and astrological circumstances of its **Collection** [Collectio], its **Composition** [Compositio] into the three principles Sulphur / Sal (Salt) / Mercury with their grade-numbers, its **Resolution** [Resolutio] products, and its **Powers** [Vires].]

With these matters set down, I would now have had to teach the method by which water, oils, salts, quintessences, and *magisteria* [concentrated essences] can be extracted from individual herbs, plants, roots, leaves, barks, woods, flowers, fruits, and seeds. But since these things have already been treated by countless authors, I deliberately passed them over — lest I seem to be playing the apothecary rather than the philosopher. If, however, anyone wants the method and the rationale set out exactly, let him read Quercetanus [Joseph Duchesne], Angelus Sala, Libavius [Andreas Libavius], Bauhin [Caspar Bauhin], Wecker [Johann Jacob Wecker], Porta [Giambattista della Porta], Castellus, Schröder [Johann Schröder], Mylius, and countless other writers on antidotaries.

CAPUT IV. [Chapter IV.]

On the prodigious powers of plants, which are shown to have taken their origin from subterranean sources. [De prodigiosis plantarum facultatibus, quas ex Subterraneis originem suam nactas fuisse docetur.]

[Margin: *Ratio metamorphoseos*. — "The reason for the metamorphosis."]

Now that the kingdom of vegetable Nature has been surveyed, it remains for me to show the causes of some of those prodigious operations observed in plants. The first of these is the transmutation of one plant into another. This happens for no other reason than a difference of site, a change of place, or transplantation.

[Margin: *Mira rerum transmutatio ac μεταμόρφωσις*. — "The wonderful transmutation and metamorphosis of things."]

For when like is joined to like — if the soil is rich and fertile — it is a matter of experience that a plant degenerates from a poorer condition into the likeness of a better and similar nature; and conversely, when the genius of the place does not agree with it, that on account of the inner properties of soil and sky it takes on a

different temperament. Hence it comes about that one part of its former virtue is abolished while another part remains. And when plants are carried off to places far apart in space, where they meet with an entirely contrary soil and nourishment, they must likewise degenerate, so that scarcely any trace of their former form remains — the same thing we said happens in animals in the preceding chapters.

For if there were not in the earth a dissimilar and disparate condition of soils, plants of every kind would be born alike in all parts of the world. This is plain from the various kinds of wine, all of which arise from the differing combination of salts, sulphur, and mercury with the earthy clods — and then from the difference of colors, with their unequal variety, and from the difference in the flavor, odor, and size of fruits, woods, flowers, and seeds. These varieties, in different regions and other places, are caused by one disposition or another of the inclination of the world and of the Sun striking the earthy body.

[Margin: *Myrtus*. — "The myrtle."]

Thus the myrtle in Egypt excels in the sweetness of its scent, while elsewhere it is an odorless tree.

[Margin: *Persica arbor*. — "The peach tree."]

In Persia the peach is found to be deadly, while in Europe it is found to be of the most pleasant taste — and so with the rest of the plants and fruits, which in suitable places display the best character, in unsuitable places the worst. But to define everything in a single maxim: the flavor, odor, and color of plants, fruits, and seeds is just such as is the quality of the nourishment by which the plant is fed.

[Margin: *Salomon novit fibras terrenas unicuique plantarum inferendarum opportunas*. — "Solomon knew the earthy fibres suited to the planting of each kind of plant."]

It was therefore not inappropriate that Abenezra [Abraham ibn Ezra], in his commentary on Book III of *Kings* [*Regum*], dared to say that Solomon planted in various places of Palestine plants of every kind — such as balsam, clove, pepper, and others proper to Arabia, India, and the rest of the regions lying under the torrid zone — and that he assigns the reason for this: namely, that (he says) through the knowledge infused into him, Solomon knew the fibres of the earthy parts diffused throughout the whole globe of the earth, and knew the temperament of the soil suited to each of the said trees and plan-

the right one for planting, and in just this way we find that he planted balsam and the other aromatic shrubs in the forest of Lebanon. Experience teaches the same thing in animals, which produce that effect in themselves which the plant—the animal's nourishment—has by its own nature and power. [Margin: The powers of plants are derived into the animals that feed on them.] So if cattle take herbs endowed with a laxative force as their fodder, their milk produces the same effect in human beings; and if they take in poisonous food, they infect both animal and man with malignant qualities—as is plain in the case of honey made by bees from the flowers of poisonous plants. [Margin: Honey that brings death.]

As for why the clotted blood of a he-goat, when taken, is so great a remedy for those suffering from the stone, there is no other cause than that such goats feed on saxifrage herbs, which mostly grow on cliffs and rocky places; and how much the stone-breaking [Greek: λιθοντριπτική (lithontriptikē, "stone-breaking" — lithotriptic)] power of these herbs contributes against [Greek: λιθίαισις (lithiasis, "the stone" — lithiasis)], everyone knows. [Margin: Why the blood of a he-goat heals the stone.]

If, then, nourishment drawn from the earth has such great power to transform the natural character of plants, surely no one ought to wonder that, from the same cause, various metamorphoses and transmutations of plants arise. For as we have said elsewhere, experience has revealed that the cinnamon plant, planted in Lusitania [Portugal], degenerated into laurel, pepper into ivy, and clove into something resembling a chestnut. [Margin: The marvellous effect of transplanting plants of foreign regions.] But to leave aside the plants of the more distant Indies: in our own European regions this is so common that it is no surprise. For we see wheat degenerate into spelt, then into oats, and finally into darnel, maize, or cattail, when sown in unsuitable places; and these same revert in the same order—from darnel to oats, from spelt back to wheat—when sown on ground proportioned to wheat. [Margin: Various transmutations of plants.] But since these matters have been set out more fully in the Seventh Book, we have decided not to repeat them. Cabbage turns into turnip, and conversely the turnip turns back into cabbage with time. Theophrastus teaches that basil changes into wild thyme or water-mint, and water-mint into mint or horse-mint. I could bring forward countless examples of this metamorphosis here, but since they are commonly known, I do not dwell on them. But now let us set down an experiment on the transformation of plants and animals.

EXPERIMENT.

On insects to be transformed from vegetables through putrefaction.

[Margin: Lib. Synt. Chymic.]

Libavius [Andreas Libavius], no obscure chemist, relates in these words how great are the marvels of Nature that can come about through putrefaction: "Among these things," he says, "putrefaction stands out as wonderful in making things rot, by a process of opening and resolving—producing incredible effects, and, because it works in a twofold manner, itself divided in two. The one kind, admitting the external air into a vessel that is not closed but open, plays in this admirable variety in both animals and vegetables, as experience witnesses and teaches. If you crush some vegetable and place it, thus crushed together with its own juice, into an open glass, this putrefaction, in the open container and not shutting out the raw air, will transmute it into little animals and insects of one and the same kind—indeed wholly new ones, never before known to anyone. Each single vegetable will generate its own peculiar kind of little animals, perhaps corresponding to its own nature and properties, though it has not been granted me to test and investigate this so far. But concerning the wonderful animals and insects arising through putrefaction from putrefied herbs and vegetables, I am certain, inasmuch as I have several times—and indeed not with one but with several herbs and seeds—made trial of the thing. Putrefaction carried out closed, that is, in a vessel well sealed and stopped, turns crushed herbs and any vegetables, well enclosed in some vessel, into a liquor containing their virtues, and far more effective in removing diseases than the raw herbs themselves usually are. In dissolving salts, minerals, and metals, and in opening up their solutions, the use of putrefaction is very great—so great that without its help nothing good at all can be achieved upon all those bodies. And it takes place in a [water-]bath, or in horse-dung, or in any other place—indeed even without any fire, yet in such a way that in winter-time the vessel is placed in a heated room or cellar, lest the liquor congeal with the cold and the glass burst into pieces; though this kind of putrefaction requires a longer space of time. Let us suppose Germany's experiment with the elder and with animals: I had collected tender and fresh elder-shoots that had first sprouted in spring from the little tree itself, and these, well crushed, I had put into a roomy glass, which—closed and set in a cellar in winter-time—I guarded with singular care for one year and another, yet in such a way that I never brought fire near it..."

CAPUT V.

On the various accidents of plants, to be unravelled by way of questions.

It is asked, first: Why are the trees that grow beneath the Torrid Zone the most solid? By frequent observation I have found that those more precious woods which arise under the Torrid Zone—such as sandalwood, ebony, and the cochineal-tree [Coccus]—besides being most solid, also have all their fibres arranged in circles, of which more later. I say, then, that this happens because of the motion of the Sun, which, with its most fervent rays, strikes them continually and uniformly from morning until evening, and then passing back and forth from the Southern region into the Northern and again from this into that. Thus too, the superfluous moisture being drawn off, it so compresses the inmost fibres of the trees that the mass seems to be made of stone, unable to float on the surface of water.

Why this does not happen in the Temperate Zone—to make the cause of this matter shine out more clearly, I have decided to demonstrate it from an experiment.

EXPERIMENT.

[Margin: Whence the differing disposition of the fibres in the trunks of trees.]

Cut the woods of various trees with a flat, straight section, and you will find that those brought here from the Torrid Zone have their fibres arranged in circles around the cylindrical trunk, while those under the Temperate Zone show—I know not what—a disposition of fibres aiming at something hyperbolic. This struck me with no small wonder; and, having speculated about the cause, I found none other than the Sun's heat, which affects the trees differently according to such a position. Let there be, for example, a trunk A B of ebony wood.

Diagram. A woodcut of a cylindrical tree-trunk, lying horizontally, cut through to show its end-grain. The cut face displays concentric circular growth-rings (the fibres arranged in circles, as described for Torrid-Zone wood). The trunk rests on a rough cut base. Cardinal directions are marked around it.

- (top center, above trunk): **Bor** [Boreas — North]
- (left of cut face): **occ** [occidens — West]
- (right of cut face): **Ort** [oriens — East]

- A (left end of trunk): **A**
- (center of cut face, faint label across rings): **A·M·S·B** [?] [the point-letters across the ring face; partly obscured by the engraving]
- B (right end of trunk): **B**

If you cut this with a straight section parallel to the horizon, you will find the essential fibres—through which the plant takes up its nourishment—all arranged in circles. The reason for this we gave just now: because trees of this kind are perpetually struck equally on every side by the Sun's rays, from which a circular disposition of the fibres must necessarily follow. Now let there be wood of our own regions, whatever sort it may finally be; and if you cut it in the said manner, you will see the courses of the fibres no longer forming circles, but aiming at something parabolic—I know not what—as appears in trunk D. The reason for this is that under the Temperate Zone the Sun looks almost perpetually upon the same face of the tree.

Diagram. A woodcut showing the end-cut face of a Temperate-Zone tree-trunk (trunk D), with the growth-fibres no longer concentric circles but drawn into a parabolic / semicircular pattern. The face is lettered to mark the northern (Boreal) and southern (meridional) semicircles.

- (left): **S**
- (top): **B** [Boreal side]
- (right): **T**
- (lower / interior, faint): **D** [the trunk-letter; partly obscured]

Let S B T be the northern semicircle, and S D T the southern. Since, therefore, the Sun perpetually strikes with its rays the meridional surface of the tree, S D T, but scarcely ever strikes the greater part of the tree, S B T—inasmuch as that part looks unswervingly toward the northern region—it comes about that the courses of the fibres toward the northern region, S B T, are bound fast by cold, while on the southern side, through the continual battering of the rays and consequently by the force of attenuating heat, they are dilated, as appears in figure T.

Diagram. A woodcut of a tree-trunk end-face (figure T) showing the fibres dilated and spread out on one side under the influence of solar heat, in contrast to the tightly bound fibres on the cold northern side. The rings are eccentric, crowded on one side and widely spaced on the other. No legible point-labels resolve on the face. [Illegible: interior labels too fine to read at this resolution.]

But whoever desires more on these matters, let him consult Book III of the *Magnetic Art* [*Ars Magnetica*], the chapter on the magnetism of plants, where we have described marvels of Nature of this kind more fully.

From these things we conclude that, if anyone were to cut a tree under the more boreal parts of the world in the said manner, the result would be that he will find the constitution of the fibres arranged no longer under a hyperbolic figure, but rather under a parabolic or elliptical one. [Margin: Why in other parts of the world the fibres take shape according to a hyperbolic figure, or a parabolic, or an elliptical one.] The reason is that, just as the shadow of the Sun on flat surfaces—under the Temperate Zone, indeed—describes a hyperbola on one side, so on the other side, namely the one tending more toward the north, it describes parabolas, and within the Arctic circle as well it describes ellipses. [Margin: The reason confirmed by the [solar] gnomon.] So too, I would believe, it comes about that, when the Sun's rays fall upon the rounded trunks of trees, they shape the trees' fibres according to the differing sections of the incident rays. See what we have also handed down on these matters in the *Great Art of Light and Shadow* [*Ars Magna Lucis et Umbrae*].

As I press on with a deeper investigation into these things, something wonderful and most worthy of observation occurs—namely, that the suckers or twigs of some tree, cut in two, seek each other only at the place where the cut was made. But let us show the matter by experiment.

EXPERIMENT.

Let both parts of some cut sucker, supported by floats of cork, be placed in a shell filled with water. I say that the parts, where they have flowed together toward each other, will join only at the parts at which the cut was made; or if they do not touch by their sympathetic parts, they will restore themselves to a parallel position. The reason for this is that they do not seek to be joined except in the way in which Nature, for their preservation, willed them to be united—for in this way they keep themselves better, and will draw nourishment more easily and in a way more suited to their nature, which would not happen if they drew toward each other in an inverted way. Let the parts of the cut sucker be C D and A B, set upon their supports and placed in the shell.

Diagram. A woodcut showing a circular shell (basin) of water seen from above, with two cut sucker-segments floating across it on cork supports. The two segments are lettered at their ends to show the matching (C–D) and non-matching (A–B) cut faces.

- (upper segment, left and right ends): **A ... B**
- (lower segment, left and right ends): **C ... D**
- (interior letters along the floating pieces, faint): **D · A · B / C** [?] [the small interior labels are partly obscured by the engraving lines]

I say that the parts B and D will never flow together, because they do not correspond in the courses of their fibres; but the part B [will join] to the part D—because they have a fitting arrangement of fibres—I say will soon embrace each other. [recte: read consistently with the argument, "part A to part D" / "B to C" by matching cut-faces; the printed text repeats "B ... D".] [?] From this, by the wonderful force of Nature, it comes about that the sucker would rather perish than be joined in a position hostile to itself. For every single thing moves and turns itself toward what is like itself, and inclines toward itself, according to its whole power—as much by its specific virtue as by its elemental virtue. See what we discoursed more fully on these matters, through various experiments, concerning the Divining Rod in the Tenth Book.

I will add here another thing most worthy of admiration, of which—since I have not made the experiment—I likewise cannot assign the hidden reason. The Botanists say (perhaps following Marsilius Ficinus [Marsilio Ficino] in his little book *On Preserving Health* [*De Valetudine Tuenda*]) when he states: "Hellebore, when it is gathered, has this property: that whether you draw the leaf downward or upward, it is then believed to happen, by an instantaneous contact, that it draws the humors either upward or downward." [Margin: A wonderful effect of hellebore.] Schröder confirms this in [his] *Porta*: "If the root of elder," he says (understand *Ebulum*, dwarf-elder), "is pulled upward, it purges by the upper passages, that is, by vomiting; but if it is drawn down through a pit made beneath, it is established that it likewise obtains its effect downward, by the stool. The catkins, too, of the same elder, if they are plucked toward the top, move vomiting; but the belly, if you pluck them downward." [Margin: The cause of these wonderful effects.] But since the matter has not yet been established for me by experiment, in investigating the truth of an uncertain cause and an effect not yet explored, I have judged that time should by no means be wasted in fruitless labor—unless perhaps we were to say that the offshoot and concourse of the purgative faculty follows toward that part where the violent motion has occurred. For we know that in the human body the humors flow together to the place where pain presses, or where some violence has been done to a limb, whether through a bruise or a blow, an ulcer or a wound. For at the touching of leaves of this kind it is certain that an agitation of the little spirituous bodies hidden in the plant takes place toward that part where the disturbance began,

whether upward or downward; and consequently, being there at last condensed, they require a greater force. So it is no wonder that the part drawn from above purges by vomiting, the part below by the stool. For a greater portion of the little bodies is always carried upward than downward; hence it also purges more violently by vomiting than where a smaller quantity acts; hence it purges downward more gently than upward.

It is asked, second: Are there truly granted those prodigious powers of plants of which the Botanists speak? [Margin: On the causes of the prodigious effects in some herbs.] I answer that many—indeed most—of the herbs adduced are superstitious fables introduced by Magi to confirm the power of Nature through things that have been falsely established by some pact, implicit or explicit, with a demon. Therefore I would not have credence given to them, since nothing is more customary for the enemy of the human race than, under the pretext of admirable powers and faculties lying hidden in herbs, to lead the too-credulous into superstitions; imbued with which, they ever direct their minds toward more occult things, until at last, drawn on by a pernicious and deadly persuasion, they devote themselves to the demon, to the ultimate ruin of the soul. [Margin: The signs of superstitious actions.] The signs of latent superstition are these: if various circumstances are required to be joined so that the herb may obtain its effect; if [it is gathered] with preliminary ceremonies and the muttering of barbarous words; if in a certain bodily posture or condition; if with the body naked; if at a certain degree of an ascending star; if, finally, [the herbs] are prescribed to be gathered with manifest adjuration of a demon. Of which kind is that stupid superstition of the counterfeit Zoroaster in the *Geoponica*. [Margin: The superstition of Zoroaster.] "If," he says, "some tree has been barren for many years, and a farmer comes girt with a sharp axe to cut down the tree, and a friend pleads on its behalf and pledges that next year it will bear fruit—and the farmer, persuaded by his friend's words, has gone off—that tree will, beyond doubt, bear abundant fruit." What has a barren tree to do here with a friend's prayers on its behalf, begging that it not be cut down? Contrivances of this kind, beyond counting, are wont to be devised by the demon's aid, by ill-employed men and Magi, to deceive the unwary. For since the natural virtues of plants operate of themselves and from their own nature, all such sorcerous circumstances and empty observances are truly worthless—unknown words, blessings, crosses, and the whispers of barbarous voices—since they can neither augment the faculties of natural things nor make them operate beyond what Nature has implanted in them, however much both Magi and demons may labor, to whom it has by no means been granted to change the nature of things. If, then, some plants exhibit certain admirable powers without the addition of superstitious operations of this

kind, you may be certain of [Margin: The signs of the truth of the prodigious powers in herbs.] the marvellous native faculty of such a plant; just as in what preceded we showed concerning the wonderful nature of palms and orchids, and also concerning the marvellous marriage of plants by [Greek: ἐμφύτευσιν (emphyteusin, "engrafting" — implantation)], that is, by grafting. But now let us set down the traditions of the ancients concerning the prodigious powers of herbs, so that the Reader, in reading such things, may not show himself too credulous, but may diligently explore what Nature can do and what it cannot—as will be made manifest from what follows.

Among the Romans, those were held in great honor who wrote on the history and powers of plants and were distinguished in this field—by a sufficiently manifest proof: that when Carthage had been taken, of all the libraries they found they gave away to various kings and princes [everything] except thirty-two volumes on herb-lore and agriculture written by Mago the Carthaginian alone, which they brought to Rome [Margin: Mago the Carthaginian, author of thirty-two volumes on herb-lore.] and ordered to be translated into the Latin tongue—Mago alone, skilled in herb-lore and agriculture, thus winning their favor. So astonished, in the end, was antiquity at the faculties of herbs, that the writers of those times related certain wonders about herbs.

[Margin: The slain whelps of a dragon recalled to life by an herb.] The historian Xanthus, in the first book of his histories, wrote that the slain whelp of a dragon was recalled to life by its parent through a certain herb, which the Magi call Balis; and that by the same [herb] Thilon, whom the dragon had slain, was restored to safety. The same writer related that, by King Juba of Mauretania, a man in Arabia was recalled to life through a certain herb—things which, however, are not to be understood to the letter, as they say, but [as referring] to the virtue implanted in the herbs.

implanted, of great strengthening power, [so that] Thilon was as it were freed from death, from which he was not far off—since by the common philosophers' refrain there is no return from privation to possession. [Margin: Fabulous accounts of herbs.] The things that follow are to be ascribed to fables rather than to histories, when they say: that the woodpecker, when a wedge has been driven into the hollows it has in trees, is accustomed to extract it by applying a certain herb—so Democritus and Theophrastus; indeed, that the herb Aethiopis, by its touch, opens all things shut, with certain murmured incantations chanted—at which, however, I greatly wonder that Mattioli [Pietro Andrea Mattioli] believed it as most true. For he says: "I remember, when in former years I was staying at

Venice, that I saw a certain man condemned to hanging, for whom all the doors were thrown open and the bolts cast off, merely by a single herb applied, with certain little signs chanted." But that this happened by incantations and not by the native virtue of the herbs, even he himself admits. He says further: "Another herb of nearly the same faculty, not unknown, is found in the mountains of Italy, which, when trodden by horses, immediately loosens their iron shoes; this herb is everywhere called, from its effect, *Sferracavallo* [horseshoe-loosener], and it is a species of *Lunaria* [moonwort]." For my part, having made trial with an iron horseshoe, I was not able to discover the truth of the matter.

It has, however, been observed that the wounds and ulcers of those become inflamed who have made a journey on foot through places teeming with pernicious plants—such as hemlock and the other kinds of aconites; [Margin: Various effects of plants.] but on the contrary that diseases are healed, where healthful [plants] have been trodden by wounded travelers—as they report of the species of plantain. The Botanists report, too: that the splenetic are healed by the touch of *Hemionitis* [moonwort/spleenwort]; epileptics by Roman peony root hung from the neck; the jaundiced by greater celandine or shepherd's purse laid under the bare feet in the shoes; that aconite *pardalianches* brings death to females [?]; that no one is troubled with bleariness of the eyes [Margin: Various effects of plants.] so long as he keeps about him a very clean root of wild dock. He will cease to be tortured with strangury who burns up his own urine [strangury?] by burning tamarisk wood. Indeed it became known to me by experiment that barbed yew, applied to the urinary canal, immediately freed the sufferer from dysuria, that is, from difficulty of urinating. They think that a swelling of the groin does not at all grow up in those who carry a myrtle twig about them; that by the touch of *Scordium* [water germander] corpses are preserved—as the records not only of Mithridates but also of Galen attest. [Margin: Herbs that keep off hunger and thirst.] The Scythian discovered the Scythian herb growing around Boeotia, very sweet indeed to the taste—whose great recommendation, of course, is that those who hold it in the mouth do not feel hunger and thirst, yet for only a short time. The herb called Hippice among the same people does the same, since it provides the same effect to horses too. And they hand down that by these herbs the Scythians can endure even twelve days in hunger and thirst—but let these things be said by way of [Greek: ὑπερβολικωτέρως (*hyperbolikōtēros*, "rather hyperbolically" — with some exaggeration)]. O how fortunate armies would be, if without other provision, by the use of an herb alone held in the mouth, they could endure thirst and hunger for twelve days!

Pythagoras handed down that by the herb *Coriocesia*, and also by *Callitia*, water is frozen—which I say is true in the case of herbs first coagulated into a nitrous substance; but this effect ought to be reckoned to come not from the herb but from the niter, as experience establishes. [Margin: Aproxis draws fire.] The things that follow are fabulous: Pythagoras says that the herb Aproxis, whose root no less than naphtha conceives fire from a distance [draws fire]; that the plant Alchemenis is born of an amber color, without a leaf. Democritus mentions the *Tardictylis* of India, whose root, ground into little pellets and drunk in wine each day, makes the harmful confess all their crimes by night, through empty imaginings of deities. By the touch of the herb Ariamis, pieces of wood first anointed with oil are kindled on the spot, if it is plucked when the Sun is in Leo—which is no wonder, since at Rome even chaff on the bridge of S. Angelo is seen to catch fire from the heat of the Dog-Star and of the Lion. The ancients handed down that, by *Therionarca* growing in Cappadocia, [Margin: Wild beasts made torpid.] Lycia, and Mysia, all the wild beasts to which it is applied grow torpid, and are revived only by being sprinkled with hyena's urine. Certainly it is known that all herbs endowed with a narcotic force—the species of nightshade, thorn-apple, and the like—produce this, when eaten, however. They also hand down that *Ophiusa* is born in Elephantine of Ethiopia, livid and horrible to look upon, which when drunk causes the terror and threats of serpents to hover [before the eyes], so that those who have drunk it inflict death on themselves from that fear; and for this reason the sacrilegious are forced to drink it—though palm-wine counteracts it. I would not easily deny that a similar power can exist, since, as we taught in the Book *On the Nature of Poisons*, most poisonous herbs excite in men [Greek: συμπάθῳς (sympathōs, "sympathetically")] various kinds of phantasms, by which they think themselves to be what they are not. See what more we have handed down on these matters there concerning the hydrophobic. Certainly *Solanum Maniacum* [maniacal nightshade] (as Dioscorides is author) makes various visions, and causes not-unpleasant images, if a drachm of its root is drunk in wine. I add to these that *Theangelis* too is wont to be born in Lebanon of Syria, which, when devoured, makes men—so they wish—foretell the future. In Bactria and around the Borysthenes [Dnieper] there grows a plant called *Gelotophyllis*, which, if drunk with wine and myrrh, they say makes various visions hover and brings no end of laughter, until pine-nut kernels in palm-wine, with pepper and honey added, are administered. The same effect among the [?] is produced by *Apium risus* [smiling parsley] and Egyptian Arum when devoured. The herb *Asciomenes* (as Apollodorus is author), [Margin: Asciomenes tames wild beasts.] sprinkled with wine, draws its leaves into itself; sprinkled with neat [wine], it tames the ferocities of all animals, tied to the neck or hung from the

yoke. Appian of Alexandria writes that the Parthians, put to flight by Antony [Mark Antony], when they were pressed by hunger, fell upon a certain herb, which those who ate it remembered nothing of other things, nor understood anything, [Margin: A wonderful effect.] except that they continually dug up stones, as if about to perform some great work; and so, raving, at last vomiting up bile, they perished—but this power must be ascribed...

[Reading order: →910→911→912 correspond to printed pages 413→414→415→416, in linear sequence. No folio reordering was needed for this opening.]

must be ascribed to a poisonous virulence imparted to the herbs, which by the power of imagination disposes the people themselves to act in this way or that. A branch of the third buckthorn [Rhamnus], according to Dioscorides, set upon doors and windows drives away all sorceries — by what power he himself would have to say. The roots of dock [Lapathum], and indeed of plantain, bound to the throat (on the same authority), he supposes to heal scrofula and the king's evil [choeradas et strumas]. Little worms found in autumn in the prickly seed-heads of teasel [Dipsacus], bound to the throat in a little bag, or hung on the left arm, the magicians believe restore those afflicted with quartan fever to health. Dioscorides writes that when the herb golden-thistle [Atractylis] is carried, a scorpion's sting is indeed blunted, yet once the herb is laid aside the pain at once flares up again. He has even handed down to the memory of posterity that those who carry the root of the herb Greek valerian [Polemonia] with them are not stung by a scorpion; or if by some chance someone is stung, he will suffer no trouble at all. But since these things are uncertain and without foundation, I have no wish to reason about them.

[Margin: Baaras, the wonder-working herb.]

Very widely known in Judea is that fabled root **Baaras**, named after a place, of which Flavius Josephus writes thus in his book *On the Jewish War*: "In color it resembles flame, and toward evening it flashes like a beam of light. But for those who approach and wish to pluck it, the thing is not easy to do, for it keeps slipping away until a woman's urine or menstrual blood is poured upon it; and even then, if anyone touches it, certain death follows — unless he carries the very root hanging from his hand. For this reason, once the root has been dug round about and is not yet uprooted, they tie a dog to it, which, wishing to follow its departing master, uproots it and immediately dies, as though in place of the man by whom it was to be taken. After this there is no danger for those who take it up. Yet for the sake of one power it is worth taking it at such great risks, for when it is applied to those who are oppressed by evil spirits [cacodaemonibus], they at once

enjoy their freedom." But since these things are reported by no one up to now except Josephus, we likewise ascribe them to old wives' ravings.

[Margin: A root that takes away the ability to eat.]

Mattioli [Pietro Andrea Mattioli] says that he had a root, found by Francesco Calzolari of Verona [Francesco Calzolari], which, he says, soaked overnight in wine, and the wine then drunk, makes it so that no one, however starved, can eat — nor taste even the least morsel of food — until he has swallowed a spoonful of vinegar. A laughable jest indeed, but the thing itself is not to be entrusted to everyone. I could adduce many similar things, true yet ripe secrets of nature; but lest the over-curious use them for evil, I have thought it best to veil them in silence. Indian gourd [Zucca Indica], swollen with a destructive and deadly poison — yet its juice, as was said in the preceding pages, once expressed, and the root ground into flour, makes the best bread, most wholesome for nourishment. To these things may also be added, from Mattioli, what people often marvel at in the shows of mountebanks. For Mattioli speaks thus:

[Margin: The mountebanks' trick.]

"Into wine they mix the powder of a certain root, by tasting which the throat is convulsed; and the man on whom they wish to play the trick they bid dip his finger in it, as if for the sake of tasting beforehand; then he reluctantly presses the finger, smeared and wet in the wine, biting it into his mouth, not without pain and outcry. Meanwhile the mountebank, just as though he were soothing the grieving man with caresses, smears the arteries of his temples and wrists with some other drug; then he throws a coin onto the ground and urges him to pick it up. There the man, bending forward, at first cannot lift it, then, as if driven out of his mind by force, collapses; and at once, after the manner of one who fears he may drown in water, he swims, and prays at the same time to be overwhelmed by the waves. The mountebank then raises him up; the man, as if about to avenge an injury, first reproaches the sorcery with a sidelong and grim look, then seems to attack the man; finally he seems to pursue the fleeing mountebank, until at last, the poison of the smeared drug being wiped away, he recovers his mind and is restored to his senses. And when he has come to himself, like a shipwrecked man who has escaped the sea, he is seen to wring out and squeeze his hair and clothes as if they were sails, to dry his arms, and to wipe his nose. These are not fables: for there is no lack of testimonies of many who have seen it, and who, suspecting a deception, have had it done — as happened this year at Prague — upon their own servants and those of their friends."

Innumerable things could be adduced here from various authors; but because they are wrapped up in countless superstitions, I have not wished to dwell on them, and have chosen to proceed only to those things which by themselves and their own nature possess a marvellous power, and produce effects that in everyone's opinion are incredible.

[Margin: παλιγγενεσία [Greek: palingenesia, "regeneration" or "rebirth"] of herbs — by what means it comes about.]

The fourth question is raised. Can an herb truly and really be drawn out of its ashes by palingenesis, that is, by resuscitation? I am not unaware that various histories are adduced concerning marvels of this kind.

[Margin: A tree in a glass phial.]

They report that Albertus Magnus [Albertus Magnus], at the time of a banquet, produced before the King of France a tree, with leaves, flowers, and fruit, in a glass phial. But I have investigated the truth of the matter with great labor, and I have not been able to find any such thing either in his Life or in the deeds of the king; nor have the Dominican Fathers admitted finding any such thing in their archive. Hence I have always believed the narration to be fabulous — invented by the alchemists and other followers of the more curious arts to prop up, with similar fictions, the truth of those mysterious and unheard-of secrets which they are everywhere accustomed to proclaim with full cheeks. In the same way, many other spurious offspring have long since come forth under the name of the holy man through the help of the Magi, for no other purpose than to shelter their ravings under the name of the great Albert, and to make these things more easily believed by a world greedy for them — the painted truth being approved, before the inexperienced common people, by the authority of a great and illustrious writer, with similar trifles taken up. That Albertus Magnus was an initiate of nature, no one would deny; but as for that most celebrated book *On the Mysteries of Herbs and Stones*, and likewise the book *On the Diseases of Women*, which are believed to be his — let anyone believe it who wishes. That all these treatises came forth from the superstitious workshop of the Arabs first became clear to me when I unfolded Solomon Ben-Gabirol [Solomon ibn Gabirol] [?], the author *On the Nature of Things*, with a certain intimate reflection upon the books ascribed to Albertus Magnus.

[Margin: The author's invention.]

Then, concerning the palingenesis of plants, Quercetanus [Joseph Duchesne / Quercetanus] and Gassarottus [Gassarottus] [?], in the book entitled *Des*

Curiositez Inouyes — that is, *On Unheard-of Curiosities* — report the case of a certain Polish physician who kept in a phial the ashes of various herbs, and would produce for his visitors whatever herb they wished, simply by applying the warmth of a lamp. As this savors of something marvellous, so too whether it can really be done remains to be set forth.

That in ash there lies salt, and in salt — as in a center — the seminal power [virtutem seminalem] of any vegetable thing whatever, has already been shown in various books of this work. It can therefore happen that the salt extracted from plants by an art not known to all, just as the herb has power by its spermatic virtue, so too, joined to that same salt by an inseparable knot, while the plasmatic faculty is roused by a gentle and mild heat in the salt with its seminal force, is carried by a certain innate appetite to forming that for which it was destined by nature — the saline corpuscles, in which the plastic power lies hidden, flowing together into that form which the seed requires; and thus they present a plant under that form which the plant, from which the salt was extracted, requires by its own nature. We gave an experiment of this matter in the preceding books, concerning the ashes of various plants, whose lye, exposed in the winter months to freeze, displays in the icy crust those plant-forms from whose ashes the lye had been made.

I dare to affirm that I busied myself with this truly marvellous experiment long and much, until at last I found another method by which I roused a plant out of its own ashes within a hermetically sealed phial with a long neck; and I displayed it in my Museum for nearly ten years to be viewed by all who came, until in the year 1657, when the Queen of Sweden, Christina [Queen Christina of Sweden], deigned to honor me with a visit to my Museum and viewed an artifice of this kind with the greatest delight of her mind. After her departure I had placed it outside the window; returning the next day — for it was the month of February — I found that the more vehement cold had broken the phial and put an end to the spectacle, as though it disdained to show itself any longer after a queen of such great name had honored it with so great a distinction of inspecting it. I, however — whether for the sake of the expenses to be incurred, or weary of the great labor — no longer undertook the work [ἐγχείρησιν] [Greek: encheirēsin, "undertaking"], and left it in its own chaos; yet I reserved the method and the procedure by which I used to make an artifice of this kind for a separate little treatise, wholly on the palingenesis of plants from their ashes, where the whole carrying-out of the procedure will be described in detail.

Diagram. A woodcut of a tall, round-bottomed, long-necked glass phial (a typical alchemical pelican/matrass form), standing on a small footed base. Within the phial a small, leafless, branching tree or shrub-like growth rises from the bottom — the palingenetically regenerated plant. Across the upper part, around the neck, a banderole (scroll) bears the caption.

- Banderole (across neck): "Artis et Naturæ Conatus" [The Endeavor of Art and Nature]

Now, since Emperor Ferdinand III [Ferdinand III], of glorious memory, having been informed of this resuscitation of herbs, indicated to me that he had a not dissimilar method for drawing plants out of their ashes, and perceived that I was held by the greatest desire for it, His Sacred Majesty, to satisfy my wishes, did not disdain to impart to me, with truly great generosity, the whole sequence of the matter and the procedure in carrying out the work. And although Fr. Gaspar Schott [Gaspar Schott], formerly my colleague here at Rome in literary matters, has already inserted it into his works, nevertheless — lest the reader go away cheated of his hope, and that the origin from which it flowed might be established — I shall set it forth here again at length, to this end: that the reader, who will perhaps have greater leisure, may himself not cease to undertake, for the confirmation of the truth of the matter, the experiment which I, through the intervention of various occupations, have not been able to undertake. This, then, is the secret.

EXPERIMENT I.

παλιγγενεσία [Greek: palingenesia, "regeneration"].

Or the Regeneration of Plants from the Seed of any Plant whatever.

THE PROCEDURE.

Take the seed of any plant whatever, fully ripe, gathered in fair weather and under a clear sky (*Lib. 4*). Pound it in a mortar, and place it in a clean phial, closed as well as possible, and take care that not even the least bit escapes; and keep the phial also stored in a protected place. This done, you will observe an evening hour of the clearest sky, so that on the following night you may collect the falling dew.

Open the phial you have kept; take out the pounded and crushed seed, and spread it upon a glass tablet. Leave this tablet with the seed exposed in the open air in some garden or meadow; and lest any of the more abundant dew be lost by flowing off the tablet, place the tablet together with the seed in a rather broad

dish. Thus it will come about that the dew, falling abundantly upon the seed, will more conveniently impart its nature to it by these nocturnal soakings. At the same time, for more conveniently receiving the dew, let a fine and very pure linen cloth be stretched, fastened to four stakes, which, soaked...

with the nocturnal moisture, may then be wrung out into a most clean glass vessel, to about eight measures.

Further, let the seed, soaked with the nocturnal dew, be again shut up in its phial, and — lest anything escape from it or be drawn out by the heat of the Sun — let it be put back in its former place before sunrise. Let the dew wrung from the linen cloth be very frequently strained; once strained, let it be distilled several times, until it comes out free of all dregs and earthy impurity. The dregs left behind you will calcine, and they will yield a salt beautiful to behold, which presently is to be dissolved in the distilled dew.

Let the dew, imbued with this salt, be poured upon the seed kept in the phial, to a height of three fingers; then let the phial, hermetically sealed with crushed glass and borax, be kept in a warm and moist place, or even buried under horse dung for the space of a month. Then take out the phial and observe: you will see the seed transmuted into the likeness of a jelly, a spirit floating on top like a little skin variegated with various colors, and within the skin and the muddy earth the dew, existing according to the nature of the seed, like a green seed.

Suspend this phial, thus sealed, throughout the whole summer in a place open to the rays of the Sun by day, of the Moon by night, and of the other stars; but when the sky is troubled or rainy, keep it in a dry and warm place, until at last, the clouds being driven off, clear weather shines forth, to which you will then expose it.

It sometimes happens that this work is completed in nearly two months, or sooner, sometimes after a year, according to the constitution of the seasons.

For the rest, the signs of the work's perfection are these: the muddy matter at the bottom swells up high, the spirit and the little skin decrease day by day, and the whole matter at last thickens; while in the glass, from the reflection of the Sun, subtle exhalations arise, and as it were clouds — the first rudiments, so to speak, of the growing plant — but still feeble and without heat, and rising only in the form of a spider's web, now ascending, now descending, according to the efficacy of the solar ray striking the phial.

At last, out of all that spirituous matter subsisting at the bottom, an ash is formed, white-blue [albo-caeruleus]; and then, in the course of time, a stalk, herb, and flowers are produced in the form and species of the seed. This species appears when heat is present; in its absence it vanishes, returning into its own chaos. But as often as you apply fire, so often will the plant, the heat reviving the matter, present its form; and in this way it will last perpetually, if the vessel has been well stopped.

[Margin: Paracelsus's fictions.]

Paracelsus [Paracelsus], in book 6 *On the Nature of Things*, adduces many utterly false things concerning the resuscitation of things, though some true ones also. But in order to show that resuscitation is possible, he adduces things which no philosopher ever admitted. For example, he says: the cubs of lions, wholly devoid of life and dead, are called back into life by the breath of the lioness or the lion alone; indeed, that unless a roar be added, they remain perpetually dead. That this is false, experience proves: the cubs of lions are by no means dead, but only half-asleep, and are merely roused by the roar — just as we see a sleeper roused from deep sleep by a great outcry agitated by unfamiliar movements. But who could conceive that by a roar alone there can be given to the cubs that which they do not have? By similar examples, weak enough — indeed absurd —

[Margin: Paracelsus's fictions.]

Paracelsus is accustomed to ascribe the giving of life to metals through their reduction into quicksilver, that is, mercury; and in doing this he perversely violates the laws of the grades of nature. For what fellowship the life of animals has with the inanimate nature of minerals, I do not grasp. I say therefore that it cannot be that what does not have life of itself and by its own nature, nor can have it, should yet have life given to it — as the alchemists trifle concerning the vital seed of the Mercury of the Philosophers, when they attribute to it a vegetative faculty and one that multiplies its own species. Who does not see that all these things are absurd and contrary to the principles of nature? Yet because ashes derive their origin from a vegetable nature, certainly out of the seed-stuff [seminium] lying hidden beneath them, by the benefit of the vivifying salt, there is no doubt that a plant can be roused. For each thing acts according to the grade of nature suited to it; nor can a mineral body generate a plant, nor a plant an animal, unless first a seed-stuff of sensitive nature has existed in it. Metals therefore are constituted not by a vegetative faculty, but by ὑποδιάθεσιν [Greek: hypodiathesis, "underlying disposition"], that is, by the superaddition of metallic vapors and exhalations packed together in appropriate matrices. A plant

generates a plant, nothing else; an animal produces an animal, not a plant, not a mineral. Hence to argue from some one grade of nature to disparate ones is not permitted in sound philosophy. Now, then, let us see how Paracelsus supposes a plant can be roused from the ashes of burnt wood.

EXPERIMENT II.

Of Paracelsus.

"The resuscitation," he says, "and restoration of wood is exceedingly difficult and arduous, yet possible to nature; but it cannot be done without notable skill and industry. That it may be revived, it is best done in this way: Take wood, which was first charcoal, afterward ash, and put it in a cucurbit together with the resin, the liquor, and the oiliness of that tree — let the weight of all be the same — let them be mixed; let them be liquefied in a gentle heat, and there will be a mucilaginous matter. And thus you have the three principles from which all things are born, all are generated: namely phlegm, fatness, and ash. Phlegm is mercury, fatness is sulphur, ash is salt; for everything that in fire smokes and evaporates is mercury; what blazes and is burned is sulphur; and every ash is salt. When now you have these three principles together, put them in a horse's belly [in venter equino, i.e. fermenting dung] and let them putrefy. To...

[Margin: Libavius, *Syntagma Arcanorum Chymicorum*, fol. 48.]

their own term. If afterward that matter be buried in fatness and infused, you will see it revive, and a tree and small wood thence be nourished, nobler than the former by its virtue." There was no need of so many operations to make the salt vegetate, since the ashes of plants (as we ourselves have very often experienced in the salt of wormwood [absinthium]), planted in virgin earth, will within a short time present a plant of the same species as that which had been resolved into ashes. But of these things more fully elsewhere.

That a plant can be born from its own ashes — that this in no way repugns to the power of nature — is clear from various places of this work: from the marvellous power of nature in the generation of plants and stones depicted in every kind of figure; likewise from what we said in the preceding passages concerning the seed-stuffs of various plants and animals existing within the elements. All these things are confirmed by the history which Libavius [Andreas Libavius], in his *Syntagma on the Arcana of Chemistry*, adduces concerning a little plant arisen from distilled water. I shall here append the letter — worthy of admiration —

which Cornarius [Cornarius], Court Physician of Brandenburg [Brandenburgicus Archiater], had written to Libavius concerning the marvellous origin of this herb:

"You now have a picture of the little plant in the bivelatine water [aqua bivelatina] which is in Meissen [Misnia], not far from the town of Zwickau [Cycenaea], distilled for me — but a picture, alas; would that you had seen it living and had it, which truly was far more delightful, far more lovely than you see, and which the painter in depicting it scarcely sketched, not to speak of the color, for the picture was illuminated with its own colors, which by the rubbing of the page have nearly faded away. Never indeed without great admiration did I look upon it, as often as I beheld the glass, as did others also. The glass is altogether such as the picture exhibits, or even of slightly greater capacity. The light-greenish color sprinkled at the bottom is from the glass, by no means from the water, or from some sediment clinging to the bottom; for the water is still most pure, and entirely free of all phlegm. In the little plant itself you do not see a stalk, base, or root by which it might be supported — nothing notable, except a very small one; for it seemed to adhere to the pointed bottom of the glass by a single thread only, and thus to the sides it scattered little branches full of...

Diagram. An uncaptioned woodcut of a wide-bodied, short-necked glass jar or bottle with a ribbed/banded base, standing upright. At the bottom interior a small, delicate plant-like growth (the "little plant" of Cornarius's account, resembling a sprig of rosemary) rises from the pointed bottom and spreads small branches toward the sides. No labels are present on the figure.

oblong little leaves, not broad in proportion to the whole size, but oblong, sweetly green, after the manner of a tender rosemary plant, of a color tending from green to citron, not fully green. I do not doubt that it could have risen and grown higher, since, when the glass was somewhat shaken, it stood firm and erect with a feeble tremulous motion; but, injured in winter by the vehemence of the cold, and torn from the bottom, it floats in the water — still, which is wondrous, with its color whole, though somewhat diminished, a viscosity gathering about it. This happened in the year 1608; the water was distilled in the month of June by Martin Gallus, an assistant of the apothecary, and the herb was first observed in the month of November." Thus Cornarius to Libavius.

I have no doubt that the history is most true; for, as we said in the preceding pages, it could easily have been born from the seed of some herb which had previously existed in the water — especially since no water can be so purified by distillation that there do not always remain in it dregs, even imperceptible ones,

from whose seed-stuff this plant afterward arose. For since we so greatly admire the hidden power of God in nature, and God is utterly wonderful in his works,

[Margin: God to be admired in natural things.]

who would now dare to doubt that in the salt of plants and animals there lies hidden a certain occult seed, which, according to a prior disposition of the subject, comes back from time to time from potency into act? Indeed the wisdom of God exceeds all the admiration of mortals even in this, that it can preserve nature even in an imperceptible thing, in which all the wise men of the world would swear that nothing at all remained — a most luminous argument indeed, by which the future resuscitation of our bodies may, by some such shadowy likeness, be in some way conceived by the weakness of the human intellect. For the confirmation of these things I shall here add another case, conceivable by almost no human intellect, which Johannes Marcus Marci [Jan Marek Marci] of Bohemia, Court Physician, already renowned to the world for learning of every kind, transmitted to me in past years, confirmed on the authority of many.

[Margin: A wonderful apparition of a snake in a distillation.]

For while a physician was distilling a certain water, after a notable ebullition of the water, there at last appeared within it the form of a variegated-colored snake, coiling itself after its manner — all who were present being astonished at the outcome of the matter. And so, when various men had been consulted about the prodigious origin of this serpent and its cause, they all fell silent, saying this one thing only: that it would be idle to unfold hidden effects of nature of this kind, which nature had willed to be inaccessible; that to attempt them too presumptuously, to penetrate the inaccessible and impenetrable abyss of nature, is not permitted — only to admire it. But that the reader may weigh everything more accurately, here is the whole procedure of the matter, which the above-praised friend of Johannes Marcus Marci [Jan Marek Marci], a singular friend, transmitted to me to this end: that I might find at least some cause of this prodigy.

Reading order used: correspond to printed pages 417, 418, 419, 420, in that sequence — confirmed by catchwords ("Expe-" on the prior page 416 → "Experimentum" opening p. 417; "nucis" foot of p. 417 → "nucis videre est" opening p. 418; "Sunt;" foot of p. 419 → "Sunt, qui" opening p. 420). No folio reordering was needed for this set.

An unheard-of experiment performed by the most excellent Nicolaus Franchimontius [Nicolaus Franchimont], Protophysician of Prague.

Take oil of vitriol [oleum vitrioli], whitened by repeated rectification, one part; the best spirit of wine, rectified through white tartar, two or three parts. Mix them, and let them be distilled from a cucurbit set in sand, with a rather strong fire applied, and a very capacious receiver attached. During the distillation a vapor came forth, wandering about through the receiver; and below it, of the thickness of the wrist [carpi crassitudine], appeared the figure of a living snake, colored in a variegated pattern of whitish-gray, coiling itself into multiple spirals and bends as the spirit advanced from the cucurbit into the receiver. This persisted for at least two hours, and at last was resolved into a most burning spirit. Had reason not held my judgment in suspense, I would have sworn that what I beheld was alive.

Nicolaus Franchimont, Doctor of Medicine and Professor of its practice at Prague.

For my own part, I confess that I was not a little astonished at this occurrence. But once, instructed by repeated experience of similar things, I had considered the matter more closely, this single explanation of the prodigious effect occurred to me. As we have taught in the foregoing pages, the seeds [seminia] of things are present in all things beforehand; so too it is likely that there was, either in the vitriol or in the wine rectified through tartar, some seed [seminium] of a serpent. This, then aroused by the heat of the fire, was by the agency of the plastic virtue [plastica virtus] — its salts joined together by a certain magnetism — reshaped into the form of a serpent, in no way otherwise than we shall show can be done with serpents by similar experiments. If, however, anyone should wish to perform an experiment of this kind according to the prescribed ἐγχείρησιν [Greek: encheirēsin, "the procedure / hands-on operation"], he will assuredly labor in vain, since the seed of things is not always present in each and every one of these ingredients. Hence I judge that in this case the experiment achieved its effect by chance, in that the seed [seminium] of some snake of this or that species happened to be present in it at the time.

I have heard that the Count of Hannover [Comes Hannovianus] keeps a stone that reproduces the form of a serpent coiled into spirals, found by hunters inside a stag's stomach — a thing that will easily be believed by anyone not ignorant of the nature of stags in hunting serpents.

[Margin: The cause of this prodigious effect.]

The fifth question is asked: By what power, and in what way, do certain plants compose themselves toward the Sun's motion with such great appetite? Experience teaches that they do turn themselves.

The heliotropes, or the plants they call sun-followers [solisequae], are held by so intent a longing for the Sun that they seem unable to be drawn away from its loving gaze by any barriers. I say this happens partly because of the great benefit that comes to the plant from this for its own preservation, and partly because of the vehement magnetism that passes between it and the Sun, by which, willing or unwilling, it is drawn; and the drawing is accomplished in the manner that follows.

[Margin: Why the sun-following herb turns toward the Sun, and turns itself.]

The stalk, the flower, and the seeds of heliotropes, if one examines them rightly, are so constituted that they can easily be twisted. This being granted, it follows that the moisture which plants of this kind have drawn in by the dewy dampness of the night is — as we have shown by the examples given — present in their seeds in the very same way. As the Sun rises, swelling at once at the arrival of the kindly guest, they turn themselves to where they can be freed from their superfluous moisture. The Sun, when it strikes straight upon the stalk and the disc of the flower with its blazing rays, brings about the thinning [attenuatio] of the saline spirits [spiritus salini] lurking in these herbs; and there follows the rush of the resolved spirits, by which, set in motion, they turn toward those parts where they find the pores most widely dilated by the Sun's heat. Hence it comes about that these spirits are carried in no other direction than that which faces the Sun. This is also established by open experiment: for if the plants stand in a shady place where the Sun cannot strike them, then no turning toward the Sun follows either, but, as if indignant at the obstacle, they always hold themselves fixed in the same position; yet as soon as they are lit by the Sun, then too, dilated with eager gaze and as if dancing for joy, they turn to where so great a benefit flows to them. But since we have treated of these matters in Book 3 of the *Art of Magnetism* [Ars Magnetica], on the method and rationale of constructing clocks by means of sun-following and moon-following plants [solisequae lunisequaeque plantae], together with various experiments, we refer the reader to that place.

[Margin: The cause of this tropic motion in plants.]

EXPERIMENT.

Take a sun-following plant: this plant, being filled with saline-sulphureous-mercurial spirits [spiritus salino-sulphureo-mercuriales], depends upon the resolution of those spirits. Place it in an earthen or bronze vessel filled with water, in such a way that, fixed into a cork, it can move freely; this done, set fire beneath the pot, and — a marvel to behold — at once the stalk will begin to twist itself and to be animated into a circular motion. The cause is none other than this: that the spirits, thinned by the heat of the surrounding medium and by the action of the fire set beneath, rushing out through whatever gateway is given them, will display this marvelous effect upon the twisted arrangement of the fibers. This may also be seen in a wand of hazel or filbert-nut [virga columnae sive avellanae nucis] —

— of the nut, which, placed upon two forks at the fire, will at once twist itself into circles in the manner of a roasting-spit. This thing first became known here at Rome, to the admiration of all, through the servants of a certain Cardinal, who, fixing onto hazel spits the little birds they had caught in hunting, noticed that the birds were moving together with the spits. They came to me without delay to assign the cause of this prodigious operation. Performing the experiment of the matter myself, I indeed found out the truth; but the moving force, which they had supposed to be present in the little birds themselves from some hidden property, I detected as lurking in the hazel wand and in its natural constitution. But since the experiment is set forth in the *Art of Magnetism* [*Ars Magnetica*], third edition, folio 503, I have been unwilling to repeat it here.

[Margin: The shoots of the hazel placed at the fire twist themselves into circles in the manner of a spit.]

I confess that there are marvelous things in the nature of things which are everywhere ascribed to hidden qualities, even though their causes at once reveal themselves in the open, if they are rightly weighed in the balance of empirical reasoning. See what we have related at length about the oat-spike [spica avenacea] cited in the *Art of Magnetism*, and its circular motion, on page 411.

The sixth question is asked: Why do the leaves of some plants — such as the acacia, the mimosa, and the like — now open at the Sun's approach, now close at its withdrawal? The leaves of the acacia, indeed, as daily experience in our own household garden teaches me, from the point of midnight all the way to noon, together with the rising of the Sun, so gradually unfold themselves that — the plant, as if exulting with a certain joy at the company of the welcome guest —

they display the most beautiful array of leaves, not without the admiration of those who behold it. But when the Sun declines toward the horizon, they fold themselves in the same proportion in which they had unfolded at the Sun's rising, so that after the Sun's setting the foliage seems transformed into a thorny growth, after the manner of junipers.

[Margin: The acacia's leaves unfold as the Sun ascends, fold up as it descends. And the cause of this matter.]

And so I say that in the acacia this happens because of the moisture with which they are laden at the fall of the nocturnal dew, from which they take on a parched and wrinkled appearance. But as soon as they are struck by the points of the solar heat, with the moisture thinned they become, as it were, more apt for unfolding themselves, the more they were weighed down by the slighter moisture that gradually exhales away. Hence before noon they are seen to unfold themselves most fully; but after noon, the moisture now consumed and the Sun's heat now increased, growing as it were flaccid, they gradually contract themselves, until after the Sun's setting they bristle like junipers. And just as they are soon filled again by the fresh dampness of the nocturnal dew, so too, swollen as if by the acquisition of fresh strength, they are again emptied of their superfluous moisture at the Sun's approach — whence the dilation.

[Margin: The cause of this matter.]

The same is to be said of the leaves of the elm, the poplar, and similar trees, which, as soon as the Sun reaches the point of the summer solstice, tend to turn their leaves over. So I say, therefore, in the case of the acacia [recte: the wording here resumes the elm/poplar discussion — the margin and text shift to the elms]. And let no one suppose that this happens at the very point of the solstice; by no means: for a conversion of leaves of this kind requires some latitude of time in order to produce its effect. It happens in this way: the leaves of trees of this kind, being for the most part still filled with abundant moisture up to the time of the solstice, it comes about that, as the Sun's heat grows, they are with time thinned and resolved into vapor, and rendered lighter. This accomplished, it follows that the leaf-stalks [pedunculi] which support the leaves, being likewise made thinner and now freer and lighter, released from the obstacle of the superfluous moisture, soon begin to twist; until, the superfluous moisture being consumed and no other supervening, they remain in that position, turned opposite to the prior one, which the twisting of the stalks has imparted to them.

[Margin: The motion of the elms and poplars around the solstice.]

And this I judge to be the genuine cause — leaving the judgment of others intact — of the conversion of the leaves of certain trees at the time of the solstice. As for why this action appears chiefly in the leaves of the poplar, the fig, and the elm, the reason is this: that these leaves have leaf-surfaces of different colors — one of which is green and deep, the other of a whitish hue. And so, from the difference of colors, they are more easily observed by men; although I myself judge that in most plants, if they are rightly observed, this same thing occurs. And these are the things which I have thought ought to be indicated to the *exotic* reader concerning the foreign properties of plants. [recte: *plantarum proprietatibus exoticis* — "the exotic properties of plants"; "Lectori" = "to the reader."]

Diagram. A woodcut, set within the left-hand column, showing the sun-following experiment described above : an earthen or bronze pot placed over a fire (flames shown beneath at the base), with a tall stalk rising from the water within the pot and bearing a heliotrope-like flower-head at its top, leaning over to one side to illustrate the stalk twisting in circular motion. No printed labels appear on the figure.

Diagram. A pair of woodcut figures at the foot of the left column, illustrating the acacia leaf in its two states. Two pinnate (feather-like) leaf-sprays are drawn side by side beneath two captions:

- Left figure: caption **Mane.** ("In the morning.") — the leaflets are shown spread open and outstretched along the stem.
- Right figure: caption **Vesperi.** ("In the evening.") — the leaflets are shown folded up and drawn together against the stem.

SECTIO V.

THE HIDDEN WORKSHOPS, OR LABORATORIES, OF THE VARIOUS ARTS [OCCULTA VARIARUM ARTIUM ERGASTERIA SIVE OFFICINAE]

In which, according to the prototype of the Subterranean Archeus [Subterraneus Archeus], marvelous operations are established.

PREFACE.

Now that the Kingdoms of Nature — both of animals and of vegetables — have been set forth, nothing further remains except that we should now examine, with

equal step, the innermost secrets of the Kingdom of inanimate things. It must therefore be understood that a certain marvelous analogy lies hidden in this threefold Kingdom of Nature, by which all things are found to be present in all things, in a certain manner. For just as sensation is present in animals, so too — that it is present in its own way in some vegetables — the plant called *mima* [mimosa] sufficiently demonstrates, which contracts itself at the very lightest touch. And it appears to be present even in some stones, such as the Astroites [Astroites], when, placed in vinegar, they are seen to be agitated of themselves with a forward motion. I shall say nothing here of the wonderful nature of the Magnet, which sufficiently and more than sufficiently shows, by its marvelous motions, that it expresses in itself both sensation and life in a certain manner — concerning which see the matter treated at length in our Book *On the Art of Magnetism* [Ars Magnetica]. In animals and vegetables there occur, as we have taught, certain marvelous metamorphoses; they occur also in inanimate things, as we shall see a little later. Just as animals and vegetables are endowed with wonderful virtues, so too is the inanimate economy of metallic minerals endowed with the same. By applying the active to the passive, Art accomplishes marvelous things both in animals and in vegetables, as was said in the preceding sections; and the same Art accomplishes them also by principles drawn from the subterranean nature of minerals. But as to how much benefit flows from these things into the uses of human affairs, I shall lay open in order in this Section of the Book. May God assist our undertakings.

PARS I.

ON THE CHYMIURGIC ART [DE ARTE CHYMIURGICA].

CAPUT I.

On the Secrets of Chemistry [De Arcanis Chymicis].

Although in Book XI we pursued, most fully, the *Chimiotechnia* — which they call Alchemy — yet there we were wholly intent on this: that we might utterly overthrow the χρυσοποιητικήν [Greek: chrysopoiētikēn, "gold-making (art)"], that is, the gold-producing Art, together with the most empty ostentation of secrets practiced by those who, by shameful lies, with a counterfeit zeal for pyrotechnics, most perniciously impose upon the World. But many things are found in the true and divine study of Chymiurgy which have been discovered to be most useful to the human race; of these we shall treat in this place with what brevity we can. And in order that we may proceed with some method, we shall first investigate the secrets of the seven metals, and then go on in order to the rest.

§ I.

On the Secrets of Gold, or on Potable Gold [De Auri Arcanis, sive de Auro potabili].

I shall not speak here of the virtues and faculties of gold, since I have set this forth most amply in the Tenth and Eleventh Books. Only in this place shall I bring forward a few matters most controverted among the Chemists; and they are these: Whether Potable Gold [Aurum potabile] can be made by the Spagyric Art [Ars Spagyrica].

I find among the Alchemists, regarding the Magistry [Magisterium] said to produce a longer life by means of Potable Gold, so many and such bitter contentions and endeavors, that with good reason I find Potable Gold as entangled in an inextricable labyrinth as is the Philosophers' Stone [Lapis Philosophorum].

[Margin: Whether Potable Gold can be made.]

There are those who would have it that *Potable Gold* and *Magistry* signify "every precious thing fit to be drunk." There are others who take it for a purely allegorical allusion. In this way, some Alchemists call the fifth essence of wine [quinta vini essentia], reduced to its ultimate perfection — which Lull [Raymond Lull] calls *Caelum* ("Heaven") — potable gold. But setting these things aside, let us proceed to resolving that question which is asked: whether gold can truly and properly be dissolved into a liquor fit for drinking, and, when so reduced, be furnished with the marvelous virtues which they boast of.

All those affirm it who are more than fairly devoted to that artificial Philosophers' Stone — the pseudo-chemists — without which, namely, they maintain that gold cannot be reduced into a liquor. From which it is easily concluded against them that, just as that much-vaunted Stone has never existed in the nature of things, so too neither has potable gold; and accordingly the Alchemists wear themselves out in vain, at so great expense and labor, in the preparation of potable gold.

[Margin: It is the opinion of many that gold cannot be dissolved.]

Paracelsus [Paracelsus], being least of all consistent with himself in all things, is likewise found in the preparation of potable gold exceedingly slippery and unstable. For he says that potable gold is a liquor of gold without the admixture of any corrosive, known to very few; yet afterward, in the *Book on Long Life* [*De Vita Longa*], he openly contradicts himself, where he so commends potable gold made by means of corrosives that, unless these are separated out but remain together with it, he calls it "dead." For he supposes — against the opinion of all —

that corrosives become health-giving on account of the presence of gold. While he himself perhaps saw this, and repented of the error he had committed, in the *Book Archidoxis* [Archidoxis] he supposes that by the often-circulated fifth essence of wine he can accomplish it, being persuaded that in this way it can rightly be prepared without corrosives.

[Margin: Paracelsus's opinion on potable gold.]

The other view is that of those who assert that gold can in no way be dissolved into a liquor, on account of its untamable nature and firmness, by which it resists even the strongest and most prolonged fires without any harm or detriment to itself, losing no part of its weight; nor can it be corrupted by however sharp menstrua, or by other tests of fires, of the cupel, and of furnaces. And if it is sometimes dissolved by strong waters [aquae fortes] or by quicksilver [hydrargyrum], yet, the moisture of the menstrua having evaporated, it is soon reduced to the first state of its nature. There is the further point that gold resolved into a liquor in this way is found to be — I will not say a health-giving drink, but rather most noxious and pernicious — on account of the corrosive faculty lurking in the liquor. So think Cardanus [Girolamo Cardano], Baccius [Andrea Bacci], Caesalpinus [Andrea Cesalpino], and other chymiatrists. Hence Libavius [Andreas Libavius] rightly says: "They are to be laughed at who thrust upon us, under the name of potable gold, gold that is drunken from the frequent evaporations of quicksilver, and that hence melts at a candle."

[Margin: Gold cannot be dissolved — it is the opinion of many.]

[Margin: The various opinions of authors on potable gold.]

We accept the Suchtenian opinion [Suchtenian = of Alexander von Suchten], which calls the potable gold of the physicians "a red form extracted from antimony while it is liquid, but golden when coagulated." Joannes Baptista Birellus [Giovanni Battista Birelli] offers, for potable gold, a tincture of gold; Lull, the calx of the same gold — concerning which you may see, most fully and most contentiously, Paracelsus, Quercetanus [Joseph Duchesne, "Quercetanus"], Birellus, Ulstadius [Philipp Ulstad], Mylius [Johann Daniel Mylius], and countless others.

But let us now examine, with what χειρουργία [Greek: cheirourgia, "manual operation / procedure"] we can, the method which the Chemists use in dissolving gold into a liquor. Gold, then, in order that it may become potable: some prefer it true, natural, and simple, first reduced into little plates — refined gold [obrizum], I mean — most carefully, and pure unalloyed mineral, whether solid, or from

grains of gold found in rivers; and they take also ἄπυρον [Greek: apyron, "unfired" — gold that has never experienced fire]. Others, by an indiscriminate selection, take into the magistry gold that has already passed through fire; indeed, they do not even disdain the ordinary gold of the moneyers and goldsmiths (whom they call ζυγοστάτας [Greek: zygotatas, "weighers / assayers"], δοκιμαστάς [Greek: dokimastas, "testers / assayers"], and χρυσοπλάστας [Greek: chrysoplastas, "gold-shapers / goldsmiths"]).

Once gold of the better sort has been procured, there is no less disagreement among the Artificers concerning the menstrua that dissolve gold into a liquor. Now menstrua can be considered in two ways: one drawn from corrosive minerals; the other from the vegetable economy. The former, being utterly dangerous, I would judge not to be readily employed; the latter, on the contrary, since it can be taken without any harm or damage. Nor is it enough that a corrosive menstruum can be corrected by other medicaments and sweetenings; for although various things can be supplied that may blunt their caustic virtue, yet not such as can at once deprive the spirituous corpuscles of the salts of all caustic force. Yet so great is the obstinacy of some Alchemists in the dissolution of gold that, with no regard had to the menstruum, they strive to dissolve it even with deadly agents whatsoever.

[Margin: It is the opinion of many that gold cannot be dissolved.]

Of this stamp are the following menstrua: oils and stillatitious liquors from sublimated quicksilver; strong waters [aquae fortes], that is, *aqua regia* [aqua regia], or even *aqua stygia* [aqua stygia]; a solution of sublimated sal ammoniac; a solution of salt of arsenic [sal arsenici]; radicated vinegar [acetum radicatum]; the most sharp oil of vitriol; quicksilver — whose pernicious qualities, implanted by nature, when they saw that by no art could they be separated from their menstrua, they turned to the solvents of the vegetable nature.

[Margin: The deceit of the Alchemists in making potable gold.]

Of this kind are the liquor of honey and honeycombs [liquor mellis & favorum], and the less harsh juice of manna; some also use as menstrua vinegar, brine, garum [garum, fish-sauce], the juice of barberry and of lemons; another, a liquor prepared from the essential salt of tartar by a sevenfold extraction, mixed with spirit of wine or with the fifth essence; they use the descensory spirit of wine of nitrous woods, with its own salt added. But those who want milder agents take for menstrua spirit of wine, or *aqua vitae*; the juice of barberry and of lemons distilled through a retort only; others, the acid juice of the citron-apple, vinegar,

malmsey wine, water of bugloss tinged with its own salt, a stillatitious liquor extracted by spirit of wine from the calcined salt of sugar-candy (as they call it), joined to a distilled liquor of acid pomegranates and acid oranges.

[Margin: The various menstrua by which the Alchemists dissolve gold.]

and so on. With these menstrua the chemists suppose that gold can be dissolved. But anyone who weighs the matter on the more careful balance of reason will see that gold can be dissolved only by the agency of mineral liquors. By botanical juices it cannot — or only with difficulty — as experience has taught me. [Margin: Juice of plants does not dissolve gold.] For a gold coin kept buried among menstrua of this kind for a long time was afterwards drawn out, just as before, without any diminution of itself. The reason is none other than that menstrua of this sort are moved by no sympathy toward gold, as happens in the case of mineral menstrua. For gold placed in aqua regia is immediately dissolved, whereas gold merely smeared with mercury is at once made brittle.

A solvent is therefore sought in which gold, once placed, will liquefy no differently than snow thrown into water — so that it grants the gold no return to its former solid state. Many have sought such a solvent, but none has yet found it. Of this matter Libavius [Andreas Libavius] writes thus: [Margin: Libavius's process.] "From what one might form such a menstruum lies among the secrets. From the nature of the juice it is certain, but it is also necessary, that this liquor be viscous — which is the common nature of the material of metals — and that by its power it be gold, and unite with gold, as ice with boiling water; for that liquor differs from gold in nothing but its coagulation." Libavius, then, in describing a menstruum that dissolves gold, does nothing but explain the unknown by the unknown — and in such plain words that he does not seem to have understood even himself what he was saying. I interpret his words thus: it is certain that it lies in the nature of the juice — yet *from which* juice, this is among the most hidden things, that is, it is known by no one. Yet, so as not to seem to have said nothing, in what follows he nonetheless teaches the method: that unknown solvent, by means of salt and of sulphurous calcanthum [vitriol], will produce the effect of solution — provided, however, that the liquor has first been reduced, by very frequent cohobation, to a substance of altogether ethereal subtlety, and that in this way it furnishes the menstruum of the Philosophers. With such species of unknown things the alchemists entangle themselves, lest they should seem to know nothing. If Libavius forbids corrosives in the dissolution of gold, as we said above, then how he dares here to prescribe a solvent of salt and calcanthum of the greatest corrosiveness — let whoever can, work that out. But leaving aside

these trifles of the alchemists, let us now turn our pen to practice, that from it the truth of potable gold may shine forth.

The various processes for making potable gold.

[Margin: Libavius's other process.] **Process.** Libavius first composes a menstruum to dissolve gold *from one pound of good vitriol, of saltpetre [halonitrum], of sal ammoniac — 1 3 pulverized — and mixes them, and distils through an alembic over a slow fire into a long receiving vessel: for then the liquor will come forth with heat, 1 3 of which, joined with 2 3 of calx of gold prepared through mercury, when shut in glass dissolves into a clear water, in which you will again be able to dissolve both gold and pearls; some add mercury sublimite — which is rightly rejected — but in addition this requires a craftsman and physician practised in these matters with exquisite prudence.* Rightly so indeed — but who will find such a chemist as can dissolve gold with such very sharp corrosives in such a way that it can be taken safely?

[Margin: Dorn's process.] **Secondly.** Dornaeus [Gerhard Dorn] and Leo Suavius [Jacques Gohory] proceed in this fashion: leaf gold or gold powder, in the quantity of an ounce, is immersed in distilled vinegar; after maceration is completed they begin the distillation, for the gold drawn off by the vinegar yields a kind of juice, which is distilled until the sharpness of the flavor departs. Afterwards an aqua vitae is made by the infusion of aromatics in burning wine [spirit of wine], and in five ounces of this the juice of gold is digested for a month in a circulatory vessel which they call a Pelican; and the gold will be reduced to its perfection as potable gold. As to the vinegar in which they say the gold is dissolved, they proceed variously: some sharpen it with crystals of their own, others with the salt of wine-lees, or with crystals collected from oil of vitriol, others with euphorbium, or even with common rock-salt. But turn and turn this stone over as much as they please, they will never produce from it that true potable gold which they claim. For even they themselves, when they saw that with distilled vinegar alone the magistery could not gain a good outcome, were therefore led — willing or unwilling — to corrosives (such as the crystals of vitriolic oil are) and were compelled to take them up for the dissolution of gold. But as for their calling this an incomparable medicament and a wonderful strengthener of the heart and of the powers of the whole body, I should judge that this is to be ascribed not so much to the gold as to the aqua vitae made by the infusion of aromatics in burning wine.

[Margin: Alexius of Piedmont's process.] Alexius [Alessio Piemontese], in his *Secrets*, prescribes an exceedingly laborious operation in the making of potable

gold; yet if you examine it rightly, you will find it — like the others already cited — sophisticated. The menstruum runs thus: to the cooked and filtered juice of lemons he adds double the quantity of unskimmed honey and a half-part of salt; he boils it in a cauldron until it ceases to foam, and distils it by degrees; he calcines the *caput mortuum* [dead-head, the residue] for three days; to one pound of the calx he adds a third of manna and a sixth of crystalline sugar; he pours this, transferred into a glass cucurbit, the liquor extracted by distillation; and on top of it double the quantity of spirit of wine; he distils the whole by degrees, and thus sets aside the liquor drawn off in this way. Meanwhile he grinds leaf gold — first well purified by cement, or by antimony [stibium] — mixed with rose- or violet-julep, or with honey; the ground material he washes with tepid water, and in this manner makes a fine powder, which, placed in a cucurbit, he covers with just as much of the aforesaid distillate as can equal five fingers' breadth; he then distils. For then the liquor will come forth with heat, of which 1 ℥ joined with 2 ℥ of calx of gold prepared through mercury, when shut in glass dissolves into a clear water, in which you will again be able to dissolve both gold and pearls; some add [?] [Margin: Process [?]]. From the receptacle he now transfers it through an alembic by a slow fire into a narrow-mouthed phial; this being drawn off to dryness through the alembic, he adds fresh water as many times as is needed, until the entire quantity of the distillate has been drawn off from the gold by turns,

which, once collected and placed in the alembic without distillation, he keeps in a bath for half a month; and when it has been melted off he separates [?] it, the golden juice being left at the bottom of the cucurbit. And this is the knot of Alexius, by which he supposes he can dissolve gold without corrosives. But since we have already said above that the menstrua of vegetables are disproportioned for resolving irreducible gold, so likewise you may judge that the golden juice which remains at the bottom is nothing else than a certain amalgam of the leaves of gold mixed with antimony and juleps — and nothing is easier than to reduce this to its former state, as we shall say below.

Another process for potable gold.

There was communicated to me not long ago, by a most powerful prince, the true and genuine method and procedure for making potable gold, which I shall set down in this place; and afterwards I shall also explain what is to be hoped from it and what I think of it.

Take salt of tartar reduced into water, 1 ℥; place it in a bladder-vessel [vesica] and distil to dryness; pour the distilled water back over its salt, and again distil the

dissolved matter to dryness; and do this so many times, distilling and coagulating, until the oil of tartar comes out as well purified as possible. This done, place the oil in a glass bladder-vessel A, together with gold first purged through the cupel and reduced to the finest and impalpable powder; over this mixture pour 3 ounces of aqua vitae from wine — the more generous, the better the extract.

Diagram. A vertical apparatus for the slow digestion of the gold-and-oil-of-tartar mixture, shown as a rectangular frame enclosing the assembly. At the top is a tall domed vessel (a bronze vessel, *vas aeneum*, or "bath of Mary," *balneum Mariae*); within it hangs a pear-shaped glass flask. Beneath the bath sits a small round lamp that supplies the gentle heat. The labels, from top to bottom:

- (dome, top): "Cooperculum" — the cover/lid of the bath-vessel
- B (upper-left corner of the bronze vessel)
- C (upper-right corner of the bronze vessel)
- A (within the inner pear-shaped flask): the *vesica* (the sealed glass flask holding the mixture)
- (label on the flask): "Vesica" — the bladder/flask
- D (lower-center, below the flask): "Balneum" — the bath (of Mary)
- (mid-level label): "Fornax" — the furnace [?]
- E (the small round vessel at the bottom): "Lucerna" — the lamp

The said bladder-vessel A, sealed as well as possible, is placed in the bronze vessel B C D — that is, in a bath of Mary — with the light of a lamp E set beneath it; and within the space of three months you will find the water tinged like a ruby. This, once taken out, you again pour over the gold and the oil of tartar, continuing in the same degree of fire with the new water over the gold; and you will repeat this so many times until the gold is wholly stripped of its splendor, and you will have what you desire.

And this is the process. It must now be seen whether the water drawn off from it is truly potable gold. I answer that it is not, but is only a certain accidental tincture — which I demonstrate thus. First, because the oil of tartar extracted from its salt, as well as the menstruum of aqua vitae for dissolving gold, cannot (as we said above) be proportioned to the gold. Secondly, that reddish color which came forth by such manifold repetition of distillation ought by no means to be reckoned to have drawn its redness from the gold, but rather from the oil of tartar mixed together with the spirit of wine. Take this proof of it: for if you precipitate even a single drop of oil of tartar into aqua vitae, at once that very color which you first obtained by so many distillations will reveal itself by a

single precipitation. [Margin: Experiment.] As for your finding the gold stripped of its splendor, this does not happen because the splendor of the gold, or some substantial part of it, has been scraped off and joined to the menstruum; rather, by the force of the fire applied to it, it seems to have contracted some stain, though only a superficial one — a pallor which it can contract from countless other things, especially from contact with mercury, as we showed in Book XI. Add to this that the gold cannot even be said to be dissolved into a liquor — which is a clear sign that it stands in its natural perfection without any detriment to itself. Hence such gold cannot in the least be called true and genuine potable gold, but is sheer, pure accidental tincture; and it is worth just as much as if someone were to prepare upon a flint stone an excellent broth furnished with various seasonings — for it is certain that the broth would have acquired no virtue from the flint, but only from the things added.

[Margin: The process of Andreas Blavius.] Another specimen of potable gold is set before us by Andreas Blavius [Andreas Bachmann/Blavius], who explains it in a certain letter which he wrote on potable gold to Pietro Andrea Mattioli [Pietro Andrea Mattioli]. In it, although he does not appear to despair of the making of potable gold, he yet displays so many and so great difficulties that it readily appears it was never made by him — since so many doubts hold his mind perplexed. Nevertheless, because the mind greedy for gold cannot enjoy its desired tranquility unless it satisfies itself with some specimen — if not true and real, at least supposed and apparent — it is that which follows. "Three things," he says, "are required for making the Magistery: most highly purified gold, common salt of the better sort, and a little distilled vinegar." (For he utterly rejects corrosives from vitriol, alum, nitre, and mercury, as wholly pernicious.) [Margin: The process of Andreas Blavius.] Yet he takes up gold purified through antimony (which he prescribes is to be purged in a quantity tenfold that of the rest); from these, mixed together and placed in the alembic, he draws out a certain fatness not unlike white wax, in flavor altogether sweet like sugar, and in smell quite similar to musk — which by the violence

of the fire at length coalesces into the sweetest crystals clinging to the wall of the vessel, while at the bottom there remains a most limpid oil of the sun, greenish-from-white in color. Within this, he says, if you place leaves of gold, they will liquefy within three days, and the whole gold will be turned into a potable water, still possessing an acidity like the juice of lemons. And this is the method of Andreas Blavius in making potable gold — which, however, whether it is truly potable gold, remains to be examined. Blavius, then, takes the whole salt and oil of tartar with distilled vinegar for his menstruum; and it was shown above that

this cannot furnish the desired effect, since — apart from the fact that oil of tartar is of a nature heterogeneous to gold — it likewise cannot resolve it radically; nor does this power seem granted to ordinary salt, since he says that, once reduced to a sugary sweetness, it is stripped of all the sharpness wholly necessary for dissolving metallic bodies. It remains, therefore, that this ought not and cannot be called potable gold, but only an accidental tincture resulting from the precipitation of oil of tartar into a saline liquor — which even he himself afterwards is not ashamed to admit, in these words: "There is also another mark of true potable gold, by no means to be neglected: that although, mixed with imperfect metals, it perfects them, yet of itself, that it may be true, it ought never to be able to be reduced — which, however, in waters of this kind that stain with color, is easily done; for when spring water is poured in, with which they mix a little tartar, and this exhaling somewhat upward, the powder of gold ought to settle at the bottom." And a little before he says thus: "If you do not desire the substance of gold dissolved, but rather its tincture, I think that, if you make the trial, you will be able to draw it out from that water of ours with no very great labor." Here he expressly signifies that neither has the substance of gold been radically dissolved from itself by these menstrua, nor that he has drawn out from it the tincture of gold, that is, true potable gold — since he refers others to the experiment. At length he concludes: "As to what concerns the warding off of diseases, similar waters, used with due method applied, have profited greatly; but as for those who, like some universal medicine, have cured all diseases indiscriminately, restored fallen teeth and nails — I have so far seen none." But as for his saying that within this magistry a certain oil extracted from common salt has entered, in which the golden leaf or its powder (as he puts it, which they call calx), first purified through antimony according to the rule of art, is little by little and gradually turned into water within three days, easily distillable through the alembic — he indeed says so, but we know what antimony can do and what it cannot. It is true that this, joined with the aforesaid oil, leads gold into a liquor — yet in such a way that the antimony always floats on top while the gold seeks the bottom; and who does not know that antimony abounds both in mercurial spirits and in other most pernicious faculties, which, as they easily corrode gold by their innate sharpness, so likewise I should reckon the resolution to be ascribed not so much to the oil of salt as to the antimony. But how a liquor of this sort can be taken without danger, let those judge who have skill in alchemy. I could adduce in this place countless practices, partly collected from authors and partly communicated by various princes; but because they are all to a man stuffed with chemical paralogisms, I judged that they were by no means to be adduced; rather,

I shall here lay open only the errors and the solemn paralogisms which the chemists commit in the making of potable gold.

CHAPTER II.

An Iatro-Chemical Inquiry, by which the truth of Potable Gold is explored.

Since the Philosophers' Stone and Potable Gold are set on an equal grade of dignity, it ought to seem in no way surprising to anyone that the minds of mortals, allured by such great secrets — being as greedy for gold as drunk with the drinking of it — have attempted countless ways by which they might happily reach the harbor of such great magisteries. [Margin: No one has yet found the method of making potable gold.] But just as up to now there has been no one who has shown the true and real method of making the Philosophers' Stone, so likewise there has been no one who has demonstrated the true, real, and genuine procedure for making potable gold. This I show thus. For gold to be dissolved into a drinkable liquor, this cannot be done, in the opinion of all the alchemists, except by calcination. [Margin: The twofold calcination of gold.] Now calcination is twofold, proper and improper: the former is done by the agency of a most violent fire, as is evident in the calx of stones, which, reduced to calx [lime] in this way, cannot be brought back to the former state of stone; the latter calcination is that which is done by the dissolution of corrosive menstrea. I have called it improper because gold dissolved in this way — however much it may seem reduced almost to nothing by the torments of the very sharp water of Styx — [Margin: Gold reduced to nothing by no torments.] is nonetheless, despite all this, able to be brought back to its former nature, even reduced to an impalpable fine dust of the smallest particles. Besides these calcinations, no other calcination can be assigned in the nature of things. And that gold cannot in the least be calcined by fire, by calcination properly so called, is admitted by all — because no violence of fire can corrupt its substance. Yet granting (though not conceding)

that gold could be reduced to calx — I now ask whether gold thus calcined retains its natural virtues or not. The former, unless I am mistaken, all will admit, unless they wish their potable gold to be utterly dead, destitute of all natural virtues — which no one but a madman will concede. Since, then, the substance of gold, according to its physical composition, consists of moist and glutinous (or, what is the same, mercurial and sulphureous) particles, so united among themselves that — no differently than the asbestos stone in perpetual fire — it lasts inseparably and can be dissolved by no violence: surely, once calcination by fire has been

performed, that exact union of parts would undoubtedly have to be dissolved. [Margin: Gold calcined by proper calcination does not remain gold.] For since calcination is nothing else than the dissolution of the union of parts effected by fire — if this be granted, I say that all the natural virtues and faculties of the gold must necessarily vanish once other things have been introduced. For the mercurial moisture, now given over to freedom, would by the violence of the fire be scattered into thin air, the sulphureous glue being consumed by fire; and so nothing would be left but a dry, parched earthy substance, stripped of all native virtue. For since the virtues of gold proceed from such-and-such a combination of sulphur and mercury in its composition, once the mercury and sulphur are destroyed the virtues too must necessarily be destroyed — which was to be demonstrated. [Margin: The magnet loses its virtue by fire.] And this is evident also from the magnet, which, when reduced to calx by fire, soon loses all the force of its attractive faculty together with its sulphureous (so to speak) soul, which vanishes away. From this it is clear that gold can in no way be calcined by calcination properly so called, nor, when calcined in this way, can it retain its virtue along with it, for the reasons indicated a little before. This is evident also from the fact that, the essential sulphureo-mercurial bond being destroyed, the virtues — which necessarily and inseparably depend on that bond — cannot subsist, nor, for the same reason, can they be reduced back into the former substance of gold. I am speaking here, however, of the calcination of the most perfect of all metals, that is, of gold, not of the rest of the metals, of which afterwards. This, then, being now clearly demonstrated, let us proceed to expound the second species of calcination, which we called improper, by which gold is corroded and reduced into the minutest parts — indeed, together with the moistening menstruum, wholly into a liquor. [Margin: Whether gold dissolved by corrosives can be brought back.] It is therefore asked whether by these liquors of sharp menstrua gold can be so dissolved into water that it cannot be reduced to its former state.

I say first that it is impossible that what the highest violence of fire cannot do, heterogeneous liquors — whether mineral or vegetable — should accomplish. For even though gold, through reverberation effected with saline or sulphureous materials, may be so altered as to its external figure that, stripped of all form, it shows no trace of gold, nevertheless by the skill of an expert spagyrist, through a suitable additive, it can be so freed from the spirits of salts and of sulphur that, without any harm to its qualities and virtues, it is brought back to its former form — which we showed by various experiments in Book XI. No menstrua of the liquor of Mercury, then, no torments of the strong waters, the regal waters, and the waters of Styx, no force and efficacy of the salts of nitre, alum, and vitriol, can

so mortify the unshaken substance of gold that it cannot be reduced to what it was. Hence we infer again: if the most efficacious corrosives of all, which we have recounted, can do nothing toward corrupting the substance of gold, much less, we affirm, can the moderate corrosives — such as ordinary salt and vinegar and the other vegetable menstrua of barberries and lemons — do this.

But here some will object to me that gold, by the calcination of fire alone, has been reduced to an impalpable fine dust without any addition of a corrosive, and then dissolved by a certain celestial Raymundine water [aqua coelica Raymundina] into an indivisible liquor — and sold (whether for an equal profit, I know not). [Margin: Objection.] Certainly that this was a plain imposture, this celestial Raymundine menstruum — drawn perhaps better from the hollow of the Moon than from the economy of a lower nature — abundantly teaches. [Margin: Refutation.] But lest we seem to grant them nothing, let us suppose that it was made of some sublunary material free of all corrosion. Hence I argue thus: either he calcined the gold by fire alone (as Paracelsus [Paracelsus] himself admits), or by some other means. Not the former: since that invincible substance of gold is so far from suffering any detriment to its powers in the fire that rather, in it — as we taught a little before — it triumphs and exults in a garment of more brilliant splendor; which, however, would by no means happen if it had been reduced to calx by the agency of fire, inasmuch as its substance would then be destroyed together with its powers. Not the latter: since gold reduced to calx by mercury and the other very sharp menstrua already mentioned neither reproduces nor preserves either color or flavor — the truth of which the following experience has taught.

EXPERIMENT I.

Take calx of gold dissolved by mercury or by other menstrua; place it in a crucible and commit it to the fire of fusion, and at once you will see it melt like salt; but when the fumes and spirits have perceptibly evaporated out of the calx, you will find the gold restored at the bottom to its former shape; while you will discover — no better than by a dizziness of the head and the token of a sharp taste — that the smoke and water were nothing but the vapor of the menstruum or of mercury, or the acidity of the menstruum. [Margin: Objection. Refutation.] It now remains to explain how that aforesaid chemist dissolved that golden calx so that it might become potable gold, since the use of corrosives in this magistry, as harmful and abomin-

[Margin: From honey and manna the sharpest solvents can be made.] [Margin: A true and real tincture of gold does not exist.]

he should reject the whole business. From this he invents some sort of "celestial water" of Raymond Lull [Raymundinam, i.e., of Ramon Llull], which he pours over the calx and seals into an alembic; then, after digesting it for several days over a gentle heat, he finally reduces it by repeated operation into a water of golden color. This he asserts to be the true and real mode of potable gold prepared by a philosophical method — a golden liquor never reducible back into its former substance.

For my part, I would judge that this "celestial water," the worker of such great marvels and free of all corrosion and acrimony, was drawn rather from the concavity of the Moon, as I said above, than fetched from anywhere else — since a little earlier we showed that gold cannot be dissolved except by an actual or a potential fire lurking in the solvents. Therefore I take this "celestial water" the author invents to be nothing other than a solvent compounded either from honey or from manna, the celestial dew. Many chemists prescribe just such a thing in the dissolution of gold to avoid corrosion; and so as not to appear to be following them, it is likely that he prescribed this "celestial water" hidden under some allegorical manner of speech, lest he be convicted of having used corrosives. But who does not know that from honey and manna — sweet as those liquids are — the very sharpest solvents are nonetheless made? And so, willing or unwilling, he is forced to take up corrosive solvents of this kind to accomplish the dissolution. Yet just as these are out of proportion to dissolving gold, so too they will in no way be able to dissolve gold into an irreducible drinkable liquor — as will afterward be seen by experience.

CONSECTARIUM I.

[Corollary I]

[Margin: A true and real tincture of gold does not exist.]

From what has been said it is plainly clear that, just as gold cannot properly be calcined, so too it can by no means be sublimated through the alembic in such a way that a true and real tincture — what they call the *soul of gold* — is extracted from it without the total destruction of the gold, for the reasons indicated above. We do not deny that gold can be made subtler, dissolved, and carried up through the alembic by skilled chemists with the addition of certain ingredients or solvents; the crux of the difficulty does not lie there. The question is whether gold sublimated in this way is irreducible — and this we deny again and again, as has already often been proved. But since our adversaries have no other means of establishing the truth, they try to establish it from the golden color in which the

liquor shines. Yet who does not see how frivolous this argument is? Are they not mindful of the saying, *Trust not too much in color*? For that golden color can be induced in countless things — of which here is the following experiment.

EXPERIMENTUM II.

[Experiment II]

Concerning the deceptive color in potable gold.

Pour distilled vinegar over white lead [ceruse], and set it in a water bath for several days to digest; you will find the vinegar imbued with a tawny color. Separate the liquor by decanting, and distill it through the water bath to about [?] [the source reads "ad :circiter:" — the target quantity is left blank]; at the bottom you will find a matter sweet like honey and imbued with a tawny color. Distill this through ashes, and at the end of the distillation a blood-red liquor will come off, ruddy like the juice of the mulberry, with the residual matter spongy and light — which may not unfittingly be called a *caput mortuum* [dead head].

Now who does not know that ceruse is the whitest of things, and distilled vinegar clears to a most limpid clarity like water? So one would argue falsely who said that the ruddy thing produced by distillation was the tincture, or the soul, of the lead itself out of which ceruse is composed. For lead has no such tincture, nor any other watery substance resembling distilled vinegar. Thus we have most amply set forth that the whole redness of this tincture comes from the fire — the property which this mixture acquired through the heat or burning of the fire. [Margin: In the eighth book *On the Origin of Colors* in metallic bodies.] For if this were a true, real, and properly so-called tincture, it could by no means be reduced back into its former state — which experience teaches to be false. For if you expose this mixture to fire with the addition of a little sheep's fat, at once the ceruse is melted down into the lead it formerly was, [Margin: Reduction of ceruse into lead.] as Angelus Sala [Angelo Sala] — no contemptible chemist — also proves at length in his *Chrysologia*.

The same effect is evident not only in ceruse but also in iron, tin, calcined antimony, marcasites, and crystals: the liquor drawn out of them turns no less yellow than gold does. Gold, as we have found by experience, dissolved in *aqua regia* [royal water] reddens intensely; silver dissolved in strong waters [acids], with black; copper with acid liquors is tinged a green color. Yet all these, once separated from the dissolving solvents, easily resume their former color.

CONSECTARIUM II.

[Corollary II]

From these things too it is clear that the attempts of those Alchemists are vain who try to resolve gold by their *Sisyphean* labor into a water, a calx, an oil, a tincture. For although we have asserted that gold, like the other mixed bodies, is rightly composed of salt, mercury, and sulphur in countless places, it must nonetheless be understood that all these things behave one way in mineral nature, another way in vegetable and sensitive nature. For the latter, in the form of water and oil, once the separation of the principles is made, yield up their salt, sulphur, and mercury with almost no trouble, because mixed bodies are most easily resolved. Gold, however, is so compacted by nature with an equal weight of its principles that no one has yet been found who has reduced it, once dissolved by chemical art, into an irreducible state — so much so that, by the testimony of Roger Bacon himself [Rogerio Baccone], an alchemist of better repute, *to make gold is easier than to —*

[Margin: Gold is more easily made than destroyed.]

— *destroy it*. From this, the boast of the Alchemists is vain, who by fruitless labor try to elicit mercury from gold against the counsel of nature. [Margin: Empty contrivances.] These are empty contrivances — nothing other than the frivolous and deceptive showpieces of mountebanks and idle scoundrels. But granting (though not conceding) that it could be resolved: what use to medicine is to be hoped from it, I do not see; for the mercury separated in such a way, soon restored to its former nature, neither differs from common mercury nor adds anything to it.

[Margin: A true tincture of gold does not exist.]

Others sweat mightily over extracting from gold a tincture that would present a water of silvery color — but with fruitless labor. For the tincture of gold is not bound to its body's substance alone, but all its parts, inseparably united, exist in a pure way — outwardly yellow, inwardly ruddy — as Sala testifies: the Mercury on account of its supreme maturity, the Sulphur on account of its fiery faculty, the Salt on account of its fixed nature, from union and an indissoluble bond. And so from these three is born that tawny color of gold, which (as is now clear from what has been adduced) cannot remain in gold dissolved to the point of irreducibility. But let us proceed to the experiments.

EXPERIMENTUM.

[Experiment]

[Margin: Experiment.]

If anyone dissolves gold in *aqua regia*, a liquor will emerge from it not unlike a dyer's color [baphico colore], with which it will also tint whatever it touches when poured over it. Yet this tincture neither ought nor can be called an irreducible tincture of gold, since it can be reduced without any difficulty.

[Margin: How the tincture of gold may be reduced.] For if you keep the dissolved liquor in a water bath for several days, then draw off the *aqua regia* by fire or let it evaporate, and commit the remains to a limpid and clear water to be dissolved, you will draw out an oily cream like blood, of such redness that you could swear you had attained the perfect tincture of gold. Yet as soon as you bring it near the crucible, the heat of the fire resolving the liquor into vapor, you will find not a tincture but a solid body of gold. You will experience the same with gold reduced into an impalpable powder of the most intense red, which —

— [the column on the right continues:] — gold can be considered in two ways in its dissolution: intrinsically and substantially; and then extrinsically and accidentally. In the first way we assert it can in no way occur; for in this manner, with the metallic form destroyed, it could be called gold and not-gold, which is absurd — and I would have the Alchemists carefully note this. In the latter way, only accidentally, the form of gold vanishes — no otherwise than as fixed salt, reduced by deliquescence into water, [Margin: Gold is transmuted only accidentally.] loses the form of salt by accident, but recovers it when brought near the fire. The same must be held of gold dissolved by corrosives. For gold resolved into a liquor by the said solvents must be reckoned not to recede in the least from its metallic subsistence or form, but only to hide it — being diffused and dispersed through the smallest and subtlest little corpuscles. These, since they retain the nature of the whole, can also easily be joined and united to it from the sympathy implanted in them toward the whole, the gold returning to its former form. And therefore the *magisterium* that is made from gold ought to be called not gold but a golden magisterium — not the tincture of gold, but a golden one — as will be shown a little later.

CAPUT III.

[Chapter III]

Whether Gold, or Magisteria made from gold, obtain in Medicine the use, virtue, and efficacy that the Alchemists boast of; and whether it can or ought to be called a universal Medicine.

Now that it has been shown that gold cannot be reduced into a drinkable liquor with the substance of the gold preserved, it remains now to discuss whether, in medicines, it obtains the use that the Alchemists so greatly boast of. That gold is endowed with a remarkable virtue for strengthening the heart is received by the unanimous consensus of all physicians, ancient as well as recent.

Deservedly, then, it may be asked: whence comes such a virtue to it, and of what kind is it? To decide this:

It must be known that the virtues and qualities of things can be considered in two ways. First, according to the primary, manifest, and elemental qualities; second, according to certain specific virtues, which some wrongly name *occult*, but which we more truly call those deriving from a likeness to the whole substance. These are certain endowments implanted by Nature in individual things, which — since they emanate from the substantial form of things — cannot likewise be separated from it without the destruction of the substance. [Margin: The cardiac quality of gold is specific, not elemental.] And it is in this way that the cardiac power and faculty of gold must be understood. For just as the magnet, by the sympathetic virtue implanted in it by Nature alone, so desires iron that, when it is restored to its freedom, wherever and whenever it can, it is borne with a wondrous appetite toward the iron, draws it to itself, and over a remote distance moves and agitates it this way and that in marvelous ways — so too gold, applied to the human body, by the magnetism of the virtue implanted in it, at once flows to that member to which it is roused by a natural philtre of love, and exerts upon it the virtue implanted in it. But this would by no means happen if the dissolved substance of gold degenerated into a potable and irreducible liquor; for once the substance is destroyed, the virtues must likewise necessarily be destroyed — who does not know this? Or has anyone ever observed a magnet, reduced by the force of fire into a calx, still imbued with the attractive power for iron? Surely no one. Persuade yourself that the same happens with gold for certain.

[Margin: What the magisterium of gold is.]

This being supposed, one might deservedly ask why so many and such great *magisteria* are extolled from gold by physicians. I answer: those magisteria are not made, nor were they ever made, in the way that the Alchemists — ignorant of physiology — claim they must be made, such as: the Elixir of the Philosophers,

the Calx of the Sun, the Tincture of Phoebus, Potable Gold reduced into an irreducible state. For in this way, the form or substance of gold being destroyed by fire, there is no return from privation to possession; and consequently, the form being abolished, the remaining body must necessarily remain dead and stripped of all virtues.

Paracelsus himself even admits it in Book 6 *On the Nature of Things*: "Take," he says, "no metallic arcanum or medicament within the body unless it has first been rendered volatile and can be reduced into no metal." But how a magisterium — of gold, for example — could be resolved into an irreducible state: *here is Rhodes, here is the leap* [hic Rhodus, hic saltus]; since without mercury, or strong waters, or any solvents whatever, gold cannot be dissolved, as we showed above; and if it is dissolved, it is nonetheless not so radically resolved that it cannot be reduced into its former state; but if it is reduced by fire through calcination, I affirm that by this very act it is ruined and destroyed, and therefore of no use. How, then, magisteria from metallic bodies may acquire a medicinal virtue, will be shown below:

[Margin: How dissolved gold operates in the human body.]

If gold is reduced into the smallest corpuscles by corrosive solvents, and once dissolved in this way various kinds of cardiac remedies are joined to it, I say that gold, reduced in this way into its smallest parts (yet without substantial transmutation), together with the said cardiac remedies, produces nobler effects than gold constituted in its solid substance. For since the individual corpuscles of the dissolved gold are strong with the virtue of the whole, they, mixed with the other adjuncts, will surely acquire a more intense degree of the property in the composition. Indeed, if any corrosive still remains in the gold or in the dissolving solvents, it is nonetheless so blunted by the virtue of the other added species that it will not easily harm one who takes it in a draught. Hence those greatly delude themselves who ascribe the power of the magisteria of gold to gold alone — since they produce their effect no otherwise than as we have said, from the mixture of many species of great virtue. So they are to be called not so much magisteria *of gold* as *golden* magisteria. For the substance of gold is not properly transmuted into a liquor by corrosives, but only its particles, gnawed away by the acrimony of the solvents and mixed with the others, produce those marvelous effects (if they are genuine), which can afterward easily be reduced back, by the evaporation of the vegetable matter, into a single body of gold, as we said a little before.

But to demonstrate that this liquor is not of gold but golden and compound, it is easily made known by a chemists' experiment, as follows.

EXPERIMENTUM

[Experiment]

Of the composition of the golden magisterium.

Take powder of precipitated gold, well dried and lightly spread over a marble slab; with spirit of Spanish or Malvasia wine rectified three times with dried balm [melissa] and separated from its phlegm, sprinkle it and mix it well together; and, thus prepared, let it dry in the sun or in a warm place. With this sprinkling repeated six or seven times, to one ounce of the prepared powder add a scruple of saffron, six grains of grey amber [ambergris] and of oriental musk, and store the whole mixture in a glass vessel for use. By the testimony of Sala and Crollius [Oswald Croll], this is of such great efficacy that it seems to work miracles.

[Margin: The virtues of potable gold are not from gold alone, but are to be ascribed to the admixtures.] But you should judge that these things come not at all from gold alone, but from the cardiac substances. For gold strengthens by its specific and magnetic virtue, indeed, but it does not nourish, which is proper to vegetable ingredients; [Margin: Gold does not nourish.] for, as we taught in the preceding chapters, no mixed body can nourish us unless it first has life in itself; and gold, since it is an inanimate mixed body, acts upon the human body no otherwise than the other minerals — like the diamond [Adamantis],

— the beryl, topaz, amethyst, carbuncle, sapphire, and the specific virtues of the other gems: by a certain radiant and imperceptible effluvium of the virtues appropriated to each.

CONSECTARIUM I.

[Corollary I]

From this it is clear that, if the ancient chemists sometimes make mention of potable gold, they by no means understood it of a substance of gold irreducibly resolved into a liquor, but called their medicines and the magisteria of various compositions "golden" by a certain figurative naming, from their marvelous virtue. Just so, as usage demands, we are accustomed to call a thing of great virtue and price "golden" — [Margin: Many things are called "golden" not from gold but from their excellence.] a book *golden*, a man endowed with outstanding virtues *golden*; and times filled with felicity and an abundance of all good things we are wont to call *golden ages*. And it is expressly clear in the spagyric writings

of Lull, Villanova [Arnald of Villanova], and Paracelsus, in which various magisteria occur — Emetics, Cathartics, Diaphoretics, Anodynes, Bezoartics — which are sold under the name "golden," in which nonetheless gold has no place at all.

CONSECTARIUM II.

[Corollary II]

From these things I infer that a golden magisterium can in no way be prepared for use as an absolutely universal and catholic medicine — which the Alchemists nonetheless do not cease to proclaim with full cheeks. [Margin: From gold a universal medicine cannot be made.] For since gold is endowed by nature, by the consensus of all physicians, only with the heart-strengthening virtue, it must surely produce an effect peculiar and proportioned to that endowment. Hence, if it is strong (as many think) with an astringent power, I affirm that it cannot be supposed — not to say believed, but not even conceived — to have, as well, the opposite cathartic or laxative virtue, owing to the dominion of contrary virtues in one and the same subject. If it is strong with a softening [malactic] power, it cannot have a hardening [sclerotic] one, and vice versa. If it heats, it will not cool; if it moistens, it will not dry, and vice versa. But since the kinds of diseases are of the most diverse condition — some arising from febrile heat, some from cold, some from superfluous moisture, others from dryness; some requiring in consequence cathartics, others astringents, others diuretics, still others restringents — surely no absolutely universal medicine can be assigned in the nature of things, composed of an equal and most perfect harmony, fit to drive off all diseases, whatever Lull dreams of his celestial Elixir, or Paracelsus, Quercetanus [Joseph Duchesne], and others of their universal mysteries. This I would say not only of the elemental but also of the specific qualities. And it is plainly evident even from theriac: if any other medicine could be called universal, surely that one could be — and yet that to administer it in many diseases is not without danger is better known than need be said. The same must be said of quintessences and the other magisteria; for although they are composed of countless species, they nonetheless always bring about effects contrary to, and exceedingly dangerous for, some diseases. Whoever has rightly understood the art of contraries will find what I have said to be true. For I would not easily deny that a medicine can be given which, by reason of the consideration of virtues mutually restraining one another, may be able to help in driving off several diseases — as is evident from theriac and the elixir of life. For

who would offer the elixir of life, of the most powerful heat, to a patient tormented by the most burning fevers?

Some experiments concerning the admirable properties of gold.

EXPERIMENTUM I.

[Experiment I]

To make fulminating gold, or the Calcination of Gold for fulminating gold.

The calcination of gold is nothing other than the process by which the solid body of gold is attenuated, made subtle, softened, and — torn apart into imperceptible corpuscles — reduced into an impalpable dust, to the end that it may become apt and suitable for receiving the operation of the Magisterium. This calcination is done in two ways: either by the moist or by the dry. The dry method, by the aid of fire, is thought by the Alchemists to be possible — which we have denied. The moist is usually done with *aqua chrysulca* [gold-dissolving water], otherwise called *aqua regia* [royal water], in this manner:

[Margin: Making of fulminating gold.]

Take *aqua fortis* [strong water] made from two parts vitriol and one part distilled niter — one pound, for example; in it dissolve two ounces of well-purified sal ammoniac. In the *aqua regia* thus prepared, dissolve gold cut into small fragments over a gentle heat with some boiling. To the clear and yellowing solution contained within a glass vessel, instil drop by drop a lye made from tartar; and when a vehement boiling is finished, the gold subsides to the bottom like mud. This done, let the remaining salt liquor be washed off so long until no more acrimony appears. Let the sediment of the gold then be taken out and dried with the gentlest heat; and in this way you will have that admirable [Greek: χρυσοκέραυνον (chrysokeraunon, "gold-thunderbolt" — fulminating gold)], so called because its grains — two or three of them — exposed to fire, when they catch flame (and it catches it most readily), make a huge crash; and, with a motion opposite to that of gunpowder, driving downward, they bore through and shatter everything. For, as Angelus Sala testifies, by the force of this calx when it caught fire by a fall, a huge slab of marble on which it had been placed was thrown apart and torn into fragments — not without danger to the bystanders.

We have seen it prepared another way. Take 8 ounces of *aqua fortis*, 3 ounces of duly purified sal ammoniac and niter; let them be mixed and distilled through a retort with the degrees of fire observed, and you will obtain a *stygian water* most apt for dissolving gold. And this too, in the calx prepared by the first method, is

most worthy of admiration to ob-alis nitri"; p.430 "cibulo" → p.431 "cibulo ponunt"; p.431 "Expe-" → p.432 "Experimentum IV."]

[Margin: An experiment by which the fulminating power of the gold-lime is removed.]

to be observed: that if you mix nitre and vitriol — the two parts which constitute the gold-lime [auream calcem] — together with one part of flowers of sulphur, and burn the mixture in a crucible until it takes on the appearance of Armenian bole, the whole powder loses its fulminating power. The reason for this can be none other than that the sulphur destroys the windy spirits of the nitre. Since these are the cause of so great a fulminating force, once the cause is removed, the effect too must necessarily cease. On the admirable cause and rationale of this powder, see what I have set out at fullest length in Book I [Margin: *Liber IV* — see note (a)], and what I shall also expressly treat in Book XII [recte: see note (a)].

CAPUT IV.

On Silver, or Terrestrial Luna.

Silver is called *terrestrial Luna* [Luna terrestris] by the chemists because of a certain hidden correspondence and symbolic affinity it bears both with the celestial Moon and with the microcosmic moon — what they call the brain. [Margin: Silver, the metals' colours, each proper to its own.] Now just as the individual terrestrial planets — that is, the metals — take diverse colours from nature (Saturn or lead shows itself in a squalid black, Jupiter or tin in white, Mars or iron in red, Mercury in a livid hue, Venus or copper in green), so they imbue Luna with a blue colour. And although Luna seems content with this single colour, it nevertheless contains within itself the colours of all the remaining metals — a fact long since made known by the sole experience of the spagyric art. [Margin: Silver contains all colours within itself.]

For in its solid substance silver shows itself white; but when dissolved into water by the appropriate menstrua, it is converted into a colour most like sapphire. If you then draw off by the known art the menstruum in which it was dissolved, it will at once present itself to view in a mournful guise, clothed as if in some dark garment. Yet when committed once more to the fire, it will restore itself to a far more splendid and solid state than before, gleaming with a tawny and red colour out of the whitest white.

[Margin: The tincture of silver.] There have been many who, with the greatest labour, strove to extract a tincture from silver, and I myself toiled at that task to

no small degree. Silver, dissolved by the force of distilled vinegar, did indeed appear most pleasing to the eye under a certain blue colour; but once the menstruum was afterward drawn off, it left behind just as much silver as had been put in. [Margin: A counterfeit exposed.]

Others labored with enormous efforts to reduce silver to its prime matter [materiam primam]. A certain man showed me something of this sort, in the form of a resin: white, translucent, heavy, brittle, fusible, incombustible at every degree of fire — and he boasted that this was the true magistry of Luna [Lunae magisterium]. But when, at my request, he refused to submit it to experimental test, I at once concluded that, like a man with a bad conscience, he knew his magistry to be sophistical. And so he went off, and never appeared again.

For my part, if any such thing exists, I frankly confess I have never seen it. I did see a powder of silver that strongly resisted the fire — one that could not be reduced to its former state by any force of the sharpest menstrua, nor by the voracity of mercury; yet committed at last to the cupel with a little lead, we found by experiment that it was, as it were, recalled from death to life.

[Margin: A fraud.] But those who take equal parts of filings of silver, of sublimate mercury, and of sal ammoniac, mix them well together, and sublime them so long that the sal ammoniac and vitriol [?] rise to the top while the mercury settles at the bottom of the vessel — and who then proclaim this as the living miracle of the lunar magistry — are to be rejected as open impostors. For whoever weighs an operation of this kind in the balance of reason will clearly see that it was the living mercury, dissolved by the spirit of salt and vitriol, and nothing else; since the silver that had been put in shows itself of exactly the same weight as before. [Margin: Silver calcined by any means whatever can nevertheless be reduced to its original nature.]

Likewise to be reckoned false craftsmen [pseudotechni] are those who, by amalgamation of the lime [calx] with mercury in any way whatever, and then by means of flowers of sal ammoniac, radicated vinegar, and other agents, dissolve silver into a most subtle blue powder — but if you send the magistry back to the judge and trial of the cupel, you will find that it has soon returned to true and natural silver.

Whether silver, no less than gold, can be reduced into a liquor or lime — or cannot — is a matter of controversy. So, to be brief, I say this. Since gold and silver are called the perfect metals by the chemists, because they have a more compact nature than all the rest and the proximate principles of Nature exist in

them under a certain equal proportion, it is certain that there is also the greatest difficulty in dissolving them radically — though not as great a difficulty as with gold. Still, I do not doubt that some method can be devised by which silver may be reduced into an irreducible state; but since that method is as yet undiscovered, I leave it to the chemists to investigate. Hence too the magisteries of Luna can be carried out far more readily than those of Sol.

But lest I seem to have omitted anything, I will append the procedure for the magistry, which I learned from skilled chemists.

Just as gold, then, so too silver cannot be dissolved without a corrosive, whether into a lime or into a tincture. The corrosive menstruum for dissolving Luna is this:

1. Take 2 lb. of Hungarian vitriol, whitened by gentle heat and reduced to fine powder.

[Margin: The preparation of the tincture of Luna by corrosives.]

1 lb. of salt of nitre [sal nitri], cleansed as thoroughly as possible from its salt and dregs and reduced to powder. Let them be mixed well and distilled by the art known to the spagyrist, and you will have a menstruum in the form of a most limpid water, pregnant with its spirits.

2. This done, take three ounces of Luna duly purified from all impurities by means of Saturn (that is, lead). Place these in a urinal-flask, and pour over them six ounces of the aforesaid menstruum. Let the urinal-flask, set in tepid water, be left until the separation of the parts takes place.
3. When the solution or separation is finished, pour upon the liquor now dissolved nine ounces more of the aforesaid menstruum, and digest it within a bath of dew [balneum roris] over a continuous fire for 40 days, always pouring back whatever has distilled off.
4. You will separate the water, or superfluous moisture, from the magistry in this way. Great care must be taken to keep the fire at a constant degree. Draw off the water in the usual manner through the same first degree of fire; preserve the drawn-off portion in a glass vessel; then place the residue in an alembic luted with clay, set it in a sand-bath, and distill, so that you may by a stronger fire draw out what water remains. Here — unless you wish to lose your oil and your labor — you must proceed with great caution, lest with too strong a heat a greater quantity of spirits escape along with the moisture. The magistry should therefore remain at the

bottom of the vessel for 4 or 6 hours, like fossil salt. For in this way, when the vessel is opened, you will find at the bottom a stony material, very black below and at the sides, but white above and transparent like crystal.

And this is the magistery that was sought. And it has admirable properties.

[Margin: The admirable virtues of the tincture of Luna.] Of these, the first is that, although it stains the hands with a black color, it has nevertheless wholly lost the corrosive faculty that resides in aqua fortis. The second: it presents to the tongue the taste of vitriolic acidity. For if you dissolve the magistery in tepid water in a copper bowl, or cast into it copper plates, you will soon see the silver, separated from the magistery, adhering to the copper in a spongy form; yet once melted, it returns again to solid silver. Third: if you reduce the material of the magistery to powder and expose it to the Sun, it will take on a form as black as ink — which likewise happens if you mix the material with dissolved gold. [Margin: The dry tincture catches flame.] Fourth: experience teaches — with Sala [Angelo Sala] as witness — that a particle of this stone, cast into open fire, burns like saltpeter; indeed, when set upon paper and brought to the utmost dryness, it leaps up with great force in a conceived flame like gunpowder. The reason for this is the muddy [latulentus] spirit of nitre with which it is charged: for nitre, in the form of a menstruum, utterly refuses fire, but once joined to Luna it reverts to its original nature and catches fire in the usual way. [Margin: It helps in diseases of the head.] Fifth: by the common opinion of physicians it is held to be a great and specific remedy in infirmities of the head — such as epilepsy, hydrocephalus, paralysis, and the other dangerous catarrhs — given in a dose of 5 or 8 grains with malmsey wine in the morning.

CAPUT V.

On the Magisteries of Iron, Tin, Copper, and Lead.

The imperfect metals, on account of their impure principles, are less sought after for internal uses. For even if they are prepared with great and remarkable skill, there nevertheless remains in their root a kind of contamination — I know not what — resulting from impure, undigested, and corrupted salt, sulphur, and mercury; and while drawn forth by nature toward the best through the contamination of minerals and the onrushing force of invading vapors, they have nonetheless degenerated, ill-disposed in the wombs of the earth from their corrupted matter. And although I have treated very fully of the generation and properties of iron, tin, copper, and lead in Book X, I shall here append a few

additional things bearing on internal uses — and chiefly those that concern medical use.

Certainly metals of this kind, just enumerated as imperfect and badly compacted, can for that very reason be dissolved into liquors with almost no trouble, the substance being preserved. So, that steel [chalybs] may be made potable [Margin: The preparation of potable steel], it must, by Lull's [Raymond Lull] prescription, be calcined in fires. Some, however, prefer to calcine it by one and the same operation through a liquor of salt, or also through distilled vinegar, in which the well-washed filings of the iron are immersed.

I would judge the best procedure to be the following, since for [the right-hand column continues:]...internal uses it is taken, so that we attenuate its crocus with vinegar, or with spirit of salt and similar menstrua, so that it liquefies of itself — though it can also be driven by reverberations, now with salts added, now omitted. At last the quintessence of wine [quinta vini essentia] is added as the completion of the work, and yields potable iron [ferrum potabile]. For iron, now broken and tamed by the violence of fires, and likewise subjugated by the voracity of sharp menstrua, the liquor of wine, repeatedly drawn off, thoroughly dissolves; and so, mixed with the iron, it degenerates into an absolute tincture. [Margin: Soluble preparation. — Use of potable steel in medicine.] This abundance is then drawn down by distillation into a small quantity, whereby there is left an oil-like liquor, fit for both internal and external uses — wonderfully beneficial to the dropsical, the splenetic, the hypochondriac, the affections of the spleen, the celiac, the dysenteric, and the asthmatic.

In our pharmacopoeia, for steeled wine [vinum chalybeum] for the splenetic, the dysenteric, and the obstructed, they take 8 lb. of malmsey wine — or Muscatel, as the Syracusans commonly call it — which they put in an earthen vessel, big-bellied and with a long neck. Then [they add] 1 lb. of filings of the purest iron, or of steel, in a crucible...

[Margin: Potable tin. — The philosophical tree.]

crucible they place [the filings] until it grows white-hot; and as soon as they see it thus glowing, they pour wine, contained in an earthen vessel, over it up to a third part, and stop the mouth, lest the spirits evaporate. After the third operation, what is finally left will settle in the space of 24 hours; and you will have a magistery of admirable benefit in the said diseases. For the rest, see what is fully treated concerning Iron in Book X.

Whether tin — which is also called white lead — can be made potable, many doubt, on account of the principles of mercury and sulphur ill-digested within it; for if corrosive menstrua are added in its dissolution, they leave behind a thoroughly bad and altogether virulent effect — as those who purge and calcine tin learn daily, to their great cost. Hence the chemists left no stone unturned to reduce it to better profit, raised to the lunar dignity; but, defrauded by a vain labor like Sisyphus's, they failed. It would nevertheless be a most excellent collyrium [eye-salve], if someone could, by long circulations, free it from the deadly virulence hidden beneath it. But this care must be left to the chemists.

[Margin: Potable copper.] On the nature and property of copper, see what has already been treated in various places; nothing remains except to set out whether it can be made potable. The alchemists, relying on the hope that, if they could transmute it into pure silver, they would as a consequence extract from it a lunar tincture of wondrous virtue — but beyond the loss of all their goods and even of life, some indeed gained nothing but the gallows, while others gained an undying disgrace with perpetual damage to their reputation. Others, made wiser by the harm of many, abandoned the alchemical vanity of ἀργυροποιία [Greek: argyropoiia, "silver-making"] and bent themselves to this one thing: to extract from copper the vitriol which they had learned to be the most excellent remedy of all minerals against the principal diseases. But since I have treated very fully of it in Book VI, chapter X, I refer the reader there, where you will find unfolded whatever can be desired concerning the nature and property of copper and the generation of vitriol. I shall say nothing here about lead and mercury, since I have examined these in countless places throughout. It only remains for me to append a few experiments concerning the properties of gold and silver.

CAPUT VI.

On Metallic Trees and Their Artificial Production.

We call *metallic trees* those efflorescences — exanthemata — which burst forth in nearly every mineral from the ducts of the veins, than which nothing more admirable can be seen. You may see some in the form of little crystalline shrubs, some like corals; some green, white, or saffron-colored, or composed of various colors, which spread out through a trunk into certain many-forked branches — of the kind we usually display in our Museum. They arise from the radiation of mercurial and saline spirits, by which the corpuscles of minerals, joined to corpuscles, are now spread out lengthwise, now breadthwise, now straight, now

obliquely, in such proportion that the result very nearly resembles a tree with branches, so that nothing seems lacking to it except life.

Diagram. A woodcut, set into the left column, of a tall ovoid glass phial (a closed flask, narrow-mouthed, with a swelling bulbous body resting on a footed base). Inside the phial grows a branching dendritic structure — the "metallic tree" — rising from the bottom on a slender trunk and spreading into many fine forked branches that fill the upper body of the flask, illustrating the artificial *arbor philosophica* described in the text. No labels or caption.

Here you have, briefly, the origin of mineral plants wrought by nature's workmanship. It only remains for us to show how, by the spagyric art, similar things can be produced within some phial.

EXPERIMENT I.

The philosophers' tree growing before one's eyes.

[Margin: The philosophical tree.] Take one and a half [?] ounces of the purest Luna, or silver purified through the cupel; 2 ounces of aqua fortis and of mercury, in which the silver taken is to be dissolved. Then mix these two materials and pour them into a phial, over which pour a pound of common water; stop it well, and you will see it grow daily, both in the trunk and in the branches.

EXPERIMENT II.

That the tree within the phial be wholly gilded, and bear apples like pomegranates.

[Margin: Another philosophical tree.] Take equal parts of antimony reduced to powder, of common aqua fortis, and of oil of sulphur, and pour them upon the "stone of three" [lapidi de tribus]; for these, placed in a phial, will in time show a tree gleaming with golden branches, on which you will find attached droplets of a crimson color, representing pomegranate apples.

EXPERIMENT III.

The philosophical tree.

[Margin: 3. The philosophical tree, in a phial.] Take equal parts of the tincture of Luna and of mercury; place the amalgam made from them in a well-stopped vessel, and leave it until it turns into a powder — which is called black sulphur.

To this add an ounce and a half of sulphur, and one ounce each of tartar, borax, and myrrh; let them be well mixed, and, placed in a phial, let it be closed with a hermetic seal. Then place them within warm sand, and within two or three days you will see a beautiful miracle of art — namely, a philosophical tree.

EXPERIMENT IV.

The tree of Luna.

[Margin: 4. The tree of Luna.] Take 4 oz. of cupellated silver. Dissolve it in spirit of nitre, [draw off] the spirit by a bath of dew, and Luna will remain at the bottom. Over it pour distilled rainwater; digest for several days and distill; do this six or seven times, always pouring on fresh distilled water. Afterward, into that solution of silver made again with distilled rainwater, throw 6 oz. of fixed nitre [nitrum fixum]; digest together for two weeks, and the Lunar tree grows — a most delightful spectacle.

EXPERIMENT V.

The method of fixing nitre.

Take one pound of nitre, liquefy it in a strong crucible, and gradually throw in flowers of sulphur, until at last it no longer catches fire; then it is enough. Remove it from the fire, and let the fixed nitre be purified by dissolution and filtration. Throw this into the dissolved Luna, as I instructed above.

Another method. The philosophical tree from Mercury and Luna.

[Margin: The tree of Luna and mercury.] Take an ounce and a half of cupellated silver; dissolve each separately in spirit of nitre, and let the dissolved [portions] of living mercury [be combined?]. Take 1 [?] oz. of living mercury, [dissolve it,] and let them be joined together in a capacious phial; add 12 or 20 ounces of distilled rainwater, set it in warm ashes, and [leave it] for the digestion of the space of one hour — unless it should wish to grow at once. Throw into that solution 3 oz. of sal ammoniac, and you will have what is sought.

EXPERIMENT VI.

To represent a certain region within a phial.

[Margin: The expression of a region.] Take aqua fortis, and dissolve in it Luna, Mercury, Sol, and Venus; then separately dissolve vitriol in aqua fortis. Let all these, placed in a phial, be well mixed; and the mixture, having been placed [in

the phial], is to be set out to digest in the sun. If you find this material flowering, pour off the thinned water and pour on fresh and most limpid water. Let the aqua fortis be made from alum, saltpeter, and vitriol. In this device you will see with admiration hills, crags, plants, little flowers, and rivers expressed after the type of some real region.

EXPERIMENT VII.

To exhibit the Idea of the Macrocosm.

[Margin: The Idea of the Macrocosm.] Although I have not performed this experiment myself, yet since it was communicated to me by an excellent chemist as a great secret, I will append it here. Dig up rich earth beside the brooks that run down at the foot of the mountains (such as the mines of gold and silver are); from it make the saltpeter set forth in Book VI [Margin: the right column continues from p. 432 left] which...

[The text of Experiment VII continues into the right-hand column:]...[the saltpeter] which could be discovered neither by water, nor by fire, nor by automatic instruments. [Margin: The vanity of perpetual motion.] Let us now see the credibility of the promised miracle.

Take 5 or 6 ounces of amalgam of Venus [copper], with as much of amalgamated tin; grind all together with 10 or 12 oz. of sublimate mercury, and place it upon marble in a cellar. Then, within the space of 4 hours, the whole will dissolve into a liquor not unlike olive oil. Distill this, and at the end with a most violent fire, and you will see a dry sublimated substance; pour the distilled water back in turn over the earth remaining in the alembic, and dissolve what can be dissolved; filter the solution, distill the filtrate again, and so on. There will appear most subtle atoms, or corpuscles, which are to be preserved in well-closed glass in a dry place; and behold, you will see wonders, on account of which the whole world has hitherto labored too painfully. These are the boastings of the alchemists, miracles of a great art to be urged upon the ignorant common folk, though the effect was never brought into practice.

For who could ever discern how, in this magistry, perpetual motion might be exhibited? What kinship, indeed, or what likeness, is there between metals, amalgams, distillates, sublimates — or rich, swollen, immobile earth — and perpetual motion? And who could guess how these things, in their sluggish nature, could drive the Sun, Moon, and Stars through their periods? The author of this fanatical contrivance I can certainly find to be none other [than...]

other than the one who stirs up and agitates the brains of such insolent men into countless superstitions — Paracelsus [Paracelsus]. I have long known that Drebbel [Cornelis Drebbel] devised something similar, but since I have set out elsewhere what that was, I do not wish to repeat it here.

EXPERIMENT IX.

To represent the spheres of the elements in a glass flask.

[Margin: How the powers of the elements are exhibited in a flask.]

This device must be understood in a twofold way: first, that the elements, wound about a center, perfectly imitate the elemental sphere; or that liquids enclosed within a cylindrical glass flask float one above the other horizontally and παραλλήλως [Greek: parallēlōs, "in parallel"].

That the former cannot be done, we demonstrated at length in the First Book of the *Centrosophia*. To establish, outside the center of the earth, another center surrounded by the elemental spheres globed around it exceeds all the power of angels and of men; such a work is reserved to God alone. But that the latter can be done with almost no trouble, we showed in the Third Book of the *Art of Magnetism* [Magnes, sive de Arte Magnetica] by exhibiting many experiments.

But here some may object — alleging perhaps my ignorance in matters of nature — that I too presumptuously dare to deny the concentration of liquids to Nature, since Nature demonstrates daily that it can occur. For what else are drops of water but little spheres which have their center of conglobation outside the center of the earth? This is also seen, clearer than the midday light, in mercury poured out upon a marble slab and at once split into innumerable mobile globes. I reply that it is perfectly true that liquids of this kind do concentrate into globules — Nature being in no way contrary to this, but rather it is quite in keeping with Nature.

[Margin: Why water and mercury form into globes.]

For when drops globe themselves up on a dry surface, this must by no means be thought to happen by the force of a center, but by reason of the moisture, which of itself and by its own nature shuns what is dry. For when, with a dry surface resisting, the moisture cannot

spread itself out into a flat surface, it necessarily lifts itself up into something resembling a globule. This appears plainly in mercury — which is also called "dry water," water that does not wet the hands — because of the inner force of its

dryness. For the homogeneous parts of mercury, defending themselves most strongly against dryness so as not to be dissolved, are compelled, as Nature requires, to globe themselves into a union which cannot occur except in a spherical form. Yet here one imagines a center in vain, around which the parts would be globed by its force. Indeed, if these things happened by the force of a center, there would be no reason why a large quantity of mercury, whether contained within a vessel or spread out on a slab, would not at once coalesce into a perfect globe — which nevertheless contradicts experience, since mercury contained within a flask presents a flat surface, no differently than other liquids, and likewise when poured out in large quantity onto a slab.

That certain very small particles in liquids of this kind do at once form themselves into globules — you must judge this to happen not by the force of a center but, as I said, by the force of dryness. For just as dryness naturally shuns moisture as its contrary, so too, when it cannot spread out while dryness stands around it, it readily forms itself into a globe because of the slight weight of its minute mass. This appears in daily experience with cups, in which liquids are seen to be raised into swellings at the rims of the goblet, while they are pressed down by the intervening mass of the liquid.

The matter must be understood otherwise as regards liquids contained in some glass vessel being globed about their own center, exactly as happens in the elemental sphere. For this — whatever the alchemists may dream — cannot be done; indeed, it plainly involves an open contradiction, from the fact that in the said vessel the fiery liquid, the very lightest, would be in the lowest circle, and the heaviest. And let the same judgment hold of the others, those liquids representing water and air. Who does not see how utterly absurd all this is? But I wished to set all this out here, lest anyone in the future be able to say that I have philosophized badly.

CHAPTER VII.

Recapitulatory canons, by which artisans may be guided in chemical operations, and by which true operations may be distinguished from false ones — drawn both from the author's own mind and from that of other rightly-judging chemists.

CANON I.

On the nature and faculty of solvents or menstrua.

The whole of chemistry, as has often already been said, extends itself into the threefold Monarchy of Nature: the Animal, the Vegetable, and the Mineral. Each of these is composed of the three proximate principles of Nature — Sulphur, Mercury, and Salt, or what is the same, Oil, Liquor, and Earth — distinct from one another in form, weight, consistency, property, action, and powers. None of these can be dissolved, nor changed into different forms, without the ministry of fire, whether actual or potential. And since fire is always hot and dry, it cannot come about that it should produce its contrary, that is, the moist, which it lacks; nor can a liquid and watery form be given to any thing naturally dry and arid — as many have very

wrongly opined, while they were not ashamed to call fire moist. But see this opinion more fully refuted by us elsewhere.

Fire is the active principle of all things, whence all things subjected to fire are necessarily altered and cast down from the natural state of their proper temperament — with the exception of gold, asbestos, and the like, which, as has been said, withstand unconquered whatever torments of fire there may be. The rest, however, are dissolved by fire — metals easily, vegetables more easily, animals most easily. All these depend on the compactness of bodies: the more fixed they are, the more difficult, and the less compact, the more easy, do their parts undergo dissolution.

CANON II.

On solvents, or menstrual liquids.

All those liquids which have the power of attenuating and dissolving fixed and compact bodies can be called solvents. These can rightly be subdivided into three kinds, so that some are watery and tasteless liquids; others sharp and corrosive; and others, finally, fatty and oily. Of the first kind are all those watery, tasteless liquids which, when poured over vegetables and animals, by decoction and

infusion do not so much dissolve as soften them and reduce them to the finest substance.

But the second kind, the sharp and corrosive liquids, by the force of their sharp spirits dissolve all metallic and stony bodies; and without such a liquid no stone or metal can be dissolved. They either transmute all bodies accidentally, or reduce them into liquids or the finest powders or similar substances. Of this kind are all the kinds of aqua fortis [aqua fortis], vinegars, and — those which act more mildly — the various juices of plants and fruits, as we taught a little above. Hence metals, stones, and the other minerals — marcasites, pyrites, and likewise shellfish — as soon as they have been dissolved by corrosive liquids of this kind, cease to be simple bodies and are enrolled in the number of compounds. Yet as soon as they are freed from these, then those too return, by right of restoration [postliminio], to their former solid consistency, deposited from the liquid. We gave examples in what preceded.

CANON III.

[Margin: Friendship and enmity among solvents.]

There is also among solvents a certain remarkable sympathy and antipathy to be observed. For some solvents, when reduced to a liquid form, dissolve; others precipitate them into the finest powder. Some dissolve one body and leave another untouched. The salts that are friendly to mercury are hostile to sulphur. Hence I rightly conclude that no universal menstruum — such as the alchemists

boast their Alkahest [Alcahest] to be — can be assigned, since they are found to be mutually contrary, in so many quarrels and discords. Much less can there be given such a one that could extract the natural powers and properties of these bodies, whole and entire, comprehended in a single essence.

[Margin: The effects of acid spirits.]

All acid spirits can be condensed and coagulated into a brittle form, and converted into powder. Some can even be fixed in such a way that they can withstand the most powerful test of fire. Hence the philosophers easily arrived at an account of their composition. But sulphurous, oily, or combustible menstrea have no commerce with metals and stones.

[Margin: Stones are not dissolved by oils.]

Hence those who boast that they can dissolve metals, stones, and gems in spirit of turpentine and other distilled oils, and extract tinctures from them, are to be held

for true impostors. In the same way, those who, by the aid of spirit of wine, dissolve woody and resinous substances, will nevertheless not be able to dissolve metals without a corrosive liquid. Hence whatever you extract from metals by means of rectified wine should by no means be called a tincture, but the menstruum which you applied — pure substance of wine, somewhat altered as to color by the metallic corpuscles. And let the same be said of the menstruum of distilled vinegar.

CANON IV.

[Margin: Various liquids that color are to be examined.]

There are certain liquids which, when poured over certain mineral bodies, acquire various colors according to the diversity of the minerals. Hence the inexperienced think this is a proper tincture extracted from the said bodies — in which they greatly delude themselves, since it happens to them merely by accident, as we said above. Waters, both of vegetables and of animals, in order to behave properly, need before distillation a prior digestion and a suitable maceration; yet this distillation must be carried out without any addition of another liquid, since when the water of that liquid is joined to it, it disposes toward putrefaction and utterly destroys the powers innate in them. The water that comes out in the distillation of these is better than that which comes out last — the former on account of the easily soluble condition of the body, the latter on account of the obstinacy with which it clings to the body.

[Margin: The remarkable properties of wine and vinegar in distillation.]

As is evident in the distillation of wine, in which the better spirit is the one that comes out first, the worse the one that comes out last, since it is pure phlegm. In vinegar, however, the matter stands otherwise: in it the phlegm comes out first, the spirit last, for the reasons just stated. For there are certain sulphurs so subtle and of so volatile a nature that, with water added, they can easily be separated from their bodies while their native odor and savor are preserved; whereas certain others are so coarse, earthy, and heavy that they cannot be distilled without empyreuma [a burnt smell], whence they often retain a most foul odor that can be corrected by no art.

CANON V.

[Margin: The solution of tartar.]

The hypostasis and sediment of tartar, if you regard its predominant character, is a certain vegetable salt, belonging to a certain very fine, muddy earth which the vine draws to itself. And as this is different according to the diversity of the soil and of the vines planted in it, and of the wines pressed from the grapes, so it must be judged to possess different properties accordingly. Hence from nobler and clearer wines comes a nobler tartar than that which is drawn from those wines infected with various mineral refuse. That wine is infected with various earthy filth, experience teaches. For even if it has been duly purified, and is therefore clear as crystal, it must not on that account be regarded as a pure and unalloyed salt, like salts extracted from other vegetables; rather, it still has mixed in it some portion of earthy parts — which will be evident to one who takes experience as his guide. For it neither dissolves in cold water, like other salts, and if it is committed to fire, water will come out together with oil; while from the lime that remains in the bottom a white and corrosive salt is prepared, by some power I do not know. Exposed in a cold and moist place, it dissolves by deliquescence into an unctuous liquid, which some wrongly call oil of tartar — though it is nothing else than dissolved salt of tartar.

And just as tartar is a kind of ferment of wine, and its salt is by its nature earthy and spongy, so too from all the liquids with which it is joined it imbibes the sharp spirits drawn to itself, and unites with them most intimately. And for this reason it is, in everyone's opinion, reckoned the most powerful menstruum of those which resolve into powders both metals and other bodies. Yet with mercury alone it carries on grave enmities. For mercury, even if it be so fixed that it withstands the strongest fire, nevertheless, if you join to it even a little tartareous salt and commit it again to fire, the mercury — terrified by the arrival of the foreign guest — at once leaps forth, revived into its pristine form.

[Margin: A beautiful experiment.]

This is indeed a most beautiful and unique test, by which the falsity and imposture of those who impudently boast that they can fix mercury into silver is exposed.

CANON VI.

[Margin: The menstruum of sal ammoniac.]

Sal ammoniac has two parts to its composition: namely, a volatile salt — which is sometimes found in the soot of wood, in the blood, and in the veins of animals — and a common salt; which is established by this experiment.

[Margin: An experiment.]

Take volatile salt with a due quantity of common salt; if you mix these properly, you will produce from them a sal ammoniac of the same constitution as common sal ammoniac.

Since, therefore, sal ammoniac is composed of such sharp and subtle substances, no one should marvel that spirit of nitre and other waters are so sharpened by it that they resolve gold into a transparent liquid, as was shown in what preceded.

[Margin: The salt and experiment.]

This too is worthy of admiration: that, mixed with metals and the other minerals, it ascends into the alembic under the form of a most subtle soot, not resolvable into any liquid, unless perhaps some other liquid be added to it. Concerning nitre and its wonderful powers, it would here be most amply discoursed of, were it not that we had accomplished this in the Sixth Book; so we refer the reader to that place.

CANON VII.

[Margin: Coral, pearls, etc.]

Those mixed bodies which have obtained a middle nature between bones and stones are: corals, pearls, unions [large pearls], crab's eyes [oculi cancri], mother-of-pearl, and all shellfish. These contain in themselves water and combustible oil, no less than wood and the other vegetables, though not so abundantly. Their ash, although in external appearance similar to the lime of stones and to the salts of vegetables, yet no salt can be extracted from it, nor compacted into grains, as many inexperienced people in nature think. For what comes from it is nothing else than a certain earthy substance, not unlike lime to the taste. Hence, consequently, those delude themselves who think that bodies of this kind prepared in a saline form with spirit of vinegar are "salt of corals" and of pearls — and they improperly so call it; whereas in reality they are properly whole bodies dissolved, which subsist under such a form by the aid of the spirit of vinegar adhering to them. Hence it is only by the force of sharp menstrua, which, while they most intimately penetrate the said bodies, dissolve them at the same time into powder, with none of their substance lost.

In our College we dissolved a tincture of corals without a menstruum: the corals being first ground up and placed within a bladder, we urge them with a strong fire, whence, the spirits being gradually separated, a reddish liquid matter comes out like pitch; this, then collected and extracted again by retort with spirit of

wine, gives a tincture gleaming like a ruby; and this we use for the true tincture of corals — although I think the sediment which it leaves behind is nothing else than the same substance of corals which we had put in: so difficult is it to dissolve that into a true and real tincture, since by nature it is tenacious and will not be separated from itself. Let the same be said of precious stones. For those who calcinate them stratified with sulphur, nitre, or other salts in a most vehement fire, and afterward strive to reduce their substances into a liquid, greatly delude themselves; since, their substance being destroyed by calcination, just as the natural temperament is wholly dissolved, so too its powers must necessarily be at the same time dispersed and destroyed. And those who claim that they extract a salt from precious stones calcined in this way

delude themselves likewise, since this salt was not extracted from the substance of the stones, but is the very salt of the lime from which the stones were calcined — being of an exceedingly corrosive faculty; while nevertheless impostors of this kind are not ashamed to sell it as the magistry of oil, of salt, and of the essence of pearls. So small is their error! — those who endeavor to extract oil from crystal.

CANON VIII.

[Margin: The reduction of asbestos, talc, and the like into oil.]

There have been, and to this very day there are found, false craftsmen who boast that they can resolve asbestos, talc, and the like into oil. And that the deceit of men of this kind may more clearly appear, I will add what happened not so long ago. A certain one of such fellows was carrying about a phial of ashy contents, in which he said was contained true and legitimate oil of talc, and he defended his error so haughtily and with such obstinacy that he allowed himself to be torn from it by no arguments. At last I put to him the following enthymeme: Either the oil you promise is true, and extracted from the true substance of talc, or it is not. As he affirmed the former, so it was incumbent on me to prove the negative. And so I pressed him in this way: If it is true and natural oil, it will certainly be able to be set aflame, just as all other oils. He said yes.

[Margin: The detection of the fraud.]

But I took up the point that this could not be proved except by experience. So, having led him off to a pharmacy, I asked that he anoint with his oil a cotton thread that happened then to come to hand — which he did not unwillingly. A light being brought, the thread, however and by whatever means it was applied to the fire, could not be set aflame, just as a thread soaked in other oils would be kindled in an instant. Hence it was concluded by all that this "oil" was called oil in

name only, but was really water, calcined in some way or other with talc added, and accustomed to be used in the usual cosmetic paints of women. Whereupon, confounded, he slipped away without taking leave of his host — especially since I demonstrated that talc cannot be calcined into oil by fire. And what we have said of talc can be said with much greater right of the unconquered resistance of asbestos to fire.

[Margin: Asbestos cannot be reduced into oil.]

Hence it has always seemed to me a ridiculous endeavor of the chemists, who think that asbestos and talc, vexed with the most vehement torments of fire in a glassmaker's furnace, can be calcined; and — what may seem foolish — to solicit from them a liquid, of which even while they were still raw they were deprived; and thus to draw a true, genuine, and inflammable oil from what they did not possess even after calcination, their substance now being destroyed. Yet if anyone should accomplish this, I declare that he has found the greatest of all secrets, far more excellent and useful than the mystery of the Philosophers' Stone — of which kind is perpetual fire, about whose invention no less than about the secret of the Philosophers' Stone

so many Phoenixes of genius have sweated with fruitless labor. I do not, however, deny that talc, asbestos, and the like can be resolved into lime by vehement fire — since I have seen here at Rome that these, placed upon an earthen tile of glass, with a most vehement blast of flame [?] reaching the upper openings of the furnace, are easily resolved into lime; but I have never heard of oil being extracted from them. But he who desires to know more of the indomitable nature of asbestos, let him go to the Tenth Book, where he will find its nature fully set forth.

CANON IX.

[Margin: Oil of sulphur is not really given.]

In the same way are deluded those who think that they can extract essential oil from sulphur by distillation. For even though mineral sulphur is dissolved by fire, and on account of the unctuousity of its fatness can be set aflame, yet experience has taught us that what remains in the bottom of the receiver after distillation is not oil but pure, unalloyed sulphur — purer, however, and more purged of earthy refuse by the fire; indeed, of the same substance as when you had placed it in the alembic, which would not be the case if it had been resolved into oil; for in that state it would no longer be reducible into its former substance. Nor again is that acid substance which is separated from it through the alembic oil, but its

sooty salt, which ascends like smoke into the head of the alembic, and there is dissolved into a liquid — which, if it were oil, could certainly be set aflame, which contradicts experience. I say nonetheless that this liquid, whatever it may be, is imbued with some specific power of the sulphurous corpuscles, and in this way performs its effect in medicine.

CANON X.

Those err likewise who think that they can extract an essential tincture from antimony. But although it is established that antimony is composed of combustible sulphur, fusile and sooty mercury, and a certain vitrifying salt, in it the essential tincture is not distinct from these substances. Hence the various colors which it can take on are to be ascribed not so much to the antimony as chiefly to the fire — no differently than when, from mercury, salt, and sulphur mixed together and incorporated, a red powder is wont to be made, which we call cinnabar [cinnabar]; which nevertheless does not prevent that, being again separated, the mercury can return into its pristine form. To separate, therefore, from a body what is not in it, who does not see is a vain enterprise? Yet that it is imbued with the power of antimony, as I said a little before, I do not deny — just as the magnet communicates its power to iron without any diminution of its substance.

Corollary [CONSECTARIUM]

[Margin: How metals and stones are to be considered — Quomodo metalla & lapides considerata sint.]

From all this it is clear that from metals and minerals that have been calcined, true and essential preparations [magisteria] can scarcely be extracted. Rather, the whole of their virtue must be ascribed not so much to solvents [menstruis] as to the natural power itself, and so these preparations are merely composite. Note, however, at this point that metals are to be considered under two distinct headings. First, there are the metals and the other minerals that share the metallic nature: of themselves and by their own nature these are fusible, and so they can also be reduced again to their original form, as has been shown throughout the preceding experiments in various ways. Second, there are the stony substances, which once dissolved into lime [calx] can never be brought back to their former state. Marble, for instance, once reduced to lime, cannot be restored to genuine marble; and once the substance of such bodies has been destroyed by actual fire, the virtues innate in them must of necessity be

destroyed too, while other virtues arise in their place from the new matter that results.

From this it is further clear that the preparations of metals and stones extracted by solvents have no virtue except what comes from the imperceptible little bodies [corpuscula] abraded from the whole and mixed into the solvent. These then, under the heat of the fire, take on now this color, now that, with the chromatic power of the salts cooperating. From this it is likewise clear, as we said, that things calcined by fire are destroyed together with their virtues — but not so when they are dissolved by the sharpest solvents. For in the latter case a reduction back to the original is possible, whereas in the former, now dead, it is not; yet even though dissolved bodies acquire another form, they are not thereby wholly stripped of their virtues, as we shall now show.

Experiments [EXPERIMENTA]

On the dissolution of bodies [Circa dissolutionem corporum.]

Death, or the mortification of metals, says Paracelsus [Paracelsus], is the removal of the cohesion [compages] of the bodies themselves and of their sulphureous oiliness [pinguedo], which can be taken from them in many ways: whether by calcination, reverberation, dissolution, cementation, and so on. If there is a death and dissolution of the whole compound, then it must necessarily no longer be what it was, being transmuted by corruption into another form — as Aristotle [Aristoteles] rightly teaches, and with him the whole Senate of the Scholastics. And that this corruption is brought about especially by calcination through fire we have already shown by many arguments. But if the calcination of metals is done by salt, or by sulphur, or by strong waters [aquae fortes], or by common mercury —

I say that bodies are then only dissolved into a lime or a powder, without any loss of substance, since they can be reduced once again to what they were; and this is borne out by experiment. If a metal reduced to the thinnest sheets is, to speak as a chemist, stratified and cemented with salt, it will indeed pass into a lime — yet in such a way that the metal can be brought back to its former state. The same is to be said if any metal whatever is dissolved by sulphur, or by strong waters. For this dissolution is not, strictly speaking, a corruption — that is, not a radical or essential destruction, as happens through fire — but only an accidental one. For the sharpness of the solvents dissolves the metals into certain minute little bodies in such a way that each one nevertheless retains the virtue and quality of the whole. And just as these little bodies are carried back toward the whole by a

natural appetite and sympathy, so too, once the solvents are drawn off, they return to what they were.

Since, then, these little bodies are no less filled with marvellous virtues than the whole was, there is no doubt that, by repeated sublimation, the sharpness of the solvents being deposited, they gradually grow mild — and so become remedies fit to drive off even the gravest diseases, especially if their tincture is extracted with the spirit of a generous wine. For since the little bodies possess the virtue of the whole, there is no doubt that, once mixed into a solvent, they easily communicate their virtue to it. There follow the calcinations taken from Paracelsus.

EXPERIMENT I.

On calcining metals by mercury [De Calcinandis metallis per Mercurium.]

Let common mercury be placed, in an earthen vessel bellied below and narrow above, over a charcoal fire, until it begins to smoke and to issue from the mouth of the vessel like a white cloud. Once this is observed, let the metal, reduced to fine sheets, be set at the mouth of the vessel. In this way the mercurial power will penetrate the metal and render it friable like a lime. The same will happen if the metal, broken down into grains, is, to speak as a chemist, amalgamated with mercury, and the mercury is then squeezed out through leather: as the mercury passes out, the metal will remain within the leather like a lime or sand — which can again be brought back to its own state by fusion.

EXPERIMENT II.

To make Crocus of Mars [saffron of iron] [Crocum Martis conficere.]

Iron is reduced to Crocus of Mars [Crocus Martis] in this way: let glowing-hot plates of steel [chalybs] be quenched in the best generous-wine vinegar, until the vinegar takes on an intense redness. Once this is observed, draw off the moisture of the vinegar from the whole mixture by distillation; dry the residue at the bottom into a powder, and you will have a most exquisite Crocus of Mars. At the Roman College [Collegium Romanum] Crocus of Mars is made otherwise, in this way: the thinnest plates of steel are stratified with sulphur and tartar in equal parts; reverberated, this gives a noble Crocus of Mars, which must be scraped off the plates.

EXPERIMENT III.

To extract Vitriol from Copper [Ex Cupro Vitriolum extrahere.]

[Margin: First method; from copper to extract vitriol — Primus modus; ex Cupro Vitriolum extrahere.]

Let plates of copper be smeared with salt water, or with rock-salt [sal petrae], and hung up in the air until they turn green. Wash this green off with spring water, wipe the plates clean with a cloth, and steep them again with the said water as before; and so you will proceed until

the water emits, into the upper part, abundant intensely green portions of vitriol. Draw off this water by distillation, and you will find at the bottom an excellent vitriol fit for medical uses. The Alchemists, however, separate vitriol in this way:

[Margin: Another method — Alius modus.]

let plates of copper be smeared while suspended in aqua fortis, or aqua regia, or sal ammoniac; and once they have shown green and have dried, the scrapings wiped off with a hairy pencil-brush will give an excellent vitriol. In this fashion you will continue until the plates are entirely consumed.

[Margin: Purification of saltpetre water — Aquae salis petrae purificatio.]

Saltpetre water is purified if you dissolve the saltpetre in a boiling bladder [vesica]. [Margin: Dissolution of sal ammoniac into water — Salis Ammoniaci in aquam resolutio.] You will dissolve sal ammoniac into water if, after calcining it, you set it to dissolve by deliquescence upon marble in a damp and cold place.

EXPERIMENT IV.

To draw verdigris, or green copper, out of copper [Ex cupro aeruginem sive aes viride educere.]

Let copper reduced to sheets be stratified in a crucible with salt, sulphur, and tartar in equal parts, all ground and mixed together — the crucible such that it can withstand the reverberatory fire for 24 hours, yet so that the sheets do not melt. Then, with the crucible broken open, take out the sheets and expose them, together with the sharp matter adhering to them, for several days; and the matter on the sheets will be converted into a most beautiful green copper [aes viride], which is of great use in tinging gold and silver.

[Margin: Preparation of Crocus of Venus — Croci veneris confectio.]

But burnt copper [aes ustum], which they call Crocus of Venus [crocus veneris], you will sublime as follows: let plates of copper be smeared with salt reduced to a paste together with the best vinegar; then, placed in a crucible, let them be burned for a quarter of an hour over a strong fire — yet so that they do not flow — in a windy furnace. Let the glowing plates be quenched in vinegar (in one pound of which half an ounce of sal ammoniac has been added); and the scales which cling to the plates after quenching, cast them into the vinegar. Repeat this again and again until the plates are consumed; then, either by distilling, or by letting it evaporate of itself in an open vessel, draw off the vinegar, and you will find the copper converted into a stone, which is the genuine Crocus of Venus.

[Margin: Crocus of Venus — Crocus veneris.]

EXPERIMENT V.

To make white lead [ceruse] from lead [Cerussam ex plumbo conficere.]

Suspend plates of lead in an unglazed pot over strong vinegar made from generous wine, the pot well stopped so that it does not exhale. Place this pot in hot ashes; then within ten days you will find an excellent white lead [cerussa] adhering to the plates, which you wipe off with a hairy pencil-brush for use. And you will repeat this until the plates are consumed. But if you add a little sal ammoniac to the vinegar, you will have a most splendid white lead, very well suited for whitening lead and copper.

[Margin: Preparation of white lead — Cerussae confectio.]

EXPERIMENT VI.

To draw Vitriol out of gold, from Paracelsus [Vitriolum ex auro educere, ex Paracelso.]

Although above we said that gold is indissoluble, yet since Paracelsus claims that from it a vitriol and a sulphur of great value can be extracted, useful both in medicine and in the transmutatory art, we must now inquire whether this can be done. The extraction of vitriol from gold is performed thus.

Take two or three pounds of refined gold [aurum obrizum] drawn out into sheets. Suspend these, over salt extracted from urine — which they call children's urine [puerorum urina] — together with spirit of wine, which Paracelsus in his own manner calls "the strings of wine" [filipas vini], in a wide glass cucurbit well sealed, and buried in horse-dung, or in the heat of grape-husks [vinacea]. Leave them to digest for 14 days; when these have passed, open the cucurbit, and you

will find clinging to the gold sheets a flour-like fine dust, which you wipe off — for this is the vitriol of gold. Decoct this with rain-water first distilled, and stir it with a spatula until the sulphur of the gold appears raised to the surface of the water like tallow [sebum]. This you gather; and finally, the water having been drawn off to dryness, there will come forth the desired vitriol of gold, of a sweat-promoting [diaphoretica] virtue miraculous to a degree.

[Margin: Whether gold can be reduced into vitriol — Aurum in vitriolum reduci nequit.]

Now the question is whether this vitriol is something drawn out of the substance of the gold. I answer that it is not. For since gold cannot be destroyed by any violence of fire, who does not see that much less can children's urine calcine it into vitriol? I say therefore that these are certain efflorescences born of the urine and adhering to the gold sheets. The proof of this is that if you were to repeat this operation a thousand times, the gold sheets would always remain in the same state under always the same weight, as experience has shown us. So if nothing else is lost from the gold, then surely what adheres to the sheets cannot have been drawn out of the substance of the gold. That flour, therefore, comes from elsewhere — namely, from nothing other than the decoction of the urinous salt (as Paracelsus will have it), and must necessarily have grown upon the gold sheets.

Yet this vitriol Paracelsus exalts in his own manner, promising himself from it vast treasures of riches — by means of a fixed sulphur [sulphur fixum], which he prepares in this way. [Margin: Fixed sulphur — Sulphur fixum.] First he draws off its acidity by a triple distillation, down to sweetness, with no trace of stench left behind. Then he reverberates this, first into a white color, afterward into a red like cinnabar; and you will have a fixed sulphur of such great virtue that it converts any silver [luna] whatever into gold, and the human body into the highest health and a longevity of life beyond what one may write (for so he speaks). But since in Book XI we have demolished these vapourings [affanias], I refer the reader there, where he will find these deceitful wares amply laid open. If Paracelsus had known such a medical secret and restorer of life, he could certainly have carried his life on a little further than the 50 years he lived.

PARS II.

ARS METALLOSTATICA

OR [SIVE]

On the Art by which, through the science of weighing, the mixture of metals and minerals can be known with certainty — together with the weighing of the moisture and dryness existing in every mixed thing, whether mineral, vegetable, or animal.

CHAPTER I [CAPUT I.]

In which the mixture of gold is explained [Quo Auri mixtura declaratur.]

[Margin: How the reckoning of carats is to be understood — Quomodo Carattarum ratio intelligenda sit.]

In the Eleventh Book we showed that the highest fineness of gold does not exceed 24 carats [Caratas], as they commonly call them and name it pure gold; whereas below 24 it is not to be called pure gold, but mixed. For the quality of gold in any body is expressed by the parts of pure gold that are in that body — taken not by magnitude but by weight — of which kind of parts the whole body consists of 24. But let us make the matter clear by an example. Suppose there is some golden body, say of 24 ounces, which, duly and properly purged of the things it was mixed with, is reduced to 20 ounces, while the remainder — whatever kind of metal it was — has gone off in smoke. I say that the body of 24 ounces was not pure gold of 24 carats, but only of 20, because that whole mixed mass had only 20 ounces of pure gold; indeed, not only that mass of gold, but also that of which it was itself a part, or whatever part of it there might be, would be said to be of 20 parts. So indeed that each part of pure gold, however small, may be called a particle of gold of 24 carats — for in the alloying of metals the alloy of the parts is not one thing and that of the whole another, but for both there is one and the same quality.

And this is what goldsmiths observe in investigating the quality of gold. For they do not purify some whole proposed body of gold, but reduce its smallest particle to the quality of pure gold. For once this has been reduced, they not only rightly

determine of what quality, and of how many parts, that body was from which the particle was taken, but also what still remains — diminished, that is, by that purified part — as was made clear in the foregoing example. For once the decoction of an ounce-sized particle into pure gold has been carried out, if they find that nothing has been lost from the purer weight of the ounce-sized particle of gold which they had taken to be purged, they at once infer that not this particle alone, but the whole body from which the particle was taken, is pure gold of 24 carats. But if they detect that the weight of the assumed one-ounce particle has been diminished — for instance, where before the purging it had been of 24 scruples [scrupula], but is now of 20 scruples — then they infer that the proposed mass of gold is of 20 carats, and that the rest is composed of other metals.

For since in this comparison of qualities the reckoning of the parts of gold is taken separately, and separately that of the alloyed metals, it is clear: if the weight of the whole body be understood as divided into 24 equal parts, of which 20 are gold, two silver, and two copper, then each part of gold, together with each part of silver, [is greater than] each part of copper — because gold surpasses all the other metals in weight, as does silver itself surpass copper, just as experience teaches.

Now among the various and manifold compositions of gold, by which it can be alloyed with other metals, the goldsmiths and money-changers [collybistae] have retained, by the consent of all, that one more convenient than any other, which differs least from the likeness of gold: namely, the mixture of copper and silver — which, however, must as to weight always be equal. [Margin: The best alloy mixture for gold — *Aeris & argenti mixtura auro optime alligata.*] And so the said money-changers take of pure gold, of whatever quality or weight, as many parts as the gold to be produced is to have parts — fewer, however, than 24 parts — and they supply the remaining parts with copper and silver, taking from each equal parts by weight; and mixing these together they produce gold of the desired quality, and name it from the parts of pure gold taken up in the mixture. Yet sometimes they always admix a little something more of silver and copper, in case some of these should be lost in the fusion. And in this manner they require 23 parts of pure gold, $\frac{1}{2}$ of silver, and $\frac{1}{2}$ of copper, so that the mass may reach 24. But in a mass of 22 parts of pure gold, one part of silver and one part of copper is required; and so for the rest.

[Margin: How much silver is in the gold — to explore — *Quantum auro insit argentum explorare.*]

These things, then, having been duly set forth, let us now see how, by this new metallostatic art, we may explore how much silver and how much copper are in any golden mass. I suppose, then, first, from Ghetaldi [Getaldo]: that the weight of gold in water is one thing, and in air another — and the same is to be understood of silver

and copper. For in water metals weigh less than in air. This being laid down, I suppose, from Ghetaldi [Getaldo] and Mersenne [Marsenno]:

- That the weight of pure gold which in air is 19, will be in water 18.
- The weight of silver, which in air is 31, in water is 28.
- The weight of copper [aes], which in air is 9, in water will be 8.

[Margin: The proportions of gold, silver, and copper to the weight of water — *Proportiones auri, argenti, aeris ad gravitatem aquae.*]

That is, gold stands to water in weight as 19 to 1; silver to water as 31 to 3 [?]; and copper to water as 9 to 1.

From this it is clearly evident that, if some mixed body consists of parts of silver and copper equal in weight, [one can determine] what weight it has in water and what in air. But so that the method by which one may weigh the said bodies in water may be understood, I will set it out with several illustrations.

By hydrostatics, the weights of things of any kind whatever are usually weighed in four ways:

1. Either homogeneous bodies in homogeneous liquids;
2. or homogeneous bodies in heterogeneous liquids;
3. or heterogeneous bodies in heterogeneous liquids;
4. or heterogeneous bodies in homogeneous liquids.

To avoid confusion, in this place we shall use the two ways more suited to our purpose, following Ghetaldi [Getaldo] in almost everything.

[Margin: How bodies are to be weighed in water — *Quomodo corpora in aqua ponderanda sint.*]

Note first: the metallic body proposed for weighing should be hung by a horse-hair from one pan of the balance; in the other pan let a weight be placed; and let the metallic body to be weighed be let down into water enclosed in a vessel, so that it hangs freely in the water and the water does not touch the pan. Let A B be

the balance-beam, C D the tongue [librile], G the pan. Let the pan have, set into the underside of its convex part,

[Diagram appears at foot of left column — see below.]

a hook from which the metallic body H to be weighed, tied to the horse-hair, can hang down, and be let down into the vessel I full of water. In pan E let the counterweights be placed; with a balance of this kind you will weigh any metallic bodies whatever with ease.

I said that the body to be weighed should be hung by a horse-hair, because the hair is almost as heavy as water, and so it will add or subtract nothing of weight in the body being weighed.

Diagram. A hydrostatic balance shown at the foot of the left column. A vertical post rises to a ring or suspension loop at the top (labeled C), from which the balance-beam hangs. The horizontal beam runs from point A on the left to point B on the right, with the central tongue at D. From the left end (A) a pan hangs, labeled G; from the right end (B) a second pan hangs, labeled F. Beneath the left pan, a cubical weight (the metallic body to be weighed, H) is suspended on a thread.

- C (top): suspension ring / fulcrum point
- A (left end of beam): left arm terminus
- D (center of beam): tongue [librile]
- B (right end of beam): right arm terminus
- G (left pan): pan holding the suspended body
- F (right pan): counterweight pan
- H (below left pan): the metallic body to be weighed, hung by the horse-hair

If the body to be weighed should be so heavy that it cannot be sustained by a single hair, let it be hung by several hairs joined together; and lest the joining of the hairs add anything of weight to the body being weighed, let there be placed in the other pan just as many hairs equal to those that hang from the pan to which the body is attached, down to the suspended body. With this addition of hairs the pans will balance equally; and although those hairs by which the body is hung are longer than the others added to the other pan by the length of the parts by which it is tied, nevertheless, since those parts are as heavy as water — existing together with the body itself in the water — they will have no weight. And therefore those hairs which otherwise exceed the said parts, even if longer, will not be heavier than the others, since, as has been said, those parts exist together

with the body itself in the water. Thus, then, solid bodies are to be weighed in water — which it was worthwhile to have noted.

But by "water," or "a part of water equal to the weighed body," understand a cubic, spherical, or cylindrical body, within which the said bodies would be contained, in this way: if a solid body were to stand freely beneath the water, a body of this kind would be equal in weight to as much water as would stand under the same shape of the vessel — that is, to as much water as, say, a cubic body would contain. Let there be some solid body B of cubic shape, which, immersed in the vessel c d full of water, floats freely in A. I say that the place or surface of the body in which the water is contained — which is the same as the water contained within the cube B at A — is equal in weight to the weight of the solid body B. Or, if one were to make a hollow vessel equal, as to its inner surface or place, to the solid body B, then water poured into it to fullness would be equal to the solid cubic body B. But if the said body should partly project above the water and partly be submerged, like the solid body M, I say that the part of water c d e f into which it is immersed is equal to the whole solid body M — that is, the quantity of water c d e f counterbalances the whole body M. All of which is beautifully demonstrated by Archimedes [Archimedes] in his book *On Bodies that are Carried in Water* [*De iis quae vehuntur in aqua*]. From this arise these propositions:

1. Every solid body of matter lighter than water is not entirely submerged, but projects with some part of itself.

Diagram. A small geometric figure in the right column showing two square/rectangular vessels of water used to illustrate the Archimedean displacement argument. On the left, a square frame labeled at its corners E (upper left), with a smaller square B at the top center representing a cube fully immersed (floating freely in A), and A marked within the lower interior. On the right, a second square vessel labeled c (upper left) and d (upper right), with M (a partially submerged solid) at the top and L marked in the lower interior. The bottom edge of the left frame is labeled D.

- E (upper-left corner, left frame): corner of the containing vessel
- B (top center, left frame): immersed cubic body
- A (interior, left frame): the location/water within the cube
- D (bottom, left frame): lower edge of the vessel
- c (upper-left, right frame): corner of the second vessel
- d (upper-right, right frame): corner of the second vessel

- M (top, right frame): partially submerged solid body
- L (interior, right frame): water beneath the submerged body

ARS METALLOSTATICA

(continuing the axioms with which the Caput opens)

2. Any solid body of material heavier than water — that is, a body that displaces less than its own volume of water — will sink to the bottom, as is clear in the case of the solid body L.
3. Any solid body of material that exactly balances the water in weight keeps the position it is given within the water, as is clear in the case of A in the previous figure. All of these things have already been demonstrated in Book V of this first volume.

PROPOSITIO I.

Given the weight of a solid body and its heaviness relative to the weight of water, to find that body's heaviness when placed in water.

Suppose the solid body C hangs by 2 pounds from the water-surface AB. Suppose further that the ratio of the weight of the water to that of the solid body C is fivefold, so that the solid body C is of lighter material than water. You will find the heaviness of C when situated in the water AB as follows. Determine the weight of a mass of water equal in volume to C itself; suppose you find it to be, for example, 10 pounds. Subtract from these the 2 pounds, and there remain 8 — the heaviness of the solid body C in the given water AB. But let us now reduce the points already stated to practice by means of problems.

PROPOSITIO II.

Given the weight of a body of water, to find the weight of a piece of lead having a volume equal to that whole body of water.

Suppose some body of water is proposed whose weight is 100, and it is required to know how great the weight of lead would be that has a magnitude equal to the proposed water. For example: let the vessel A be full of water, the weight of which water is 100, and let it be required to know — if that same vessel were filled with lead — how great the weight of that lead would be. Take some leaden body whose weight is 23. Then find the weight of water having a volume equal to that lead, which is to be done in the way already stated in the preceding example.

Suppose, then, that the weight so found is 2. Set up the proportion: as 2 is to 23, so is 100 to another number, which comes out to 1150. That number, then, will be the weight of lead having a volume equal to the proposed water — that is, the weight of the lead that the vessel contains. (Note that what we say here about a leaden body is to be understood in the same way for a body of bronze, tin, or iron.)

PROPOSITIO III.

Given the weight of a leaden body, to find the weight of a body of water equal to the lead.

First suppose some leaden body A is proposed, of whatever shape, whose weight is 23, and let it be required to know how great the weight of water will be that has a volume equal to the proposed lead A. Weigh the lead A in water in the way already described, and let it have a weight of 21. Since, then, the number 23 exceeds the number 21 by the number 2, the weight of water having a volume equal to the lead A will be 2.

PROPOSITIO IV.

Given the weight of a body of wax, to find the weight of a body of water equal to it.

[Margin: Comparison of wax with the weight of water.]

Suppose, then, some body of wax A is proposed whose weight is 21, and let it be required to know how great the weight of water will be that has a volume equal to the wax A. But since wax is lighter than water, if it is dropped into water it will not be carried downward. So take some solid body F heavier than water, such that the body made up of both bodies A and F, when let down into the water, is carried downward. Let the body F, then, be of lead, whose weight is, for example, 23, and whose weight in water is 21. Therefore the water having a volume equal to the lead F will be of weight 2.

Now since the weight of the wax A is 21, and that of the lead F is 23, the weight of both bodies AF together — namely wax and lead — will be 44. [Margin: The weight of wax and lead joined together is sought in water.] Let the wax and lead be joined, and being so joined let them be weighed in water, and let them have a weight of 20. Since, then, the number 44 exceeds the number 20 by the number 24, the weight of water having a volume equal to both bodies, wax and lead together, will be 24. But the weight of water having a volume equal to the lead F

is 2. Therefore the remainder, which is 22, will be the weight of water equal in volume to the proposed wax A.

Again, let there be some leaden body A whose weight is 2300, and let it be required to find the weight of water having a volume equal to the lead A. Take some small body of lead F whose weight is, for example, 23, and find the weight of water equal in volume to the lead F, as has been said, which is 2. Set up the proportion: as 23 is to 2, so is 2300 to another number, which comes out to 200. The weight, then, of water having a volume equal to the lead A will be 200. Similarly, if some body of wax A has a weight of 2100, and it is required to do what has been prescribed: take some small body of wax F whose weight is, for example, 21, and having found the weight of water having a volume equal to the wax F, which is 22, set up the proportion: as 21 is to 22, so is 2100 to another number, which comes out to 2200. Therefore the weight of water having a volume equal to the wax A will be 2200.

PROPOSITIO V.

Given the magnitude of a leaden body, to find the magnitude of tin equal in weight to that leaden body.

[Margin: Lead has no comparison ratio with tin.]

Suppose some leaden body is proposed whose magnitude is 740, and let it be required to find how great the magnitude of tin will be that has a weight equal to the proposed lead. Take some leaden body D whose weight is 115, and then

let there be found, by hydrostatic weighing, the weight of tin equal in magnitude to the lead D, which is 74 — how this is to be done was stated just above. Then set up the proportion: as 74 is to 115, so is 740 to another number, 1150. That number, then, will indicate how great the magnitude of tin will be that has a weight equal to the proposed lead A.

PROPOSITIO VI.

Given the weight of oil, to find the weight of a mass of water having a volume equal to the oil.

[Margin: Comparison of oil with the weight of water.]

Suppose some body of oil is proposed whose weight is 550, and let it be required to find how great the weight of water will be that has a volume equal to the proposed oil A. Take some solid body — say a leaden one — and find the weight

of water having a volume equal to the lead, which is 12. Similarly find the weight of oil having a volume equal to the same lead, which is 11. Set up the proportion: as 11 is to 12, so is 550 to another number, which comes out to 600. That number, then, will indicate how great the weight of water will be that has a volume equal to the proposed oil.

PROPOSITIO VII.

Given the weight of quicksilver, to find the weight of a mass of water having a volume equal to the mercury. (Here we always take "mass" for magnitude.)

[Margin: Comparison of mercury with the weight of water.]

Suppose some body of quicksilver A is proposed whose weight is 95, and let it be required to find how great the weight of water will be that has a volume equal to the proposed quicksilver A. Take some clean and polished glass vessel whose weight is, for example, 91. Let that vessel, full of water, be weighed in water, and let it have a weight of 55. Since, then, the number 91 exceeds the number 55 by the number 36, the weight of water having a volume equal to the vessel itself — that is, to the solid substance of the vessel — will be 36. Then place into the vessel itself the proposed quicksilver A. It makes no difference whether the vessel is full or not. And since the weight of the quicksilver A is 95 and the weight of the glass vessel is 91 [recte: 19? — see Numerical impossibles], the weight of the quicksilver together with the vessel itself will be 156. Let the vessel together with the quicksilver A be weighed in water, in such a way that the water fills the empty part of the vessel, and let the weight of the vessel in water together with the quicksilver be 143. By the number 45 [recte: 13?], the weight of water having a volume equal to the quicksilver, together with the vessel, will be 43. But the weight of water having a volume equal to the vessel is 56 [recte: 36]; therefore the remainder, which is 7, will be the weight of water having a volume equal to the proposed quicksilver A.

PROPOSITIO VIII.

[heading not separately printed; the rubric is supplied by the running side-note]

[Margin: Comparison of mercury with the weight of lead.]

Again, let there be proposed some body of quicksilver whose weight is 190, and let it be required to find how great the weight of lead will be that is equal in magnitude to the proposed quicksilver. Find the weight of water having a volume equal to the quicksilver, which is 14. Then, having found the weight of lead equal to that same water — as was said in the preceding cases — that will be the weight

sought. For suppose the weight of lead found is 161. Since, then, the water whose weight is 14 is equal in magnitude to the lead whose weight is 161, and the lead whose weight is 161 is also equal to the quicksilver, the lead will be equal in magnitude to the quicksilver A. Hence the weight of lead equal in magnitude to the proposed quicksilver A has been found — which was the thing to be done.

Having taken, as we said, some solid body, and having found the weights of the liquids — namely of water and of quicksilver — equal in magnitude to the body, which are 14 (the weight of the water) and 190 (the weight of the quicksilver): set up the proportion, as 190 is to 14, so is the cube of 10 (that is, 1000) to another number, which comes out to $73 \frac{7}{9}$ [?]. That number, then, will be the cube of the diameter of a sphere of quicksilver having a weight equal to the proposed sphere A of water. Therefore the cube root of the number $73 \frac{7}{9}$ [?], which is 4 (approximately) [?], will indicate that diameter itself.

PROPOSITIO IX.

[heading rubric carried by the figure-less text]

Suppose some large body of quicksilver A is proposed whose weight is 5700, and let it be required to do what has been prescribed. Take some small body of quicksilver whose weight is 95, and find the weight of water having a volume equal to the quicksilver C, in the way that has been described, which is 7. Set up the proportion: as 95 is to 7, so is 5700 to another number, which comes out to 420. That number, then, will indicate how great the weight of water will be that has a volume equal to the proposed quicksilver A. Conversely, let some body of water A be proposed whose weight is 420, and let it be required to find how great the weight of quicksilver will be that is equal in magnitude to the proposed water A. Proceeding as above, and having found the weight 7 — namely of water having a volume equal to the quicksilver C — set up the proportion: as 7 is to 95, so is 420 to another number, which comes out to 5700. That number, then, will indicate how great the weight of quicksilver will be that is equal in magnitude to the proposed water A.

PROPOSITIO X.

Given a body of gold, and water equal in weight to the gold, to find the weight of quicksilver.

[Margin: To find the weight of quicksilver [equal] in magnitude with [a body of] gold.]

Take some body of gold, and coat it with a very thin film of wax, so that it does not become lighter than quicksilver, nor be dissolved by it. Then find the weight of water having a volume equal to the body of gold itself, as has been said, which is 7. Similarly find the weight of quicksilver, as of water having a volume equal to the same body of gold —

— let the weight of quicksilver be found, which is 95. Set up the proportion: as 95 is to 7, so is 5700 to 420. The weight, then, of water having a volume equal to the quicksilver will be 420.

Conversely: let some body of water be proposed whose weight is 420, and let it be required to find how great the weight of quicksilver will be that is equal in magnitude to the proposed water A. Having coated the body of gold with a film of wax, as above, and having found the weights 7 and 95 — namely of water and of quicksilver equal in magnitude to the aforesaid body of gold — set up the proportion: as 7 is to 95, so is 420 to 5700. The weight, then, of quicksilver equal in magnitude to the proposed body of water will be 5700.

PROPOSITIO XI.

In liquids of unequal density, the ratio of the weight of the lighter liquid to the weight of the heavier liquid will be as the part of the solid body immersed in the lighter liquid is to the part of the same body sunk in the heavier liquid.

Let AB be a liquid lighter than DC, and let the solid body EF be lighter than either liquid. When it is immersed in the liquid AB, let it rest with its part GF above the water-surface; and when put into the liquid CD, let it sink with its part KI.

Diagram. Two rectangular vessels seen in cross-section, side by side, each filled with a hatched (rippled) liquid. A floating block straddles or sits in each.

- A (top left of left vessel): corner-label of the lighter liquid's surface
- E (top, above left block): top corner of the floating solid
- G (left, at waterline of left vessel): waterline corner of the immersed part
- F (right, at waterline of left vessel): waterline corner; part GF rides above the surface
- B (bottom right of left vessel): bottom corner of the left vessel
- C (top of right vessel): top corner / surface of the heavier liquid
- H (top, above right block): top of the floating solid in the right vessel
- K (left, at waterline of right vessel): waterline corner of the sunk part
- I (right, at waterline of right vessel): waterline corner; part KI is sunk

- D (bottom right of right vessel): bottom corner of the right vessel

I say that the weight of the liquid AB has to the weight of the liquid CD the ratio that KI has to GF — because the liquid of the vessel AB exactly balances the solid body HI (or EF) immersed in the water, by Proposition 5 of Archimedes, *On Bodies that Float in Water*. The proportion of the immersed part to the floating part will therefore be the reciprocal — that is, KI to GF.

Now let there be proposed liquids of differing density: spirit of wine, as in vessel AB marked with the number 1; in vessel 2, wine; in vessel 3, spring water; in vessel 4, oil; in vessel 5, mercury; and so on for the rest. From the immersion of some single solid body lighter than water, you will find the weight of all the liquids relative to one another in the proportion of the immersed parts. In wine it will emerge by $1/5$ [?]; in spring water by $2/5$ [?]; in sea water by $3/5$ [?]; in oil by $4/5$ [?]; in mercury by $5/5$ [?] — that is, it will emerge entirely. From the proportion of the immersed parts, then, you will easily arrive at the weights of the liquids. For as the immersed part of the solid body behaves in the different liquids, so is the weight of liquid 1 to the weights of liquids 2, 3, 4, 5.

Diagram. A row of vessels in cross-section, each filled with hatched liquid, with a small square block floating at a different depth in each. The blocks are numbered 1, 2, 3, 4, 5, 6 across the top (a small label **a** sits at the upper left). The engraved caption beneath names the six liquids in order.

- a (upper left): figure label
- 1: block in the first vessel (spirit of wine), floating highest
- 2: block in the second vessel (wine)
- 3: block in the third vessel (spring water)
- 4: block in the fourth vessel (oil) [order per caption]
- 5: block in the fifth vessel (mercury / sea water) [?]
- 6: block in the sixth vessel
- [Caption, verbatim]: *Spiritus vini. Vinum. Aqua font. Aqua marin. Oleum. Mercurius.* — "Spirit of wine. Wine. Spring water. Sea water. Oil. Mercury."

As for the method by which Archimedes — knowing the weights of three bodies of equal volume to water, namely one of the crown itself, another of a mass of gold, and a third of silver — was able to detect the goldsmith's theft in the king's crown: various procedures have by now been handed down by various authors. We, following the way Ghetaldus [Marin Getaldic] did it, will now show how to accomplish the same thing by the single device of the golden rule.

PROPOSITIO XII.

To discern, by reckoning of weight, a portion of one metal mixed into another metal.

[Margin: Archimedes' method, by which he detected the goldsmith's craft.]

Let the weight of the crown be 95 pounds, and let it be required to separate out the other metal mixed into it. I proceed thus. Let two bodies be conceived, one of gold and the other of silver, each as heavy as the crown. Then, of three bodies of equal volume to water — one for the body of gold, another for the crown, a third for the body of silver — let the weights be found according to what was said before. Let those of the first body be [as the difference between 5 and $9\frac{5}{11}$], or what is the same thing, $4\frac{4}{11}$; to 95, namely the weight of the crown, so is the difference between 5 and 6, that is, 1, to $22\frac{5}{11}$. Therefore $22\frac{5}{11}$ will be the weight of the silver in the crown; and when this is subtracted from the total weight of the crown, the remainder, $72\frac{6}{11}$, will be the weight of the gold sought. Or, if for the third term of the proportion one likewise takes the difference between 6 and $9\frac{5}{11}$, which is $3\frac{5}{11}$, the fourth term will be $72\frac{6}{11}$ — the weight of the portion of gold; and when this is subtracted from the total weight of the crown, there will remain $22\frac{5}{11}$ for the weight of the portion of silver.

PROPOSITIO XIII.

How may it be discerned how much bronze has been mixed into gold?

Let there be a body mixed of gold and bronze, and let it have a weight of 171 pounds. It is asked: how great is the portion of bronze mixed into the gold, and how great the portion of gold? Proceed thus. Let two bodies be conceived, one of pure gold, the other of bronze, each as heavy as the mixed body. Then of three bodies of water — one equal in magnitude to the body of gold, another to the mixed body, the third to the bronze — let the weights be found in the way described above, which are 9, 11, and 19. With these found, set up the proportion: as the difference between 9 and 11 is to $34\frac{1}{5}$ [?]; the portion of the mixed body that is bronze will therefore have a weight of $34\frac{1}{5}$; and when this is taken away from the total weight of the mixed body, there will remain $136\frac{4}{5}$ [?] for the weight of the portion of gold. Or, if for the third term of the proportion one takes the difference between 11 and 19, the fourth term, $136\frac{4}{5}$ [?], will be the weight of the portion of gold; and when this is taken away from the total weight of the mixed body, it will leave $34\frac{1}{5}$ for the weight of the bronze.

The operation stands thus:

[Margin: How the first and second operation each stand.]

10. The difference between 9 and 19 gives 171. 2. The difference between 11 and 19 will give what? The fourth term will be $34 \frac{1}{5}$, the weight of the bronze.

The second operation stands thus:

10. The difference between 9 and 19 gives 171. The difference between 11 and 19 will give what? The fourth number will be $136 \frac{4}{5}$, or $7/9$ [?], the weight of the gold.

By this method you can discern not only the mixture of another metal in gold, but also the mixture of the remaining metals in any one of them. And by this device the proportions of all metals and liquids, as regards their weights, have been found by mathematicians, as appears in the following table, extracted from Ghetaldus [Marin Getaldić].

TABULA

in which 12 bodies are compared with one another as regards weight.

The composite table forms a square divided by its diagonal into two triangular sub-tables. The upper-left triangle is **Tabula A** (headed at top left "Tabula A." with the twelve body-names running across the top and a right-hand label column "D."). The lower-right triangle is **Tabula B** (labelled at bottom right "Tabula B." with a left-hand header "C." and the body-names running across the bottom). Each cell gives the weight-ratio of the row-body to the column-body. The whole grid is transcribed below as a single matrix; left-edge row labels and right-edge "D." labels both appear, as do top and bottom column headers.

Praxis of this Table.

This abacus is laid out as two triangular tables. The first, marked with the number ADC, contains the weights and magnitudes of the 12 bodies compared one with another, and assigns the true proportions, in weight and magnitude, of all twelve bodies compared with one another. The other triangular table is marked with the number BCD. In the first, some body — whatever it may be — is set down as 12, and the rest are compared to it. In the second table, some body — whatever it may be — is set down as 100, and the rest are then compared to it.

It only remains, then, for us to set out its use in a few propositions; for this knowledge is wonderfully useful and profitable in every investigation of weights. Note, however, that weight is considered in one way here, magnitude in another: for if two of the twelve bodies, differing [in kind], have the same weight, you will necessarily find one larger than the other — for one must be larger than the other by exactly as much as, under the same magnitude, the one is lighter than the other. But let us show this very thing by practice.

PROPOSITIO I.

To find the proportion of the weight of gold and silver to one another.

In the first triangular table ADC, look for gold in the topmost border AD and silver in the border AC, and in the common angle you will find $1 \frac{26}{31}$, which is the proposition of the weight of silver to gold — where silver stands as 1.

Diagram. Two circles of equal size set side by side, captioned above "Magnitudo aequalis" ("Equal magnitude"), illustrating that at equal volume gold weighs $1 \frac{26}{31}$ to silver's 1.

- Left circle, interior: **$1 \frac{26}{31}$** (i.e. $1 \frac{26}{31}$)
- Left circle, below: *Gravitas auri* — "Weight of gold"
- Right circle, interior: **1**
- Right circle, below: *Gravitas argenti* — "Weight of silver"

So gold stands as $1 \frac{26}{31}$. Gold is therefore heavier than silver by $\frac{26}{31}$. For if these two bodies are taken —

ARS METALLOSTATICA. (continued)

are equal in magnitude. I say that the silver body will stand to the gold one as 1 to $1 \frac{26}{31}$. For since bodies equal in magnitude differ greatly in weight, the one that is less heavy — namely silver, compared with gold, which is heavier — will stand to it as 1 to $1 \frac{26}{31}$. But if you consider the magnitude of the silver and gold bodies, you will find that the gold body stands to the silver one in magnitude, again, as $1 \frac{26}{31}$ to 1. And necessarily, if these two bodies are taken as equal in weight, the gold body will be smaller, as 1, while the silver body will be larger, as $1 \frac{26}{31}$.

Diagram. A pair of circles set side by side, captioned above with the heading "Inæqualis Magnitudo argenti ad magnitud. auri" [Unequal magnitude of silver to the magnitude of gold]. The left circle is the larger, representing silver; the right circle is the smaller, representing gold. The weight-ratio is inscribed inside each circle.

- Left circle (silver): $1 \frac{26}{31}$
- Right circle (gold): 1

PROPOSITIO II.

To find the proportion of gold to iron.

Look in the rim of the Table at A D C; and in the rim A C [find] iron, and on the side A D [find] gold, and you will find in the common angle $2 \frac{1}{8}$, the proportion to iron that you sought. For suppose iron to have a weight of 1: then gold will have a weight of $2 \frac{1}{8}$; so that if the iron weighs 1 pound, the gold weighs $2 \frac{1}{4}$ [recte: $2 \frac{1}{8}$ — the text just gave the ratio as $2 \frac{1}{8}$; " $2 \frac{1}{4}$ " here is inconsistent]. If you attend to the magnitudes of these bodies when equal in weight, the magnitude of the iron will stand to the magnitude of the gold as $2 \frac{1}{8}$ to 1 — that is, the iron body will be larger than the gold one, under the given proportion.

PROPOSITIO III.

To find the proportion of bronze to lead, both in weight and in magnitude.

Look as before in the rim A D [for] lead, and in the rim A C [for] bronze, and the common angle will give you $1 \frac{5}{18}$, the proportion you sought. For as 1 stands to $1 \frac{5}{18}$, so does the weight of bronze stand to the weight of lead, by which lead's weight exceeds that of bronze by $\frac{5}{18}$ — so that if bronze has 1 pound by weight, lead will have, in addition, 1 pound plus $\frac{5}{18}$ of a pound. But if you consider these bodies as equal in weight with respect to magnitude, then conversely, as $1 \frac{5}{18}$ stands to 1, so will the bronze body stand to the magnitude of the lead body.

PROPOSITIO IV.

To find the proportion of water to wine.

Look in the rim A C [for] wine, and in the rim A D [for] water, and the common angle will give the desired proportion, $1 \frac{1}{55}$ — that is, water is heavier than wine by $\frac{1}{55}$. For as 1 stands to $1 \frac{1}{55}$, so wine stands to the weight of water. In the same way you will find that wax stands to honey in the proportion 1 to $1 \frac{105}{210}$. And so for the rest.

Praxis Tabulæ triangularis. B D C.

PROPOSITIO V.

The proportions of this Table do not differ from the previous one except in the assumed weight of 100 — for example, of pounds — which is compared with any other of the twelve. For in this Table the weight of a body is always set as 100, and to this given value the remaining bodies are proportioned, both as to weight and as to magnitude.

For example: if you wish to know what the ratio is in weight of gold to silver — since gold is heavier than silver, let us set its weight as 100. Look, then, in the rim C B of Table D B C [for] gold, and in the rim D B [for] silver, and the common angle will give you $54 \frac{23}{57}$, the proportion of gold to silver that you sought. For if two bodies equal in magnitude are taken, one of gold, the other of silver, and the gold is heavy as 100, the silver will be heavy as $54 \frac{23}{57}$. Therefore, as 100 is to $54 \frac{23}{57}$, so is the weight of gold to that of silver. But if these two bodies are taken as equal in weight with respect to magnitude, the proportion will hold conversely: for as 100 stands to $54 \frac{23}{57}$, so the silver body stands, in its magnitude, to the magnitude of the gold body. These same things are to be understood concerning any other bodies set out here in the table; and so these rules are always to be observed:

1. Whenever two differing bodies are of equal weight, one of them will necessarily be the larger — that is, unequal to the other in magnitude.
2. Whenever two differing bodies are equal in magnitude, necessarily one of them will be unequal to the other in weight. How these Tables are constructed was shown in the preceding pages.

From this it is clear how, once the proportion of two spheres cast from different metals is had, their weights are to be determined. But since this is not part of our undertaking — to set forth statics — I leave the rest to the curious reader to

explore; let it suffice us, meanwhile, to have demonstrated the proportions of metals to one another, both as to weight and as to magnitude.

LIBER DUODECIMUS, Sect. V. Pars II.

CAPUT III.

De variarum rerum ponderationibus.

(On the weighing of various things.)

There is nothing in the nature of things that cannot be investigated by weight — as was shown partly in the preceding pages, and as we shall pursue further in this chapter. Earthy substances or minerals of any kind whatever can be examined in the same way that was shown in the first proposition, by means of our hydrostatic balance. For any body whatever, fastened to the hook of one pan and immersed in water, can be assessed by the counterbalancing of another body set in the air-pan: if you first weigh both in air, and then within water, the difference of weights will give the sought-for proportion of weight between the one body and the other.

[Margin: The varied weight of waters.] As for the element of water, I say that there are as many different degrees of weight in waters as there are different kinds of water. For the weight of spring water is one thing, of salt or sea water another, of river water, of standing pools, and of rain another, of mineral water another — which also differ according to the kind of hot springs; the weight in different plants, oils, quintessences, and similar liquors is yet another; and the weight of blood and urine in animals is another still. [Margin: The varied weight of blood in human beings according to the degree of age.] And indeed in human beings this varies greatly according to variety of age and complexion, since the blood of a boy, an adolescent, a grown man, and an old man each has its own; and one weight belongs to the melancholic, sanguine, phlegmatic, and choleric, and another to the healthy and the sick. That the same difference of weights occurs in animals, only one who has never observed the marvelous transformations of things could fail to know. Human beings, animals, and plants, according to the diversity of climate, take on different complexions, and so too different tempers and varying weights — all of which we have already noted in the preceding pages.

As many as are the differences of seas and rivers, so many are the differences of the weights of waters; for water in the Northern Ocean is of one weight, in the

Southern of another. So too the water of the Indus, the Ganges, the Tigris, the Nile, the Danube, the Rhine, the Rhône, the Tiber, the Po, the Tagus all differ among themselves — some of them not a little. [Margin: The reason there is scarcely water that does not differ in weight from another.] The most wise Ferdinand II [Ferdinand II de' Medici], Grand Duke of Tuscany, affirmed to me with certainty that he had perceived this by experiment itself. [Margin: All waters can by their own nature be made to counterbalance one another on account of admixture.] Yet this too is remarkable: that waters, by the already-mentioned art [the spagyric art], can be reduced to such fineness that they all exactly counterbalance one another. From this it shines out clearly that the diversity of such weights arises from no other cause than the admixture of different mineral or earthy parts with which they are charged, and from the juices [in them]. Quite similar is the diversity of wines in weight and lightness — the cause of which we can give as nothing other than the differing conditions of the earthy clods, and the differing aspects of the Sun, which strikes the slopes of valleys and mountains. But let us set forth how great are the secrets of statics that lie hidden in the nature of things.

Experimenta Statica miscellanea.

(Miscellaneous statical experiments.)

EXPERIMENTUM I.

To investigate the attractive power of the magnet as to weight.

[Margin: To investigate the statical power of the magnet.] Place a magnet in one pan, and in the other a body of iron counterbalancing the magnet; then, taking away the magnet, put in its place any other body counterbalancing the magnet. This done, apply the magnet above the iron, and note how much it is attracted; and [observe] up to what point the iron rises toward the magnet, drawn by the magnet — which will be the outermost point in the sphere of magnetic activity. This done, and the magnet set aside, place gradually so much weight in the opposite pan, until the iron has risen to the place which it held when drawn by the magnet: for the weight added in the opposite pan will be the power, or attractive faculty, of the magnet.

EXPERIMENTUM II.

To investigate, by the spagyric balance, how much moisture is in some green wood or herb.

[Margin: To investigate how much moisture is in plants.] Let some earthy wood first be cut into pieces — or any plant whatever — which is then committed to fire for so long, until the whole has been reduced to ash. If, then, the wood first turns out to have weighed 4 pounds, you will know that there was just so much moisture in the wood or plant — namely two pounds. I speak here of elementary moisture, not radical moisture, which always remains in the salt that is drawn out of the ashes.

CONSECTARIUM.

(Corollary.)

From this experiment it is clear that the moisture not only of every kind of vegetable, but also of any animals whatever, reduced beforehand to ash, can be found. [Margin: To investigate the moisture in individual things.] And so, if someone reduces several mixed things — whether vegetable, or sentient, or of mixed nature — separately to ash in the manner described, I say that he will find not only how much moisture each one had, but also the proportion of the ash of one to the weight of the ash of another. This is indeed a matter of great importance for coming to know the degrees of the primary qualities.

ARS METALLOSTATICA. (continued)

EXPERIMENTUM III.

To find how much salt is in any one of the mixed things assumed before. Proceed thus.

First, having weighed the mixed things, write down the weight separately; then weigh again the ash left from the burning, and, this noted, let the ash be put into water in a wooden vessel and stand there so long, until a lye [lixivium] is made from it. Afterward, the water having been separated off, you will see the salt adhering to the vessel in the form of crystals — keep this. But the lye, evaporated by fire to dryness, will leave in its bottom a dead residue [caput mortuum]; if water is again poured over this in the said wooden vessel, it will in time give a lye, which being separated, you will set aside the salt that finally adheres to the vessel, scraped off; and you will repeat this as many times as needed, until no more salt remains in the dead residue. Then the salt collected from each repetition, examined by weight, will give you how much salt was first present in the said mixtures. Whatever is left in the bottom after the evaporation of the lye, you will reckon as the saltless earthy substance.

EXPERIMENTUM IV.

To weigh air at different times.

[Margin: To investigate the quality of air.] Air is by its nature changeable, and does not always remain in the same state; so if you should wish to investigate its weight, proceed thus. Take dry wool compressed into a little ball; weigh it first, placed in one pan, in the driest weather; then, in weather of a more humid constitution, weigh again the wool left in the same place, and you will find a notable difference between the second air and the first. From which it is clear that, if anyone weighs the said wool in the morning, at midday, in the evening, or at midnight, he will be able to find a difference in air, as to weight, at each of these four daily stations — which I would have understood likewise of the four seasons of the year. In the same way one could find the difference of air in subterranean caves compared with the external air, in valleys compared with the air on mountains, and indeed of the same air when altered by the various blasts of winds. See what we have treated at length about these matters in the *Ars Magnetica*, concerning the new instrument by which the dryness and humidity of places is investigated. I have seen one who gathered the proportion of air to another degree of tenuity from the motion of bellows: for bellows drawing in thick air move more slowly in expelling it than in a thinner air; whence nothing else seems to be required here but to investigate the differences of the motions by the vibrations of a pendulum. Air can also be weighed in a balance: take a large play-ball, which you first fill very full with humid air; this weighed, you force a more subtle air into it by means of [?]; and from the weighing of it the difference will at once become known.

EXPERIMENTUM V.

To investigate the vigor of the Sun.

[Margin: To investigate the vigor of the Sun.] The vigor of the Sun consists in this: that in different climates and places it acts differently even upon mixed bodies of the same species, whence arise also different qualities of those mixtures. Let us, then, make the experiment first upon grain. Let there be taken from the plains of different climates grains, for example of wheat, in such a quantity of equal grains — so much from the one, so much from the other — then let them be weighed individually, and you will find a notable difference: those which are lighter will have had the greater efficacy of the Sun, those heavier the less. And in this same way you will also find the vigor of grain on the plain and on the mountain or in the valley. The reason is that where the Sun's efficacy is greater, there too is less moisture and greater dryness — for just as green wood [weighs] more than dry, so too the more humid grain must of necessity weigh more than the dry; and

consequently bread from the wheat of a more southern climate is whiter than bread baked from the wheat of a more northern climate, the moisture in the bread producing blackness.

EXPERIMENTUM VI.

To investigate how much a plant has grown on individual days.

Let there be made from wood a square rod A B, divided into any number of degrees; this has at A a crosspiece of wood, inserted into the rod A B, which at each end, C and D, has a little wheel — which they call a "currulum" [pulley] — fitted to the ends in such a way that a fine silk thread can easily be wound this way and that. Let this thread have at one end — as at E — a light weight tied on; the other end is to be tied to the tip of the plant at F. If, then, you have a mind to investigate the daily growth of a plant, proceed thus: let the rod A B, with its transverse little beam C D, be fixed firmly in the earth next to the plant; this done, let [the thread] be tied on...

Diagram. A plant-growth measuring instrument. A growing plant (shown with leaves and roots) rises from the ground at the base; behind it stands a vertical graduated scale fixed in the earth. At the top a horizontal crosspiece carries two little wheels (pulleys). A silk thread runs over the pulleys, tied to the plant's tip at one end and to a small hanging weight at the other, so that as the plant grows the thread shifts against the graduated scale.

- A (top center of the crosspiece): top of the vertical rod / junction with crosspiece
- C (top left end of crosspiece): left pulley
- D (top right end of crosspiece): right pulley
- B (foot of the vertical scale): base of the rod, fixed in the ground
- E (right side): the small hanging counterweight
- F (left, at the plant): point where the thread is tied to the tip of the plant
- Scale graduations marked: 5, 10, 15, 20, 25, 30, 35, 40

LIBER DUODECIMUS, Sect. V. Pars II.

the tip of the plant G F: at F it will be tied with the silk thread, and the other end E, by its own weight, will draw out the tip of the plant by means of the wheels C D. This done, note carefully to which degree, in the region of the fulcrum B A, the tip F corresponds — or even to which degree the knot in the silk thread points on

the transverse beam C D, graduated into any number of parts. And in this way, on individual days, you will obtain the difference of the plant's growth — especially if on the following day you repeat the observation, and write down the differences of growth separately. By this method you will discover the daily growth of different plants with almost no trouble. The usefulness of this thing is great: for from it you will easily come to know the quantity of nourishment that the plant draws to itself each day. Likewise you will have noted the ratio of moisture and dryness in plants — for moist plants take their growth more quickly than dry ones, as do warm-moist plants more quickly than cold-dry ones. The remaining benefits I leave to the reader to weigh.

EXPERIMENTUM VIII.

To find how much quicksilver is in a mineral clod.

[Margin: To investigate how much quicksilver a mineral body contains.] Take an earthen flask, into which you will put the mineral clod, with an alembic placed over it together with a receiver; then, fire being applied beneath, the mercury will gradually take wing, ascending in the form of vapor; and when it reaches the cold cap, it will at once, restored to its own nature, slip down into the receiver. If, then, the mineral clod was first of 8 pounds, and you find 6 pounds of mercury, you will surely infer that there were two pounds of earthy matter in the mineral clod, and six of mercury — supposing the ore to have been taken from a mine from which quicksilver [hydrargyrum] is extracted. In this way it is permitted to investigate the mixtures of the rest of the minerals; but since in the preceding Books we have treated similar things at length, we refer the reader to them: see especially what is to be investigated in the first Book, *On the Cosmocentric Art*, by means of pendulums, and what we set forth in the fifth and tenth Books, *On the Hydrometer Instrument*.

EXPERIMENTUM IX.

To measure the speed of a bird flying in the air.

[Margin: To investigate the speed of the flight of birds.] We first explored this matter in the flight of swallows, which are swifter than all other birds. [Margin: Something so fixed, of the magnitude of an enemy's gate (?) — see note] We took a pendulum of such length that its vibration, or diadrome [diadromus, single swing], corresponded to one second of an hour. This done, in a suitable place we observed the motion of flying swallows over a certain space, and found that for one swing of the pendulum a swallow covered 100 geometric feet from one terminus to another. From this we gather that, if it continued its flight in a

straight line at equal speed, [it would cover] a quarter of [?] the space in one hour. And so, with almost no trouble, by the help of the rule of proportions, in this way: in one second, or in 60 first minutes [i.e. minutes], the swallow covered a space of 100 geometric feet. In 3600 seconds — that is, in one hour — how much? And the computation done, there came out 72 miles (each of which consists of 1000 geometric paces), which we find a swallow could cover by continued flight; and consequently in 24 hours, or one natural day, 1728 Italian miles, or 432 German leagues, taking 4 miles for one league. But in flying around the whole globe of the earth, it would take up almost twelve days and eleven hours. [Margin: In how much time a swallow could fly around the earth.] Anyone could take this experiment not only concerning the time of the flight of swallows, but of any other birds and running animals whatever, for investigating their proportions of speed to one another — which I would have understood in the same way of the motion of arrows and the speed of cannonballs.

EXPERIMENTUM IV. [recte: this experiment is numbered IV again, out of sequence after IX; the running number is anomalous in the source]

To investigate, by the anaclastic art, both the weight and the lightness of various liquids.

It is known to all that a ray — whether solar or visual — observes different laws of refraction according to the condition of the different media, as we have demonstrated at length in the *Ars Magna Lucis et Umbræ*, in the Book *On the Anaclastic Art*, or of refractions. So then, lest I omit anything of curious matters, here, as in a fitting place, we shall teach how the weight and lightness of different liquids can be investigated by means of the art of refractions. [Margin: To investigate the weight of liquids.] First, then, let a vessel be made of bronze plates, fashioned in the shape that L M represents. Second: in the bottom of the vessel let a coin be placed, [which] you see to be at E D. Third, draw back from the vessel M L straight toward H, by so great a space, until the coin...

Diagram. A woodcut illustrating the refraction experiment for the weight of liquids. At the upper left stands a man (in 17th-century dress) sighting along a line of vision; lines of sight run from his eye down toward a shallow round basin or vessel at the lower right. The vessel (a broad, shallow cylindrical pan) contains a coin in its bottom; sight-lines converge on the basin, showing how the apparent position of the submerged coin shifts by refraction.

- A (upper left, at the man's eye): the observer's eye / station point
- H (lower left): the point to which the observer draws back

- R (mid-upper, on the sight-line): point on the line of vision
- L (left rim of the vessel): one edge of the basin
- M (right rim of the vessel): the other edge of the basin
- E, D (in the bottom of the vessel): the position of the coin

the coin no longer appears. At that point, halt again at H. Fourth, fill the whole vessel L M — first with the clearest spring water — then return to position H, and the coin e d, which at first eluded your eyes, will now show itself fully. In the empty vessel L M the coin was not previously visible, because the line of sight a s, extended in a straight line, was carried to b c, leaving the coin untouched. But once the vessel is filled with the clearest water, the incident visual rays A R, A S are at once refracted at the surface of the denser medium — from R to d, and from S to e — and they make the coin, hidden just a moment before, visible to the eye A by means of the refracted lines d R A and e S A.

[Margin: To investigate by the anaclastic art the difference in density of liquids.]

Now if you pour out the clear, limpid water and refill the vessel to the brim with a new but denser water, such as seawater, and look at the coin — fixed in the same place — from the same determined station A, you will find that the coin e d has receded somewhat toward L, as though to e g, having left its station. The reason for this is none other than the obstruction of the denser medium: the visual rays, unable to penetrate it, are refracted under a greater angle. From K, that is, they are refracted into d, and from S into g. Consequently the coin will no longer be seen at E D, but at e g. From this the difference of the liquids — as to density and fineness — will readily suggest to you the difference of the anaclastic angles D R e and e s g. On this matter, see our *Ars Anaclastica*, where we have set out the calculation in full.

In this way you can, with no trouble at all, investigate the propositions concerning the lightness and density of wine, of aqua vitae compared to water, of oil, and of any transparent liquid whatever. I have thought fit to add these things here so as to give the curious reader an occasion for the investigation of many other secrets of Nature far greater than these.

[Margin: To investigate the densities of liquids.]

Experimentum X.

Musicas proportiones ponderibus explorare. — To investigate the musical proportions by means of weights.

Take two strings equal in length and thickness; if you stretch them with weights, you will obtain the harmonic proportions in fitting agreement with what you seek. Thus two weights are hung from the said strings, which, if they are in double proportion, will necessarily cause those strings, when set vibrating, to give you —

Diagram. A schematic of five weighted strings hanging side by side from a horizontal frame, numbered left to right 1, 2, 3, 4, 5, each terminating in a small weight (drawn as a flat coin-like disc). Beneath the row of weights, a series of nested arcs connects pairs of strings, each arc labelled with the harmonic interval it represents.

- Strings (left to right): 1, 2, 3, 4, 5
- Arc from 1 to 2: *Diapason* (the octave)
- Arc from 2 to 3: *Diapente* (the fifth)
- Arc from 3 to 4: *Diatesseron* (the fourth)
- Arc from 1 to 3 (lower nested arc): *Dis diapason* (the double octave / fifteenth)
- Arc from 1 to (4/5) (lowest, widest arc): *Diapason cum Diapente* (the octave plus a fifth / twelfth)

— the diapason, that is, the octave. And if the weights fixed to the strings stand in the ratio 2 to 3, the strings, set in motion, will necessarily yield you the diapente, or fifth. If the weights stand as 3 to 4, they will sound the diatessaron for you; if as 1 to 4, the disdiapason; if as 1 to 3, the diapason plus diapente; and if, finally, the weights stand as 8 to 9, they will give you the tone — and so on for the rest, which we have demonstrated very fully in our *Musurgia*, to which I refer the reader.

[Margin: To investigate the harmonic proportions.]

I could bring forward countless further examples at this point, but since we have reserved these matters for the *Ars Magna* of heavy and light bodies, it will suffice merely to have indicated them here.

Pars III.

DE ARTE VITRIARIA.

In which we treat not only of the wonderful works of glass, but also of the fashioning of crystals, pearls, and precious stones after the living model of Nature.

Caput I.

De Vitri natura. — On the nature of glass.

Glass is the last thing into which any mixed body can be reduced, and its nature is so marvelous that it can scarcely be described in adequate words; if only it did not have an inborn fragility attached to it, surely nothing could come near it in value. For what is clearer than its substance? What more limpid? What more beautiful? Indeed, as Job testifies: "Gold shall not equal it, nor the topaz, nor the beryl, nor any other precious stone" [Margin: Job 36:26 — recte Job 28:17]. Pliny [Pliny the Elder] reports that under the Emperor Tiberius a tempering of glass was devised by which glass could be made flexible, and that on this account the artisan's entire workshop was abolished — so it is handed down — lest the value of the metals copper, silver, and gold should thereby be diminished.

[Margin: Flexible and unbreakable glass.]

For, as Isidore relates (*Etymologiae* XVI.16.15): "It is reported," he says, "that under Caesar Tiberius a certain artisan devised a tempering of glass by which it could be made flexible and ductile. When he was admitted to Caesar, he handed Caesar a phial, which Caesar, indignant, threw onto the pavement; but the artisan picked it up from the pavement, and it had buckled somewhat, like a bronze vessel. Then he drew a mallet from his bosom and straightened the phial. At this Caesar said to the artisan, 'Does anyone else know this method of compounding glass?' Whereupon, when the man swore in reply that no other knew it besides himself, Caesar ordered him beheaded, lest, if this became known, gold should be held as worthless as mud, and the prices of all metals be diminished."

[Margin: Glass valued among the Indians at the highest price.]

Among the Indians, as soon as it became known, it was preferred to all things and exchanged at an inestimable price — so much so that a few glass cups are said to have been bartered in the Eastern kingdom of Tidore at a valuation of 200 gold pieces. In how great admiration the glass triangle [prism] was held among the

Chinese, let anyone who wishes read in the history of the expedition to China by Father Nicolas Trigault [Nicolas Trigault]. So that we may set out in order the many uses of his account for the human race —

First, who would not marvel at the ingenious vessels and cups, full of admiration, that are fashioned by the use of glass? How great is its usefulness in making mirrors! How highly is it valued in these latest times for the making of optical tubes [telescopes] and microscopes, by which astronomers have penetrated with lynx-like eyes even the very canopies of the heavenly bodies and the stars, and by which they have performed the anatomy of the tiniest animals and of things almost imperceptible! But since we have dealt with these and similar matters most fully in the *Ars Magna Lucis et Umbrae*, in the book on mirrors, we refer the reader there. By means of glass siphons almost the whole of elemental nature has been laid open to physics through manifold experiment. How great are the benefits that come to us from its transparent nature in the construction of windows! And although by its own nature it is fragile and a work of art, it nonetheless deserves to be held in that place where, among the works of Nature, it ranks as a gem. Liquids such as the *aquae fortes* [strong acids], quicksilver [hydrargyrum], and the like, are usually contained in no vessels except glass ones.

[Margin: The usefulness of glass.]

[Verse:] *Whether it first retains the hard fire, or the heaped-up mass of iron, Or even binds it, joined to a kindred metal, It flashes forth, and the obstructing mass, with ungovernable weight, It bursts, exulting, and, mighty, subdues all things — save one alone. But when we attempt to bind the lively motions with glass, the love feels its forces shattered here by the barrier, and the glassy bite probes the bodies in vain.*

These things, then, being set forth, let us now unravel each point by way of Questions. And so it is asked first: What is the material of glass?

[Margin: The material of glass.]

I am not unaware that some say the material of glass is ash and lime, others assign a different material according to each one's own ingenuity — which it would take too long to recount. We say that ash is not the sole material of glass, but rather sand — not any kind of sand, but sand consisting of a glassy material, of the sort that certain flints are, and crystalline gravel, and the sand of the stone they call Alebandic, to which we also reckon jet, which Pliny calls obsidian stone.

Stones, then, that promise a certain transparency yield, the more lucid they are, by reason of a certain crystalline admixture mingled with them, glass that emerges so much the more beautiful, brighter, and more lucid.

[Margin: Sand and ash make glass.]

When these stones have been ground into sand, the ashes of burnt plants are joined to them (of the kind they call *hali* and *soda*). Since these herbs are by their very nature niter-bearing, they are mixed with the sands for this purpose: so that out of the inmost substance of the sandy stone they may draw forth a nitrous material similar to themselves, which, together with the nitrous and saline corpuscles lurking in the ash, may at last, by the force of the most blazing heat, be melted down into glass. The ancients, for the said reason, used to add pure native niter to the sandy material, and some do so even to this day. But experience has taught that the nitrous ashes of certain plants render not only the same effect as niter, but a nobler one.

Glass, then, is made: first, from transparent, crystal-form stones, fusible by their own nature, and also from concreted juices and from the liquors of other things joined to these by a certain natural kinship; and from these a glass of better quality is produced. [Margin: From crystalline stones.]

Second, from those stones which, although they do not possess crystalline hardness, are nonetheless translucent and white. [Margin: From translucent stones.]

Third, from stones that are indeed white, but not transparent — such as certain flints heaped up by the force of the waves at the mouths of rivers. [Margin: From white, non-transparent stones.] These are prepared in this way: first the said stones must be burnt; then, placed under pestles, they must be broken and ground so that sand is made from them; then they must be sifted, to separate the purer particles from the impure. Stones, however, that have been washed by waters and taken up at the mouths of rivers for this use need no further purification, since they are tumbled by the perpetual attrition of the waters.

Once these have been prepared, the making of glass is done by this art: to three parts of the sand of the said stones they add one part of niter, and from these, melted together, arises a mass which Agricola not improperly calls *Ammonitrum*, that is, "sand-niter" [Arenonitrum]. To make up for any deficiency of niter, a portion of fossil salt, or of any other salt whatever, is added to the sand. The deficiency of all these is nowadays supplied, among the glassmaking craftsmen, by the ash of the burnt herb *anthyllis*, which the Arabs call *kali*, and the Italians

and Spaniards *soda*; it grows for the most part in salty soils, and so by many is not unfittingly called *salsula* [saltwort], because an abundant salt is drawn from it. There seems to be a great quantity of this herb on the island of Malta, and in some places of Calabria. But the Spanish soda is most commended above all the rest.

[Margin: Spanish soda surpasses for glass.]

It is truly worthy of admiration that at Venice the skilled craftsmen mix in a portion of magnet [lodestone] with these as well, because by this admixture the glass acquires a wonderful splendor. The reason for this is none other than that for the most part an admixture of iron filings adheres to the stones, which, drawn off by the magnet, frees the rest of the glass mass from the impurity of the shadowy parts.

[Margin: An admixture of magnet with glass.]

Furthermore, furnaces differ according to the diversity of operations. Here at Rome they raise most furnaces into a fourfold tier of stories, of which the lowest is the κονιστήριον [Greek: konistērion, "ash-place" — the place fitted for receiving the ashes], the second the πυρευτήριον [Greek: pyreutērion, "fire-place" — destined for kindling the fire]; in the third are fitted the vessels and pots suited for melting the glass material; and above is the receptacle, constructed for a certain tempering of the heat, lest the newly molten glass, exposed to sudden cold, should burst. All the receptacles of a furnace of this kind are constructed not of iron, not of lime, not of living stones, but of raw bricks made from clay suited for this work and for sustaining the strongest fire. The pots, too, which contain the glassy material, are made here at Rome from a certain clay brought from the territory of Savona. Then the furnace is kindled with long oak or holm-oak logs and the like, for eight days — as here at Rome — but under fixed degrees: first gentle, then stronger, and finally strongest.

[Margin: The manner of making glass vessels.]

When the material within the pots has thus been liquefied, the glassmakers, with three-foot tubes of iron or bronze inserted into the pots and turned about, draw from them as much as they judge sufficient for the work to be made. They turn it on a marble slab placed before the little window, and blow through the tube repeatedly; and lest the blast entering through the tube should harm them, they apply it, drawn back from the mouth, to the jaw. Then, lifting the tube and twisting it several times in a circle, they make the glass long; next they form the same in a hollow bronze instrument, which serves the function of a mold; then,

by heating, blowing, pressing, and enlarging, they shape it into the form of a cup or vessel or other thing conceived in the mind, attach handles, paint it with various colors — and in this way they commit the finished vessel to the furnace for the purpose of cooling. But since these things are everywhere commonly to be seen, I have not thought fit to set them out at greater length.

As for the different species of glass, they are almost as many as the species of minerals, since almost all concreted juices coalesce into glass. Glass, then, can be considered under a twofold difference: as natural and artificial. Of the former kind are crystal, beryl, topaz, and however many transparent gems are at last fusible in fire. Of the second kind are the calxes [oxide-ashes] of metals, which by the benefit of the spagyric [alchemical] art are melted down into glass — gold excepted. In this way Saturn, that is, lead, is decocted into tin, into copper, and finally into glass, as we shall see later. Third are the smalts or enamels, which are nothing but glass decocted from metallic bodies.

[Margin: The differences of glasses.]

I will not speak here of the sands of the river Belus in Syria, at the foot of Mount Carmel, coagulated by the power of fire into the purest glass — some of which are true, while many are wrapped up in fabulous tales — to be found in Josephus, *On the Jewish War*, Book 2. Experience teaches this: that every fusible thing, whether stone or metal, can be forced into glass.

[Margin: Every fusible mineral can be forced into glass.]

Moreover, there is nothing that more easily takes on all colors than glass, and that displays the same colors more splendidly; whence, not without deceit, men so artfully tint glass that it can appear as emeralds, hyacinths [zircons], amethysts, and chrysolites — of which a little later. The colors that are commonly employed for tinting glass are of mineral nature.

The properties of glass are truly marvelous, some of which we shall set out here:

1. Glass thoroughly cooked with sulphur is hardened into stone — so say Pliny and Agricola, *De Ortu Subterraneorum*, Book 5. [Margin: Glass hardened into stone by sulphur.]
2. The white of eggs mixed with quicklime turns into a glue most apt for cementing the fragments of glass. [Margin: A glue for glass.]
3. Glass is liquefied by the heat of fire, and congealed by cold, whether it be of the watery or the airy [kind].

4. Glass vessels alone can contain quicksilver, all other [vessels] being at length eaten away by it.
5. Glass made red-hot and then thrown into cold water is rendered so brittle that it can be crushed into a fine powder with the hands. [Margin: How the brittleness of glass is brought about.]
6. Glass can be so tempered by a certain water that one little fragment of glass, broken at the very tip, reduces the whole mass into an imperceptible powder. This comes about if you make the fragment red-hot again and again with fire, and quench it repeatedly in the coldest water. But concerning this truly wondrous experiment, see what we have treated most fully elsewhere. [Margin: A wondrous experiment in glass — the resolution into powder in a moment.]
7. Glass added to the fusion of metals renders them fluid, on account of the great heat which it then possesses in its fusion, and which it imparts to other fusible things.
8. Glass in fire is soft and ductile, but once cooled nothing is more fragile. The rest we shall pursue in what follows.

§. I.

De Metallorum vitris. — On the glasses of metals.

All metals become vitrified — gold too, although, on account of its most tenacious humidity, it can scarcely be tamed; yet some Alchemists think that gold can be coagulated into an ash-colored body, and thence pass into the form of a ruby. But if they first calcine it by the power of fires, it can indeed be forced into glass, yet never reducible to its pristine form. And if gold be dissolved into mercury, [they say] it is vitrified by sublimation with salts. But let him believe it who will; for experience has established none of these things up to now. It is likewise false that gold can be transmuted into silver if one part of the *aqua regia* [red eagle-water], which is extracted from silver, be cast upon ten parts of the best mineral gold.

[Margin: Silver becomes vitrified.]

2. Silver, however, being more corruptible by cinnabar (with which it is cemented), as Libavius [Libavius] testifies, is so tamed and dried out that, with salt added, it readily passes into glass. It takes on an azure color when the silver has first been reduced into a calx or blue saffron. Gaston Claveus

[Gaston DuClo] observed that, crystallized in a glassmaking furnace for two months, a full twelfth part of it passed into a citrine glass.

Experimentum

Quo argentum in vitrum deducatur ex Bodino. — By which silver is reduced into glass, from Bodin.

Let silver be dissolved in common *aqua chrysulca* [nitric acid]; let the solution be precipitated in sweet water, in which a little sal ammoniac has been dissolved. Let the calx thence collected be mixed with chrysocola [borax], and in this way it is fused into glass by fires. But if it does not become sufficiently translucent, let borax be added to the calx and the operation repeated for so long, until you become master of your wish. But how a glass of this kind of Luna [silver] may again be reduced into silver, Bodin [Jean Bodin] teaches as follows: he commits the ground glassy material to an earthenware shard, and places this in another more capacious dish, basin, or pot; with fire added, he says that the silver penetrates even the shard itself, and is found in the lower vessel or more capacious shard placed beneath the first, with the residues remaining in the upper shard.

[Margin: The reduction of glass into silver.]

For my part, in this place I think he more fittingly meant by "shard" the ashen little dish which they call a cupel — of which [I treat] amply in Book XI — although this, even if it sometimes absorbs the silver (if it has not been rightly made), was nonetheless destined by the craftsmen only for soaking up the excrementitious dregs.

2. Geber [Jābir / Geber] testifies that tin becomes vitrified, because in its depth it has a fugitive mercurial substance which, just as it flees away through long delay in the fire, so too, deprived of all humidity, at last coalesces into glass. In this way the burnt ceruse of tin is turned into a white ash, and thence into a glassy substance of a milky color, with which individual [craftsmen] coat their vessels, so that in the fire they may be covered with a white, glassy crust. [Margin: Tin becomes vitrified.]

Lead is reduced into glass with almost no trouble — there is no need to demonstrate this with many roundabout words, since this artifice is in nearly daily use among the founders of metals. Black, red, citrine, and otherwise differently colored glass is made, according to the condition of the leaden calx

calcined into litharge, or ceruse, or plumbago, or minium. [Margin: The glass of lead.]

The glass of antimony, than which nothing is more common, serves for vessels in which wine, poured through, is rendered wonderfully cathartic — the frequent use of which is in our pharmacopoeia. Medals and coins, too, are made from this kind of regulus or glass of antimony, which, dropped into wine, render it cathartic. We have also rings made from the glass of antimony, which do the same when cast into wine. Geber draws a wonderful variety of colors out of the ceruse of lead and tin: [Margin: The glass of antimony.] [Margin: A variety of colors from ceruse.]

Liber XII — ΠΟΛΥΜΗΧΑΝΟΣ / SIMIA NATURÆ, Sectio V, Pars III — De Arte Vitriaria

[Margin: plumbo, stanno.] ...both, in fact, when stirred together over coals, are calcined. And so, with borax added, along with as much oil of tartar as is enough to incorporate them, lead under the fire of fusion passes easily into glass — the lead indeed into a citron-colored glass, the tin into a watery-white glass. These, however, when subjected to a rapid and strong fusion, are reduced back into their own metals, which are harder than they were before.

[Margin: Glass of copper. (*Vitrum æris*.)] That copper [æs] too can be brought down into glass, the following experiment will show.

EXPERIMENTUM

[An experiment] showing that copper can be brought into glass, and again reduced back into copper.

Melt a portion of copper [æs] in a crucible — say, one pound. From this molten copper, separate off half, which you will place in a second crucible. Now if you sprinkle arsenic onto one part of the liquefied copper, you will find — once it has hardened in the cold — that this part has degenerated into a glassy material, brittle just like glass, rough, and altogether impossible to work with the hammer. The remaining part, free of arsenic and restored by cooling, will easily turn out pliable and malleable. In this experiment one observes a certain remarkable restoration of copper to its former state: for if you saturate with borax the copper that has been reduced to a brittle condition by the action of arsenic, it will soon

be restored to its former coppery state. If you ask the cause of each of these truly extraordinary effects, I answer as follows.

First, I say that copper, when set in fusion and imbued with arsenic, is — by the sharpness and outstanding dryness of the arsenic — stripped of all moisture. Hence, once its binding moisture [glutine] is consumed, the parts must necessarily become disunited, and consequently the copper becomes diseased [morbidum] and brittle like glass. If, however, you imbue this with borax, then — wonderful to relate — it is at once restored to its former state, because the borax gives back to the copper the very softness which the dryness of the arsenic had taken away.

§. II.

Concerning the glasses commonly called Amausa, and Encausta, or Smalta, and their products.

Nothing in the art of glassmaking presents itself as more worthy of admiration than Smalt [Smaltum], which some call *amausum*, the Greeks ἔγκαυσον [Greek: enkauson, "encaustic" — burnt-in (enamel)], and others *encaustum*; in Germany, because of its easy fusion, they call it **Schmälteglas**. [Margin: The dignity of encaustic works. (*Dignitas operum encausticorum.*)] The crafted works that arise from it are held in such esteem that, among kings and princes, no treasure [cimelion] is reckoned of any value — whether it be coins, or rings, or watchcases — unless they are painted with encaustic colors. It is a work truly full of wonder, on account of the great variety of its most brilliant colors. For if the work finds a skilled and richly gifted artist [Margin: ἔγκαυστοποιῖα [Greek: enkaustopoïia, "the making of encaustic work"]], it will surely far surpass all the workmanship of gems and precious stones, whether you regard the variety of colors or their splendor. The stones produced from it are also far more lucid and brilliant than Oriental ones, and more pleasing to the eye.

Smalt, then, is a most pure glassy body — yet not transparent or see-through like glass, but rendered opaque with diverse, most splendid colors. If you ask by what art encaustics or smalts of this kind are prepared, I say they can be cooked out of all the metals. [Margin: The method of preparing them. (*Modus eas conficiendi.*)] For when any metal whatever has been reduced to a calx or earth, and this is placed in the pots of the glassmakers' furnaces, then — by the violence of a most blazing fire — it is at last roasted and turns into a pure glass, though not diaphanous and transparent. Yet it is free and immune from all the impure and black dross of the metal's body that was previously in it. Therefore, once the

impurities have been consumed by the force of the fire, that pure essence shines forth from the glass in most delightful and precious colors — like a little fire enclosed in pure crystal, the sort of thing one sees in amber [electro] and in the carbuncle. And so smalts, in proportion as they are skillfully wrought, are excellent. There lies hidden, then, in the calx of the metals something not unlike pure light, which, purged by fire, rises up into a glassy smalt — a certain most beautiful likeness of the World-Mass [Mundana massa], which, purified of all filth by the last conflagrations [noviss. incendiis], will be fused into a gem-like glory. But let us now proceed to the making of smalts or encaustics of this kind.

[Margin: Encaustic green from the calx of copper [Venus ♀]. (*Encaustum viride ex calce ♀.*)] The calx of Venus [copper], by the fusing force of the fires, will give a dark green smalt — and most green of all if it is spoiled by smoke. But you will obtain a pure smalt, endowed with excellent greenness, if you grind and levigate the calx of Venus with salt water, or brine, on a marble slab so exactly that it does not offend the touch of the finger; then wash it so many times with pure fresh waters until no more impurities are detected in the water. This, however, must be done with waters that are actually hot. The calx thus prepared is melted into a more perfect, more fusible, and softer glass than if you had fused it without washing and grinding.

The same art applies to the calx of lead, of Jupiter [tin], of Luna [silver], [Margin: Encaustics of various colors from the calxes of various metals. (*Encausta varii coloris ex calcibus.*) — ☞ ♄, ♀, ☉ ...] except that the calxes of different metals supply *amausa* of different colors. First indeed, lead and iron give a tawny *amausum*; tin a white and most brilliant one; silver a blue [cæruleum] one. These, mixed together in various ways, produce an enormous variety of colored smalts. But now let us explain how and by what method they are fused together from these.

At Venice, smalt of every kind of color is manufactured, drawn out partly into long threads, partly into rods or round masses. These are used especially by those who practice the glassmaker's art at the lamp [ad lampadem], from which they make votive crowns [rosaries], women's ornaments, earrings, rings, and flowers with such variety — gems so similar to natural ones that they sometimes even deceive the eyes of experts. Here you may see coral, amethyst, diamond, emerald, crystalline, and gem-like imitations, wrought, so to speak, to the very envy of nature itself, with such splendor, and with such a diversity of colors

[Note: printed page 453 carries the running header for the recto; the verso (printed 454) header is recorded above. The signature mark at the foot of printed 453 reads:]

and intermixing of colors with one another, that when they have been carried over to the barbarian Indians, in comparison with them they have reckoned gold, silver, and gems as nothing. From smalts of this kind they fashion figures and little images of every sort. [Margin: Wonderful things are made from it. (*Mira inde fiunt.*)] Surpassing all admiration are the little bundles of plumes [feathers] made from the finest smalt filaments; and were it not that the cheapness of the material stood in the way, they would not be unworthy — for the excellence of their splendor and the beauty of their most brilliant filaments — of the caps of kings and princes. Yet all these things are made with no help from the furnace, but by the use of the lamp alone. But since the matter is worth seeing, I shall describe the manner of proceeding in a few words. [Margin: The method of working smalt at the lamp. (*Modus laborandi smalta ad lucernam.*)]

They set up a lamp fitted with a wick of finger-thickness, which they keep placed on a table before them. Then they bring the smalt threads or rods up to the lamp, drawn out by the blast [of breath] into a long, flame-like ray, which is of such efficacy that it melts the smalt almost in an instant. The melted smalt they transform, by the dexterity of their hands, with pincers — now into little globes, now into some radiant ornament, now into something else, whatever they wish. And in this, what is most worthy of admiration is that, from the varied mixture of the different little smalts melted together, there emerges such a diversity of colors as not even a painter could surpass.

Since I would frequently visit makers of this kind — both to investigate the rationale of the art, and for the delight which I took in such ingenious works — among other things I put to them was this one question: whether a pneumatic machine could be made that would, by its own blast, supply the continuous and laborious blowing by which they were being exhausted? I replied that I saw no difficulty preventing the desired machine from being built, and I gave my pledge to investigate the manner and method of constructing it; which at length I explained ought to be made in this way, which I now set down.

I had two bellows made, not unlike those with which portable organs are fitted, before which was set a wind-chest [anemotheca], or receptacle of the wind;

and from this a fine little channel, or small siphon, was led out as far as the wick of the lamp. In this arrangement, the workman, seated on his stool, by the alternating pressures of his feet alone alternately raised the bellows; and as these expressed the wind they had taken in through the very narrow little siphon, so too, while they descended with the greatest slowness — without any fresh prompting of the feet by which the levers were pressed — they left the craftsman

a long enough pause for working. And so, without any blast of the mouth, the bellows supplied the craftsman with a most copious and most vehement blast, for accomplishing whatever he wished. But since the matter is worth considering, I shall add the machine here.

[*Note: the text promises a figure of the bellows-machine ("machinam hic subdam"), but no such illustration appears on this page; only the feather-bundle figure (described below) is engraved in the margin.*]

And since a little before we made mention of plumes [feathers], I shall explain in a few words how, and by what ingenuity of skill, they make them. [Margin: How the various precious stones are made from smalt. (*Quomodo ex smalto varii lapides pretiosi conficiantur.*)] From wood they have ready a hank [mataxa], on which threads are everywhere wound by the women. Then they take a smalt rod of whatever color they wish, which, placed in the flame, they first draw out by the blast into a most fine thread; this they fasten to the hank. Then, as the hank is turned around, it draws the thread, the smalt material following on and continuous, spread out into threads; and in this way, with the utmost speed, they gather around the hank as great a supply of smalt threads as they wish. Then the threads, made up according to the length and thickness of the future bundle, they fit into a quill-tube [pennaceus tubulus] — as you see here in the margin —

Diagram. A small marginal woodcut showing a bundle of fine smalt-glass filaments shaped into the form of a feather (plume). The bundle is broad and rounded at the top and tapers to a point at the lower end, where the filaments are gathered and bound. The text describes the filaments being bound "below with silken threads" (*infra sericeis filis colligata*). No labels or caption are present.

— which, when bound (tied below with silken threads), they make into a work so handsome, so brilliant from the filaments, that there is scarcely anyone who can sufficiently marvel at the beauty of the work; and many people ignorant of the art persuade themselves that they are the plumes of some exotic bird — whether of a bird of paradise [manucodiata], or of a Balearic heron [ardea Balearica].

CAPUT II.

Concerning the skillful manufacture of gems and precious stones.

Art, the imitator of Nature in all things, aims at this above all: that, as far as can be done, it may attain Nature's effects — if not by true and real efficacy, then at least according to a certain analogy and as closely as possible to the truth. This is evident both in the other matters already discussed in the preceding pages, and

especially in the skillful manufacture of stones, gems, and pearls. Lest I should seem to have passed this art over, I shall here describe it at somewhat greater length — since it can be most useful for many purposes, provided fraud is absent, especially in the promotion of Divine worship and in the working of ecclesiastical ornaments. [Margin: How the various precious stones are made from smalt. (*Quomodo ex smalto varii lapides pretiosi conficiantur.*.)]

I say therefore, first, how the precious gems — sapphire, emerald, amethyst, hyacinth [jacinth], carbuncle, topaz, and the like — can be wrought to the life out of smalt material alone. And lest in this place an occasion for imposture be given to men corrupted by the stain of avarice, we shall at the same time add the method by which the counterfeiting of gems can be recognized with little trouble. But lest we keep the reader longer in suspense, let us make a beginning of the ἐγκανστοποιΐα [Greek: enkaustopoïia, "encaustic-making"].

We say that Smalt is the same thing as what the ancients called Encaustum, and it is nothing other than the pigment of liquefied and colored metal. [Margin: What ἔγκανσον &c. is. ([Greek: enkauson] &c.; [Greek: encausis, "burning-in"]; pyr [fire], to burn in.)] Hence those are called *Encaustae*, ἐγκανσταί [Greek: enkaustai, "encaustic-workers"], who

burn in colors upon liquefied metals; who glue down the melted encaustic upon gold, or burn in the metallic pigment upon gold, or lay gold over the liquefying and colored metal; by whose means works are made so charming and elegant that — whether you regard their rarity or the dignity of their splendor — nothing seems comparable to them. But how and with what ingenuity they are made out of *Blasius Vigenère* [Blaise de Vigenère] and *Bulengerus* [Bulenger], who translated his work from the French tongue into Latin, I shall explain in a few words.

CAPUT III.

How gems can be made from Smalt or Encaustum.

Encaustic work, then, is made from glass and from metals, which wonderfully agree with one another of Nature's own accord. The glass which is used for encaustic work ought not to be made from flint, or from beech-ash [fago], or from the marsh caltrop [tribulus paludum], but from rock or stone, so that the glass may become bright, splendid, and crystalline — from which the encaustic to be burned in upon the metals is produced. The ashes from flint or caltrop, and from which glass is made, they dissolve in warm water; and applying pieces of white

cloth, they pass the pure and clear water through into a vessel set beneath. Whatever there is of impurity in the ashes settles in the former vessel and is not transmitted through the cloth; only the very clear and limpid water [is passed], which, with a moderate fire, grows together into a white salt once the watery moisture has exhaled. This [salt], mixed with sand or stone, or with purified rock, and drenched with minium [red lead], is put into the glass furnace.

That minium is either mineral, that is, metallic, or factitious, made from burnt lead. That red calx of lead is made in a vehement and closed fire, lest it exhale into the air — [it may be called] ἀήρ ἐπιρροίας [Greek: aēr epiirroias, "air of inflowing/effluence"] [?], or "reverberated fire," and one that wanders and strays in a closed space. The glass-craftsmen fashion a certain vessel from white greasy earth, with the pounded bones of rams and other materials, very capacious and very large, which can be corrupted or dissolved by no fire, however violent. That vessel they put into the furnace and place in the middle, full of ashes fit for making glass, which are liquefied by the force of the fire; then they thrust burning iron tongues [linguas — iron rods] into that blazing vessel, to which that greasy and liquid material adheres, from which glasses are made.

That Alkali salt, then, drenched with minium, persists in burning flames in an earthen pan [capedine] for six whole days. On the first and second day that minium-tinted material turns yellow; on the third and fourth it turns green; on two others it whitens, and takes on the color of air [aëris — a sky-blue/grey], and becomes crystalline — from which are made counterfeit gems, and encaustic, that is, smalt. In order that the crystalline material may be compacted and grow solid, it is necessary to apply a metallic calx fused together from both lead and the purest Cornish tin [stanno Cornubiensi] in a reverberatory furnace, so that it may bring solidity to the tin-encaustic or smalt, and so that the body may not be transparent. [Margin: Without lead no metal turns to glass. (*Sine plumbo nullum metallum vitrescit.*)] Without lead no metal can pass into glass. Therefore, when you have mixed that crystalline material and the calx of lead and of tin — each reduced to a very fine powder — together, and have made out of them, as it were, an open loaf or a kneaded mass,

you will dig a hole in the middle, so that the useless moisture may exhale, and you will let it dry out gradually of itself. Then you will put that dried mass into the glassmaker's furnace, until it begins to liquefy; soon you will draw it out of the furnace and let the material cool. At last, with fire applied beneath, you will let it liquefy in an earthen vessel that is not dissolved by fire, and you will draw off with iron spoons the greasy scum floating on top, until in 24 hours the boiling

material becomes most purified and most limpid. This will be your white smalt, [Margin: White smalt. (*Smaltum album.*)] which can be tinged with any color whatever.

If you grind that smalt with crystal into a powder, and liquefy it in the glassmaker's furnace, and add a metallic rock, or a subterranean metallic stone, there will arise a splendid black. [Margin: Black. (*Nigrum.*)] If you add burnt silver with sulphur, you will make a Turquin blue [cæruleum Turquinum]. [Margin: Blue. (*Cæruleum.*)] If you cut copper into thin sheets and roast it for five days, and throw it into that smalt, you will make a green. [Margin: Green. (*Viride.*)] Burnt copper [Æs ustum] is tinged with a translucent emerald color. Sea-green [Cæsium], glaucous [glaucum], violet, ashen — these are made from that smalt, into which you have mingled a metallic stone tempered in various ways. [Margin: Sea-green. (*Cæsium.*) Violet. (*Violaceum.*)] If you put in niter or rock-salt, you will express the color of pearls. Red smalt holds the principality among the rest; [Margin: Red smalt. (*Smaltum Rubrum.*)] a thin gold-leaf [flavum bracteolatum] with silver added makes a straw-yellow [luteum paleatum], likewise a golden-yellow [luteum aureum], and a pomegranate-yellow [luteum mali punici]; but the citron-yellow [luteum citrinum] is made from the rust of anchors that the force of the sea has gnawed away, or from saffron of iron [crocus ferri], which you will distil from vinegar. Red smalt is the firmer, the gladder [in color], and the more whole, the longer it endures the fires.

You will make a red if you throw copper [æs] reduced to a calx, by the force of fire, into glass or white smalt, together with iron filings [ramentis ferri] and orpiment [auripigmento]. If you throw in more glass, you will make a more splendid rose smalt; [Margin: Rose smalt. (*Smaltum Roseum.*)] it is a diluted murex [purple], or a more diluted oyster-purple. If you put in more lead, beware of mixing in tin, for it will be of less splendor. You will make a clear red if you pour over the gold lead and quicksilver, likewise spirit of copper, and the incombustible sulphur of copper.

The tincture of that copper is so saturated and prominent that it increases and heightens the native color of gold. [Margin: Golden. (*Aureum.*)] But that heightened color is destroyed by a vehement fire. That heightening of color in gold is brought about by the volatile spirit of copper, which is cooked out together with the gold gradually in a little earthen cup — a little crucible of the metal-smelter [caliculus metallifusor]. Therefore, in order to heighten the color of gold, you mix some quicksilver

with the gold and the spirit of copper, because the quicksilver prevents the tincture and colors from being burned away, and it delays the force of the fire for that span of time in which the tincture and color sink intimately into the gold. Gold tinged in this way is laid, as it were, like gold-leaf beneath pyropi [fiery-red gems]: for gold which is tinged tawny, with the body of copper applied, is always blackening, livid, and withered; because the substance of copper, which of itself blackens, cannot be freed from its spots, whether you scrape it, or cook it, or wash it with gum and sandarac. But the gold which is tinged with the spirit of copper is the Orichalcum and electrum [amber-alloy] of the ancients, from which cups are made [Margin: True orichalcum or electrum. (*Verum aurichalcum sive electrum.*)] that betray and reveal poison, if any has been put in. This gold too, heightened with the spirit of copper, is converted into glass by the force of lead alone, and of no other metal, from which is made a clear red smalt or encaustic. Indeed, gold by the force of lead becomes volatile, or is changed into an oil, which is called the golden glass [vitrum aureum]: which St. John in the *Apocalypse* attests that the pavement of the Heavenly Jerusalem was, as it were, paved with glass tesserae (*Apocalypse* 21). St. Jerome holds that golden glass to be the electrum of Ezekiel, [Margin: The electrum of Ezekiel. (*Electrum Ezechielis.*)] called חשמל [Hebrew: ḥashmal, "electrum / amber"] by the Hebrews.

Not unlike this, in former times they cooked and embodied together rough and pure silver with copper and lead, so that a clear red might come into being, which they commonly called *Nellaram* [niello — *Nellara*], when the liquefied silver, thrown into water, broke up into grains. Smalt is laid on and burned in upon gold, silver, and copper, but not upon other metals; likewise upon glass and earthenware potsherds; indeed, an art has recently been discovered of burning smalt onto marbles and the hardest stones, in such a way that they are not damaged by the fire.

[Margin: The metals on which colors are burned in by smalt. (*Metalla quibus inurantur colores smaltei.*)] In order that you may burn in the metals, and out of the metals the colors, grind the smalt into a most minute powder in a very hard iron mortar with an iron pestle and a little water; for the business will succeed better with a mortar than if you were to grind it on a porphyry stone. The colors that are burned in from the metals are these: black, violet, green, ferruginous or chestnut, ashen, blue or glaucous, red, clear, yellow from gold — all of which colors are translucent and splendid, while white and the Turquin sea-green are opaque. When you have ground these metallic colors in the mortar with a little water, pour off whatever water there is, and lay that most fine powder in a glass pan, onto which you should pour only as much aqua fortis — which they make by

distilling from niter and vitriol over a fire — as will float over the powders and cover them. And so many times wash those powders, soaked in aqua fortis, with limpid spring water, until it draws off nothing of impurity, but comes out clean and clear. The aqua fortis purges the greasy metallic part; the limpid spring water washes and removes anything of earth that was mixed in. Smalt ground in limpid water is easily kept whole; out of the water it conceives impurities.

These powders are collected on a little copper tile, and are applied to a work of lower relief with great care and diligence, so that they may be kept separate one from another, lest by chance a confusion or disturbance of the powders or colors should occur. When they have been properly arranged, moisten ordinary paper with water, and press out the water between your hands, so that the paper may serve in place of a sponge, by which — the moisture being burned off — it may dry the smalt, which when dry is broader and brighter [hilarius] than when moist. That arrangement of the powders is commonly called the *prima pellis* [first skin]. Then the smalt, placed on an iron sheet, is little by little thrust into the furnace, where it blazes up until it begins to liquefy and stir; for then it must be drawn out of the furnace, so that it may cool. Soon a second and third arrangement of powders is added, and the work is committed to the furnace and to a vehement fire, until the smalt has been completely burned in with the colors. Then the work, drawn out of the furnace, is polished with a suitable stone, and is finished with Samian stone [samius lapis].

So that the prominence of any figure, or a swelling work, or [a relief] raised more or less into a boss, may be burned in with the encaustic, you will take seeds [pips] of a pear moistened with limpid water, and with them you will moisten the smalt, which, becoming viscous and as if smeared with glue, will easily adhere to the work; otherwise it would not adhere to a boss, or to projecting figures, or to a prominent shape — although smalt adheres with no trouble to the bottom of vessels and of works of lower relief. Clear red does not adhere except to gold. Opaque red can be properly set on silver and copper; the other encaustics or smalts can adhere to gold, silver, and copper. Then they are said to be glued onto the gold; the metallic pigment is burned into the gold; with the liquefying and colored metal the gold is painted, delineated, distinguished; the encaustic is smeared over the gold, overlaid: when the metal has been burned in upon the encaustic, the work is finished.

Into most encaustics or smalts there is mixed vitriol, minium, or earth of a leaden vein. Crocus of Mars [crocus Martis] or niter of iron, native or artificial scrapable

verdigris [æru^go rasilis], magnesia [manganese], and metallic rock, which is wont to grow beneath dry and lean fields.

From these things it is plain that a general mass is made from prepared crystal, [Margin: A general mass to be made for fashioning precious stones. (*Generalis massa ad lapides pretiosos fingendos fit ex crystallo.*)] purified to the utmost by salt of tartar, to which is added fixed alkali salt; and into a pounded mass of this kind colors are mixed, which the purer they are, the more excellent the glass becomes, and consequently, the finer the preparation and the more ingenious the cooking, the more outstanding the stone becomes. In a word, the whole hinge of gem-making turns on this: that you make, out of suitable metals and minerals, smalts or glassy colors, and liquefy them into a material which consists of one part prepared crystal and two parts fixed salt.

If you desire the making of sapphire, [Margin: The making of sapphire. (*Confectio Saphyri.*)] then take two-thirds of alkali salt, one-third of prepared crystal, half a drachm of *zaphara*; mix them, and skillfully cook them for three days in the glassmaker's furnace. If you ask what *zaphara* properly is, I say that it is that pale earth [lurum] from Saturnine magnesia [magnesia Saturnina], which they also call *bismuthum* [bismuth]; and this tinges the glassy mass with a blue color, which the potters too generally use;

Liber XII, Sectio V, Pars III — De Arte Vitriaria (continued)

Reading order: the four PDF pages are taken in printed-page sequence — 457, 458, 459, 460. Catchwords confirm: 457 "quia" → 458 opens "quia..."; 459 "factitias" → 460 opens "factitias...". [Margin: The practice of potters in vessels of a sky-blue tinging color.] of the potters. For [this earth], when it has been ground smooth on a porphyry stone and smeared, still raw, onto the fired vessels, tinges them with a subtle color — which nevertheless, by the force of the fire, soon turns to sky-blue in the firing.

[Margin: The making of emerald.] **Emerald is made thus.** Crystal is ground to a powder and melted in the glass-furnace; the mass that comes out of it is so like a native emerald that it even deceives experts — except that, when exposed to the sun, it appears leaden. It sometimes takes on a verdigris hue, but in the fire, because of the copper [aeris] in it, it gives off a flame.

[Margin: Another method for emerald.] **Emerald can also be made another way.** Take a third of red lead [minii], one ounce of prepared crystal, two drachmas of verdigris; mix and melt them together. For there is in copper [aeris] a wonderful and hidden power toward emerald, by which they readily unite.

[Margin: The making of topaz.] **Topaz is made** by melting together a quarter [ounce] of white lead [cerussae] and half an ounce of crystal in a wind-furnace — which they call the *anemia* [?] — inside a crucible reinforced with clay and sealed shut. By "white lead" [cerussa] nothing else is understood here than the calx of lead, which others also call Spanish white [album Hispanicum]. Some compound this [topaz] also from the calx of copper [aeris], native red lead [minio nativo], and crystal, with a quadruple [portion] of calx of Jupiter [calce Jovis = tin] added — though from these ingredients I judge that not so much a topaz as a chrysolite is made.

[Margin: The making of hyacinth.] **Hyacinth of a blue color is made** from prepared crystal and two ounces of white lead [cerussa], with 1/16 [part] of vitriol added. Giovanni Battista della Porta [Giambattista della Porta] proceeds thus in making hyacinth: he takes 3 parts of common salt and 1 of saltpeter [halonitri], mixes them, and throws [the mixture] into molten lead, stirring it with an iron spatula; and the ash that results, washed clean, he melts down into a gem. But if you wish to make this [gem] red instead of blue, take 4 parts of white flint [silicis albi], 2 of lead-ash or white lead [ceruffa], 4 of niter, and two drachmas of iron scales; cook them in the furnace, and you will have a red hyacinth.

[Margin: The making of ruby.] **Isaac the Hollander** [Isaac Hollandus], in his book *On Minerals*, together with **Paracelsus**, think they can make a most excellent ruby with the red tincture of the philosophers' stone. But just as that philosophers' stone has never yet been seen by anyone, so too no faith should be placed in [their claim] of making a ruby more excellent than all oriental rubies and carbuncles — but on this more fully in what follows. Now someone might find it astonishing that so great a diversity of colors should come from metallic calxes. But anyone who has rightly grasped what we set down in the Eighth and the Ninth Books cannot fail to see the origin of the colors. [Margin: Calxes of metals and the colors they impart.] The salt of the metals is the producer of all these. For the blue color is nothing other than the salt of silver, from which the precious stones descend; from the white lead [ceruffa] of tin and the red lead [minio] of lead, art and nature working together according to the differing grades of color, the same [stones] come into being. From the spirit of copper [aeris] is made a salt, and then an oil, which joined to gold constitutes the elixir for

[making] emerald. [Margin: Water suitable for forming gems and diamonds.] From the crocus of Mars [croco Martis = iron oxide] is made Mercury, that is, a water most powerful for [making] gems and most fit for forming diamonds.

There is almost no mineral or metal that cannot be forced into crystal; and the reason is ready to hand, since the solid subsistence of minerals and metals is nothing other than the saline power of Nature, which — just as it confers a condensing power on all things, as we showed in the Sixth Book — so too supplies firmness for taking on a settled form. This shines forth most of all in crystal and the other transparent gems, which are the pure, sheer effects of the differing salts; and experience confirms it in the Spagyric Art.

[Margin: How gold may be forced into crystals.]

1. **Gold can be forced into crystals** by sublimation and the violent driving-out of fire, in this way: let gold dissolved in aqua regia be distilled again and again, until it is fully dissolved; then, the water having been drawn off down to an oiliness, it is set aside in a cellar, where it at last passes into reddish crystals — reducible, however, back into gold, as we have taught elsewhere.

[Margin: Silver into crystals.] 2. **Silver is forced into crystals** if you dissolve it in aqua fortis; the clear solution, purified of its dregs, is distilled down to half; from this, little stones form in the cellar, which are then worked up either to make a medicine against epilepsy or to make a gem.

[Margin: Copper into crystals.] 3. **They gather crystals from copper** [aere] by dissolving copper in aqua fortis: burnt copper [aes ustum], red as blood, is taken; let the solution be made so that it digests for a month in a strong glass [vessel], until green crystals form, from which both a tincture of Venus is made and an oil is extracted. We, however, in our dispensary, reduce niter and vitriol — which we call liquid copper [aes liquidum] — into crystals with almost no trouble at all, by dissolving them either through distilled water or through spirit of wine and passing them through a strainer; for this, exposed to the sun in an earthenware crucible, blossoms out into fine hexagonal crystals.

[Margin: Iron, how it crystallizes.] 4. **Iron crystallizes** with red oil of vitriol [chalcanti] together with twice as much spring water; in this mixture filings of melted iron are dissolved; the solution, purified through a filter, is boiled down in a glass [vessel] to a remaining third part; this, then set aside in a cold place, separates out little stones, which are at last purified with distilled water and filtered, until, finally coagulated, they take on the most brilliant nature of crystal.

[Margin: Tin, how it crystallizes.] 5. **Tin crystallizes** if, with sulfur added, it is burnt to ash, that is, to a calx; or also if its white lead [cerussa] is extracted by means of distilled vinegar. The extract is dissolved in rainwater previously distilled; the filtered solution is coagulated in the very slow evaporation of a [water-]bath, and this operation must be repeated seven times, until at last there emerge little crystalline stones, pure and clear. They are called the Little Stones of Jupiter [Lapilli Jovis].

[Margin: Lead, how it crystallizes.] 6. **Lead is forced into crystals** in the same way as tin — namely, from white lead [cerussa] or red lead [minio], which is first dissolved in sweet [fresh] water; the dissolved [matter] is filtered and coagulated; and this you will repeat as many times as needed, until you find the purest crystalline little stones blossoming out.

In this way the Spagyrist force mercury, sulfur, and the rest of the minerals into crystals. But since these matters have been discussed elsewhere too, we have not wished to dwell on them here.

[Margin: The new and splendid making of tables [menfae].] To the glassy and smalt — or if you prefer, encaustic — arts can be reduced those tables now on view at Rome, admirable as much for their novelty as for their rare invention, which gleam with such great elegance and brilliance that one who does not know the craft would suppose them to be made from the most polished marbles, jaspers, alabasters, and other stones of great price. I will describe this truly most elegant craft in a few words. [Margin: Scagliola, the stone, the foundation of the table.] A certain kind of talc, which they call *scajola* [scagliola], they have brought — not without expense — from Sicily, where it occurs abundantly; though in Etruria too, between Monte Pulciano and Pienza, I have observed unmistakable signs of it. This scagliola they reduce to a very fine powder, and from it they make what they call a *paste*; then they make a table or panel of any shape from rough marble, which they also hollow out somewhat, and as a foundation they lay over the whole the paste-mass mixed with marble gypsum, worked up with linseed oil to a black or sooty color, and they then level and polish it so that it gives back [a reflection] like a mirror or a touchstone [lydium lapidem]. This done, they steep the separated masses of paste with every kind of color; then they sketch whatever they please on the now-leveled surface of the table — namely scenes, the figures and images of birds and animals, with various foliage wondrously interwoven among itself; and once the drawing of the subjects is complete, in keeping with the various shades of the images, they hollow [the surface] out with a fine graver, and, as the colors require, they level off the injected paste, polishing it with

pumice into a most splendid table or surface, shining like a mirror — which, for the splendor and apparent dignity of the work, they sell at a low price, say for 10, 15, or 20 scudi; whereas if it had been made by the inlaying of variegated marble, it would scarcely be paid for with 100, 200, or 300 scudi. So that it is the esteem of men alone that makes things dear.

[Margin: Florentine encaustic painting.] While I was staying at Florence in the year 1661, the Most Serene **Giovanni Carlo, Cardinal de' Medici** [Cardinal of the Holy Roman Church], out of his affection for me and my studies, brought me into his chamber, and after he had shown me the most beautiful and brilliant paintings with which the whole room was adorned, he asked what I supposed such paintings to be; and when I answered that they had doubtless been made by some most noble painter, he added: "You are mistaken, my Father; no brush has touched these paintings" — and when I marveled at this, he explained the whole [art of] painting and the method of proceeding in it, [a method] not at all of the same kind as they are accustomed to employ in making and elaborating the tables. And images and paintings of this sort are everlasting; and if at any time they are dimmed by dust or damp, they are restored to their former splendor by a simple washing with water alone. [Margin: The images of the domes of Saint Peter's.] Here too may be recalled the works of mosaic [Mufiva, seu Mufaica], such as the images of the domes [of the basilica] that are wrought of Saint Peter's; and they are not to be distinguished from the foregoing, except that the mosaic work, steeped in various colors and then cut into tesserae, is first baked in a furnace into an everlasting work of painting.

CAPUT IV.

De Gemmarum Adulteriis

[On the Counterfeiting of Gems,]

SEU

[OR]

On the faked composition of stones and gems, proven partly by my own experiment, partly by the authority of the most skilled writers and by the communication of friends.

In the preceding chapter I reviewed several methods by which one may imitate gems. It remains, in this chapter, to show in passing how this is done according to the mind of **Boetius** [Anselmus Boetius de Boodt], so that false [gems] may more easily be distinguished from true ones.

[Margin: How gems are made to appear larger than they really are.] Gems offer themselves to the sight as larger than they are when the lower part — that is, the part enclosed in the setting [cista] — is faceted [caelatur] with many surfaces [facets]. For by the manifold reflection of the surfaces, a certain appearance of magnitude is held out to the beholder. Likewise, when between the lower surface and the foil [bractea] placed beneath it there is an intervening air, empty of body, the gem appears larger than it is — because the air takes the place of body, and so makes the gem [appear] thicker than it is. [Margin: How gems are colored.] If, instead of air, glass or crystal is placed beneath, even without intervening glue or color, the gem is seen as much larger than it is. If color is added in the joining — with a tear of mastic [maftichis lachryma], or if the glass be colored with the gem's color — it appears not only larger but more highly colored; and this method is frequent and in common use. Gems are also rendered more highly colored when their lower surface is smeared with a transparent color and then a gleaming foil is placed beneath. A transparent color is made by adding mastic purified by fire. It is purified if a grain of mastic, sticking to an iron point, is held to the fire until it begins to flow and the opaque impurities are squeezed out by pressure of the fingers...

and discarded from the transparent part. The colors that are added are various, and such as the gem requires. In the individual chapters I will teach the true colors that belong to each gem; for here only the faking of gems in general is shown. I have said that the noblest fakery is when crystal, or a pseudo-diamond [pseudoadamas], or some other gem lacking color and transparent, is steeped in some colored water, or in fire, or tinged in some other way, so that the body of the gem inwardly takes on a transparent color. [Margin: The making of gem-penetrating water.] A water that penetrates gems is made from turpentine and aqua vitae, and to this is added a color extracted from metals and dissolved in distilled urine-water and drawn off through an alembic. Into this warm water a warm crystal is put and steeped for several hours, until it takes the tincture into itself. And it takes it readily, because the stone is made softer. [Margin: The inducing of a red color.] For inducing a red color one needs crocus of Mars [iron oxide]; for green, verdigris; for sky-blue, [salt of] silver [Lunà], sal ammoniac, and aqua fortis; for deep blue [cyaneum], verdigris and lapis lazuli. Now since, as I said, the gems are softened, they can be restored to their former hardness in this way. A case [cyst] is made from wheaten paste, into which crocus of Mars is thrust. [Margin: How a softened gem recovers its hardness.] Then one gem, or several, are wrapped in paper and laid upon the crocus, so that the gem is covered all around by the crocus by means of the paper. After that the paste is closed up and committed to the oven with the loaves [of bread], and after the

bread is taken out, what remains [in the oven] for six more hours recovers the former, or a greater, hardness than the gems had before.

[Margin: The whole [art of] tinging crystals in the fire, on the authority of Giambattista della Porta.] *Crystals are tinged in the fire (Giambattista della Porta being the author) in this manner: Six parts of antimony [stibii], four of orpiment [auripigmenti], three of arsenic crystalline [arsenici crystallini], two of sulfur, two of tutty [tutia] are taken; all are ground separately, and sifted through a fine sieve, and put into a pot. Pieces of crystal, suspended either on copper wires or sunk in the powders, are set to the fire so that they glow white-hot for four or five hours — but without the blast of bellows, lest they fly apart or melt. The proof of a legitimate color is, if the piece taken out is of the most flaming and most brilliant color; if less, it is to be put back into the fire again, and after some delay removed in the same way. But diligent care is to be taken that, while they are taken out, they not be chilled at once. For they crack and split into many pieces. If a hyacinth color is wanted, they are quickly taken from the fire; if a deep purple is desired, they are left longer in the fire.* Thus far della Porta. Colored gems such as sapphire, topaz, amethyst, and garnet [appear as] diamonds, if their color is taken away. [Margin: The making of diamond.] For this purpose sapphire is especially chosen, which — buried in iron filings or in chalk [cretà] — is heated until it makes the craftsman master of his wish, as I shall teach in its place. By the benefit of fire too, with della Porta teaching it, only one part of a gem can be deprived of its color, so that the gem may appear partly diamond and partly sapphire. In the same way

a ruby gives back the appearance of a diamond in one part. He says that the part whose proper color we wish to preserve should be smeared with chalk; thus the other part, which is exposed to the fire and naked receives the rays of the flame, admits a color and shows itself a diamond. Artificial [factitiae] gems sufficiently like true ones are made from crystal, topaz, flints, and other soft gems, or from a more noble glass, or from metallic bodies, or from a mixture of these. [Margin: The procedure of Alexius Pedemontanus.] **Alexius Pedemontanus** [Alessio Piemontese] describes the following paste for artificial gems: He takes three ounces of lead calcined by potters, and only so much of the aforesaid water poured over it that it stands above by one or two fingers, and he stirs it with a finger so that the lead settles to the bottom. After that he pours off the water and keeps it for the vitrifying vessel, lest the matter stick to the vessel. Then he takes three ounces of dry red lead [minii sicci], mixes it with the lead, adds one ounce of crystal or calcined chalcedony, and two or three scruples at most of the thinnest little leaves of copper. These well mixed and ground, he puts into a well-

leaded and moistened clay pot, and committed thus sealed up to the glass-furnace or to the winds [furno... aut ventis] for a day, and so the best paste is obtained.

For counterfeiting emeralds he takes alkali salt, which he dissolves in water, filters, and lets dry out, and repeats this operation a third time; afterward he reduces it to a fine powder, just as also the crystal. Then he takes two and a half ounces of crystal, two ounces of alkali salt, one ounce of verdigris steeped in vinegar and strained; he mixes [them], and puts [the mixture] into a leaded little vessel, and seals it well with clay so that nothing escapes, and lets it dry out for three days, or longer, and finally commits it to the potter's furnace for a day. If he wants a ruby, [he adds] cinnabar in place of verdigris; if a sapphire, lapis lazuli; if a hyacinth, he adds coral. [Margin: How crystal is calcined.] **Alexius** calcines crystal or chalcedony in this way: one ounce of calcined tartar is dissolved and strained in one ounce of clear water; the crystal, however, and the chalcedony are heated red-hot in an iron spoon and quenched in the aforesaid water, and this operation is repeated seven times; calcined in this way it is best ground into powder and added to the mixture or paste. If an emerald is wanted, [the calcination is done] in a bronze mortar; if a ruby, [it is] to be pounded in an iron one. But because artificial gems are rendered softer than crystal on account of the additions of other matter, **Alexius** teaches a water by whose benefit they are hardened. [Margin: The hardening by means of water, prepared in a certain way.] He therefore directs one to take pieces of magnet [magnetis], and to calcine them as was said of crystal, and then to grind them into powder, to set them in a damp place so that they dissolve into water; this water he wishes to be nourished with Roman or Hungarian vitriol, crude, like a pap [pulse]; then from it he prescribes that a water be distilled off through a retort, so that barley flour may be moistened with it, and a hard paste made, into which the shaped stones are put. For if it is baked with the bread, left in the oven, and taken out with the bread, he says they acquire the greatest hardness...

artificial gems, exceedingly elegant and very like the natural ones. He affirmed to me that he had made them in no other way than the aforesaid. The said work seems neither costly nor of great labor, yet it has not so far been tested by me.

[Margin: Which colors express which gems.] The nobler paste for artificial gems, on della Porta's testimony, is that which is made from crystals, flints, or Bohemian topaz; for if glass or lead is added, they become heavier and softer. Flints and topaz, however, are calcined like crystal. Then the color that is wanted is added. Red lead [minium] and green of copper [verdigris] give the color of emerald; white lead [ceruffa] and crocus of Mars [give the color] of hyacinth; red

lead [minium] and white lead, of chrysolite; *zaphara* or lapis lazuli, likewise sal ammoniac and silver, exhibit the color of sapphire. Gold is said by some to impart the color of ruby to crystal. Tin is said to show the watery sheen [aquas] of a diamond. Those curious about these matters will discover, in the work itself, various colors from various mixtures of metals. The less noble paste for gems is [made] if glass is added to crystals or flints. Giovanni Battista della Porta, in his *Natural Magic* [*Mag. Nat.*], teaches various methods by which artificial gems may be prepared, to whom I refer the reader. The things that here seem to be wanting from me are treated in the individual chapters on the gems, where the fakeries or imitations of the gems are also shown. Here nothing else seems to remain except that, if anyone wishes to feign gems, he be taught to govern the paste with an even fire, lest with an uneven [fire] they betray the fakery by bubbles or by a smoky tint [atromo (recte: atro) fuco]; and then that the material of the paste be exactly cleaned, and washed of its filth after calcination, lest the gems have faked flaws. These things indeed a diligent craftsman, if he is careful, will easily observe without any further admonition.

[Margin: Foils.] **A note on foils or little leaves [Bracteis seu Foliolis], which are placed beneath gems to increase their splendor, from Boetius, book *On Stones*.**

This practice concerns only transparent gems, which indeed cannot shine unless they have beneath them something that reflects the light, like a mirror. To this end foils or metallic leaves have been devised, which not only do this but also wonderfully enhance the color of gems; and they are tinged with various colors at will, so that in this way gems that were before as if dead and of a dilute color may appear more vivid and more highly colored. Foils are beaten with a hammer from copper alone, or from copper, gold, and silver, to the likeness of the thinnest paper; then they are polished with the finest chalk or with Tripoli clay [argilla Tripolitana], and smoothed with emery stone [smiride lapide] until the marks of the stone no longer appear on the foils. With the foils prepared, a double furnace is built, an upper and a lower; in the topmost part of each there is an opening; in the lower furnace coals are kindled, and from all [sides]...

[Margin: Birds' feathers, by which [colors] are tinged.] burnt beforehand. Green feathers of birds dyed into a hyacinth color tinge [the foils], if they are burnt in the furnace [recte: the foliage burnt in the furnace tinges them — see parsing note]. If other colors are desired, it is done with birds' feathers: for green is had from green, sky-blue from sky-blue, red from red, and yellow from a yellow-colored feather, if the foil is scorched in the furnace, they will tinge [it]. The color

of sapphire [is had] from the sky-blue feathers of geese; the color of emerald, from box-tree leaves and from the flocks of scarlet cloth.

In Bohemia, where there is a great supply of topazes, pseudo-diamonds, and beryls — of a color, however, deficient — by the mere placing of a gold or silver foil beneath, they transmute [these stones] into the appearance of various gems. [Margin: A foil of various color placed beneath exhibits various gems.] For if you place a gold foil, or one imbued with gold — that is, of a *lacca* color, that is, of a red color shining through from the gold — beneath a topaz first fashioned into a polyhedral shape, that [foil] will display to you a ruby of most beautiful color. If you have imbued a silver [foil] with green so that it shines through from the silver ground, it will display to you an emerald of the most pleasing color; thus too a foil placed beneath [a stone] will display a sapphire shining through from sky-blue. In this way, according to the condition of the colored foil, they express amethysts, hyacinths, chrysolites, and other most beautiful gems — even in a single crystal or the most brilliant beryl. In round crystals of this kind the thing does not have the same success, for the fakery readily appears, the colored foil revealing itself to the eyes; but only in many-sided ones [does it succeed], because the colors, variously reflected around the angles, cover the little foil with their varied shadowing. But let us now proceed to describe another method of making faked gems.

PROPOSITIO I.

Rubini confictio.

[The faking of ruby.]

A ruby is usually adulterated or faked in three ways. First, when — if it is without any redness, or with little, as we said a little before — a red foil, or color, or some glass tinged with a red color and gleaming, is laid beneath it. This method is by some thought to be free of fraud, because, namely, the true gem appears [merely] assisted, not by its own color. Nevertheless it is fraud to increase the price of a gem by an alien color. [Margin: The impostures of gem-dealers.] On account of this imposture a certain gem-dealer suffered loss of reputation when he tried to deceive the Emperor **Rudolph** [Rudolf II]. Secondly, when another noble whitish gem — such as a white sapphire, crystal, topaz, or pseudo-diamond — is substituted in its place, and, on account of the color, the foil, or some other transparent body laid beneath, so reddens and radiates that it differs in nothing from a true ruby. Thirdly, when two parts of glass are glued together with mastic in such a way that the mastic, tinged with the color of scarlet [cocci], shines

through both bodies of glass, so that it appears a true ruby. The second of these methods [was used] to deceive the Emperor Rudolph [Radolphum (recte: Rudolphum) Imperatorem]...

the second and third are the most commonly used. Yet they are not so very hard to detect. Stones faked by the first method are recognized because they do not sparkle precisely, will not stand up to the file, and yet in color appear more beautiful than the true ones. [Margin: Detection of the fraud.] Some are accustomed to detect this fraud exactly: for if the stone lacks a red color, and the flat face of the gem is placed over the fingernail, and the eye is directed toward the surface of the gem and the nail, a whiteness without any color will appear. Nevertheless, the lower-grade gem-cutters know how to carve the surfaces of the gem so artfully at various angles that, because the light is reflected in every direction by the manifold surfaces, the fraud cannot always become apparent even to a skilled craftsman. On account of these frauds, rubies in this age are not made to be worth as much as they once were.

Some counterfeit the ruby with orpiment [auripigmentum], which they cook down in a vessel that is not perfectly sealed, over a slow fire; and the fragments of glass that stick to the sides — though quite brittle — they apply to wax figures, so that they may serve as rubies, which they reproduce exactly.

PROPOSITIO II.

The making of pearls. [Margaritarum confectio.]

Pearls are held in such high price for scarcely any other reason than that they cannot easily be counterfeited. Gold is most easily adulterated. Gems fashioned from doubled glass and set in gold so deceive the eyes that even skilled gem-cutters cannot tell them from the genuine unless they remove them. [Margin: Pearls hard to adulterate.] A pearl alone can neither be corrected nor made more elegant by foreign coloring. Yet Linschotanus [Jan Huyghen van Linschoten] reports that, to make pearls beautiful, the Indians pound rice together with salt and rub the pearls vigorously with that mixture; in this way they become as beautiful as crystal and do not lose their luster. It is no wonder, then, that chains of pearls are preferred to gold ones by great ladies and noblewomen, and that they display their wealth better by them than by gems or anything else that is liable to adulteration or coloring.

Various authors hand down methods for how false pearls may be made. [Margin: The making of imitation pearls.] Some form little beads from the powder of

shells, others from chalk; these they afterward coat with silver leaf, then moisten with egg white and let dry, so that they may look like pearls. Others there are who compound them from powdered pearl with egg white, and then dry them; but the trick is easily detected by their weight and color. Giovanni Battista Porta [Giambattista della Porta] describes this method: *Let pearls be placed in a little bag together with powder of pumice and bone, and let them be handled by hand in water, until you find them washed and polished; then, dried, reduce them to fine flour. Let them be dissolved in lemon juice, and let them stand until you find them dissolved, and you see a certain greasy substance like oil floating on the surface of the liquid; take this up with a silver spoon. Afterward form the powder into beads, by hand or in molds; pierce the pearls with a silver stylus and a pig's bristle, anoint them with oil, and, hanging on a thread, enclose them in glass and expose them to the sun. When you see them dried,*

wrap them in barley leaven that is neither salted nor sour, and let them be baked in an oven, or give them to pigeons to swallow, or [steep them] in the milk of the wild fig, and you will have excellent ones. If you prefer otherwise, once the pearls have been dissolved with a coloring agent or with aqua fortis, you will wash them in clear or distilled water; and with your hands washed — so that they do not become dirty and pale in the handling — thus [bind them] with the dried milky juice of the fig, in a hot bath of distilled spoonful-water; or you will glue them with egg white, pierce and dry them, always washing and mixing with silver-water. You will prepare the silver-water thus: let the purged silver, dissolved in aqua fortis, settle; let the water evaporate over gentle coals, leaving a third part; then, the vessel drawn from the fire, set it aside, and leave it in the open air at night until it freezes, and you will find the silver in the form of a little crystalline stone. You will wash it with spring water, so that they may be seen brighter; you will store them in a glass and earthen vessel, and let it dissolve in rotten dung, in which you will allow the artificial pearls to steep and linger, and you will find them bright and of a translucent silver color. Thus far Porta — where many points occur that might be marked with asterisks. For these methods of coloring, even if they are not altogether displeasing, nonetheless are not entirely satisfactory, because from the powder of dissolved pearls a body can never be made so solid and heavy as it was before; nor do I see why he directs that they first be devoured by pigeons. But let us leave everyone to abound in his own opinion, and return to our own matters. I have observed another method, which imitates Nature exactly, and likewise a method by which pearls can be enlarged; but these, as secrets, I have deliberately decided to reserve for another place.

PROPOSITIO III.

The making of the sapphire. [Saphyri confectio.]

The sapphire is commonly counterfeited splendidly with blue glass cemented between two Bohemian diamonds [i.e. rock crystals]. Others melt a blue mass from glass in the fire, have it polished and hardened, and sell it to the inexpert as sapphire. This craft is commonly carried out by various methods. Most often, into a glass mass prepared from crystal or flints a portion of zaffer [zaphara, cobalt oxide] is thrown — namely two drachms to one pound — and the mass, glowing in the fire, is stirred as well as possible with an iron hook. Then a small piece is taken out and tested, to see whether more zaffer or more of the mass should be added; if it appears in the proper measure, it is allowed to bubble for six hours; afterward it is taken out, and the mass, resembling sapphire, is handed over to a skilled engraver to be carved and polished. If the mass has been made properly, the false sapphire can scarcely be distinguished from the true. Those that are fictitious usually have little bubbles or specks in their body, which arise because the fire does not act evenly upon the mass. So says Boethius [Anselmus Boetius de Boodt].

PROPOSITIO IV.

The imitation of the opal. [Opali imitatio.]

The opal cannot be adulterated with doubled glass, or with coloring, as the other gems can. Yet Porta writes

that calx of tin thrown into glowing crystalline glass clouds and colors it like an opal. But one must repeatedly take it out of the fire and adjust it, until one obtains what one wishes. Quercetanus [Joseph du Chesne] asserts that a glass alembic is tinted on the inside with various colors by the spirit of niter, so that it looks like an opal. Whoever wishes to know the method of tinting, let him read the little book that he published on the true medicine of the ancient Philosophers.

PROPOSITIO V.

The composition of the emerald. [Smaragdi compositio.]

Emeralds can be adulterated by almost every method. The nobler method is made with crystal, glass, and calcined and fused flints, if a small quantity of red lead [minium] is added to them: thus I have seen excellent ones made. Others add burnt copper [aes ustum] reduced to a very fine flour, with half its weight of

saffron-of-iron [crocus ferri] added; and they cook it for the space of six hours, then let the vessel cool by itself, and commit the gem to polishing. If one has worked exactly, he will make emeralds altogether like the American ones.

How an emerald may be made. Another way, from Cardano. [Smaragdus quomodò fiat. Aliter ex Cardano.]

With greater effort an emerald is made. Crystal is ground very finely; *marcia cocta* [Margin: *Marcia cocta* — material of potters for coloring vessels] and the most splendid verdigris, or worm-shaped verdigris, is added; a raw brick is dug out; these three are put in, and it is baked in a brick-kiln among other [bricks], with a marker added — that is, a lump similar to emerald is extracted, which is cut out and polished. It is glass, indeed, but so elegant that — had not those who first discovered it (for this is a new discovery, of about ten years ago) wished to grow rich too quickly with large pieces, and thereby cast suspicion by their abundance and size — the fraud might even now lie hidden, to the great and incredible profit of the discoverers, though they have not been without profit. I have seen ones so beautiful that, set in gold, they surpassed the native stones in splendor. It succeeds best if they are entirely free of bubbles: for bubbles declare it to be glass and make it a base stone; yet it is touched by the file, for it is glass. For every gem passes into glass with the smell of lead, but especially when it has been reduced to a fine powder.

How a sapphire may be turned into a diamond. [Saphyrus in adamantem quomodò verti possit.]

The third method of adulterating gems is far nobler and less condemned, art striving with nature. A gem is changed into a gem by the power of fire. A bright sapphire, but otherwise of dilute color, is joined with gold and gradually set to the fire until it melts; let the gold boil for three or four hours; then the gem is lifted out and allowed to cool gradually [Margin: The making of a diamond], and you will find a diamond: for the gem remains, nor is it touched by the file, but whatever is

of blue color perishes. [Margin:...tum ex Saphyris (i.e. "...is made from sapphires").] Therefore we seek out sapphires of the most dilute color: for they are cheaper, and pass over into diamond more quickly and are transformed more perfectly. He who first discovered this grew very rich, and in a short time; afterward, the matter being uncovered, profit was still left to the art: for it shines very brightly because of the sapphire's hardness. There are some who make beautiful diamonds from aquamarine, a cheaper and softer gem. There are some

who do not bake the sapphire in gold, but only the sapphire wrapped in chalk in the fire, and it succeeds in the same way. It must be observed, however, that the fire be gradually surrounded around the cold gem, and again that, the work finished, it be allowed to cool by the extinguishing of the fire; for it is not safe to draw it out of the fire. It is a flaw if any trace of blue color remains.

PROPOSITIO VI.

The composition of the topaz. [Topazii compositio.]

Topazes of golden color, on account of their elegance, are adulterated by all the methods by which the other gems are usually adulterated. The more excellent method is when in crystal, flints, and fused glass a golden color is brought about; this is done if to each pound of glass is mixed a quarter of an ounce of saffron-of-iron [crocus ferri], and a tiny bit of red lead [minium] is added — but the red lead is to be added first, the saffron after, as Battista della Porta attests. [Margin: The various methods of making topazes.] If three times its weight of lead is added to calcined crystal, the topaz emerges without any further addition, if it remains in the furnace for a day. You will make it another way thus: make a flour from burnt copper [aes ustum], native cinnabar, and crystal, and add four times as much burnt tin; put it into a casting-vessel of the strongest clay, and commit it to the furnace for a day; but let the fire not be violent, and let it always remain at the same degree, for the aforesaid powder flows easily.

PROPOSITIO VII.

The composition of the beryl. [Berylli compositio.]

Beryls are of no greater authority than Oriental topazes, once called chrysolites: accordingly they can be valued at the same price. Yet according to the elegance of the color the price is increased or diminished — and this is to be observed in all gems. [Margin: The making of the beryl.] The beryl is adulterated by those methods by which all other gems are. The nobler method is when burnt copper [aes ustum] is reduced to a very fine flour, so that it escapes all touch, and is mixed with crystalline glass or calcined crystal with that glass added, and is committed to the furnace; one drachm of copper per pound of glass mass suffices.

PROPOSITIO VIII.

The composition of crystal. [Crystalli compositio.]

Crystal is of use not only for women's adornment — when chains, beads, and other such things are made from it — but also for mirrors, eyeglasses, cups, goblets, plates, basins, and the like.

For when it is free of flaw, such cups or goblets are sought after by princes and are held at a fairly high price. Indeed, a golden goblet the size of a foot can sometimes be sold for a hundred crowns [scuta], and occasionally even for more. Small pieces of crystal, from which beads or little crowns are made, are cheap, and do not exceed the price of the engraving. From crystal too, with glass added, and the purest sand and the most noble alkali salt, glassware very like true crystal is made at Venice. Crystal also serves for imitating gems: when, calcined, it is mixed with three parts of lead; to this metallic substances are commonly added, so that the desired color — of emerald, topaz, or some other gem — may come forth. [Margin: False diamond from crystal.] By means of crystal, the fire and rays of the sun are also commonly gathered: namely when a round, slightly convex surface is set opposite the sun in such a way that the body which is to receive the fire is placed around the center of the convexity. In softer and more delicate bodies it also takes the place of the iron cautery, although I judge that it burns and pains no less than iron. It is adulterated with crystalline glass, which is very like it — but it is softer and heavier than crystal. False diamonds [pseudo-adamantes], when they are skillfully engraved, are even set in gold; and when they are small, they so rival true ones that they cannot be told apart except by experts. Hence it comes about that among the Bohemians, Hungarians, and Muscovites they hold no small authority; yet they are not sold at more than the price of the engraving, unless they are hard and sparkle splendidly. The same reckoning holds for citrines and iris-stones, all of which are worth no more, above the price of the engraving, than the buyer wishes: for they are had in fairly large supply, and large pieces the size of a fist, not yet worked and entirely transparent, are sold for only one or two crowns. Worked and fitted into goblets, and left to the seller's discretion and the buyer's fancy, they are often sold for a fairly large price.

PROPOSITIO IX.

The composition of the chalcedony. [Calcedonii compositio.]

The chalcedony is commended against all symptoms of black bile — that is, sadness, fear, and the assaults of demons. Nor are there lacking vain authors who promise victory (which is given only by GOD) to the one wearing it. From the West Indies some are brought that are moderately translucent, paling from white; some are marked with milky bands, which they proclaim, when hung on, to avail for abundance of milk. Today, on account of its abundance, it is not held of much value; yet if larger pieces are splendidly carved, and a notable color is not lacking, they can sometimes be sold for a great price, and at not much cheaper a price than sardonyx. The chalcedony scarcely deserves adulteration; nevertheless you will imitate it thus: you will put crystal into the fire to be melted down, mix in a little silver-calc, let it remain in the furnace for a day, and you will have what you sought.

PROPOSITIO X.

The composition of the onyx, or false onyx. [Onychis compositio, seu Pseudonyx.]

The simpler onyx is scarcely ever imitated by anyone. But that one which has a white body distinguished from a black one is imitated very often — namely so that, engraved, it may afterward be sold as a cameo. It is made in this way: [Margin: The method of making false onyx.] little shells of the sea, which Italian women use for rouge, are reduced to fine flour and placed in lemon juice that has been several times purified through a filter — yet so that the juice floats three or four fingers above; let it be left thus for ten days, the juice well covered, in warmth; afterward pour off the juice, wash away the residue with water, and grind it on a porphyry slab with egg white that has first been very well beaten, and cast it into molds. Afterward polish the outer formed part very well, so that it may be set very well and skillfully upon a black underlayer, and the fraud may not easily become apparent to just anyone. During the grinding, other well-ground colors can be added, so that sardonyx too can be feigned in this way, and no less the other gems or other precious stones.

PROPOSITIO XI.

The imitation of the turquoise. [Turcoidis imitatio.]

The Venetian glassmakers imitate the turquoise excellently at Venice. I saw a Frenchman who could imitate it so skillfully, from another material, that it could not be distinguished from a true gem because of the black little veins which he inserted into it. He sold them as imitations, and at a fairly large price, because of their elegance. I think he used native chrysocola and a petrifying water, with a few other things added. To recover a lost color, some dissolve the transmarine color [ultramarine] in aqua chrysulca [aqua regia]; and, that distillation having been drawn off, they dry the surviving remains, and rub the turquoise with them. Others place [the turquoise] in aqua chrysulca, and, wiped off, commit it a little to vinegar, then plunge it into the coldest water — for then it becomes more colored. But by these arts the color is gradually drawn inward into the skin, vanishes, and the gem is rendered more unpleasing and baser. It is more correctly done when the upper skin is eaten away with oil of vitriol, so that the underlying color makes the gem more elegant.

Cardano, fol. 290, in his book *De Subtilitate*, writes thus about the imitation of agate: [Margin: The description of agates.] *To all gems is set, as a single one, the agate stone; it too is in the number of the gems, but of so varied a kind that you would not believe it to be a single stone. White, red, saffron-colored, ash-gray, green, black, variegated, blue — why do I delay? To this one stone alone the colors of all the other gems do not suffice. It represents groves, meadows, animals, rivers, flowers, trees, with Nature at play. Most famous in the histories is the agate of King Pyrrhus, representing the nine Muses with Apollo striking the cithara in the midst, and each one with her own ornaments, so that it might seem*

then that Nature had contended with the painter; and this ought rather to be called a miracle than a gem. We have two agates, in one of which Nature has painted a hemisphere of the sky, with distinct orbs, and in the middle a round earth as if rising above water. In the other a chasm of the earth seems to emit smoke, which darkens the air. Moreover, what is worthy of admiration is that the color of the smoke is one thing, that of the air another, which is obscured by it: for the smoke is white as though dense, the air somewhat reddish and moderately transparent. Other agates also represent the eyes of birds — and we have such a one — others those of fishes. The Pontic agate, which is interspersed with bloody or black drops, represents the images of mountains and valleys. Some are called leucophthalmi [representing] human eyes, lycophthalmi [representing the eyes] of a wolf,

aegophthalmi [representing the eyes] of a goat. I have also seen a green transparent one most beautifully distinguished by two white lines, which I would doubtless believe to be of [its own] nature. For just as among animals the mule [is born] from an ass and a mare, and the lycisca from a wolf and a dog, so too stones are sometimes mixed from a varied kind, their material mixed together with the causes producing them.

Moreover, as for the agate of King Pyrrhus, I think it too ridiculous that it should by chance have been so exactly adorned and distinguished. This therefore happened thus. A painter painted some stone of the marble kind with strong colors, so that the nine Muses might admire Apollo playing in the midst; then, whether by chance or by design, that stone lay buried for many years, in that place where agate-stones are wont to be produced. It happened therefore that all around there was produced a transparent and watery agate, and the [stone] thus found represented the Muses and Apollo, as though fashioned by the industry of Nature, since the agate was now a gem. For if pitch and moss clinging to trees pass into agate in the course of time — as I have had an agate with five ears of grain, which you would say had just fallen from the wheat, and yet they were stone, indeed gem — and so too no small part of the moss was present, how much more easily could that painted soft stone have passed into agate. Therefore if someone should observe the places of agates, and especially where the transparent ones are generated (for this is necessary), let him bury a true painting made of perpetual colors — such as blue and golden and those consisting of metal — and especially if he should smear the work with Punic wax tempered with a little oil, or with some other perpetual but transparent unguent, such as is that which among us is called liquid varnish [vernix], which is wont to be laid over more precious finished paintings; the agate will be born thus painted.

But you will say, this painted agate would be frequent, if it could be prepared by so small an art. But you do not notice that first it must be buried where agates are produced; then that the agate which forms around must be splendid and transparent; then that within a few years it must pass into a gem before the painting perishes, nor be first washed out by any external moisture, nor the image obliterated; and finally it must happen that it be dug up finished. For how many fishes are there that no one ever fishes, and wild beasts in the woods, and birds that no one ever catches, but which perish of their own accord in their proper places — just so many

gems are reckoned to be, which, lying hidden in the places where they are produced, never come forth into the light, but, just as they had coalesced into their first

mother the earth, so by age they return again into the same. And although the agate is noble in its variety, yet because it shines little, it rarely has a great price among the gems. Thus far Cardano — things which do not differ from what we ourselves set forth in Book VIII, On the generation of figures born in stones, to which we refer the Reader.

PROPOSITIO XII.

The separation of gold from lapis [lazuli]. [Auri à Lazulo separatio.]

How gold is to be separated from lapis lazuli, after it has been ground. [*Quo pacto aurum ex lapide Lazuli, postquam tritus fuerit, separandum sit.*]

To a pound of the stone now ground on the porphyry slab, mix an ounce of purified mercury, and mix well in a mortar; then press it out through a linen cloth, and the mercury will draw out the gold together [with it] through the cloth. Afterward put the pressed-out material into a crucible and commit it to the fire, and thus the mercury will fly off into the air, and what will remain in the crucible will be pure gold. If the joined color is left in the fire, it renders it more splendid, softer, and easier for guiding and spreading with the brush.

PROPOSITIO XIII.

The use of the color for paintings. [Usus coloris ad picturas.]

On account of the immense price of the ultramarine color, painters are not accustomed to use it as [they do] other colors; rather, they paint the images which they want blue with common blue prepared from Armenian stone [Armenium], or from glass of that color, which they call smalt [smaltum]; then the parts in which the light rests with white lead [cerussa]; afterward with those colors, as the matter requires, properly applied and very well dried, they smear over that whole blue painting with ultramarine color moistened with nut oil and spirit of turpentine, as though with a varnish or some very thin coating. In this way, through the overlaid color, as through ice or glass, the underlying [parts] shine forth, having obtained from the covering not only a more excellent beauty but also permanence — so that not even in two hundred years does the least bit of light or of beauty depart; nor is it any wonder, since the color which the fire could not consume, much less can the air or the sun eat away. So says Boethius [Anselmus Boetius de Boodt].

PROPOSITIO XIV.

The ultramarine color of lapis. [Color ultramarinus Lazuli.]

How the ultramarine color may be separated from the stone in another and quicker way. [*Quo pacto ultramarinus color alio modo, et brevius à Lapide separetur.*]

Take a pound of the stone reduced to a very fine powder, and ground with clear water on the porphyry slab, and put it into a glazed dish, until the powder dries in the shade; which again, if it has coalesced into a mass, [you will] re-[duce] into powder...

Reading order used: The four un in natural sequence by printed page number — = printed p. 465, = printed p. 466, = printed p. 467, = printed p. 468. The text is continuous across all four (catchwords confirm: 465→466 "dien-/dienfis"; 466→467 "aptiuf-/aptiufque"; 467→468 "& far-/& farmentis"). The translation follows this order.

you will reduce it. Then have ready at hand: of Greek pitch [picis graecae], 3 oz.; of pine resin [resinae pini], 4 oz.; of mastic [mastiches], 3 oz.; of frankincense [thuris], 3 oz.; of olive oil [olivarum], 2 oz. Set a glass dish over a slow fire, and first put in the oil; when it is thoroughly hot, add the resin, then the pitch, then the frankincense, and last of all the mastic, stirring well all the while. Then pour it into another little dish and let it boil a little. Once this is done, have ready another small vessel into which you have put the dry powder of the stone; pour the said ointment over it, stirring gently with a flat tool, so that a good mixture is formed. Then leave the mixture for a day. When you wish to draw off the color, pour the paste onto boiling water and stir and agitate the material well; as the water begins to cool, throw it out and pour on more hot water. Do this until the water draws off the color, and repeat as many times as needed until you have extracted all the color. You can keep the separate extractions apart, so as to have the colors distinct.

If the color appears to have picked up some filth, you will restore it as follows: just add tartar-water [aqua tartari] to the color until it is covered by the water; let it stand for a day; afterward wash the color with clear water, and you will have it cleaned.

You will prepare the stone for the said work in this way: when you have broken it into fragments, put it in a vessel and roast it, then wash it with vinegar; thus the best part will remain — the part that resists fire.

Various Artifices of Tinctures of Every Kind

[*Artificia varia Tincturarum omnis generis*]

I shall add in this place certain fine recipes [Greek: ἐγχειρήσεις (encheirēseis, "manipulations" or "procedures")] by which tinctures can be made with little trouble that are not at all unlike Ruby, Emerald, and Sapphire and the rest. These were communicated to me — out of his singular affection for me — by the most excellent Lord Martinus Bernardus [Martin Bernard], Doctor of both branches of Medicine and chief physician [Archiater] to the Most Serene King of Poland; and he carried out the experiment in my presence in our pharmacy.

EXPERIMENT I.

A red tincture resembling a shining carbuncle.

Take gum lac [gummi laccae]; once it is dissolved in clear water, you will add to it a little alum — commonly called *Rocca* [alum of Rocca]. Then put the whole mixture into a glass bladder, which the chemists call a *Matracium* [matrass]; place this on hot ashes, and it will turn an intense red like a ruby. If you then pour in a little oil of tartar [oleum tartari], you will obtain the color commonly called *incarnatinum* [flesh-pink]. And you will obtain a most excellent dentifrice if you dilute the gum lac with sage- or rosemary-water and extract the tincture.

EXPERIMENT II.

A tincture resembling an emerald color.

Take a portion of violet syrup [syrupi violacei] in a phial; pour clear water over it, and add to this a few drops of oil of tartar. Once the precipitation is complete, you will have a tincture very much like the color of an emerald — that is, green.

EXPERIMENT III.

To make a tincture similar to a sapphire color.

Take quicklime [calx viva] in a copper vessel, diluted in clear water; add to it a little sal ammoniac [sal ammoniacum]. When you have let it settle for about 12 hours, you will at last find that the whole liquid has changed into a sapphire blue color [colorem caeruleum], not unlike ultramarine. And so that these colors may become more brilliant, the colors or tinctures must first be strained through diaphoretic paper [charta diaphoretica]. Their use is particularly fine in the construction of thermoscopes [thermoscopia].

EXPERIMENT IV.

A most rare secret in which a method of preparing writing-gold is handed down.

Many marvel at that excellent method of writing in gold that the ancients commonly used, and they cannot grasp its technique. Hence many think the art is, as it were, lost, and as difficult to discover as it was. We have thought it right to make known here, for the public good, the method which the above-praised most excellent Doctor Martinus Bernardus [Martin Bernard] taught us. One proceeds as follows: Dissolve gum arabic [gummi arabicum] in a little vessel until it reaches a thick consistency like porridge; then strain it through a very clean linen cloth. Of this gum, take a portion the size of a hazelnut and place it in a very clean earthenware bowl (of the kind they use everywhere here in Rome at table). Then take gold leaf [aurum foliatum] — the more, the better — mixed with the gum, and grind it with your fingers for as long as it takes until the whole gum is intimately blended. For the better the gold is worked into the gum, the better the result will be: keep at it with your fingers, pouring in lukewarm water as you go. When this is done, then again pour hot water over it and leave it for 12 hours, until — the poured water being drawn off by tilting — fresh lukewarm water is poured on; and when you have done this several times, then you will leave it until the dregs have settled, which are the material suitable for writing in gold. These, then, distributed drop by drop into shells, will give you the writing-gold so long sought after. If you wish to use it, add one drop or another from water of white glue [aqua glutinis candidi] (of the better sort, such as is prepared in Germany) for thinning, and put it to use. A truly most excellent secret, and tested in my presence.

I could add in this place, by way of a finishing touch [ad coronidem], the method and procedure for making the true and genuine Chinese varnish [Chinica vernix]; but because the description is too long for the page to admit, we have reserved it to be communicated, perhaps more fittingly, in another place, dear curious Reader. This was communicated to me by the Reverend Father Eustathius Iamar [Eustachius Jamar], of Liège,

[Printed p. 466]

PROPOSITION XV.

How artificial stones, and huge masses of rock for columns and other monuments, may be made.

There is a great dispute among the Authors as to whether artificial stones can be made by casting [per fusionem]. Some think that the columns and obelisks brought to Rome from Egypt are nothing but fusible stones melted down and cast in suitable molds into so great a mass. But we have refuted this fable most fully in our *Oedipus* [*Oedipus Aegyptiacus*] and *Obeliscus Pamphilius*; for they were fashioned out of living rock, of the kind whose quarries are still to be seen in Upper Thebaid. Yet I do not deny that there is a certain method and a definite mixture of materials that can be cast into stones; indeed, I recall having seen the practice of it among the more skilled workers of marble and the stonemasons. Moreover, that the mosaic or *musive* tesserae of the ancients were nothing but a fusible paste cut into triangles, squares, and similar polygonal figures, even mosaic-work [Greek: λιθόλεμμα (litholemma, "stone-flake / stone-inlay")] itself plainly teaches; and lest anyone be able to doubt the matter, we shall teach it by experiment. For not only are artificial gems made, but also rocks and marbles — just as is plain from what was said a little above about the tables that are now made here in Rome by a newly discovered method.

EXPERIMENT. *On castable stone [Lapis fusilis].*

Let stones, marbles, jaspers, etc., be reduced to a very fine powder; to this let there be joined lime, gypsum, salt, ox-blood. Let all these be mixed and put into vinegar, wine, beer, or milk or its whey, and stirred in various ways until they are reduced to a porridge. When this is done, let the metallic colors you wish be mixed into the porridge, with a little ox-gall [fel bovis] added, and then let them be mixed with a wooden spatula with such care that the artificial marble obtains all the veins of color, just like real variegated marble — no differently than we know is done in preparing Turkish paper [carta Turcica]. Then pour it into the mold or form already prepared, and when dried it will take on a hardness altogether like stone, which then, planed down with pumice and given a final polish with soap or oil, receives a most perfect finish. The talented will easily grasp my meaning from this brief description. So, on to other things.

PROPOSITION XVI.

A method for composing artificial pearls.

[Margin: *Perlae fictae* — Artificial pearls.]

Pearls are made here in Rome so similar in form to real ones that, in respect of brilliance and appearance, they can scarcely be distinguished from real and natural ones, by this procedure. They purify the whites of eggs as cleanly as possible by means of a sponge; into this they sprinkle and mix the finest talc, or

also shavings of mother-of-pearl [concha perlata] together with natural pearls first reduced to a very fine powder. They grind this mixture thoroughly on marble, so that a dense amalgam is formed, which is dried in the sun or behind a hot furnace. From this mass they form pearls of whatever size they wish, which they pierce with pig-bristles and set out in the sun to dry; and you will have the job done. But if they do not shine enough, they smear them on the outside in the usual way with prepared egg-white and set them out in the sun to dry, and they have what they sought.

PROPOSITION XVII.

Artificial corals.

[Margin: *Corallium fictum* — Artificial coral.]

In a similar way artificial corals can be made. Grind cinnabar [cinnabaris] with egg-white on marble for an hour; afterward dry it like potter's clay [terra figulina], then mold from it little balls or a branching shrub-shape as you please. Take the dried material like the pearls, smear it on the outside with egg-white, and once dried, the corals come out so similar to natural ones that they can scarcely be told apart.

There is truly a great property hidden in egg-white, for from it a varnish [vernisium] can be cooked out; and when gold and silver shavings are mixed with it, [Margin: *Venturini lapidis confectio* — Preparation of the Venturine stone] they make a stone not unlike the one they call *Venturinum* [aventurine / goldstone].

PROPOSITION XVIII.

The transmutation of flax into silk.

[Margin: *Experimentum mirificum* — A wonderful experiment.]

If a lye [lixivium] is made from the lime and ash of the woad herb [Isatis], very strong, and flax is boiled in it, the flax passes into a wonderful silken material, splendid and very fine, most suited to spinning. And this too is marvelous: if the downy parts of feathers, scraped from birds, are boiled in this lye, they can be spun and woven no differently than cotton [gossipium]. But this secret also reveals the method and procedure for spinning asbestos material [materia asbestina], about which I kept silent in Book VIII, in the Chapter on Asbestos.

PROPOSITION XIX.

The making of amber.

In Pliny's time amber [Succinum] was dyed at pleasure with the root of the kid [hoedorum] and of alkanet [anchusa], and also with shellfish-purple [conchylum] — that is, with the late-violet color [violae serotino colore]. In this age the art of dyeing amber has perished. Yet if what is commonly written is true — that, plunged into boiling wax, it becomes soft — it will easily be able to take on any colors. The imitation of amber is proposed by many. Cardanus [Gerolamo Cardano] tries to imitate amber by putting ants, gnats, flies, bits of straw, and powdered amber into egg-white and gum tragacanth tears [tragacanthi lachryma], so that it gives off a good smell and draws up bits of straw — and better

[Printed p. 467 — running header: ARS PYRABOLICA]

Let it suffice, then, for the investigator of Nature that the way is shown so easily in this chapter that he cannot be deceived. Whoever wants the exact history of amber, let him read the treatise of Andreas Libavius [Andreas Libau], a most learned man.

[Continuation of running header: ARS PYRABOLICA — and the start of a new Pars]

PARS IV.

ARS PYRABOLICA

Which they also call Pyrotechnics [Pyrotechnia].

PREFACE.

How great and how prodigious are the works that the pyrotechnician — Vulcan — performs in the hidden tunnels of the earth is plainly shown by earthquakes, by the swallowing-up of mountains, by the new generation of lakes, and by the overthrow of cities and kingdoms. Since these are in fact nothing but ignited exhalations of sulfur and niter shut up in the passages and caverns of the mountains, certainly it was not without reason that the art of siege-craft [ars poliorcetica] — which they call pyrotechnics or pyrobolics — drew its first origin from this. And we have thought it fitting to set forth here, very opportunely, according to the pattern of Nature, what wonders may be produced from it; and first indeed we must treat of how, and in how many ways, gunpowder [pyrius

pulvis] — the agent of so many marvelous effects — is made; then how it is to be applied to engines for arranging festive shows. The invention of gunpowder is, without any controversy, first attributed to Berthold Schwarz [Berthold Schwartz], a German monk of Goslar and an alchemist, in the year 1354 — who, however, is said to have made the discovery not so much by human industry as by chance, from a mixture of powder, niter, and charcoal accidentally set alight, and revealed with a great crash and violence.

[Margin: *Historia Pulveris Pyrii, ejusque primae inventionis occasio* — The history of gunpowder, and the occasion of its first invention.]

I recall that I once read the story from a very old German book, of this tenor: Berthold Schwarz, a monk of Goslar of the order of Saint Benedict, since he delighted wonderfully in chemical matters and had already by his skill in them acquired for himself a great reputation, when at a certain time he had made a compound out of sulfur, niter, and charcoal, and — by I know not what chance — a spark of fire had slipped into the material, at once with a great crash it lifted up the pot and dashed it against the vault and shattered it. Astonished at the effect of the thing and its novelty, he applied himself more diligently to investigating the cause. And so, repeating the operation many times, when he always found the same effect, turning over something deeper in his mind, he put the material into a channel constructed of iron plates; and when he had put a single leaden ball into it, the material being fired at once scattered whatever lay before it with an enormous noise. And so, filled with great joy at the discovery of so notable a benefit, he nevertheless wished the matter to remain secret to all until his own time. There was at that time, in a place near Goslar, a huge forest infamous for robbers, who had set up their station there in certain spots, most convenient for every occasion of committing robberies. At that same time, on account of the violent plunderings and the multitude of murders, the Magistrate of Goslar was deliberating how this plague of criminal men might be put down, and no method could be found. Berthold, informed of this matter, approached the Magistrate and promised that he would exterminate the robbers with little trouble, provided that — mindful of the benefit conferred — they should show themselves not ungrateful to him and to his Order. The pledge being made, Berthold, having forged a good number of iron pots, which he filled with the material now known to him, with stones

[Printed p. 468 — running header: LIBER DUODECIMUS, SECT. V. Pars IV.]

CHAPTER I.

On the making of gunpowder [De pulveris Pyrii confectione].

For the making of gunpowder three things are entirely necessary: saltpeter [sal nitrum], sulfur, charcoal — about whose preparation a few words must be said, which we have drawn partly from Siemienowicz [Kazimierz Siemienowicz], Freitag [Johann Freitag], and Tartaglia [Niccolò Tartaglia], partly from other Authors who have written on pyrotechnics; to this end, that the curious Reader may recognize nothing so admirable in the use of human affairs that has not drawn its principles from the Vulcanian workshop of the Subterranean World.

PRAXIS I.

On preparing oil from sulfur [De Oleo ex Sulphure praeparando].

Let a good quantity of clarified sulfur be taken, and with the fire of liquefaction applied, let it melt in an earthen or bronze vessel. Then let there be had old red bricks that have already previously been used in building; or, if these cannot be had, let new ones be taken, well baked and not yet acquainted with water. Let them be broken into fragments the size of a bean and thrown into the melted sulfur. Then let the sulfur be mixed with the brick-fragments until the fragments drink in and absorb all the sulfur. Let these afterward be placed in an alembic hanging from a distilling furnace, and by the chemical method let the oil be distilled: it will be most burning, and most well-suited for preparing artificial fires. So say the practitioners.

ANOTHER WAY.

Let glass phials, having a somewhat oblong neck, be filled, so that a third or a quarter part of the belly is packed with the most finely ground [sulfur]. Over this let there be poured spirit of turpentine [spiritus terebinthinae] or oil of nuts or of juniper, only so much that that liquid together with the sulfur does not exceed half the belly of the phial. Let the phial be set upon hot ashes, and let it remain there for 8 or 9 hours. Then the spirit of turpentine will convert the sulfur into a most ruddy oil, most burning as before.

Certain men take, for making the most burning oil of sulfur, the following materials:

Material	Quantity
Sulfur [Sulphuris]	1 lb.
Quicklime [Calcis vivae]	half a lb. [℥ ℔]

Material	Quantity

Sal ammoniac [Salis Ammon.]	4 oz. [℥ iiij]

Siemienowicz [Siemienowicz], in his *Artilleria Magna* [*Great Artillery*], relates. The chemists teach a method of preparing oil from sulfur (which they also call balsam), whose power is such that it lets neither a living body nor a dead one pass into putrefaction, but keeps it so whole that no celestial impression, nor one proceeding from the elements, [corrupts it...]

corruption, whether brought on at their very origin or arising later, can affect it. There is also prepared (as Trithemius [Johannes Trithemius] teaches) a certain fire made from its flowers together with borax and spirit of wine, which remains inextinguishable for many years. And there is a lamp by whose light men appear without heads. But what we ourselves have judged about that fire the reader will find set out in Book IX. For they boast of many such things without any foundation — claims that nevertheless cannot stand once they are reduced to actual practice.

PRAXIS II.

On preparing an oil from sulfur and saltpeter mixed together.

Equal portions of sulfur and of saltpeter are added together and incorporated. They are then ground into the finest powder and sifted through a rather fine sieve. The whole mass is placed in a new earthenware pot, and strong white vinegar — or burnt wine [vini adusti, i.e. distilled spirit] — is poured over it, just enough to cover the material well. The pot is sealed up in such a way that it cannot breathe at all, and is left in a warm place until the vinegar has evaporated. Finally, from the material remaining in the pot, the oil is extracted by chemical apparatus.

PRAXIS III.

On preparing charcoal for gunpowder and other uses in pyrotechnics, according to the practice of the German craftsmen, as Siemienowicz [Kazimierz Siemienowicz] describes it.

In the month of May or June — when the bark of all trees strips off most easily because of the abundance of sap — cut a good quantity of rods from hazel or willow, one, two, or three feet in length, and a half-inch thick. Cut away the

knotty parts and discard them as less useful. Strip all the rest of its bark, bind it into small bundles, and dry it thoroughly in a hot oven. Then set the bundles upright in a single pile on a leveled patch of ground and set them alight. Once the kindled pile has caught flame well and the burning has been resolved into glowing coals, suddenly throw a little dampened earth over it and cover it as carefully as possible, leaving no vent, so that the whole suppressed flame — receiving no help from outside air — dies away, and the charcoal alone remains, extinguished and free of all ash. After the course of one natural day [diei naturalis, i.e. a full 24-hour day] these coals, now cooled, are to be taken out and kept for the following uses. If a sufficient supply of willow and hazel is not available for burning into charcoal, you can use dry linden [tilia] in their place.

If you wish to prepare only some small quantity of charcoal: take the twigs described above, cut and thoroughly dried, enclose them in some earthenware vessel, fasten the lid to the mouth of the vessel with potter's clay, then pack it about on every side with glowing embers, and let it remain there for the space of one hour in a single continuous and even degree of heat throughout. Let it finally cool of its own accord, and the burnt charcoal is taken out. There are those who reduce cloths and old linen fabric — well washed and dried — to charcoal in this way; and this too has a virtue not to be despised in pyrotechnics.

DISQUISITIO PHYSICA.

On the properties and functions, within gunpowder, of each material taken separately, out of which that powder is composed and prepared; concerning which we shall set out both what Siemienowicz judges and what we ourselves judge about these matters.

"Not by chance," says Siemienowicz, "nor accidentally, but through the highest grasp of natural philosophy and through speculative reasoning, was gunpowder discovered — or at least this can serve as an argument for it: that down to this very day no one has been found (though very many have tried) who could propose three similar materials which, well ground and incorporated together, would be fit to form a fire so vigorous, dreadful, powerful, and inextinguishable, right up to the consumption of the whole material, and that fire instantaneous. But since to the inventions of others further things may be added without difficulty, and since whatever has had a beginning has proceeded from the rudimentary and imperfect toward the perfect, let it be permitted to us too (since nothing about this matter has been handed down in the written records by the inventor) to set out in this place observations — speculative indeed, yet drawn

from experience — of the powers, nature, operations, and functions both of each single material taken separately and of all the materials enclosed in gunpowder when incorporated together. For we judge that the result will be this: once a more thorough knowledge of the properties and affections of these ingredients, both in particular and in general, has been gained, no one hereafter in pyrotechnics will fall into those errors whose correction is too costly and too dangerous." Thus far Siemienowicz; who, since he did not know the author of gunpowder, we have revealed in the preceding.

So this must be understood first: that gunpowder is composed of three materials — namely saltpeter, sulfur, and charcoal — chiefly for this reason, that one may remedy and supply the deficiency of another, or of the remaining two. And this appears first in the case of sulfur. Since sulfur is by nature the food [esca] of fire, readily seizes fire, and once it has seized it gives it up only with difficulty — and that with flame — it surpasses saltpeter and charcoal in this respect; and the flame of fire is much better suited than any other kind of fire for kindling saltpeter. But since saltpeter, in burning, resolves itself into a certain windy exhalation, this exhalation is of such force that it would suddenly oppress

and extinguish the flame which the sulfur had conceived; and consequently, by extinguishing the flame of the sulfur, it would also deprive itself of [the flame] introduced through the sulfur. And therefore, if some body were composed of these two materials only — namely sulfur and saltpeter, well ground and mixed together — then, on applying fire, it would indeed seize flame at once, yet nonetheless, for the reasons given above, it would also be extinguished at once. That is, that fire would not be continued, nor would it endure to the consumption and combustion of the whole material, but would consume only a very little of it, the remainder left untouched.

But a wholesome remedy has been applied to this defect, by adding to those two materials a certain portion of charcoal that has been well burned, dried, and pulverized. For this charcoal is of such a property and nature that, when even the least flame of fire has touched it, it suddenly blazes up and is resolved into fire without flame; and this fire, the more it is buffeted by any wind, the more it will be increased and preserved, until its whole substance has been turned to ashes. For this reason, then, when a body is prepared from these three materials — such as our gunpowder — on applying fire the sulfur at once conceives flame; and this flame not only introduces fire with flame into the saltpeter, but at the very same moment makes the charcoal catch fire without flame. And this fire (as said before) does not allow itself to be suffocated by any wind; on the contrary, it

takes greater increase from agitation. And since the sulfur is in contact with the fire — whether that fire be without flame or with flame — the sulfur nevertheless cannot be without flame; and this flame of the sulfur kindles the saltpeter. And therefore these three materials, mixed and incorporated together and then ignited, produce a fire that is inextinguishable, right up to the emptying-out and consumption of the whole substance. Take care, however, that in these three materials there be no accidental defect, arising either from moisture or from a disproportionate quantity of one material relative to another.

From what has been said it is now possible to conclude that the proper function of sulfur in the body of the powder is to seize fire with flame and to communicate and supply it to the other two materials. The particular task of the charcoal is in retaining, preserving, and defending the fire once introduced into the sulfur, so that it not be suffocated by that most violent windy exhalation of the saltpeter. But the greatest function of the saltpeter is to produce and cause the most violent possible windy exhalation; and in this exhalation lies all the virtue, vigor, and motive power of the powder. And therefore saltpeter is the principal and primary cause of all the marvelous effects of gunpowder; while the other two materials are added and bound to the saltpeter only for this end — that they may cause it to be resolved into fire and winds. For if anyone were to load a powder made of sulfur and charcoal only, and were to load a piece of artillery with even a very great quantity of it, I say that in such a case a powder of this kind would expel not only no iron ball or ball of any other metal, but not even chaff. The reason for this is ready at hand from what was said before: namely that an explosive expulsion of this sort depends on the expulsive virtue and power of the saltpeter alone, and of no other material whatever. I would more readily believe that a powder can be prepared without charcoal and sulfur than without saltpeter; and that two other materials can be found, one of which could perform the function of sulfur in seizing fire with flame, the other that of charcoal in preserving and retaining it without flame — than that anything else can be found apt to cause and produce so violent a windy exhalation, the agent of marvels in pyrotechnics, as we experience in saltpeter. Nevertheless, let the reader consult what we have set out in Book VI on gunpowder, things which do not depart from the pyrosophy of Siemienowicz.

PRAXIS IV.

On making fulminating gold [aurum fulminans], according to the method of Oswald Croll [Oswald Croll] and our own.

Take half a pound [℥ ℥] of common aqua fortis [strong water, i.e. nitric acid], dissolve in it one ounce of sal ammoniac — or as much as you can dissolve at a gentle heat — and thus you will have aqua regia [royal water], in which you may dissolve as much gold as you please. Then pour the solution into a roomy glass vessel and instill, drop by drop at least (because of the alarming and dangerous boiling-up), good oil of tartar that has dissolved of itself in a cellar; in default of this, take salt of tartar dissolved in common water. A good quantity of oil of tartar is required; then the gold falls to the bottom by precipitation. When the whole lime [calx] of gold appears to have settled to the bottom (which you will perceive from the color of the aqua regia, which ought to be white — for if it is still yellow, it is a sign that not all the gold has yet been precipitated), let more oil of tartar be poured in drop by drop (be faithfully warned of this at my own cost). Then, after the settling of some hours in a warm place, pour off the upper liquor, and the lime — its color almost resembling pale sealed earth [terra sigillata] — sweeten by washing four or five times with warm water; afterward dry it carefully and gradually in a water-bath [Balneo Mariae] over the gentlest fire. Or, what is safer, let it dry of itself in a glass dish in a warming-room [hypocaustum], with no heat of fire applied. Then, for greater safety, collect the lime with a wooden — not an iron — spatula, and store it for use in a small glass vessel. Note that there is great danger if it is dried in any way other than the two just described: for as soon as it feels the heat of fire, and a strong shaking with an iron instrument, it con-

conceives flame of its own accord, goes off into the air after the manner of a purple smoke with the greatest noise and crash, like niter-powder — so much so that you cannot find even a single atom of it. If some of common sulfur is safely mixed into it, and afterward it is burned in a crucible with fire applied, there remains a most subtle lime of gold of a brown color, which has lost all its power of striking — a thing remarkable and worthy of note. One scruple of that volatile gold operates almost more strongly and more powerfully than half a pound of gunpowder. A grain or two placed on a knife, if it warms when a lighted candle is set beneath it, gives off a sound such as if some great cannon had been discharged; and that sound, exceedingly sharp, almost hurts the hearing of one listening and standing by. The operation of this powder is the opposite of the operation of gunpowder: for whereas the latter exerts its force, at least, downward, [the former works upward — text gives only the contrast here].

A few scruples [of fulminating gold] upon an iron plate, thick enough, of burning charcoal, penetrate and perforate it. I judge sal ammoniac to be the cause of that percussion. For just as saltpeter and sulfur are enemies and do not tolerate one another — as we see in the ignition of prepared gunpowder — in the same way sal ammoniac is joined with oil of tartar against the foe; and from that mutual combat they make the gold, previously dissolved in the aqua regia, fall down; and the oil of tartar strikes the most highly purified spirit of niter, which in that conflict joins itself with the sulfur of the sun [Sulphure solis, i.e. of gold], its adversary. And because that sulfur of the sun is by nature most highly purified, and far subtler than our common combustible sulfur, it is therefore more potent and, in a smaller quantity, powerfully accomplishes its stupendous operations — in just the same way that we observe common sulfur and saltpeter, joined and ignited in gunpowder, make a great crash and roar. Concerning the same matter [see] Quercetanus [Joseph Duchesne (Quercetanus)] and Sennert [Daniel Sennert]: the cause, then, is the contrariety of the spirit of niter and of sulfur with the gold. For when oil or salt of tartar is poured into the solution of gold, the salt of tartar unites itself with the common salt — indeed with the alum and the ammoniac; and hence the gold, left to itself, descends to the bottom; and if anything of these salts is left with the gold, it is washed off with warm water. There remains only the spirit of niter, which has thoroughly united itself with the gold. So this spirit, if it warms, perceiving the presence of the sulfur of gold, sets itself in opposition, joins its forces, and with an onset made and with a crash bursts forth and is kindled.

PRAXIS V.

On camphor [camphora], its nature and property.

THAT IS

On the artificial preparation of camphor, from the noble Le Gallois [ex Caligero — author cited; modern identity uncertain] [?].

Take juniper gum (which is called sandarac, white varnish [Vernix albus], and mastic) made into powder, ½ pound; of distilled white vinegar, enough to cover the gum well as it sits in a glass phial. Set this for 20 days under warm horse-dung; then take it out and pour it into another glass vessel that has a wide mouth, and expose it for one month to be thoroughly cooked by the sun. You will have camphor congealed in the form of a crust of bread, and truly and natively somewhat similar [to natural camphor].

Now above we recalled certain things about the properties of native camphor; but since its use in our Work is very frequent, here too its nature is to be more fully explained from the testimonies of authors. Scaliger [Julius Caesar Scaliger], then, first, in *Exercitatio* 104, section 1, [speaks] of it thus: "But camphor is a tear of a tree by way of its sap, so that you would believe it a bitumen, just as you would have believed amber a bitumen. For, fallen from the trees, it is carried by the tide's approach onto the shores, where, buried in the sand, it is afterward dug out — along that whole tract which extends from Memel to Danzig [Gedanum, i.e. Gdańsk]. And about those heaps of sand it will be no wonder, to one who knows by what blow those regions were struck, and who has seen along the western side of Holland the heaps of sand standing out above the surface of the sea. It is therefore not dug up because it swims, but because it lies buried. But men have falsely judged camphor to be a bitumen — and that on a most wretched argument: 'Because,' says he, 'it burns.' For resin too, and oil, and frankincense undergo the same." And a little further down: "Whereas the greatest part of the wise hold camphor to be most cold, Averroes [Averroes (Ibn Rushd)], in his fifth [book], recognizes another. 'Camphor,' he says, 'the Indian, which in Arabic is more truly called قافور [Arabic: Qāfūr — camphor], 'Caphur,' warms and dries in the second degree.' There were therefore diverse species of camphor — or else there is a corruption in the manuscript, or an error in opinion. Lastly it was asked whether it is cold. For the innovators deny it. Yet it is established that it is most easily kindled, and even burns in water, besides being most fragrant. But its odor comes from the airy parts, by force of which it also burns; yet it has as much water as can be preserved beneath that coldness. It burns on account of its fattiness; and to be ignorant of this is the parent or the daughter of folly. For who would say that the hottest things burn most easily? For fire does not always pass into bodies summoned by likeness — likeness of heat, I mean — but is also enticed by some material able readily to admit it on account of its thinness." From the *Commentaries on Indian Matters*, this: "A very great tree, with boughs so spreading that it casts the widest possible shade. The substance of the wood is very light and very loose." Aboali [Aboali — i.e. Avicenna (Ibn Sīnā)] adds also whiteness. "The goodness of camphor [varies] according as it has been drawn out of the matrix by force, or expelled when ripe. For some is taken out of the veins in which it sticks, like a kind of crust. Sometimes it comes out by the bursting of the bark, and hardens after the manner of resins, at first colored; then by sun or by art it whitens. This is better than the former. Most excellent is that which whitens in the sun — for fire makes this happen. And [it is] very [prized] when first, in imitation of nature, [refined] by Riach, the king of the place — whence it gets the surname Riachina." The distilled [camphor] keeps its endowments

longer, and is more thoroughly clarified [defaecata]. Therefore it is also translucent. That which is enclosed [in the veins] is not so, and its color is darker. There are besides two baser species: one uneven, clotted, gummy; the other of a dark color. It is adulterated with honeycomb [favo] and with mas-

mastic and aqua vitae (which we described above). It is detected, set into the inner part of a loaf and placed behind the oven: if it melts, it is genuine; if it dries up, it is adulterated. They say too that the genuine kind easily evaporates, and is kept in marble boxes, with flax-seed, or fleawort [psyllium], or millet-seed poured over it. Jonstonus [Jan Jonston], *Admiranda naturae*, class. 4, chap. 9. The Moors write that camphor is the tear of a tree with branches so wide-spreading and diffuse that it can render a place shaded large enough to hold a hundred men. They add that the wood is white, fennel-like [ferulaceum], and that it contains the camphor in a spongy marrow — though sometimes, more certainly, it is made from a certain kind of bitumen in this way: Indian bitumen, which efflorescences out of native camphor, is cooked in a vessel with coals placed beneath, and the finest parts are borne, turned into a white color, into the cover; which, when we see it gathered upon them, gives [the camphor its] shape. Merchants affirm that the native kind is found in India. It is so friendly to fire that, if it once catches it, it burns until it is consumed. The flame it emits is bright and fragrant, and, raised and suspended in the air, it gradually vanishes — the cause being the extreme thinness of its parts.

I add: For use in pyrotechnics, camphor is reduced to powder if it is ground with sulfur. And the oil of camphor that serves the same use is made if a little oil of sweet almonds is added to it, and they are ground together in a brass mortar with a pestle, until it turn into green [oil].

[The following passage continues the right-hand column at the foot, completing the camphor preparation begun in Praxis V on p. 471:]

[until] it turn into oil. Or, if it [the camphor] be true and genuine, let it be cast into a glass phial, and, the mouth well stopped, let the phial be surrounded with dough kneaded from flour and water for forming loaves, and let it be put into the oven and drawn out. For the camphor, once dissolved into a liquid, will yield a most burning oil. See what we set out about camphor in Book IX.

PRAXIS VI.

On a water from sal ammoniac.

Take of sal ammoniac, 3 drachms [3iij]; of saltpeter, 1 drachm [3j]; let them be reduced to the finest powder and well mixed; then place them in an alembic, and, the strongest vinegar being poured over, let them be distilled by a gentle fire — and you will have a water most useful for many purposes.

PRAXIS VII.

On a certain artificial water that burns harmlessly upon the open palm of the hand.

Take equal parts of oil of petroleum [Petrolei], of turpentine, of quicklime, of sheep's fat [adipis vervecinae], and of pig's fat; let them be ground and incorporated, and distilled over hot ashes or over glowing embers — and you will have what you seek; for the hand smeared with it does not feel the burning of the flame.

CAPUT II.

On preparing incendiary fuses [funes incendiarii] in the common manner.

PRAXIS I.

First, from tow of flax, or of hemp, stripped by the second comb and bared of all bark, ropes are twisted, thick — half a thumb's-breadth in diameter. Then are taken 3 parts of ash from oak, ash-tree, elm, or maple that has been burned; 1 part of quicklime; and a lye is prepared in the usual manner. To this is added 1 part of saltpeter, [and] 2 parts of the juice pressed through a woolen cloth from liquid cow- and horse-dung. The whole material, well mixed, is poured over the ropes set in a cauldron arranged upon a furnace. Then fire is placed beneath, and the flame is urged gently at first, more strongly at last; and it is boiled down continuously for two or three days, always pouring on the liquor already mentioned, lest the ropes and the cauldron, lacking moisture, be scorched. Finally, from the ropes then taken out, all the moisture drawn in by the boiling is pressed out, by violently twisting the ropes with the hands and wiping off the running liquor with a linen cloth. Lastly the ropes are hung up upon long poles,

to be dried by the heat of the sun, and are kept for the usual pyrotechnic uses. Thus Siemienowicz.

PRAXIS II. of the same.

On preparing incendiary fuses lacking all smoke and stench in burning.

Take several measures of reddish sand, or of carbuncular sand [arenæ carbuncularis] that has been repeatedly cleansed, washed, and purged of all dross, and dried of all moisture; place them in an unglazed earthenware pot. Upon the sand lay a common incendiary fuse, or another twisted from cotton [gossypium], collected into a spiral — yet in such a way that intervals of half a finger's-breadth are kept between the sides of the fuse, and they do not touch one another, but stand apart at continuously equal spaces. Again pour over a good quantity of the aforesaid sand, and let the fuse likewise be arranged upon the sand, as just said. And so let the operation be continued in turn, placing layer upon layer, until the pot is full. Then cover it with an earthenware lid, and let the joints be stopped with the lute of wisdom [lutum sapientiae, a sealing clay]. Finally let the pot, thus prepared, be fenced about on every side with glowing coals, and let it remain there for some hours; afterward let it cool of its own accord; and when it has cooled, the lid removed, let the sand be poured out and the fuse taken out. Not unlike, too, is the procedure in operating with common sponges:

[Continues into the next folio.]

—only have to be cut into oblong pieces and laid in an earthenware pot on top of sand; and then, just as was described above for the fuses, burned with fire. Of these, or of the incendiary fuse described above, even quite small pieces — once lit and buried in juniper ash — will burn for several hours without any smoke or stench, and they need little help from the outside air. For that reason they can be hidden away unnoticed anywhere at all, as the occasion presents itself and necessity requires.

PRAXIS III.

On preparing pyrotechnic tow [stuppa] for artificial fires.

First make fuses out of tow [stuppa] of flax, hemp, or cotton, twisting two or three threads together but not too tightly. Place these in a new glazed earthenware pot, and pour over them: 4 parts white-wine vinegar, 2 parts urine, 1 part distilled

spirits [vinum adustum], 1 part purified saltpetre [sal nitri], and 5 parts pulverized gunpowder [pulvis pyrius]. Cook them over a fairly strong fire until all the poured-on liquids dissolve into vapor and evaporate away. Afterward sprinkle the powdered flour of the best gunpowder onto a wooden board, and let the little fuses, drawn out of the pot, be rolled over it in the powder and dried in the shade or the sun. Tow prepared this way burns very quickly. So if anyone wants the fire to advance a little more slowly, this fire-tinder [ignis esca] must be made somewhat weaker and gentler. It will then be enough if the tow is simply boiled down in vinegar and purified saltpetre, and afterward dried with powder-flour sprinkled on it. This is from the *Artilleria magna* [of Siemienowicz].

There is also another kind of pyrotechnic tow, which is not twisted into fuses but is simply dissolved and boiled down in the liquids listed above; or else it is soaked for several hours in strong distilled spirits and finally dried with the flour of the best powder sprinkled over it. Sometimes a tiny portion of gum arabic or tragacanth is added to the distilled spirits; with tow of this kind one can scarcely express how tenaciously it holds together.

Another method, that of Prechtel.

Franz Joachim Prechtel [Franciscus Joachimus Prechtelius] describes a certain pyrotechnic tow, in his *Pyrotechnica*, Part Two, Chapter Two, which burns more slowly than any of the others, in this way. Take 2 parts mastic, 1 part colophony [Greek pitch / rosin], 1 part wax, 2 parts saltpetre, $\frac{3}{4}$ part charcoal [carbo]. Those that can be pounded and softened should be crushed and reduced to the finest flour. Then let all of it, well mixed together, be melted over the fire. Next, draw some linen or hemp thread, a little on the thicker side, through the melted material, pressing it down to the bottom of the vessel; and repeat this several times, until the thread takes on the thickness of an ordinary wax taper. When you wish to use it, light the wick first, then extinguish the blazing flame, leaving only a glowing coal.

CAPUT III.

Iatro-chemical procedures [Praxes Iathrico-Chymicæ].

On several well-proven antidotes against burns caused by gunpowder, sulphur, red-hot iron, molten lead, and other such things.

Gathered from various pyrotechnic authors — Siemienowicz [Siemienovius], Tartaglia, Paracelsus, and Quercetanus [Joseph Duchesne].

PRAXIS I.

Let hog's lard [axungia porcina] boil in common water over a slow fire for several hours. Then, taken out, let it be exposed for three nights to a clear sky. Next, put into an earthenware vessel, let it melt over the fire; let it be strained through linen into cold water; and, after being washed several times and thoroughly purified, until it becomes perfectly white, let it be kept in an earthenware or glass vessel. Afterward, when need requires, let the burned spot be well anointed with it.

PRAXIS II.

Take: water of plantain [aqua plantaginis], oil of Italian walnut [oleum nucis Italicæ], of each a sufficient quantity [ana q. s.].

PRAXIS III.

Take: water of mallow [aqua malvæ], rose water [aqua rosarum], plumose alum [alumen plumosum], of each a sufficient quantity; let them be mixed with the white of an egg.

PRAXIS IV.

Take lye [lixivium] prepared from quicklime alone and common water. To this add a little hemp oil [oleum cannabinum], olive oil [oleum olivarum], linseed oil [oleum lini], and several egg whites. Stir everything well, and let the burned spot be anointed. All these ointments heal burns without any pain and leave no scar. "I have proved it on my own person," as Siemienowicz says.

From the authors Paracelsus, Quercetanus [Joseph Duchesne], Tartaglia, and others.

PRAXIS I.

Take: 1 part olive oil, 1 part oil of sweet almonds [oleum amygdalorum dulcium], 2 parts juice of onions [succus cæparum], 1 part liquid varnish [vernix liquida]; anoint the afflicted spot.

Boil abundantly in olive oil from the second bark of elder [sambucus]; then strain it. Add 2 parts white lead [cerussa], and 1 part each of burnt lead [plumbum ustum] and litharge [lithargyrium]; let them be mixed a long while in a lead mortar, and let a liniment be made. The blisters [vesicæ] are to be broken neither on the first nor on the second day, but on the third or fourth; for sometimes they are healed by dissolution alone. Leonardus Botallus, *On Gunshot Wounds [de vulneribus Sclopetorum]*, Cap. 21.

PRAXIS II.

Take: of melted bacon-fat [lardum liquefactum] taken up with nightshade water [aqua solani], 3 ij; oil of Saturn [oleum saturni, i.e. of lead], 3 j; mix.

Or take: of birdlime [viscum], root of henbane [radix hyosciami], and red poppy flowers [flores papaveris rubri], of each 3 j; saltpetre [sal petræ], 3 j; with oil of camphor [oleum camphoræ] make a liniment.

Or take: of onion juice, the onion cooked under the ashes, 3 ij; oil of walnuts [oleum nucum], 3 j; mix.

Or take: of leaves of black ivy [hedera nigra] pounded with plantain water, m. ij [two handfuls]; oil, ℥ j [one pound]; let them be boiled with 3 iiij of white wine until it is consumed; toward the end add as much wax as suffices to make a liniment.

Or take: of bacon-fat melted at the flame, and taken up with juice of beet [beta] and rue [ruta], 3 ij; cream of milk [cremor lactis], 3 j; mucilage of quince seed [semen cydoniorum] and of tragacanth, of each 3 ß [half a drachm]; mix. Joseph Quercetanus [Du Chesne], in his book *On Gunpowder for Firearms [de Sclopetario pulvere]*.

CAPUT IV.

Procedures for the compositions of rockets of every kind — which the Italians call *Raggi* and the Germans *Raketten* — according to the mind of Siemienowicz [Siemienovius] and of the other pyrotechnicians who devote their effort to making powder.

COMPOSITIO I.

For 100, 80, and 60 lb.

Saltpetre 30 ℥, charcoal 20 ℥, sulphur 10 ℥.

Here the proportion of saltpetre to the other two is equal; that of charcoal to sulphur, double. The same composition can be used without any scruple for all other rockets that fall in between, up to 60 pounds. For it is safer to have given them a somewhat slower material, even though they could have carried a more violent one — since in pyrobolic matters one errs more happily by deficiency than by excess. And a deficiency can very easily be corrected by adding more violent material, provided that, before you have made many rockets and loaded the material, you have been advised by the success of one about the rest.

COMPOSITIO II.

For 50, 40, 30 lb.

Saltpetre 30 ℥, charcoal 18 ℥, sulphur 7 ℥.

Here the proportion of saltpetre to the other two is one-and-one-fifth [sesquiquinta]; that of charcoal to sulphur, double plus four-sevenths [dupla super partiens quatuor septimas].

COMPOSITIO III.

For 20 and 18 lb.

Saltpetre 42 ℥, charcoal 26 ℥, sulphur 12 ℥.

Here the proportion of saltpetre to the other two is the superbipartiens of nineteenth [i.e. $1 + 2/19$]; that of charcoal to sulphur, double plus one-and-one-sixth [dupla sesquisexta].

COMPOSITIO IV.

For 15 and 12 lb.

Saltpetre 32 ℥, charcoal 16 ℥, sulphur 8 ℥.

Here the proportion of saltpetre to the other two is one-and-one-third [sesquitertial]; that of charcoal to sulphur, double.

COMPOSITIO V.

For 10 and 9 lb.

Saltpetre 62 ℥, charcoal 20 ℥, sulphur 9 ℥.

Here the proportion of saltpetre to the other two is double plus four-twenty-ninths [dupla superquadrupartiens vigesimas nonas]; that of charcoal to sulphur, double plus two-ninths [dupla superbipartiens nona].

COMPOSITIO VI.

For 9, 8, and 6 lb.

Saltpetre 35 ℥, charcoal 10 ℥, sulphur 5 ℥.

Here the proportion of saltpetre to the other two is double plus one-and-one-third [dupla sesquitertial]; that of charcoal to sulphur, double.

COMPOSITIO VII.

For 5 and 4 lb.

Saltpetre 64 ℥, charcoal 16 ℥, sulphur 8 ℥.

Here the proportion of saltpetre to the other two is double plus one-and-a-half [dupla sesquialtera]; that of charcoal to sulphur, double.

COMPOSITIO VIII.

For 3 and 2 lb.

Saltpetre 60 ℥, charcoal 15 ℥, sulphur 2 ℥.

Here the proportion of saltpetre to the other two is triple plus nine-seventeenths [tripula super partiens novem decimas septimas]; that of charcoal to sulphur, seven-and-one-half [septula sesqui altera].

COMPOSITIO IX.

For 1 lb.

Powder [pulvis] 32 ℥, charcoal 6 ℥, sulphur 2 ℥.

Here the proportion of powder to the other two is quadruple; that of charcoal to sulphur, triple.

COMPOSITIO X.

For 18 lotones and ½ lb.

Powder 18 ℥, saltpetre 8 ℥, charcoal 4 ℥, sulphur 2 ℥.

Here the proportion of powder-with-saltpetre to the other two is quadruple plus one-and-one-third [quadrupla sesquitertia: $4\frac{1}{3}$]; that of charcoal to sulphur, double.

COMPOSITIO XI.

For 12 and 10 lotones.

Powder 30 lotones, saltpetre 24 lotones, charcoal 8 lotones, sulphur 3 lotones.

Here the proportion of powder-with-saltpetre to the other two is quadruple plus the superdecupartiens of elevenths [$4 + 10/11$]; that of charcoal to sulphur, double plus one-and-a-half — that is, $2\frac{1}{2}$.

COMPOSITIO XII.

For 6 and 4 lotones.

Powder 24 lotones, saltpetre 4 lotones, charcoal 3 lotones, sulphur 1 loton.

Here the proportion of powder-with-saltpetre to the other two is sevenfold [septupla]; that of charcoal to sulphur, triple.

COMPOSITIO XIII.

For 2 and 1 loton.

Powder 30 lotones, charcoal 4 lotones.

Here the proportion of powder to charcoal is seven-and-one-half [septupla sesqui altera: $7\frac{1}{2}$].

COMPOSITIO XIV.

For $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{8}$, and $\frac{1}{12}$ of a loton.

Powder 9 or 10 *lotones*, charcoal 1 *loton*, or $1\frac{1}{2}$.

These are the smallest rockets, called "runners" [*currentes*], which can be loaded with ground powder alone, without charcoal. The drive [*ictus*] is then put in from another, best granulated powder. Now a *loton* is nothing other than half an ounce.

PRAXIS I.

On producing a fiery rain, and on the various colors.

To stir up a fiery rain and cloud, and sparks falling in great abundance, and long broad rays in the rockets while they burn, small quantities are usually mixed into the rocket compositions — either of pulverized glass, or of iron filings [*scobs ferrea*], or of wooden sawdust [*ferrago lignea*]. Different colors, too, can be represented in the rockets' fires. Thus: if you mix certain portions of camphor into a composition, it will produce a white, pale, milky fire; Greek pitch [*pix græca*], a red or coppery one; sulphur, blue [*cæruleum*]; sal ammoniac [*sal armoniacum*], green; crude antimony [*antimonium crudum*], a reddish, honey-colored, or boxwood-colored one; ivory filings [*scobs eburnea*], a silvery and bright white, though somewhat livid or leaden; filings of amber [*scobs succini*], a yellow and citron color; and finally hard ship's pitch [*pix dura navalis*], a black smoke, dusky and darkening the fire.

CAPUT V.

On recreational water-globes, that is, globes that burn while floating in water.

PRAXIS I.

Let a wooden globe of any size be prepared, hollow within and perfectly round. Let the thickness of the wood be everywhere $\frac{1}{9}$ of the diameter AB, as it is here in AC, or BD. On top let it have a convex cylinder whose thickness at the diameter EF is $\frac{2}{5}$ [?] of the diameter AB. The width of the priming-hole [*foramen accensorium*] CH should not exceed $\frac{1}{3}$ of the diameter. Below, together with the bung [*epistomium*] IK — through which the material for loading the globe is poured in, and through which an iron striker [*ictus*] is set in, made from an iron plate bent

into a cylinder and packed full of strong granulated powder (such as is shown under M) — let it be made equal in width to the upper cylinder. Then let it be loaded with one of the aquatic compositions given below, and let the bung be closed with liquid pitch in the manner of a stopper. Over this pour such a quantity of molten lead that the watery globe will be of such weight as to be in equal balance with a mass of water, or to slightly outweigh it. Why this is done we shall give an exact account at the end of this chapter. At last the globe, now fully prepared in every way, is pitched over with melted pitch. Then, when need urges, fire is admitted through the opened priming-hole; and once the material has properly caught the flame, it is thrown into the water. After the powder is lit, this globe will indeed stir up great commotions in the water, yet without any flame, but from the violent surge of the powder there ignited, the surge lasting within the sphere. As for those who say that flames belch forth under the water, they are to be laughed at.

PRAXIS II.

On scented little water-globes [globuli aquatici odoriferi].

Have little hollow wooden globes turned on a lathe, the size of an Italian walnut or a wild apple. Load these with one of the following compositions. Then, in some bedchamber or other enclosed place that is not too spacious and wide, light them and throw them into water — but first inserting into the opening a little fuse twisted from pyrotechnic tow, so that the material with which you have loaded the globe may be more easily kindled. The compositions are as follows.

Take: saltpetre ʒ iiij, storax calamite [storax calamita] ʒ j, frankincense [thus] ʒ j, mastic ʒ j, amber [ambra] ʒ ℥, civet [zibethum] ʒ ℥, juniper filings [serrago juniperi] ʒ ij, cypress filings [serrago cupressi] ʒ ij, oil of spikenard [oleum de spica nardi] ʒ j.

Or take: saltpetre ʒ ij, flowers of sulphur [flores sulphuris] ʒ j, camphor ʒ ℥, pulverized amber-shavings [succini ramenta pulverificata] ʒ ℥, charcoal of linden [carbo tiliæ] ʒ j, flowers of benzoin [flores belzoi] or of sweet asafoetida [asa dulcis] ʒ ℥. Let those that are to be ground be ground and pulverized thoroughly, and mixed together.

CAPUT VI.

Other procedures [Praxes aliæ].

On fiery compositions for festival days.

PRAXIS I.

You may light many candles with a single thread, if you first smear it — once it has been moistened with water — with sulphur and orpiment [auripigmentum] dissolved in oil. But each must be purified, for nothing burns from a thin or feeble fire until it has been moistened with water. They call this the Ointment of Hermes [Unguentum Hermetis]. Cardano [Cardanus], *de rerum varietate*, lib. 10, cap. 40. Della Porta [Porta] also attests the same, lib. 12, cap. 11, in these words: "Boil sulphur," he says, "and orpiment with oil, and let the thread boil in them; once dried, let it be tied to the wicks of candles and run across, for from one end lit the flame will run through all and set them alight." This is customarily done on festival days among the Turks, and most people call it the Pigment of Hermes.

But if you take one part of saltpetre [halinitrum] and add a fifth part each of frankincense, common oil, and milky spurge [lac lathyridis], a tenth part of sulphur and of wax, you will make a half-candle that will be marvelous in color, smell, motion, and crackling; nor are these without their reason. Others fill half an eggshell with quicklime, and adding a part of gunpowder on top, close it with wax and place it in the coldest water, for very often the fire is kindled and a flame flashes out. Cardano, *ibid.* But if you wish to throw a flame at a distance, pound colophony, frankincense, or amber finely, entrust it to the palm of your hand, and then let a lit candle pass between your fingers; and while you throw the powder upward, let it pass through the candle's flame, for the flame will lift itself on high. Della Porta, lib. 12, cap. 12.

If camphor [caphura] is dissolved in spirits of wine [aqua vitæ], and from it little strips of parchment are smeared and dried and lit, and let fall from a height, fiery serpents will be seen creeping through the air, not without delight. Della Porta, *ibid.*

So that the whole air of your bedchamber may catch fire as you enter it, take a large amount of well-rectified spirits of wine, and throw into it camphor cut up small, for it will quickly dissolve in it. Once it is dissolved, close the windows and doors of the chamber, so that the exhaling vapor does not breathe out; then let a vessel full of water boil over coals placed beneath without flame, until all the water dissolves into a smoke that fills the chamber and is so fine that it can

scarcely be seen. Let someone be made to enter the chamber carrying a lit candle, for the air, on seeing the candle, will all burst into flame, will set the whole chamber ablaze, and — to the entrant's greatest terror — will present the appearance of a burning furnace. If musk, or the least bit of amber, is dissolved in the water, a most powerful scent will follow the flame. Della Porta, *ibid.*

PRAXIS III.

*On the compositions for loading water-globes, that is, globes burning in water.
From the Pyrotechnia of various authors.*

1.

Saltpetre reduced to flour, 16 lb.; sulphur, 4 lb.; wooden sawdust, first boiled in saltpetrous water and dried, 4 lb.; granulated gunpowder, $\frac{1}{2}$ lb.; ivory filings, 3 4.

2.

Saltpetre, 6 lb.; sulphur, 3 lb.; ground powder [pulvis tritus], 1 lb.; iron scrapings [ramentum ferri], 2 lb.; Greek pitch, $\frac{1}{2}$ lb.

3.

Saltpetre, 24 lb.; ground powder, 4 lb.; sulphur, 12 lb.; wooden sawdust, 8 lb.; filings of amber, $\frac{1}{2}$ lb.; pulverized glass, $\frac{1}{2}$ lb.; camphor, $\frac{1}{2}$ lb.

The manner of preparing all of these is the same as we described for the rockets, except that here the material need not be so finely ground, nor pulverized or sifted; but it should still be very well incorporated by much mixing, and not too dry when it is put into the globe. And for that very reason it should be moistened with either linseed oil, or olive oil, or petroleum, or hemp oil, or oil of walnuts, or some other—

moistened with some other fat that readily catches fire.

Note. Besides these compositions, which pyrotechnicians admit they have used quite often, anyone can easily devise yet another, simply by taking the same materials in different proportions to one another. But the composition should be tested by trial as often as possible before it is put to pyrotechnic use. It is, moreover, of the greatest importance — both for arriving at a sound mixing of the aquatic compositions, and for gaining a general knowledge of the power and potency of each one already prepared — to have a thorough, item-by-item familiarity with the nature, virtues, operations, and properties of every single material commonly used in the aquatic compositions, not just the ordinary kind. For as Aristotle says (*Physics* I, ch. 20 [*recte*: I.1]), universal knowledge is acquired

from particulars already known. The following observations, then, on the individual materials should be noted.

Gunpowder [pulvis pyrius] is the first and principal ingredient, and a material most violent and ferocious in burning; hence it resists every moisture powerfully, so that its flame is not smothered.

Second place is held by saltpeter [salnitrum], well clarified and purified — whose nature I described above, and whose incredible power in gunpowder I have set out. In the aquatic compositions, nonetheless, when combined with the other materials, it carries a certain special secret virtue for scattering and spreading far and wide the watery droplets that glide over the surface, on account of the many — and most violent — blasts and winds with which it is full, this being its function and office.

PRAXIS II.

On a fiery mixture that the Sun can ignite.

Take oil of turpentine-resin, native sulphur, juniper, naphtha, colophony of flax, and camphor, pitch, halonitre [halonitrum], and duck's fat; of water of life [aqua vitae] twice the amount of all the rest. Let everything be purified of its phlegm, then all pounded together, and the mixture stored in a glass vessel and left to ferment under dung for two months, the dung being continually renewed and at the same time re-mixed. When this period has elapsed, let them be distilled. Then let the liquor be thickened with gunpowder, or with pigeon dung finely sifted. Wood smeared with this mixture and exposed to the summer sun catches fire of its own accord. Duck's fat is wonderfully effective for incendiary fires, because it is exceptionally subtle, penetrating, and hot; and the excremental dregs of pigeons readily conceive fire from the rays of the sun. I have seen this secret, set out on the bridge of Sant'Angelo in the month of July, meet with no small success.

PRAXIS III.

On balls that burn under water.

The way in which such balls can be prepared is reported by Porta, *Magia naturalis* XII, ch. 6.

First take gunpowder, which — if it is granulated — should be ground very fine and passed through a sieve. To seven parts of this add two of colophony, three of saltpeter [halinitrum], one of sulphur; let everything be ground and mixed together,

not without a sprinkling of naphtha or of liquid Ritran pitch [picis Ritran], moistening it just until the powder, pressed in the fist, coheres of itself. Let this mixture be wrapped in straw or in tiles, or else packed into pouches made of the said materials, and bound about as tightly as possible with cords; then let it be plunged into boiling pitch, and care taken that it dry out, and again, protected with straw, let it be smeared over with pitch, lest it be either dissolved by the moisture of the water or burst apart by the force of the fire. When it has duly dried, let gunpowder be inserted into the small hole through which it was kept open, and fire applied; and at once, while the devouring flame begins to burn, let it be cast into the waters. By its own weight it will seek the bottom; but, fighting the waters with its flame-vomiting violence and pushing them away from itself on every side, wrapped in black smoke, it appears to seethe from below. Rendered lighter thereby, it is carried up again through twists and winding turns to the surface of the water, so that the wave appears to burn in a most delightful spectacle — as though Neptune were besieging on every side a Vulcan that bore arms against him within the domain of his own empire, and at last, as the Vulcan languished for want of fuel, were pressing on to victory and the enemy's destruction, and finishing him off. Thus far Porta.

For my own part, I do not deny that balls of this kind can burn at the surface of the waters without danger of being extinguished. But that a flame-vomiting fire can endure in the depths of the waters I can by no means admit; since it cannot happen that, without air, fire can be preserved in the very midst of the water, as I have shown elsewhere by various experiments. At the surface of the water, however — just like ignited camphor, with which I often amuse myself — it will burn with no hindrance from the water; yet if you submerge it even the slightest bit, the flame is at once extinguished. I do not therefore deny that globes of this kind, in their struggle with the water and the air, cause great commotions and tremblings of the waters among the waves before all their heat vanishes; but that a flame under the water was ever seen by anyone — that I deny, both the one claim and the other.

PRAXIS IV.

On artificial fires that are kindled by water.

That naphtha burns in water, and likewise its species camphor, I have often said in what precedes, and Porta attests it (*Magia* XII, ch. 20), adding that certain old women of Mantua [exavio — *recte* ex Avio? (?)] once crossed the Tiber in their games with torches kindled from this material, to display a marvel to those

expecting and watching. Cardano [Cardanus] recounts three ways of making fires of this kind (*De subtilitate* II, pp. 36 and 37) in these words: *They consist, he says, of ship's pitch and Greek pitch, sulphur, lees of wine — which they call tartar — sarcocol, saltpeter [halinitrum], that kind of bitumen which they call petroleum; quicklime is added in double weight, and all are mixed together with egg yolks and buried in horse dung. Another, of sulphureous oil, of petroleum, of juniper oil, and of saltpeter [halenitrum], equal parts of each; of black pitch, fat of goose and of duck, of pigeon droppings, of that liquor which they call liquid varnish — it consists of oil of flaxseed — again equal amounts of each; of asphalt five parts; take it up in burning water [aqua ardens], and bury it in horse dung. Another, of liquid varnish, sulphureous oil, juniper oil, and that which is made from flaxseed and petroleum, and of the tear of larch [lachryma laricis], equal parts of each; of burning water three and a half; of saltpeter [halinitrum] and dry laurel-wood reduced to powder, as much as suffices for all, mixed together, to take on the thickness of mud. Take all these up in a glass vessel, and bury for three months in horse dung. If, then, balls made from these cling to wood, they kindle spontaneously in the rain — but this does not always happen; what always happens, however, is that once it has been kindled, it is not extinguished by any waters. These are Cardano's fires that burn in the waters, from which those I reported from Scaliger [Scaligero] do not greatly differ.*

In this matter Porta, Cardano, and the rest [speak] about an artificial stone that is kindled by spittle alone or by rain. But I have never at any time, however intently I sought it, been able to ascertain the truth of the thing — as I have shown in various of my Works; and so I have judged it likewise to be assigned to those paradoxes which are reserved for the coming of Elias [Elias], until in the meantime experience by trial renders me firmer in believing. I know that the Sun's rays can kindle stubble, and even the driest material; but that natural water should kindle fire — this has not been seen up to now.

CAPUT VII.

On luminous globes, of the kind we are accustomed to use for recreational fires, called by the Germans *Lichtkugel*.

Luminous globes are of two kinds: recreational and serious — that is, warlike. Of the latter I now say nothing; but how the former are prepared must now be briefly stated.

PRAXIS I.

Take crude antimony 2 lb., saltpeter 4 lb., sulphur 6 lb., colophony 1 lb., charcoal 4 lb. — or: antimony 5 lb. [Antimo: lib. g], saltpeter 1 lb., charcoal 1 lb., sulphur 6 lb., colophony 1 lb., black pitch 6 lb. [Picis nigrae lib. g]. Of whichever of these two compositions — each material being first ground — put into a kettle or a glazed earthen vessel, and let it melt over blazing coals. Then put in as much tow of flax or hemp as will absorb the whole melted material, and, while it cools, from that tow make round little balls of whatever size will seem most suitable for your uses. Then, finally, surround them with pyrotechnic tow and pack them into rockets, or into recreational globes — both the aquatic kind and those usually thrown from mortars.

PRAXIS II.

On the stars and sparks of pyrotechnic fire, which the Germans also call *Sternfeuer*, *Feuerputzen*.

Pyrotechnic stars differ from sparks in this, that they are larger than sparks, and are not consumed by the fire so quickly as a spark, but shine somewhat longer in the air in the manner of stars. They are prepared by the following method.

Ingredient	Quantity
Saltpeter [Salnitrum]	1½ lb. [℥ ℔]
Sulphur [Sulphur]	2 ℥ij
Pulverized amber [Succinum]	1 ℥j
Crude antimony [Antimonium crudum]	1 ℥j
Ground powder [Pulvis tritus]	4 ℥iiij

Or take:

Ingredient	Quantity
Sulphur [Sulphur]	2½ ℥ij ℔
Saltpeter [Salnitrum]	6 ℥vj
Most finely ground powder [Pulvis subtilissime tritus]	5½ ℥v ℔
Olibanum, Mastic, Crystal, Sublimate of mercury [Mercurius sublimatus], Sinople(?) [Sin.] — of each	4 ℥iiij
White amber [Ambra alba]	1 ℥j
Camphor [Camphora]	1 ℥j

Ingredient	Quantity

Antimony, Orpiment(?) [Auripigmentum] [finus(?)] — ½ 3 ß
of each

Let all the materials, finely pulverized and sifted, be moistened with water of glue or of gum arabic, or of tragacanth; then let little balls the size of a hazelnut or a bean be made, which, dried in the sun or in a warm stove [hypocaustum], are kept for the recreational pyrotechnic uses of which I spoke abundantly above. This only is to be borne in mind: that when they are to be packed into rockets or recreational globes, they should be surrounded on every side with loosened pyrotechnic tow. Very often the pyrobolists are accustomed, in place of these little balls, to take small fragments of the melted material — of which I shall speak below, when I teach the method of preparing the fiery rain — wrapped in tow, for the customary uses.

If you also wish to construct other stars, which are not black like the preceding, but yellow, and inclining somewhat to white, then take:

Ingredient	Quantity
Gum tragacanth or pulverized and sifted gum arabic	4 3iiiij
Camphor dissolved in burning water [aqua ardens]	2 3ij
Saltpeter [Salnitrum]	½ lb. [lib. ß]
Glass pulverized not too finely	3 3iij
White amber [Ambra alba]	½ 3 ß
Orpiment [Auripigmentum]	2 3ij

Let little balls be made as before. This is from Siemienowicz [Siemienovius], drawn from Claude Mygdorius [Claudio Mygdorio].

The method and way of making sparks is this: Take saltpeter 1 3j, melted material ½ 3 ß, ground powder ⅙ 3 g [?], camphor two ounces. Each of the materials, first reduced to a fine flour, put into some little fig-wood bundle, and pour in tragacanth water or burnt wine [vinum adustum] in which you have first dissolved tragacanth or gum arabic,

—so that it may have the consistency of some liquid pottage. Afterward, [add] 1 3j of cotton [gossypium], steeped in vinegar or burnt wine and in a decoction of

saltpeter [that has been] dried and torn into tiny shreds; roll it about, having been put in there, so that it takes up and absorbs the whole material. Then from this make little balls in the manner of medicinal pills, the size of a pea, and, sprinkled with powdered flour, dry them; and, as you know how, use them afterward.

Besides these, certain fragrant pills are prepared, which are used in certain tiny pyrotechnic devices enclosed in skins [cuticulis] or other places destined for combustion. Let these be compounded from:

Ingredient	Quantity
Storax calamita, Benzoin gum [Belzoi Gummi], Juniper [gum] — of each	2 3ij
Olibanum, Mastic, Frankincense [Thus], White amber, Amber [succinum], Camphor — of each	1 3j
Saltpeter [Salnitrum]	3 3iij
Charcoal of linden(?) [Carbonum tiliae]	4 3iiij

All are ground, pulverized, and well incorporated, and moistened with gum arabic or tragacanth dissolved in rose water; and the pills are made. Finally they are dried in the sun or by the heat of fire. So Casimir Siemienowicz [Casimirus Siemienovius] in his *Great Artillery* [Artilleria magna].

Camphor is a fire utterly inextinguishable in water; and apart from camphor this has been granted by nature to no other fatty, oily, or bituminous material — to burn so stubbornly in the wet without help from anything else, so that it seems to wish to exercise an almost despotic dominion. For when it is packed about on every side with ice or snow and kindled (the fire being nonetheless left a gaping vent to burst out through), it melts both [ice and snow] and is not extinguished in any way until it is wholly burned up. Pulverized and cast upon water, it likewise burns not unpleasantly, since it appears as though the very water on which it floats (by reason of its lightness) were burning; and it easily conceives fire — not because it is hot, but because it is rare and fatty. Hence this too is marvelous: that if it be cooked in a bronze basin set over burning water with glowing coals placed beneath, all the moisture vanishes — in a place suitably large and well closed up, so that not even the least chink remains, whether in the walls or in the ceiling, [and] the whole rarefies into the most subtle air. But when, the door being opened, a kindled torch is brought into that chamber, at once that whole air contained within conceives flame, and, without any harm either to the building or to the spectators, it burns off very gently, in the manner of lightning. The cause

of this is the rarity of the fiery substance; for fire does not burn except by the compression of parts. Hence also, in our paper [held] in this flame, [the flame] is so diluted that we may pass a hand through it without injury; and in burning water it is so thin that it leaves unharmed a linen cloth moistened with it.

[Margin: A marvelous spectacle.]

Hence once, when I had fashioned a piece of ice into the form of a candle, and — the icy cylinder having been bored through — had filled it to some extent with camphor, when that was kindled it burned, just like a candle of wax, with a most limpid light, as long as anything of the camphor remained; which thing carried those ignorant of the secret into no small wonder. Camphor is, by reason of the vivacity of its spirits, so mobile that, unless it be bound together with grains of pepper, it easily passes wholly into vapor and vanishes.

CAPUT VIII.

On various exhibitions of spectacles to be set up by the aid of the pyrotechnic art.

PRAGMATIA I.

To display a flying dragon.

It is commonly known how many people throw into the air a dragon fashioned from light paper, and lead it, by a cord tied to it, wherever they wish — even into the highest spaces of the air, to the utmost admiration of those ignorant of the matter. See what I treated at length on this device in the *Musurgia*. So then, within it [place] a few rockets [rochettae], chiefly at the neck and in the tail; then, a candle being kindled inside at night, [the dragon] will present the whole dragon as fiery, through the paper tinged with oil and steeped in a red and fiery color. You will also kindle inside a lit fuse [fomes], which reaches the mouths of the rockets; and when the fire touches these, at once the dragon spews fire fore and aft, to the great astonishment and fear of those who have not seen the device — [a dragon] which will be the more terrible the more certain words written in foot-and-a-half-high letters [sesquipedalibus literis] are inscribed on the dragon's sides. But this device should be exhibited in the dead of night and with a strong wind blowing; for in calm weather the machine is not easily animated.

Diagram. A woodcut showing a flying dragon (a kite in dragon form) launched into the air on a cord, held by a man standing at lower right who tends the line. The dragon's body bears an inscription.

- On the dragon's body: **TRA DEI** [?] (the two readable letter-groups of an inscription across the dragon's flank; the full word is not resolvable [?])
- Lower right: a standing man holding the cord that tethers the dragon

PRAGMATIA II.

To represent an eagle in the air.

Although an eagle can be expressed in the air in the same way as the dragon, there are nonetheless certain pyrotechnicians who would exhibit one in the air constructed of rockets as well — as I remember having seen myself in Germany. They form the eagle, constructed of rockets, in such a proportion of powder that one rocket does not throw the fire higher than another, but in accordance with the proportion of the feathers in the wings. Then they steep the whole body of the eagle in powder, water of life, and camphor; this material, raised on high by the force of the principal rocket and kindled, exhibits a perfect eagle in appearance, which the explosion of the rockets — indeed the very smoke — then expresses in the air. In this manner you will be able to exhibit anything whatever; for the powder-material, mixed with the rest and sprinkled over the surface of a statue or any figure at all, burns gently, and together with its little flames exhibits the perfect figure.

This invention is full of wonder, and wonderfully suited to terrifying enemies by this spectacle — especially if it is set up with letters expressing some name in the air. It does require an industrious, skilled craftsman, in order that it may attain the desired success; for the machine must be perfectly balanced, then thrown into the air in a perpendicular position by the force of a principal rocket of strength sufficient to raise the machine to a notable height.

Diagram. A woodcut of a heraldic eagle with spread wings (double-headed), constructed from a frame of rockets, viewed frontally. No labels.

PRAGMATIA III.

To express a rotating wheel in the air.

Above the pinnacle of some tower or temple, let a wheel of any size be made, set on an iron pivot [ferreo obelo] so that it can be turned without difficulty. At the

center of the wheel you will be able to fit any figure whatever — an Imperial eagle, the name JESUS [JESU] or MARY [Mariae], or even any statues you wish, made of transparent paper and illuminated by a candle placed inside. A machine of this kind can exhibit a beautiful spectacle in two ways: either by wind or by fire. It is driven by wind if you fix little vanes [scamilli] of light wood on the outer edges of the wheel, against which the wind — whether natural, or artificial, from an Aeolian machine — striking, will turn the machine, as is shown in the first Figure. You will animate the machine with fire thus: you will fit rockets on the surface of the wheel in such a way

Diagram. A woodcut showing the fire-driven wheel: a vertical standard topped by an ornamental crown/foliate finial, with a horizontal octagonal wheel rim from which rockets project tangentially; at the right a large rosette-like burst (flame/smoke) is shown. This corresponds to the wheel animated by fire.

—that they hold an oblique position; these, then, being kindled, will drive the wheel in circles together with the figures placed upon it, as you see in the second Figure.

Diagram. A woodcut showing the wind-driven horizontal wheel mounted on a low frame, with a figure of a man standing upright at its center (the statue/figure to be illuminated), and angled vanes about the rim. This corresponds to the "second Figure" / wheel driven by wind.

PRAGMATIA IV.

To display a pyrobolic organ in the air.

Let rockets be made in the order in which pipes are usually arranged in an organ, and filled with such a proportion of powder that the one which is smallest, kindled first, emits its boom [bombus], and the one next longer in order a little after, another, and the third in order a third, and so on in order, each one after another emits its booms; and you will have a pyrobolic organ, which, disposed somewhere on the height of a tower and illuminated with fire, affects the spectators with wonderful delight. Whoever has rightly understood these few points will be able to exhibit anything whatever in the air by the pyrobolic art. Wherefore I have set these things out not so much at length as merely indicated them in a few words, in order that I might offer ingenious craftsmen some occasion for greater inventions.

Diagram. A woodcut of the "pyrobolic organ": a row of upright pipes (rockets) of graduated, increasing length mounted side by side on a base, in the form of an organ's pipe-rank.

PARS ULTIMA.

On the Secrets of Certain Mechanical Arts, Established after the Pattern of Subterranean Nature.

CAPUT I.

The Art of the Goldsmiths and of the Other Craftsmen Who Work with Metals.

Goldsmiths are occupied chiefly with gold and silver in the making of precious vessels. The nobler the material they work with, the more excellent their art is above the rest. They must therefore be furnished with a great expertise in metallic matters, sufficient to satisfy the demands of their office, and they must possess that knowledge of chemical secrets which, when the occasion arises, they can put on display.

It is accordingly their business: to reduce gold and silver—when crude, stiff, and brittle—to a certain ductility and flexibility suited to the hammer; to weld broken vessels neatly together again; to adorn ornaments, rings, and gold and silver coins with the art of enamelling [encausto]; to know the different kinds of gems together with their value and price, and to set these skilfully into rings; to strike gold and silver statues; and to be thoroughly versed in the spagyric art [Spagyrica], so that with ingenious skill they may melt down metals and separate one from another, whether by aqua fortis [aquas fortes] or by the cineritious crucible they call the cupel [catinum cineritium, quam cupellam vocant], purifying each to its highest perfection. Hence no one ought to be reckoned fit for this art unless he is well endowed with judgment and experience in these matters.

Since this is so, and since they possess certain secrets that are not everywhere ready to hand, I have thought it worth communicating here to the reader those which I have learned through long and continual dealings with such men.

The first question, then, is: **How do they render gold and silver soft and gentle?** I answer that they do this in the following way. Gold is sometimes rendered so crude and stiff by the smell of lead or arsenic that it scarcely yields to the hammer. When such a defect occurs, to the said gold—melted in a crucible—add

glass powder, or some portion of alkaline salt [sal alchali] mixed with wax, or even three or four little portions, as much as can be taken up between two fingers, of ground sublimate [sublimati triti]; then let them be well heated. And although this hardened mixture may not yet have acquired the desired colour of gold, you will nonetheless easily restore it, if—after reducing the gold to thin plates—you smear it with verdigris [aerugine] mixed with sal ammoniac, urine, and vinegar, and then, heated again over coals, it is thrown into urine. By doing this you obtain what you sought.

Silver too is washed, chiefly in works overlaid with gold, if it has been boiled in water with ground sulphur. Some imbue gold and silver with a bright lustrous colour by boiling them together with the shavings of ox-horns and ram's-horns, with ground straw, and the smoke of feathers.

Silver is brought to a pliant and malleable softness in the same way. If it is too stiff and crude, once they have put it into the cineritious crucible [cineritio catino], or have steeped it by melting it with salt, tartar [tartaro], ground niter, alkaline salt, and the other methods devised by the spagyrist, they take particular care that the welding-mass [massam ferruminativam]—which they call solder [soldaturam]—be no harder than the object to be welded requires. They readily correct this, with a reduction of the carat [diminutione caratti], either by alloying it with silver, or by adding to the gold or silver a little borax or verdigris with copper or brass [aurichalco].

Concerning works to be finished by enamelling [encausto], so highly necessary to the skilful goldsmith, we have spoken above—though few are found who are expert in this art. In Germany and France no goldsmith of good repute is reckoned such unless he is strong in this skill. Besides what has been said, they possess the art of overlaying every kind of metal with gold; but I shall disclose some of their secrets.

1. They prepare gold for gilding thus: they take one fifth part of pure gold beaten out with the hammer, to which they add [?]¹—of mercury [[?]] quantity not legibly given before "mercurii"; they mix it well, then commit a small pot [tigillum] to the fire, and when it has grown hot, they cast the mixture of gold and quicksilver into the pot. Once the mercury has evaporated, they throw the remaining gold into a small dish [scutellam] filled with cold water; and in this way they have washed gold [lotum aurum] for gilding metallic works of every kind. [Margin: Method of gilding.]

For if they wish to gild copper [aes], they smear the copper plate, a little beforehand, with gold prepared as above, and leave it set out upon coals until it shines with a golden colour; then, taken out and cleaned with vinegar applied by a brush [setaceto], they polish it. [Margin: Gilding of copper.]

They gild iron in this way: they first boil the iron, placed in vinegar mixed with salt and vitriol; then, drawing it out, they smear it with gold prepared a little before. [Margin: Method of gilding iron.]

2. The method of separating silver from gold they observe thus: they perfume the gilded silver with sulphur placed around it, then they take [Margin: Separation of silver from gold.]

mercury, which they place in a small pot, into which they cast the gilded silver while heated; and at once separation follows, the mercury drawing to itself the gold that lies hidden in the silver. The silver, on the other hand—now stripped of its gold—is restored to its original nature simply by boiling it in water made of tartar. The gold they separate from the mercury by this device: they expose to the fire, in a small pot, the gold impregnated with mercury, and in this way, the mercury evaporating, the gold will remain; and this, purified in the cineritious crucible, is restored to its former brightness. [Margin: Separation of gold from metals.]

3. How gold may be separated from gilded metals. It is an artifice of great usefulness to recover the gold laid over metals and over wooden panels. Proceed thus. First take a large crucible, which, filled with mercury, is to be heated over the fire in a little chemical furnace [furnulo chymico]; and when it has begun to boil, let the gilded body be sent into that mercury. Then rub it with an iron brush [ferreo setaceto] for so long until you find that the mercury has drawn all the gold to itself. This done, take out the mercury, put it into a leather purse [coriaceae bursae], and squeeze it for so long until all the mercury has flowed out. And when this is done, what remains in the purse is gold separated from the mercury, in the form of sand; which, evaporated by being set over coals, is restored to its former state.

Another way of separating gold from gilded metals is this: let the metals be covered in a small pot with live sulphur [sulphure vivo] ground to powder; and when it has stood a while in the fire, you will pour it out into a crucible [catinum] and gather up all that which, together with the sulphur, is scraped off from the gilded metals—this will be gold in the form of a leaf [foliati] clinging to the sides of the pot. This done, you will separate the gold from the burnt sulphur by means

of the cinder-crucible or cupel with lead, just as we have already taught in various places in the preceding books.

A third method is by means of an aqua fortis compounded of saltpeter [salenitro], alum—commonly called *alum of Rocca* [Aluminze vulgo di Rocca]—vitriol, sal ammoniac, and a little verdigris. This water, by its caustic force, will begin to gnaw the gold residing in the gilded metals; and once it has drawn into itself all that has been consumed, you will let the water, now saturated, evaporate in a glass vessel set in the little furnace, and the gold will remain at the bottom. These are the three methods by which gold, in gilded objects—whether of metal or of wooden panels—is separated not without profit.

4. From the dross or refuse of the ores of gold and silver already smelted [loppis sive quisquiliis minerarum], which seem to serve no further purpose, the metallurgists are accustomed to separate gold and silver with the greatest gain. The smelters of metals call this mineral matter of gold and silver "dross" or "refuse" or "dead bodies" [corpora mortua], and everywhere cast it away as useless. How, then, they are accustomed to extract gold and silver from these, I shall here teach, and impart to the reader as a secret of great profit—one which consists in the wondrous virtue and power of mercury alone.

Let a mill be made of roughly the form which painters are accustomed to use in grinding gypsum or chalky material. Let there be a marble vessel **A**, into whose cavity is put another very hard stone, of the kind that millstones are, to which you give a handle at **C**—a handle so fitted to the vessel **A** that the material to be ground may always be put in. With this hand-mill prepared, put in as much as you wish of the mineral matter or dross or refuse, first well ground; to it you will pour vinegar, or water diluted with sublimated sal ammoniac, verdigris, and common salt. Over this you will then pour a good quantity of mercury, until the whole material is covered by it; and by working the mill for the space of one or two hours let it be most thoroughly kneaded. And the better the material is ground, the more readily will the mercury accomplish its effect, drawing into itself whatever gold lay hidden there. The mercury, then, washed with water and purged of earthy refuse, is placed within a crucible, where, roasted by the fire, it flees and passes off into vapor, leaving the gold at the bottom; or—what amounts to the same—pressed out through a leather purse, it leaves the gold within the purse. I have known a good many Venetians to have come to the greatest riches by this method; for which reason they keep it as a great secret.

Since goldsmiths often have need of the calxes [calcibus] of metals, I shall explain in a few words how they are accustomed to calcine the several metals by chemical art; for they are sure and very fine secrets.

First. They resolve gold into a calx thus. Let there be made a vessel furnished with a long neck, **A B**, into the bottom **C** of which lead is put; then upon the mouth of the vessel **A** set a gold coin or a plate, which you wish to resolve into a calx. Then let a fire be kindled in the hearth, by whose urging the lead is melted; let the fire be increased until fumes begin to rise up from the lead, which, acting continuously upon the gold coin, render it so morbid [morbidum] that, when the operation is finished, it is easily reduced to powder—though, saturated with borax, it is easily reduced again to its former substance. The reason for this is plain: for the mercurial spirits lurking in the lead, being fugitive, when they find no escape, act upon the gold coin, eat it away, and in this manner render it morbid; and this is the calx of gold. [Margin: Calcination of metals.]

Diagram. A tall, long-necked distillation flask or retort with a swelling bulbous body at the base and a narrow neck rising to a flared mouth at the top. Flames are drawn around the lower bulb. Labels:

- **A** (at the flared mouth / top of the neck): the mouth of the vessel, where the gold coin or plate is set.
- **C** (at the swelling base, partly obscured by the drawn flames): the bottom, where the lead is placed.

[The label **B** named in the text (vessel "A B") is not separately legible on the figure; only A and C are clearly marked. [?]]

Others do it thus: they put well-filed gold into the sharpest vinegar for nine days [ad novendium]; then they take it out to be dried in the sun. When dried, they grind it upon marble with water of sal ammoniac, and again set it out to be dried

—they set it out; and by repeating this seven times, you will have the calx of Sol [the Sun = gold] prepared. Others accomplish the same by pouring gold upon heated mercury; the mixture they then press with fire for so long until the fugitive mercury is separated from the gold. The gold that remains at the bottom—grind it upon marble with dissolved sal ammoniac, wash off the salt with fresh water, and you will have the calx of Sol.

Secondly. They calcine silver in exactly the same way as gold, by the vapor of lead or of mercury, to which calcined tartar and sal ammoniac are mixed, and

you will obtain the calx of Luna [the Moon = silver]. [Margin: Calx D / Calx of Luna.]

Thirdly. Venus, that is copper [aes], they calcine thus: they steep copper plates in vinegar diluted with common salt; these, when dried, they commit to the calcining furnace for three hours; then, taken out, they quench them with vinegar diluted with salt as before, and what was scraped from the plates and mixed with the vinegar is left within the salted vinegar. This you will carry on for so long until the plates are entirely consumed. This done, the vinegar being separated, you will find at the bottom of the vessel a powder, which they dry, ground and worked together with borax and tartar and the oil of the same; the dried powder they again commit to the fire for fusion, and the molten matter they receive in an iron vessel smeared inside with tallow; and when cooled they find it now white and soft, which is of much use for sophistic silver [sophisticum argentum]. [Margin: Calx of Venus.]

Fourthly. Tin, that is Jupiter, you will calcine thus: let tin plates be cut into small particles; then, within a pot strewn with quicklime, let the bits of tin be laid over the lime up to the top of the pot. Then, the pot being sealed with the lute of wisdom [luto sapientiae], as they call it, let it be placed in the calcining furnace for 24 hours. These elapsed, take out the tin, and let it, dissolved by fire, flow out into vinegar; this, then reduced to ash, you will coagulate after the operation has been repeated three times. Quench the coagulated mass in water of mercury, and you will find it hard like silver. [Margin: Calx of Jupiter.]

Fifthly. You will calcine Saturn [lead] if you pour molten lead into water prepared from a lye made of ashes. Within this water let it be quenched four or five times and then dried; the dried mass, put into a well-stopped pot, is committed to the furnace for the space of 24 hours; which, taken out, you will then find imbued with a green color—the true calx of lead, which the alchemists persuade themselves to be a short road to Sol. [Margin: Calx of Saturn.]

Sixthly. You will calcine iron in the philosophical manner thus. Let plates of well-purged iron be made red-hot, and let them be quenched seven times in linseed oil; and they will turn out soft, like wax. Cut these into small particles, then make layer upon layer, together with crude mercury, in a well-luted pot, which, set in the calcining furnace, is to be pressed with a strong fire for 12 hours; and at last take out the cooled material, which you will find glowing white like Luna [the Moon], and this you will keep in reserve. [Margin: Calx of Mars.] I could adduce here innumerable methods of calcining metals, but because we have set them

down everywhere else, I have thought fit to add in this place only those which I have learned by experience solely from goldsmiths and alchemists.

You will produce sophistic gold [aurum sophisticum] if you work the calx of Luna prepared above together with the calx of eggs [calce ovorum] and water of orpiment [auripigmenti], and, when dry, set it in the furnace. After this fourfold operation, take it out, and work it free of fume with water of sal ammoniac; then, set in dung [fimo], it will be resolved into a water, which you will strain through a filter into a glass vessel. The strained liquid, dry into a powder, one part of which is to be joined to 40 parts of well-purged copper, and you will have sophistic Sol. [Margin: Sophistic gold.]

You will make sophistic silver from one part of the calx of Luna, from 2 parts of fixed and sublimated mercury, together with as many parts of fixed and sublimated sulphur, and with water of mercury; and when it has been dried for the third time, you will repeat the same operation. This done, put it into glass, which—buried in horse-dung—you will keep until it dissolves into a water; it is then dried in the furnace of sublimation; the fixed mass you will work with water of mercury or of sal ammoniac; then, to putrefy it, you will bury it within dung; the putrefied mass you will commit to the furnace for 24 hours. Of this powder, half an ounce projected upon one pound of well-purged Venus [copper] will give you the desired sophistic silver. [Margin: Sophistic silver.]

Here too it would be proper to say how common salt, sal ammoniac, sal alkali, borax, and the like are to be prepared, together with their waters and oils. But since these are now everywhere to be had from the apothecaries and are treated in various chemical books, I have not wished to dwell upon them; here we adduce only what has been seen and proven.

On the Arts of Gilding, Ironworking, Coppersmithing, Wire-drawing, Tinwork, and the Like.

[De Arte Inauratoria, Ferraria, Æraria, Filatoria, Stannaria similibusque.]

Each of these arts has secrets not to be despised, for the softening, hardening, and tempering of iron, copper, tin, and the like. But since all these matters have been set down in Books IX and X, we refer the reader there—including the various methods of gilding silver, tin, copper, and iron, as well as the numerous methods of engraving [incidenda] upon those said metals, whatever ones you wish, by means of aquae fortes and caustic waters. But since these have become known by daily experience, I have not thought this work needs to be patched up with them.

The art of wire-drawing [Filatoria Ars], however, contains—I know not what—something admirable and paradoxical, in that gold, silver, copper, and iron (whereas tin and lead, on account of the limpness and dullness of the material, are not fit for being drawn into threads) yield threads that have altogether innumerable uses, both in the matter of clothing and in the rest of furnishings, the hangings [peripetasmatum] and ornaments of the temple—since nothing is held of value that is not interwoven with gold and silver thread.

Now there are three kinds of thread. Of the first kind are threads

most minute, fine, and round, such as the gold and silver threads that serve weavers, while the gold and brass [aerea] threads serve chiefly for musical instruments. Of the second kind are gold and silver threads which have a certain breadth, according to the nature of the things to be woven—now narrower, now broader. These threads indeed are not drawn through holes like the former, but the gold and silver are beaten into plates, yet so that they are not unlike very thin paper; these plates, then—just as here at Rome the women do—they cut lengthwise to whatever breadth they wish, and consign to the weavers and embroiderers [acupictoribus]. Of the third kind is gold reduced by the work of hammers into a very thin substance, which, kept within little books of paper, serves for the gilding of objects.

But let us now expound in a few words the practice of the wire-drawing art. Gold, silver, copper, and iron are first drawn out into oblong, fine, rounded rods; these are then drawn ever through narrower and narrower holes, by the aid of suitable machines, into thread of whatever thickness, so that they are sometimes drawn through thirty different holes, ever smaller and smaller, until they come to such fineness that they match the thickness of the finest hair. By experience I have found that half an ounce of silver, after being constricted through the most varied holes, is extended at the last hole to such a length that it equals 600 geometric feet [600 pedes geometricos]. From which arises the following problem.

PROBLEM.

Given the weight of a metal and the size of the hole through which it is to be drawn, to find into how great a length it can be extended.

First take a thread of any number of feet, drawn through the given hole, which you will first most carefully weigh. Let it be, for example, a thread of ten feet, and let it weigh one grain [granum]. In this way you will arrive at knowledge of the extension of any other body drawn through the hole. Say: *10 feet weigh 1 grain; how many grains will a thread of 100 feet weigh?* And the weight sought will

result. But having the weight of the metal, if you wish to know its length, say: *1 grain gives a thread 10 feet long; to how many feet will a scruple, an ounce, a pound be extended?*—and you will have what you sought. You will operate no differently with the rest of the metals.

For example: I wish to know into how great a length one pound can be extended. Let it be: as one grain is to a thread of 10 feet, so 6912 grains, which make one pound, to another. There will result a length sought of 69120 feet; that is, 14 miles [milliaria]. This again being posited, if you wish to know into how great a length 125 pounds of silver can be extended, say: *1 pound gives a length of about 14 miles; how much will 125 give?* And there will result 1750 miles, and so of the rest.

Hence it follows, first, if anyone wishes to know how many pounds of silver ought to be extended to make up a thread that would encircle the whole terrestrial globe: now it is established that the terrestrial circumference is 21600 Italian miles. Say, then: *14 miles give 1 pound of silver; how much silver will 21600 miles give?* And there will result 154 pounds and $\frac{2}{7}$ [154 librae è $\frac{2}{7}$ — fraction read as $\frac{2}{7}$ from the tile; printed as "è $\frac{4}{4}$ "-form, i.e. $\frac{2}{7}$]. So many pounds of silver, then, are required to make a thread that would encircle the whole terrestrial mass; the third part of which, 52 pounds, will give a chord equal to the entire diameter.

But if you desire to know into how great a length a thread could be extended which, when coiled up, would be as heavy as the whole mass of the earth: we suppose, according to what has been demonstrated by Archimedes, that the terrestrial mass, if it were solid, weighs 659236344266528723850720 00 pounds [659236344266528723850720000]. Say, then: *1 pound gives 14 miles; how many miles will 659236344266528723850720000 pounds give?*—or, into how great a length will it give?—and there will result the miles of the length sought, which thread, equal in weight to the terrestrial mass, would in length far exceed the circumference of the whole mundane mass.

It is plain, therefore, that what we have said of the silver thread can be said of all the other metallic threads. For if you wish to investigate the said matters in a gold thread, take a gold thread of any number of feet long—for example, 5—and let this thread weigh 2 grains. Say: *two grains give 5 feet; into how many feet will 20 grains in a mass of gold be extended?*—and, the operation performed, there will result 100 feet, and so of the rest.

Note first that we here take one scruple for 24 grains, and one ounce for 24 scruples, 12 ounces for one pound; so that one ounce has 576 grains, and one pound has 6912 grains.

Note secondly that the material of the metals is partly quicksilver, partly sulphur. Whatever metals, therefore, have more of mercury will yield deeper [graviores] sounds; those that have more of sulphur, sharper [acutiores] sounds. And so the chemists hold. But I, for my part, would ascribe the depth and sharpness of sounds to the elementary qualities as well: so that that body which has more communion with earth and the moist sounds deeper, while that which has more with earth and fire sounds sharper. For a moist body mixed with earth—besides that it condenses and binds together—from the close packing of its parts also renders it heavy and weighty; whence a deep sound too must necessarily follow. But a dry, earthy body—besides that it dilates and extends the body, from the variety of its parts—renders it light and porous, which lightness a sharp sound necessarily follows; though these things can easily be reconciled with chemical principles.

Gold is not only drawn out into thread to an infinite extent, but is also beaten into surfaces so thin that they affirm 1600 leaves [folia] to come out of one ounce of gold; and although

DE ARTIUM MECHANICARUM ARCANIS. [On the Secrets of the Mechanical Arts]

Gold is the heaviest of all metals; yet its leaves are of such fineness that they can scarcely be made to sink beneath water. Moreover, 1600 leaves laid out flat cover a surface of nearly 400 square feet. From this anyone could easily reckon how much gold would be required to gild the vault of some church, and how much would be needed to gild the whole mass of the Earth, were it a perfect sphere.

But let me return to my subject. As for the brilliance of the gold and silver leaves, they certainly appear so exactly worked that they seem to be pure, unmixed gold and silver to anyone who does not know either the deception [fraudem] or the craftsman's skill—when in fact a large proportion of brass [aeris] goes into them, with very great profit. They proceed as follows. From brass they draw out a rod about four feet long [quadripalmarem] by the continuous beating of a hammer, then wrap it round with a leaf of gold or silver, very finely worked and soldered onto the outer face, so that the whole appears either gold or silver. This rod, so soldered, they place inside a flame-spouting furnace, where they leave it until it is close to the point of fusion. Then they take it out and beat it with a hematite stone, using the hammer as well, hammering and flattening it until it is thoroughly incorporated into the brass. Once this is done, it is fired again and

beaten into thin plates suitable for drawing out [into wire]; and by this technique the gold and silver threads acquire much greater brilliance than if they were made of pure gold and silver. But since I have dealt thoroughly with the powers and properties of strings in the Sixth Book of the *Musurgia* [Kircher, *Musurgia Universalis* VI], I refer the reader there, where I have worked out the weights of strings made of gold, silver, iron, and brass according to the laws of harmonic art, together with a great many other secrets worth considering.

To these I will add a secret for softening horn [quo cornua mollefiat]. The first method is this. Take urine that has been fermented for four weeks in a well-covered pot. Into it put one pound of quicklime, half a pound of the ash they call *soda* — or else ash from tartar — 8 pounds of tartar and as much salt; let everything be thoroughly mixed and set over a fire to boil. Then strain it twice and keep it carefully. When you wish to soften horns, place them in this lye for eight days, and you will have horn as soft as dough. Others achieve the same with ash made from burnt poppy stalks and the lye made from it, in which they put the horns to be boiled down. The second method teaches how to soften them so that they can be cast in molds, and they proceed thus. Take one pound of the soda that glassmakers use, one pound of quicklime, and one measure of water; let everything be boiled to half its volume. Then take filings of horn of any kind, and let them steep in the prepared water for two days. Next knead the whole mass like dough with your hands first smeared with oil, and once kneaded, press it into the mold of whatever form you wish; and when it has hardened you will have the horn image you sought. The third method is this. Take juice of white horehound [marrubio albo], ivy, radish, and greater celandine, together with strong vinegar; mix everything together, and let the horns be placed in it to steep for seven days inside horse dung. Then proceed as I taught in the preceding method.

CAPUT II.

De Arcanis Miscellaneis. [On Miscellaneous Secrets]

So that I may not seem to have omitted any of the curious matters in this Work, I shall treat here a few things that I hope will not be unwelcome to the curious reader. But, to delay no longer, I shall set out the whole matter in a number of propositions.

PROPOSITIO I.

To transmute air into water.

Michael Sendivogius [Michael Sendivogius], in his *Lumen Chymicum* [*The Chemical Light*], sets out the matter thus: *Make a copper instrument of the form you see here. Inside this machine, joined together and soldered from three parts, place a sponge at the bottom; and above the sponge place two pounds of marble that has been calcined for a whole natural day inside a glassmaker's furnace, to which you will mix one pound of red marble crushed into the smallest fragments. Then, after [air] has been drawn in through the lower little channel — for the hotter the heated chamber [hypocaustum] in which the instrument is placed, and the colder the air outside the chamber's window (for the channel E D must terminate outside the window of the heated chamber —*

Diagram. An alchemical/hydraulic apparatus shown in the lower right of the page, drawn vertically. At the top is a gourd- or retort-shaped vessel with a long curved neck rising to the right; the body of this upper vessel is partly filled (the fluid line is engraved across it). Below it a second, rounded vessel sits on a small foot, connected to the upper vessel by a short central channel. The lettering keys it to the surrounding text (the "instrument" of Sendivogius for condensing air into water).

- D (tip of the upper vessel's curved neck): D — the outer terminus of the channel
- E (upper neck, below D): E — the upper part of channel E D
- A (body of the upper vessel): A — the upper chamber holding marble and sponge
- L (junction / mouth of the lower vessel): L — the connecting channel into the receiving vessel
- M (lower receiving vessel): M — the vessel placed underneath to collect the water

— the more abundant a supply of water you will obtain through the opening of the channel E D, which at D is extremely narrow,

shaped like a needle [adinstar acus], having an orifice. Through this orifice, then, the cold air insinuating itself will quickly be resolved into water, which, filtered through the marble and the sponge, will flow down through the little channel B into the vessel set below, M — in such abundance that it would suffice for people and horses to drink in time of need. So says Sendivogius, who, in the manner customary to boastful alchemists, certainly promises far more than reason and

experience dictate. He adds that water of this kind is of such marvelous virtue that he has no doubt one may at last reach the great goal of the Art by the benefit of this water. But for my part, I find no special virtue in water of this kind, other than that which in winter clings to the windows of a heated chamber — resolved partly by the virtue of the external cold and partly by the warmth within. Since this is plain water, imbued with no metallic or celestial impressions, I therefore judge it to be a foolish fantasy of the alchemists to seek in it what is not there — the fantasy by which they dream that there is nothing that cannot contribute to the great secret of the [Philosophers'] Stone. I do not deny that some water can be collected this way; but what the calcined marble and the sponge contribute to the matter, I do not see — since they are more of a hindrance than a help to the gathering of the waters, in that they absorb the descending water rather than letting it flow on further. But I see well enough what he was aiming at with all this. Since he saw that the instrument was too simple, indeed common, he seems to have invented this useless addition gratuitously, in order to confer on his secret contrivance some authority among the ignorant. I am not unaware that various hydraulic vessels can be made — of the kind that I too display in my own Museum: vessels of every sort, aeolipiles, hydrolcia [water-drawers], absorbents — which are moistened within by the attraction of cold air, or by the mere touch of a warm hand. But one that would yield, from resolved air, the quantity of water he claims, I have never seen. It seems to do only as much as a breath does, which, when breathed out onto a window cold on the outside, is immediately condensed into moisture. Therefore the fact that in heated rooms the windows run with water in winter is not due immediately to the inner air itself, but to the varied and continuous breathing of people: when it strikes the cold glass of the window, it is at once resolved into moisture — as experience shows with mirrors and glass that are breathed upon. Add to this that an entire cask of external air resolved by heat can scarcely supply an ounce of water, as I have shown elsewhere by various experiments; for unless vapor is present, air by itself holds little or no water, as I taught in the art of distillation.

PROPOSITIO II.

On Mercurial Machines. [De Machinis Mercurialibus]

It is asked whether mercury can be set into motion by artificial machines. I say that this can be done by many a method and procedure. But let me explain a few.

First. If you wish a ring to move by itself, do as follows. Make a ring hollow on the inside, of any material — gold, silver, brass, iron, glass, or earthenware — and into its cavity put a little quicksilver, for example to the halfway point, so that

half the ring is filled with mercury. This done, close the orifice as firmly as possible, so that the mercury cannot escape. Then heat the ring; and when the mercury begins to evaporate, you will see, to your astonishment, the ring make certain wondrous leaps and move this way and that, exactly as though it were animated and driven by some hidden demon lurking within.

Second. How a cart or carriage animated by quicksilver can move forward of its own accord with the greatest force. Make a little carriage of wood, fashioned with its wheels and horses — of the kind commonly made in Germany, cheap — and into this carriage fit a small tube made of brass or iron, partly filled with quicksilver. Then close the little channel so tightly that no entry is allowed to the air and no exit for the mercury to slip out. Set this on some flat, smooth table, then heat the channel with a candle; and behold, the little carriage will run back and forth across the whole flat surface on its mobile wheels, not without the astonishment of onlookers. By this same device one may put on, for the delight of spectators, men walking and birds swimming through the air — yet bound by an iron thread to a ring — and countless other spectacles.

If, however, anyone should wish to display either a human figure or a globe moving upward by a perpendicular, he will proceed thus. First make a triangular prism constructed from three iron wires *a b*, *e f*, *d c*, of the form shown here. Let it have on its lower base *b c* a shell filled with burning coals, on which is set a sphere fashioned in the form of a worldly or imperial globe, cast of brass, iron, or potter's earthenware. Fill this to about a third with mercury and stop the mouth as tightly as possible — but you will do better if you make [the opening] somewhere on the side of the globe. This done,

Diagram. The figure runs vertically down the right margin of the page. At the top a cloud-like mass with a hanging chain illustrates the suspended figures ("men walking, birds swimming through the air, bound by an iron thread"). Below, a tall triangular framework of iron wires rises on a square base-plate; at its foot sits a shell-shaped dish of burning coals (flames engraved), and above the flames a spherical globe surmounted by a cross (the *globus mundi* / imperial-orb form). The mercury-filled globe rises and falls within the wire framework as it heats and cools.

- A (left upper corner of the base / framework): A — a vertex of the triangular wire prism
- D (right upper corner): D — a vertex of the triangular wire prism
- B (left front corner of the base-plate): B — the lower base, corner *b*
- C (right front corner of the base-plate): C — the lower base, corner *c*

- F (on the globe, by the cross): F — the cross-surmounted globe (imperial orb) filled with mercury

you will set the whole machine on a table — yet in such a way that it is held up from above, either by a hook or by a hand drawn down out of the clouds, since the iron wires, being extremely fine, cannot stand up by themselves. And you will see the enclosed mercury, even at the first heating, begin to stir up its usual tumults; then it will gradually begin to rise within the iron wires (which serve as a kind of bar to keep the globe from being flung outward) all the way to the top of the prism. Then, as the vapor cools, it will begin to descend in the same proportion of motion by which it had ascended; and when it reaches the place near the coals, there, stirred up again, it will be seen to hang as if suspended. A machine truly full of wonder — yet whose explanation no one will easily grasp unless he thoroughly knows the property of mercury. It will produce a still greater effect if you pour water mixed with niter [aquam nitro subjectam] over the mercury. I could bring forward here a great many machines of this kind, but in order to leave the curious reader room to think out more, I have judged it best to set down here these few only.

CONCLUSIO OPERIS. [Conclusion of the Work]

Having struggled out at last from the dreadful and dread-filled darkness of the Subterranean World — through the hidden inner recesses of Nature's and the Ocean's storehouses, through unseen paths never until now attempted by anyone — with God as our Guide and Director, we have come into the harbor long since desired and longed for, amid the great anxiety of a troubled mind, having performed countless labors and Herculean ventures. I have done what I promised, and have carried it out so far as the weakness and powerlessness of my mind permitted. I have demonstrated the admirable order, arrangement, and purpose of the inner Fabric of the Geocosm, the kernel of all Nature being unfolded; and in all these things, both as a whole and one by one, the reader will note, unless I am mistaken, the unspeakable providence of Divine goodness, and how — amid so great and so incomprehensible an apparatus of the most disparate things — their multitude, variety, and richness have been set forth, both for the manifestation of the glory of His majesty and for the preservation of the salvation of the human race. Now at last, my hand withdrawn from the picture and my eyes lifted to heaven, nothing remains but that to the supreme and glorious εὐεργέτης [Greek: εὐεργέτης (euergetēs, "benefactor")] of Nature we render — if not the thanks we owe, then at least the thanks we can — and that we confess before all the living to Him who has dealt His mercy with us. *For it is good*

to hide the secret of a king, but to reveal and confess the works of God is an honorable thing [cf. Tobit 12:7]. And so, to the supreme King of the ages, immortal and invisible, to the holy and undivided Trinity, to the Father and the Holy Spirit, to the one God — from whom, in whom, and through whom all things exist, and without whom we can not only not do, but not even think, anything good — be all honor and glory.

Then to you, Savior of the human race, the God-man [Greek: θεάνθρωπος (theanthrōpos, "God-man")] JESUS CHRIST, the Power and Wisdom of God [σοφία θεοῦ καὶ δύναμις — cf. Greek: σοφία (sophia, "wisdom"); δύναμις (dynamis, "power")], who have deigned to bring these labors of mine, such as they are, to the best end — who, that I might complete a work far beyond my own strength, have conferred a copious gift of grace upon your little servant. You, as eternal Truth, uncreated Wisdom, and the Word of the eternal Father, have likewise illumined my darkened soul with your light, visited it with grace, lifted up my mind, roused my affection, supplied your aid. To you also, eternal Love the SPIRIT, supreme Giver of graces [Greek: πανταδότης (pantadotēs, "giver of all")], who, brooding over the dark abyss of my intellect, have made fruitful a mind condemned to barrenness with the love of heavenly things, have animated it into bearing fruit, have inspired it though it did not yet will, that I might will it — have helped the efforts of my good will, that I might be able and might act — you who in your own [servants] work the being-able, the willing, and the accomplishing. To you, finally, dispenser of the divine gifts, the VIRGIN MOTHER OF GOD [DEIPARA], I give thanks entirely [Greek: πανταχῶς (pantachōs, "in every way")]: by whose kindness, merits, and intercession — not in this Work alone, but in all the others published hitherto by my slight self — I have wished it to be manifest by these words that I have, in a marvelous manner, obtained from you, most merciful Mother, this grace: that I might accomplish something. Last of all, to the most holy ANGEL of my guardianship, divinely appointed to me, who was always present with hidden promptings, who stood by me with his light in doubtful, arduous, and most difficult matters, and gave me the occasion that what I willed I might also accomplish. Praise therefore be to God the Father of lights, without whose protection — as deservedly all human wisdom is folly — so too all the efforts of human genius give out, fruitless and vain, like worthless slag tossed about in the threshing-floor.

Omnia ad maiorem DEI gloriam Virginisque MARIÆ. [All for the greater glory of GOD and of the Virgin MARY.]

— ad adamantes formandos idonea [suitable for forming diamonds]	457.a.
— fortis compositio [composition of aqua fortis]	200.a.

Headword	Reference
— conditiones [its conditions]	215.b.
— vitae praeparatio [preparation of aqua vitae]	261.a.
— regia [aqua regia]	ibid.
— mercurialis [mercurial water]	ibid.
— perennis [perennial water]	261.b.
— mercurialis vires [the powers of mercurial water]	ibid.
— salis petrae purificatio [purification of saltpeter]	438.a.
— gemmas penetrantis confectio [making of gem-penetrating water]	459.a.
Aquilae animalium venenatorum pastu gaudent [Eagles delight in feeding on venomous animals]	122.a.
— quomodo in aere pyrotechnica artis ope repraesententur [how they may be represented in the air by the art of pyrotechnics]	480.a.
Arabes de Alchymia scripserunt [The Arabs wrote on Alchemy]	231, 236.a.
Araneus bufonem occidit, & cur [The spider kills the toad, and why]	321.b.
— qui generetur [how it is generated]	368.b. 369.
— astronomum & geometram agit [plays the astronomer and geometer]	396.b.
— ad quid utilis [for what it is useful]	376.a.
— ejus symptomata & remedia [its symptoms and remedies]	143.
— coitus [its coupling]	369.a.
Arbor quomodo inserenda [Tree, how it is to be grafted]	382.b. & seq.
— quid faciendum ut fructus differentes proferat [what is to be done so that it	386. & seq.

Headword	Reference
brings forth different fruits]	
— una [a single one]	

Index of Subjects and Words of the Second Volume (continued)

This opening continues the alphabetical subject index of Tomus II, running from mid-letter A through the start of letter M. Each printed page carries two columns; the table below follows printed column order (left printed-column fully, then right printed-column) across the four pages, in the alphabetical sequence confirmed by the catchwords ("Calcis," "Draco-," "tur," "dit").

References preserve the page number and the column marker "a" (left) / "b" (right) of each cited page, with "ibid." (same place), "& seq."/"& seqq." (and following), and conjoined cross-references kept verbatim as printed. The English bracket after each lemma is a sense-gloss of the Latin headword.

Letter A (concluded)

Lemma [sense-gloss]	Reference(s)
<i>casu subinde alias producit</i> [by chance it sometimes produces others]	387, b.
<i>in phiala nata</i> [born in a flask]	413, b.
<i>philosophica quotidie crescens</i> [the philosophical one growing daily]	431, b.
<i>Lunae</i> [of the Moon]	432, a.
<i>Luna mercurialis</i> [the mercurial Moon]	ibid.
Arbores quae sub Zona torrida nascuntur, cur solidissimae [Trees that grow in the torrid zone, why most solid]	409, a.
<i>metallicae quae</i> [which are metallic]	431, b.
Arcana Chymica [Chemical secrets]	290 & seq.
<i>Artium mechanicarum</i> [of the mechanical arts]	481 & seq.

Lemma [sense-gloss]	Reference(s)
Argentum libenter sociatur cupro [Silver readily combines with copper]	187, a.
<i>quomodo ex aqua extrahatur</i> [how it is extracted from water]	215, b.
<i>ex ejus scoria aurum extrahendi modus</i> [the method of extracting gold from its slag]	224, b.
<i>quomodo ab auro separetur</i> [how it is separated from gold]	249, b.
<i>qui in aurum convertatur</i> [how it is converted into gold]	307, a.
<i>omnes colores in se continet</i> [it contains all colors within itself]	429, a.
<i>quocunque modo calcinatum in pristinam formam reduci potest</i> [calcined in whatever way, it can be reduced to its former form]	429, b.
<i>an in liquorem solutum reduci queat</i> [whether, dissolved into a liquid, it can be reduced]	ibid.
<i>quomodo vitrescat</i> [how it turns to glass]	352, b.
<i>qui crystallescat</i> [how it crystallizes]	457, b.
<i>quomodo dulce reddatur</i> [how it is made sweet]	481, b.
Argenti natura & proprietas [The nature and property of silver]	203 & seq.
<i>inveniendi & praeparandi ratio</i> [the method of finding and preparing it]	204, a, b.
<i>adulterandi variae fraudes</i> [various frauds for adulterating it]	205, b.
<i>in medicina usus</i> [its use in medicine]	204, b.
<i>sympathia & antipathia</i> [sympathy and antipathy]	206.

Lemma [sense-gloss]	Reference(s)
<i>scoria quae</i> [what its slag is]	206, b.
<i>purgandi modus</i> [the method of purging it]	211, a.
<i>pulveris mira proprietas</i> [the wondrous property of its powder]	215, b.
<i>praecipitatio quid</i> [what its precipitation is]	243, b.
<i>quantum auro insit explorare</i> [to investigate how much is present in gold]	439, b.
<i>calx</i> [its lime/calx]	483, a.
Argentum vivum quid operetur [What quicksilver effects]	116, a.
<i>sanguinem congelat</i> [it congeals the blood]	122, b.
<i>omnium venenorum calidissimum est</i> [it is the hottest of all poisons]	122, a.
<i>quomodo frigus inducat, & qui humidum dicatur</i> [how it induces cold, and why it is called moist]	123, b.
<i>idem cum mercurio & hydrargyro</i> [the same as mercury and hydrargyrum]	150, 151.
<i>est duplex</i> [it is twofold]	152, b.
<i>ex mineris extrahendi modus</i> [the method of extracting it from ores]	211, b.
<i>eius proprietas, symptomata, remedia</i> [its property, symptoms, remedies]	140, 150 & seq.
<i>qui calcinetur</i> [how it is calcined]	383, a, b. <i>Vide Hydrargyrum & Mercurium</i> [See Hydrargyrum and Mercury].
Arnoldus illicitis artibus deditus [Arnoldus, given to illicit arts] [Arnald of Villanova]	277, a.
<i>prophetiae donum affectavit</i> [he	ibid.

Lemma [sense-gloss]	Reference(s)
affected the gift of prophecy]	
<i>hominem se fecisse arte chymica impie asserit</i> [he impiously asserts that he made a man by chemical art]	ibid.
ars magna quid veteribus [what the great art was to the ancients]	313 & seq.
<i>Aurifabrorum circa quid occupata</i> [with what the goldsmiths' art is occupied]	481, a.
Arsenici vis [The power of arsenic]	115, b. 337, a.
<i>proprietas, symptomata, remedia</i> [property, symptoms, remedies]	140, 147, b. 148, a, b.
<i>malignitas</i> [its malignity]	173, b.
<i>fodina</i> [its mine]	227, a.
Asbestus quid [What asbestos is]	66.
<i>an sit combustibilis</i> [whether it is combustible]	67, b. & seq.
<i>ubi reperiatur</i> [where it is found]	ibid.
<i>ligni formam exprimit</i> [it expresses the form of wood]	68, b.
<i>an ex eo oleum extrahi possit</i> [whether oil can be extracted from it]	71, a. 436, a.
Asbesti denominationes [The names of asbestos]	66, b.
<i>charta</i> [its paper]	67, a. 74, a.
<i>redimiculum, elychnium</i> [its band, its wick]	ibid.
<i>compositio</i> [its composition]	b.
<i>definitio</i> [its definition]	68, b.
Asciomenes feras domat [Asciomenes tames wild beasts]	412, b.
Aspalathus ubi nascatur [Where aspalathus grows]	119, a.

Lemma [sense-gloss]	Reference(s)
Asparagi in cornu arietis nati [Asparagus born in a ram's horn]	344, b. 388, b.
Aspidis symptomata & remedia [The asp's symptoms and remedies]	143.
Asthma quomodo curetur [How asthma is cured]	174, a.
Attractionis metallica causa [The cause of metallic attraction]	155, a.
Avis velocitas qui expendatur [How a bird's speed is measured]	448, a.
Aurum ab argento qui separetur [How gold is separated from silver]	119, b. 214, b.
<i>in stomacho perdicum repertum</i> [found in the stomach of partridges]	200, b.
<i>in cranio hominis</i> [in a man's skull]	ibid.
<i>in Hispaniola passim purum est</i> [in Hispaniola it is everywhere pure]	210, a.
<i>qui vitrificetur</i> [how it is vitrified]	245, a.
<i>optimum quodnam</i> [which is the best]	262, a. 289, a.
<i>omnibus fere metallis inest</i> [it is present in almost all metals]	289, a, b.
<i>ex Saturno qui conficiatur</i> [how it is made from Saturn (lead)]	295, b.
<i>quomodo alia metalla tingat</i> [how it tinges other metals]	299, a.
<i>graduatum qui fiat</i> [how it is made graduated]	300, b.
<i>debilis coloris quomodo exaltetur</i> [how one of weak color is heightened]	307, b.
<i>per additionem an licitum</i> [whether it is licit by addition]	308, a.
<i>an verum & reale arte fieri possit</i> [whether true and real gold can be made by art]	311, a.

Lemma [sense-gloss]	Reference(s)
<i>Alchymicum an licite vendi possit</i> [whether alchemical gold can be lawfully sold]	311, b.
<i>ab Alchymistis confectum, quale?</i> [that made by alchemists, of what kind?]	312 & seqq.
<i>philosophorum quid</i> [what the gold of the philosophers is]	315 & seq.
<i>potabile an detur</i> [whether potable gold exists]	419, b. & seq.
<i>an dissolvi possit</i> [whether it can be dissolved]	420, a, b.
<i>semper in suum statum est reducibile</i> [it is always reducible to its own state]	423, b.
<i>facilius conficitur quam destruitur</i> [it is more easily made than destroyed]	426, a.
<i>accidentaliter tantum transmutari potest</i> [it can be transmuted only accidentally]	426, b.
<i>non nutrit</i> [it does not nourish]	427, b.
<i>ex eo medicamentum universale fieri non potest</i> [a universal medicine cannot be made from it]	428, a.
<i>qui crystalliscat</i> [how it crystallizes]	457, b.
<i>quomodo ex loppis sive quisquiliis extrahatur</i> [how it is extracted from dross or refuse]	482, a, b.
<i>scriptorium qui conficiatur</i> [how writing-gold (ink) is made]	465, b.
<i>quomodo dulce reddatur</i> [how it is made sweet]	481, a.
<i>sophisticum qui praeparetur</i> [how sophisticated (counterfeit) gold is prepared]	483, b.

Lemma [sense-gloss]	Reference(s)
<i>quomodo in fila ducatur</i> [how it is drawn into threads]	485, b.
Aurigenesis [The generation of gold]	168, a.
<i>natura & proprietas</i> [nature and property]	200 & seq.
<i>antipathia & sympathia</i> [antipathy and sympathy]	201, b. & seq.
<i>incredibilis copia in Potosina regione</i> [an incredible quantity in the Potosí region]	208, a.
<i>eruendi modus</i> [the method of digging it out]	210, a.
<i>semen non datur</i> [no seed of it exists]	268, a.
<i>amor homines in interitum rapit</i> [love of it carries men to destruction]	283, a.
<i>anima</i> [its soul]	284, a, b.
<i>calcinatio</i> [its calcination]	243, b. 423, a. 482, b.
<i>tinctura vera non datur</i> [no true tincture of it exists]	426, a.
<i>liquida substantia qui in pristinum statum reducatur</i> [how its liquid substance is reduced to its former state]	ibid.
<i>qualitas specifica est</i> [it is a specific quality]	427, a.
<i>magisterium quid sit</i> [what its magistery is]	ibid.
<i>in liquorem dissoluti vires</i> [the powers of it dissolved into a liquid]	427, b.
<i>potabilis virtutes</i> [the virtues of potable (gold)]	427, b.
<i>fulminantis confectio</i> [the preparation of fulminating (gold)]	428, b. 470, b.
<i>bonitas qualis</i> [of what quality its]	439, a.

Lemma [sense-gloss]	Reference(s)
goodness is]	
<i>à Lazulo separatio</i> [its separation from lapis lazuli]	200, a. 464, b.
<i>à metallis</i> [from metals]	215, a. 249, b. 482, a, b.
Aurifabri circa quid occupati [With what goldsmiths are occupied]	481, a.

Letter B

Lemma [sense-gloss]	Reference(s)
Baaras herba mirifica [Baaras, the marvelous herb]	413, a.
Balenae viviparae & cur [Whales are viviparous, and why]	57, b.
<i>musco & alga obsitae</i> [overgrown with moss and seaweed]	344, b.
Balis herba [Balis, the herb]	411, b.
Balneum maris quid [What a sea-bath (bain-marie) is]	240, a.
<i>roris quid</i> [what a dew-bath is]	ibid.
<i>vaporosum quid</i> [what a vapor-bath is]	392, a.
Bargarozzi Italis quid [What "bargarozzi" is to the Italians]	364, b.
Blattae ad quid utiles [Cockroaches, for what they are useful]	375, b.
Balsamum ubi nascatur [Where balsam grows]	119, a.
<i>vitrioli</i> [vitriol-balsam]	173, b.
<i>urticae</i> [nettle-balsam]	ibid.
<i>magnetis</i> [magnet-balsam]	ibid.
<i>sulphuris</i> [sulphur-balsam]	174, b.
Basiliscus ex ovo Galli natus [The basilisk, born from a cock's egg]	90, b.
<i>Alchymistis quid</i> [what it is to the alchemists]	315, b.
Berniclae qui nascantur [How barnacle-geese	346, a.

Lemma [sense-gloss]	Reference(s)
are born]	
Beryllus qui componatur [How the beryl is composed]	462, b.
Bismuthum quid [What bismuth is]	301, a.
Bitumen quid [What bitumen is]	156, a.
<i>à diversitate rerum denominatur</i> [it is named from the diversity of things]	156, b.
<i>varia ejus genera</i> [its various kinds]	156, b. 157, a.
<i>utilitates</i> [its uses]	157, a, b.
Bombyx ex moro qui nascatur [How the silkworm is born from the mulberry]	350, a.
<i>quale insectum</i> [what kind of insect it is]	355, a.
<i>unde</i> [whence it comes]	360, a.
<i>ejus metamorphosis</i> [its metamorphosis]	ibid.
<i>ad quid utilis</i> [for what it is useful]	375, a.
Borax Aurificum candidus quomodo caeruleus reddatur [How goldsmiths' white borax is made blue]	19, a.
Boriza herba [Boriza, the herb]	202, b. 282, b.
Botanici apud Romanos magno honore habiti [Botanists held in great honor among the Romans]	411, b.
Botytes quid [What botytes is]	207, a.
Brachmanes subterraneas cryptas inhabitant [The Brahmins inhabit subterranean crypts]	99, a.
Bruchi unde [Whence caterpillars come]	363, b. 364, a.
Bufo pestis remedium [The toad, a remedy for plague]	121, a.
<i>qui ex defosso anatis corpore nascatur</i> [how it is born from the buried body of a duck]	353, a.
<i>à formicis consumitur</i> [it is consumed by ants]	367, b.
Bulbi symptomata, cura & remedia [The symptoms, treatment and remedy of bulbs]	141.

Lemma [sense-gloss]	Reference(s)
Buprestis [Buprestis (the blister-beetle)]	143.

Letter C

Lemma [sense-gloss]	Reference(s)
Cabalistarum axioma [The axiom of the Cabalists]	381, b.
Cadmia quid [What cadmia is]	207, a.
Caementatio quid [What cementation is]	244, a.
Calcecumenon quid [What calcecumenon is]	218, a.
Calcedonius qui componatur [How chalcedony is composed]	463, a.
Calcinatio quid [What calcination is]	243, a. 244, a. 254, a. 424, a.
<i>auri duplex</i> [the twofold calcination of gold]	423, a.
Calculus omnibus in rebus generatur [Stone is generated in all things]	50, b.
<i>in omnibus membris humani corporis</i> [in all the members of the human body]	51, a, b.
C. Caligula primus metallurgus [Gaius Caligula, the first metallurgist]	235, a.
Calor multarum virtutum artifex [Heat, the craftsman of many powers]	110, b. 115, b.
<i>artificialis quis</i> [what artificial heat is]	241, b.
<i>fimi, separans, vesicae, cinerum, fortis, liber, carbonum, flammaram</i> [the heat of dung, of separation, of the bladder, of ashes, the strong, the free, of coals, of flames]	ibid.
<i>balnei</i> [of the bath]	242, a.
<i>Solis coelestis & subterranei omnia</i>	314, b.

Lemma [sense-gloss]	Reference(s)
<i>constituit</i> [the heat of the celestial and subterranean Sun constitutes all things]	
Caliditatis gradus difficulter indagari potest [The degree of heat can be investigated only with difficulty]	400 & seq.
Calx plumbea quomodo in minium vertatur ejusque causa [How lead-calx is turned into red-lead, and its cause]	12, b.
<i>quid Chymicis</i> [what it is to the chemists]	243, a.
<i>ejus virulentia</i> [its virulence]	117, b.

Letter C (continued)

Lemma [sense-gloss]	Reference(s)
Calcis vivae proprietas, symptomata, remedia [The property, symptoms, remedies of quicklime]	140.
Camphora quid [What camphor is]	157, b. 471, a, b.
Canis natura [The nature of the dog]	133, a.
<i>rabidi veneni causa</i> [the cause of the rabid dog's poison]	ibid. & b.
Cantharides qui possint [What cantharides (Spanish flies) can do]	129, b.
<i>quomodo vesicam exulcerent</i> [how they ulcerate the bladder]	130, b.
<i>unde</i> [whence they come]	365, b. 366, a.
<i>earum symptomata & remedia</i> [their symptoms and remedies]	143, 370, b. 375, b.
Capnitis quid [What capnitis is]	207, b.
Caput corvi quid [What "crow's head" is]	262, b.
<i>quomodo dealbetur</i> [how it is whitened]	ibid.

Lemma [sense-gloss]	Reference(s)
Caseus qui verminascere possit [How cheese can breed worms]	357, b.
Cassia ubi nascatur [Where cassia grows]	119, a.
Cataputiae symptomata, cura & remedia [The symptoms, treatment and remedies of caper-spurge]	141.
Catillus cineritius quid [What an ash-colored cupel is]	241, a.
Cedrus ubi nascatur [Where the cedar grows]	119, a.
Cerasus ex quercu nata [A cherry-tree born from an oak]	343, a.
<i>in salice</i> [on a willow]	343, b.
Cerussa quid & usta quomodo rubra fiat [What white-lead is, and how, when burnt, it turns red]	12, a.
<i>in plumbum qui reducatur</i> [how it is reduced to lead]	425, b.
<i>ex plumbo qui conficiatur</i> [how it is made from lead]	438, a.
<i>ejus proprietates, symptomata, remedia</i> [its property, symptoms, remedies]	40.
Ceratio quid [What ceration is]	248, b.
Chalcitis virulentia [The virulence of chalcitis]	117, a.
Chalybis conficiendi modus [The method of making steel]	223, b.
<i>potabilis confectio</i> [the preparation of potable (steel)]	430, a.
<i>usus medicus</i> [its medical use]	430, b.
Charta Turcica qui praeparetur [How Turkish paper is prepared]	38, a.
Characteres Chymici [Chemical characters (symbols)]	322.

Lemma [sense-gloss]	Reference(s)
Chaotica massa quid [What the chaotic mass is]	327, b.
<i>ex ea Deus immediate omnia produxit</i> [from it God produced all things immediately]	330, a.
Chersydri symptomata & remedium [The symptoms and remedy of the chersydrus (a serpent)]	143.
Chirotheca petrifica [A petrifying glove (a petrified glove)]	48, a.
Chrysalis quid [What a chrysalis is]	359, a.
Chrysopoeia Caligulae [Caligula's gold-making]	202, b.
<i>an licita</i> [whether it is licit]	308, a.
Chrysocantharus qui generetur [How the chrysocantharus (golden beetle) is generated]	365, b.
Chymia circa quid versetur [With what chemistry is concerned]	242.
Chymiae etymon [The etymology of "chemistry"]	232, a.
<i>Spagyrica definitio</i> [the definition of the Spagyric (art)]	233, a. 238, b.
<i>laus</i> [its praise]	233, b. 312, b.
Chrysalides [Chrysalises]	355, a.
Cicadae unde [Whence cicadas come]	361, b.
<i>ad quid utiles</i> [for what they are useful]	375, a.
Ciconiae in lacu Arelatensi sub aquis repertae [Storks found under the waters in the lake of Arles]	89, b.
<i>delectantur animalium venenatorum pastu</i> [they delight in feeding on venomous animals]	133, a.
Cicuta unde nascatur [Whence hemlock]	108, b.

Lemma [sense-gloss]	Reference(s)
grows]	
<i>eâ intoxicati quid imaginentur</i> [what those poisoned by it imagine]	134, a.
<i>ejus stolones pestiferi</i> [its pestilential shoots]	126, a.
<i>symptomata, cura & remedia</i> [symptoms, treatment and remedies]	141.
Cimex unde [Whence the bedbug comes]	371, a, b.
<i>ad quid utilis</i> [for what it is useful]	376, a.
<i>quomodo fugetur</i> [how it is driven off]	377, b.
Cinabaris proprietas, symptomata, remedia [The property, symptoms, remedies of cinnabar]	140.
<i>minera</i> [its ore]	188, a.
<i>fixatio frustranea</i> [its fixation in vain]	301, b.
Cincindela quid & qui generentur [What fireflies are, and how they are generated]	366, b.
Circulatio quid [What circulation is]	247, b. 395, b.
<i>ejus machina nova</i> [its new apparatus]	396, a.
Coelum philosophorum quid [What the heaven of the philosophers is]	260, a.
Cohobatio quid [What cohobation is]	248, a.
Colcothar quid [What colcothar is]	173, b.
Colocasia ubi nascatur [Where colocasia grows]	119, a.
Colocynthis symptomata, cura & remedium [The symptoms, treatment and remedy of the colocynth]	141.
Color quid [What color is]	8, b.
<i>fundamentum habet in salibus sulphuri commixtis</i> [it has its basis in salts mingled with sulphur]	9, a.

Lemma [sense-gloss]	Reference(s)
<i>inest omnibus corporibus</i> [it is present in all bodies]	101, a.
<i>ultramarinus Lazuli</i> [the ultramarine of lapis lazuli]	464, b.
<i>ejus natura difficilioris indaginis</i> [its nature is of more difficult investigation]	9, a.
<i>infinitus numerus</i> [an infinite number of them]	ibid.
<i>causa in lapidibus</i> [its cause in stones]	ibid.
Colores in opacis corporibus differunt ab iis qui in diaphanis comparent [Colors in opaque bodies differ from those that appear in transparent ones]	9, b.
<i>unde nascantur</i> [whence they arise]	10, b. & seq.
<i>apparentes qui</i> [how the apparent ones (arise)]	15, a.
<i>in trigono quales</i> [what kind in the prism]	16, a, b.
<i>metallorum unde nascantur in Topazio, Saphyro, Carbunculo & Smaragdo</i> [whence the colors of metals arise in topaz, sapphire, carbuncle and emerald]	20, a.
<i>qui quas gemmas exprimant</i> [how they express which gems]	460, a.
Colorum diversitas in diaphanis [The diversity of colors in transparent bodies]	9, b.
<i>commixtio ex quatuor principalibus</i> [their mixture from four principal ones]	10, a.
<i>processus in tinctura ferri</i> [the process in the tincture of iron]	13, b.
<i>combinatio</i> [their combination]	14, a.
<i>tinctura in vegetabilibus</i> [their tincture in plants]	19, a.
<i>in avibus causa</i> [their cause in birds]	17, a.
<i>variae geneses</i> [their various origins]	299, b. 401, a, b.

Lemma [sense-gloss]	Reference(s)
Colubri in stillatitia aqua apparitio [The appearance of a snake in distilled water]	416 & seq.
Confirmatio chymica quid [What chemical confirmation (fixation) is]	292, a.
<i>ejus varii processus</i> [its various processes]	294 & seq.
Contrariorum luctus quid operetur [What the struggle of contraries effects]	110, b.

Letter C (concluded) — Letter D

Lemma [sense-gloss]	Reference(s)
Corallus utrum intra aquas mollis [Whether coral is soft within the waters]	158, a.
<i>an semen habeat</i> [whether it has seed]	159, a.
<i>ramos fistulosos habet & unde</i> [it has hollow branches, and whence]	160, a, b.
<i>fictitius</i> [artificial coral]	466, b.
Coralli rupes Romam transmissa [A coral rock sent to Rome]	158, b.
<i>planta ex cranio humano & delphino vivo</i> [the plant grown from a human skull and a living dolphin]	159, a.
<i>medicae vires</i> [its medicinal powers]	159, b.
<i>ortus</i> [its origin]	158, a. 159 & seq.
<i>durities unde</i> [whence its hardness]	160, a.
<i>stirpium figura</i> [the figure of its stems]	160, b.
<i>vires unde</i> [whence its powers]	ibid.
<i>tincturae varii modi</i> [the various methods of its tincture]	161, a.
<i>solutio</i> [its solution]	435, b.
Cornua qui mollescant [How horns are softened]	485, a.

Lemma [sense-gloss]	Reference(s)
Cornuum fossilium ortus [The origin of fossil horns]	62, a.
<i>differentia</i> [their difference]	62, b.
Corpus mortuum cur gravius vivo [Why a dead body is heavier than a living one]	219, b.
<i>humanum in aquis salinis inventum</i> [a human body found in salt waters]	225, a.
<i>intra aquam qui ponderandum</i> [how it is to be weighed under water]	440, a, b.
Coryli stolones igni appositi se in circulo torquent [Hazel shoots placed by the fire twist themselves in a circle]	418, a.
Crabrones [Hornets]	355, a.
<i>unde</i> [whence they come]	359, a.
Crocus Martis qui calcinetur [How crocus of Mars (iron oxide) is calcined]	243, a.
<i>quomodo praeparetur</i> [how it is prepared]	244, b. 437, b.
<i>Veneris qui conficiatur</i> [how crocus of Venus (copper oxide) is made]	438, a.
Cruces in cancrorum dorsis [Crosses on the backs of crabs]	44, a, b.
Crucifixus in lapidibus expressus [A crucifix imprinted in stones]	31, b.
Crypta petrifica Panormi [A petrifying grotto at Palermo]	46, a.
<i>in agro Neapolitano, Tyburtino & alibi</i> [in the territory of Naples, of Tivoli, and elsewhere]	ibid.
Crystallus quomodo nascatur [How crystal is born]	19, a, b.
<i>constat ex sale</i> [it consists of salt]	20, a.
<i>prodigiosae magnitudinis</i> [of prodigious]	188, b.

Lemma [sense-gloss]	Reference(s)
size]	
<i>quomodo tingatur</i> [how it is dyed]	459, a.
Crystalli minerae [The ores of crystal]	188, a.
<i>calcinatio quomodo fiat</i> [how its calcination is done]	459, b.
<i>induratio</i> [its hardening]	ibid.
<i>compositio</i> [its composition]	462, b.
Culices unde [Whence gnats come]	362, b.
<i>ad quid utiles</i> [for what they are useful]	375, b.
Culmus hordeaceus in vesica inventus [A barley-stalk found in the bladder]	344, a.
Cupressus ubi nascatur [Where the cypress grows]	119, a.
Curculiones quales [What kind of weevils are]	355, a.
Cyniphes unde [Whence stinging-gnats come]	362, a, b.
Daemones Subterranei in quibus locis visi [Subterranean demons, in which places they have been seen]	101, a. 227, a.

<i>unde oriatur</i> [whence it arises]	7, b.
<i>inest mineralibus</i> [it is present in minerals]	45, a.
Lapides ex quibus fiant [From what stones are made]	7, a.
<i>quae requirantur ad eorum consistentiam</i> [what is required for their consistency]	ibid. 52, b.
<i>quomodo in fodinis crescant</i> [how they grow in mines]	ibid. b.
<i>cur purioris aut impurioris substantiae</i> [why of purer or more impure substance]	ibid.
<i>eorum color</i> [their color]	8, a.
<i>Chromatismus in quo consistat</i> [in what their chromatism consists]	11, b.
<i>quomodo colorentur in terrae visceribus</i> [how they are colored in the bowels of the earth]	13 & seq.
<i>punctati qui</i> [which are dotted]	22, b.
<i>qui lineati</i> [which are striped]	23, a.
<i>qui conficiantur</i> [how they are made]	24, a.
<i>variarum rerum in iis expressio</i> [the imprinting of various things in them]	27 & seqq.
<i>nemorosorum lapidum quatuor genera</i> [the four kinds of wooded (landscape) stones]	39, b.
<i>quomodo animalium figurae in iis imprimantur</i> [how the figures of animals are imprinted in them]	41 & seq.
<i>generantur in omnibus humani corporis membris</i> [they are generated in all members of the human body]	51, a.
<i>in partibus animalium</i> [in the parts of]	51, b. & seq.

Lemma [sense-gloss]	Reference(s)
animals]	
<i>Duodecim in Rationali Sacerdotis Magni positi</i> [the twelve set in the breastplate of the High Priest]	83 & seq.
<i>cur igne in calcem degenerent</i> [why they degenerate into lime by fire]	170, a.
<i>cupro divites</i> [rich in copper]	190, a.
<i>quotuplices</i> [how many kinds]	309, a.
<i>quales</i> [of what kinds]	309, b.
<i>marini</i> [the marine ones]	399, b.
<i>non solvuntur oleosis</i> [they are not dissolved by oily substances]	434, b.
<i>factitii</i> [the artificial ones]	466, a.
Laserpitii ortus [The origin of laserpicium (silphium)]	338, a, b.
Laurus ex puppi navis nata [A laurel grown from a ship's stern]	343, b.
<i>in platano</i> [on a plane-tree]	ibid.
Leo ruber quid [What the red lion is]	11, b.
Lepus marinus [The sea-hare]	144.
Libavii de insectis transformandis relatio [Libavius' account of transforming insects]	409, b.
<i>de resuscitatione plantarum narratio</i> [his narrative on the resuscitation of plants]	416, a.
<i>in auro solvendo processus</i> [his process in dissolving gold]	421, a.
Ligna quomodo in saxa convertantur [How woods are converted into rocks]	46, b.
<i>cur igne in cineres degenerent</i> [why they degenerate into ashes by fire]	170, a.
Lignum fossile naturale [Natural	65, a.

Lemma [sense-gloss]	Reference(s)
fossil wood]	
<i>in agro Aquaspartano</i> [in the territory of Acquasparta]	ibid.
<i>à Caesio detectum</i> [discovered by Cesi]	65, b.
<i>ejus forma</i> [its form]	ibid.
<i>origo</i> [its origin]	66, a.
<i>alni in lapidem versum</i> [an alder turned into stone]	190, a.
Lima qui temperetur [How a file is tempered]	221, b.
Limaces unde [Whence slugs come]	357, a.
Lini Asbestini praeparatio [The preparation of asbestos linen]	174, a.
<i>in sericum transmutatio</i> [its transmutation into silk]	466, b.
Lithantraces ubi reperiantur [Where coal (lithanthrax) is found]	66, b. 189, a.
<i>eorum halitus pestifer</i> [their pestilential vapor]	126, a.
Limus Chaoticus qua virtute ab initio induruit [By what power the chaotic slime hardened at the beginning]	5, a, b.
Lithargyrii proprietates, symptomata, remedia [The property, symptoms, remedies of litharge]	141.
Lithargyrium quid [What litharge is]	207, b.
Liquor limpidus quomodo in album commutetur [How a clear liquid is changed to white]	299, a.
<i>quomodo in croceum</i> [how into saffron-yellow]	290, b.
<i>in caeruleum</i> [into blue]	ibid.
<i>in nigrum</i> [into black]	ibid.

Lemma [sense-gloss]	Reference(s)
<i>caeruleus in purpureum</i> [blue into purple]	ibid.
<i>ejus gravitatem & crassitiem explorare</i> [to test its weight and density]	448, b. 449, a.
Locustae unde [Whence locusts come]	363, a, b.
<i>quomodo generent</i> [how they breed]	363, b.
<i>combustae reliquas odore fugant</i> [the burnt ones drive off the rest by their smell]	364, a.
<i>quales fuerint quibus S. Joannes vescebatur</i> [of what kind were those on which St. John fed]	ibid.
<i>ad quid utiles</i> [for what they are useful]	375, b.
<i>qui exterminentur</i> [how they are exterminated]	376, b.
Lucerna perpetuo ardens an fieri possit [Whether a perpetually burning lamp can be made]	69, a, b.
<i>variae de ea opiniones</i> [various opinions about it]	70, b.
<i>varii ejus construendi modi</i> [various methods of constructing it]	71 & seq.
<i>Aegyptii quomodo eam faciebant</i> [how the Egyptians made it]	74, a.
Lullus [Raymond Lull]	266, b.
<i>ejus Lunaria</i> [his Lunaria]	271, a.
<i>martyrio coronatus</i> [crowned with martyrdom]	276, a.
Lumbrici qui generentur [How earthworms are generated]	356, a, b.
<i>in intestinis qui</i> [how those in the intestines (arise)]	357, b.
<i>ad quid utiles</i> [for what they are]	376, a.

Lemma [sense-gloss]	Reference(s)
useful]	
Luna chymice denotat argentum [The Moon, chemically, denotes silver]	165, a.
Lunaria Lulli quid operetur [What Lull's Lunaria effects]	231, a.
<i>Rabbinorum</i> [that of the Rabbis]	282, b.
Lutum sapientiae quomodo paretur [How the lute of wisdom (sealing-clay) is prepared]	291, a. 394, b.
Machina hydraulica [Hydraulic machine]	176, a. 193, 194, 195, 196.
<i>anemica</i> [the pneumatic one]	190, b. 191.
<i>ad aërem in fodinis emendandum</i> [for refreshing the air in mines]	191.
<i>haustoria</i> [the drawing (pumping) machine]	225, 229, a.
Magnes aureus utrum detur [Whether a golden magnet exists]	202, a.
<i>igni traditus perdit</i> [committed to the fire, it loses (its power)]	(continued)

Index of Subjects and Words of the Second Volume (continued)

[INDEX RERUM & VERBORUM TOMI SECUNDI — continued from letter M through the end of the index, concluding with FINIS.]

Reading order used: linear, → 990 → 991 → 992. On each leaf the printed page is itself two-columned; I read the left printed column top-to-bottom, then the right printed column top-to-bottom. The alphabetical sequence (M → N → O → P → Q → R → S → T → V → X → Z) and the page catchwords ("Moschini", "Ostra-", "Sal", "Transf-") confirm this order.

Each entry is given as printed: the Latin lemma (with a bracketed English sense-gloss), followed by its page-and-column references ("a" = left text-column, "b" =

right text-column of the referenced page; "ibid." = same reference as immediately preceding; "& seq." / "& seqq." = and following).

running header: "& VERBORUM"

Lemma [gloss]	Reference(s)
[Magnes, continued — magnet] ...dit virtutem [imparts its power]	424, a.
ejus vis quomodo statica exploretur [how its force is investigated statically]	446, b.
Magnetismus Naturæ [the magnetism of Nature]	6, a. 37, a.
in lapidum generatione [in the generation of stones]	8, a.
venenorum [of poisons]	137, a.
cupri ad ferrum [of copper toward iron]	257, b.
similium ad similia [of like toward like]	298, b.
quid efficiat [what it accomplishes]	328, a, b.
Magon Pœnus [Mago the Carthaginian]	411, b.
Mandicca quid [what manioc is]	139, b.
Mandragoræ symptomata, cura & remedia [mandrake — symptoms, treatment and remedies]	142
Marcasita quid & ubi [marcasite — what and where]	187, a, b.
argentea [silver marcasite]	188, a.
qui generetur [how it is generated]	8, a.
ejus proprietas, symptomata, remedia [its property, symptoms, remedies]	141, 148, a, b. & seq.
Mare Rubrum coralli ferax [the Red Sea, productive of coral]	159, a.
Margaritæ qui conficiantur [how pearls are made]	461, a. 466, a, b.

Lemma [gloss]	Reference(s)
Mars chymice ferrum denotat [Mars, in chemistry, denotes iron]	165, a.
Martagon quid Lullo [what martagon is, according to Lull]	271, b.
Mastyx qui depuretur [how mastic is purified]	458, b.
Materia prima Alchymistarum subsistere non potest [the prime matter of the alchemists cannot subsist]	255 & seq. 268, a. 271 & seq.
a Paracelso denominata [named by Paracelsus]	274 & seq.
Medicamentum quid [what a medicament is]	109, a.
Medicinalium virtutes [the powers of medicinal substances]	403.
effectus [their effects]	404, a.
terminorum explicatio [explanation of terms]	404 & seq.
vires quomodo à nonnullis investigatæ [how their powers were investigated by some]	405, a.
Melchior Cibirensis [Melchior of Cibirum (Sibiu)]	266, b.
Mensa argentea Ducis Saxoniae [the silver table of the Duke of Saxony]	203, a.
vitrea qui conficiatur [how a glass table is made]	458, a.
Menstrua mulierum quam noxia [women's menses, how harmful]	112, b.
ad solvendum aurum qui conficiantur [menstrua for dissolving gold, how prepared]	420, b.

Lemma [gloss]	Reference(s)
ex melle manna acerrima [from honey, a most pungent manna]	425, a.
ad Lunam solvendam apta [suited to dissolving silver]	429, b.
solventia quid præstent [what the solvents accomplish]	434, a.
Mercurius Trismegistus reconditæ doctrinæ auctor [Hermes Trismegistus, author of recondite doctrine]	313, a.
Mercurius incorrigibilis est [Mercury (quicksilver) is incorrigible]	151, b.
omnia conjungit [it joins all things]	ibid.
lethifer est [it is deadly]	153, a, b.
correctus fit medicina [when corrected, it becomes a medicine]	ibid.
de ejus viribus judicium Authoris [the Author's judgment on its powers]	154, a.
utrum aurum trahat & qualiter [whether and how it draws gold]	154, b. 155, a, b.
chymice argentum vivum denotat [in chemistry it denotes quicksilver]	165, a.
qui præcipitetur [how it is precipitated]	243, a.
difficulter domatur [it is tamed with difficulty]	252, a.
est indestructibilis [it is indestructible]	253, b.
utrum à succo aliquo coaguletur [whether it is coagulated by some juice]	271, b. 272, a.
an in hominis sanguine [whether [it is found] in human blood]	ibid.
quomodo sublimetur [how it is sublimed]	260, b.

Lemma [gloss]	Reference(s)
utrum in motum artificialibus machinis animari queat [whether it can be animated into motion by artificial machines]	486, a, b.
Vide Argentum vivum & Hydrargyrum [see Quicksilver and Hydrargyrum]	
Metallum quid sit [what a metal is]	164, b.
igne cur purius reddatur [why it is rendered purer by fire]	170, a.
quomodo mollefiat [how it is softened]	200, a.
qui per plumbum fulminetur [how it is detonated by means of lead]	249, a.
Metalla quomodo in duritiem excrescant [how metals grow into hardness]	163, b.
quomodo virtute cœlesti generentur [how they are generated by celestial power]	166, b.
excoquendi ratio [the method of smelting]	171, a.
commixta ubi reperiantur [where they are found mixed together]	187, b.
quomodo paranda ad cocturam [how they are to be prepared for firing]	197, a.
tria tormenta sustinere debent in depuratione [they must endure three torments in purification]	197, b.
separandi modus [the method of separating them]	212, b.
plumbo comburuntur [they are burned with lead]	249, b.
quantum mercurii contineant explorare [to test how much mercury they contain]	448, a.
sine plumbo non vitrescunt [without	455, a.

Lemma [gloss]	Reference(s)
lead they do not vitrify]	
qui smalto inurantur [how they are enamelled]	456, a.
Metallorum colores [the colors of metals]	18, b.
attractiones [their attractions]	155, a.
transmutationes [their transmutations]	ibid. b.
materia [their matter]	162, b.
genesis [their genesis]	ibid. & 253, b. 237, a.
forma [their form]	164, a.
productioni quid conferant elementa [what the elements contribute to their production]	167, a.
fluxibilitas in igne unde [whence their fluidity in fire]	170, a.
venæ qua ratione innotescant [by what method their veins are discovered]	179 & seq.
ustio quomodo fiat [how their roasting is done]	197, a.
mistura [their mixture]	205.
scoria [their slag]	206, a.
transmutatio quid [what their transmutation is]	256, b. 257, a.
prima materia qui paretur [how their prime matter is prepared]	255 & seq.
calcinatio per mercurium [calcination by mercury]	437, b.
calces quos colores adducant [what colors their calxes bring on]	457, a.
calcinatio [calcination]	482, b.
Metallurgia quid & in quo consistat [what metallurgy is and in what it	162, 233, a. 38, a.

Lemma [gloss]	Reference(s)
consists]	
Metallurgus quid nosse debeat [what a metallurgist ought to know]	171, a, b.
Meteororum circulatio [the circulation of meteors (atmospheric exhalations)]	170, b.
Microcosmus est fornax distillatoria [the microcosm is a distilling furnace]	392.
Mineralia quæ venenosa [which minerals are venomous]	108, a.
alia majora, alia minora [some greater, some lesser]	252, b.
quotuplicia [how many kinds]	399, a.
Minium liquefieri non potest [minium (red lead) cannot be liquefied]	163, a.
Mistura ollaria quid [what a potter's mixture is]	105, b.
ignea quam Sol accendere possit qui præparetur [how a fiery mixture is prepared that the Sun can kindle]	477, a.
Mixta omnia ex quibus constent [of what all mixed bodies are composed]	124, a. 298, a.
Mola ad conterendam materiam mineralem [a mill for grinding mineral matter]	198.
Monoceros quid [what the unicorn is]	63, a.
nunquam fuit [it never existed]	ibid.
Monocerotis cornu ubi [where the horn of the unicorn (is)]	63, b.
est spicula piscium [it is the spike of fishes]	ibid.
Romæ [at Rome]	64, a.
ab Alberto Magno observatum [observed by Albertus Magnus]	ibid.
cur in Anglia præcipue sit [why it is]	ibid.

Lemma [gloss]	Reference(s)
found especially in England]	
fossile [as a fossil]	64, b.
Mons aurifer qualis [the gold-bearing mountain, of what kind]	208, a.
Montes an ab initio rerum exstiterint [whether mountains have existed from the beginning of things]	5, a.
ardentes [burning mountains]	157, a.
Monstra unde nascantur [whence monsters arise]	96, a.
Morbi ex sulphure, mercurio & sale constant [diseases consist of sulphur, mercury and salt]	135, a, b.
quinam à sale [which [diseases come] from salt]	136, a.
quinam à tartaro [which from tartar]	136, b.
fossorum [of miners]	172, a.
metallici eorumque cura [metal-induced [diseases] and their treatment]	173 & seq.
Motus in rerum natura quis [what motion is in the nature of things]	298, a.
Motus perpetuus fieri non potest [perpetual motion cannot be made]	72, a.
est pure artificialis [it is purely artificial]	233, b.
ejus inventiones decem ad Authorem transmissæ [ten of its devices submitted to the Author]	234, a.
quomodo arte Chymica exhibeatur [how it is exhibited by the chemical art]	432, b.
Moschini [Moschini (musk-substances)]	355, a.

Lemma [gloss]	Reference(s)
Mundus vicissitudini obnoxius [the world is subject to vicissitude]	105, a.
Trismegisto quadruplex [fourfold, according to Trismegistus]	313, a.
Subterraneus omnium origo [the Subterranean (World), origin of all things]	385, a.
nil est nisi fornax distillatoria [it is nothing but a distilling furnace]	390.
Mus Alpestris qualis [the Alpine mouse, of what kind]	87, b.
Mures varii [various mice]	87, b.
qui nascantur ex limo [how they are born from mud]	346, a.
ex bovillo stercore quā [from ox-dung, how]	352, b.
quomodo propulsentur [how they are driven off]	377, a.
Muscæ unde [whence flies]	361, a, b.
variæ [various kinds]	362, a.
ad quid utiles [for what they are useful]	376, a.
Musicas proportionales explorare [to investigate musical proportions]	450, a.
Myrrha ubi nascatur [where myrrh is produced]	119, a.
Myrtilus lapis [the myrtilus stone]	22, b.
Myrtus qualis in Ægypto & aliis locis [the myrtle, of what kind in Egypt and other places]	408, b.
Mysios virulentia [the virulence of the Mysian [substance]]	116, a.

N.

Lemma [gloss]	Reference(s)
Napelli umbra noxia [the harmful shade of monkshood (aconite)]	125, b.
symptomata, cura & remedia [symptoms, treatment and remedies]	142
Naphta quid [what naphtha is]	156, a.
Naturæ operationes miræ [the wonderful operations of Nature]	22, a, b.
pictura [her painting]	27 & seq.
gluten humidum [her moist glue]	169, a.
principia tria [her three principles]	169, b.
circulatio in quo consistat [in what her circulation consists]	170, b.
imitatio difficilis [imitation of her is difficult]	236, a.
prototypon in arte respiciendum [the prototype to be regarded in art]	238, b.
labor in rebus producendis [her labor in producing things]	251, a.
in metallis generandis [in generating metals]	256, a.
circa productionem metallorum industria [her industry in the production of metals]	269, b. 270, a.
principia [her principles]	331, a.
pericyclosis in insectorum genesi [her cycling in the genesis of insects]	374, b.
principiorum vis [the power of her principles]	385, a.
Nidus in petram conversus [a nest turned to stone]	48, a.
Nitrum quomodo fixetur [how niter is fixed]	432, a.
Nutrimmentum unde fit [whence nourishment comes]	136, a.
semper ei aliquid fæculentum adhæret [something feculent always clings to it]	ibid.

O.

Lemma [gloss]	Reference(s)
Ochra qualis [ochre, of what kind]	163, a.
Og gigas [Og the giant]	60, a.
Oleum philosophorum quomodo conficiatur [how the philosophers' oil is made]	247, a.
Oleandri symptomata, cura & remedia [oleander — symptoms, treatment and remedies]	142
Olea calefacta cur fluent [why oils flow when heated]	169, b.
Onager Indicus [the Indian wild ass]	63, a.
Onyx qui componatur [how onyx is composed]	463, b.
Opalus quomodo conficiatur [how the opal is made]	461, b.
Operarum in fodinis officium [the duty of the workers in the mines]	172, b.
Ophites [ophite (serpentine stone)]	22, b.
Orchides [orchids]	348, a.
uniformes unde [whence the uniform ones]	349, b.
Organum pyrobolicum quomodo in aëre exhibeatur [how a pyrobolic organ is displayed in the air]	480, b.
Orichalcum qui præparetur [how orichalcum (brass) is prepared]	218, a.
est nativum & factitium [it is both native and artificial]	ibid.
præparandi modus [the method of preparing it]	218, b.
veterum quale [of what kind the ancients' was]	456, a.
Oryx caprarum genus [the oryx, a kind of goat]	63, a.
Ossa gigantum [the bones of giants]	53, a.
elephantorum [of elephants]	59, a.
quomodo generentur in terra [how they are generated in the earth]	60, b.
quibus in locis crescant [in what places they grow]	ibid. & seq.

running header: "INDEX RERUM"

[Continuation of letter O]

Lemma [gloss]	Reference(s)
Ostracea unde originem trahant [whence shellfish (oysters) take their origin]	119, b. 345, b.
Ostracites quid [what the ostracite is]	207, b.
Ovum philosophicum quid [what the philosophical egg is]	240, b.

P.

Lemma [gloss]	Reference(s)
Allantis corpus quale [Pallas's body, of what kind]	55, b. 56, a.
Palma ubi nascatur [where the palm grows]	119, a.
in basi statuæ Cæsaris nata [grown at the base of a statue of Caesar]	341, b.
in lecto capitolii [on the bed of the Capitol]	342, a.
Panspermia rerum quid [what the panspermia (universal seed-store) of things is]	326 & seq.
Papiliones [butterflies]	335, a.
unde [whence]	359, a, b.
Paracelsus	266, b.
qualis fuerit [what kind of man he was]	277, b.
contumeliosus in omnes medicos [abusive toward all physicians]	278, a.
omnia ex aliis habet [he got everything from others]	278, b.
superstitiosus [superstitious]	279, a.
magiæ deditus [given over to magic]	ibid.
verum hominem se conficere posse	249, b.

Lemma [gloss]	Reference(s)
arte Chymica impie præsunit [he impiously presumes he can make a true man by the chemical art]	
sine auro lapidem fieri posse asserit [he asserts the [philosophers'] stone can be made without gold]	263, a.
Paracelsi fucus [Paracelsus's deceit]	296, b.
intolerabilis præsuntio [his intolerable presumption]	ibid.
libri prohibiti [his prohibited books]	ibid.
arrogantia [his arrogance]	278, a. 296, b.
processus in materia prima præparanda [his procedure in preparing the prime matter]	255, a.
in lapide conficiendo [in making the [philosophers'] stone]	297, a.
aurificium [his gold-making]	297, b.
processus falsus [his false procedure]	ibid.
modus in resuscitatione plantarum [his method in the revival of plants]	415, a, b.
de auro potabili opinio [his opinion on potable gold]	420, a.
Pastinaca marina [the sea-pastinaca (stingray)]	144
Pavonum pennæ quales [peacocks' feathers, of what kind]	17, b.
Peccatum originale malorum causa [original sin, the cause of evils]	125, a.
Pediculi unde in hominibus nascantur [whence lice are born in men]	370, b. 371, a.
quomodo pulsentur [how they are driven off]	377, b.
Pelicanus quid [what the pelican (alembic) is]	240, b.

Lemma [gloss]	Reference(s)
Pennæ vitreæ quomodo parentur [how glass feathers are made]	454, b.
Peripleumonia qui curetur [how peripneumonia is cured]	174, b.
Perlæ, insectum, unde [pearls, an insect, whence]	360, b. 361, a.
Persica sine ossiculis ut fiant [how peaches are made without pits]	390, a.
miræ magnitudinis [of wondrous size]	390, b.
qualia in Persia & Europa [of what kind in Persia and Europe]	408, a.
Peruvia quot millones auri suppeditarit [how many millions of [units of] gold Peru has supplied]	208, b.
Petrificatio nidi, chirotecæ [the petrification of a nest, of a glove]	49, a.
plantarum [of plants]	48, b.
figuræ humanæ [of a human figure]	ibid.
Deiparæ imaginis cum crucifixo [of an image of the Mother of God with a crucifix]	ibid.
omnium pene rerum [of almost all things]	49, a.
corporis humani [of a human body]	50, a.
equinæ ungulæ [of a horse's hoof]	ibid.
Civitatis Africæ [of an African city]	ibid.
hordei integræ [of whole barley]	50, b.
fœtus in utero muliebri [of a fetus in a woman's womb]	51, b.
Phallum Hollandicum unde [whence the Dutch phallus (fungus)]	351, b.
Phantasticæ facultatis vis [the power of the fantastic (imaginative) faculty]	114, a.
Phlebotomum qui temperetur [how	221, b.

Lemma [gloss]	Reference(s)
the lancet is tempered]	
Phoenix Alchymistis quid [what the phoenix is to the alchemists]	315, b.
Pilæ sub aqua ardentes qui præparentur [how balls that burn under water are prepared]	477, a, b.
Pisces fossiles [fossil fishes]	86, a.
quomodo saxorum meditullia penetrarint [how they penetrated the cores of rocks]	87, a.
in subterraneis fluminibus [in subterranean rivers]	89, b.
in Helvetia ex montibus erumpunt [in Switzerland they burst forth from the mountains]	ibid.
Piscium δορυφόρων prælia contra balænas [Greek: δορυφόρων (doryphorōn, "spear-bearing" — the battles of the spear-bearing fishes against whales)]	64, a.
ortus [their origin]	364, a.
Placodes quid [what the placodes is]	207, b.
Plantæ quomodo nascantur [how plants are born]	338, 339, & seq.
è statuis æneis natæ [born from bronze statues]	342, a.
ex animalibus [from animals]	343, b.
propriū sibi animal producunt [they produce an animal proper to themselves]	347, a. 373, b.
quomodo dividantur [how they are divided (classified)]	380, a.
quantum singulis diebus excreverint explorare [to ascertain how much they	447, b.

Lemma [gloss]	Reference(s)
have grown each day]	
Plantæ venenosæ quæ [which plants are venomous]	108, b.
unde originem trahant [whence they take their origin]	117, b. & seq.
comparantur cum venenatis mineralibus [they are compared with poisonous minerals]	118, b.
cur subinde animalcula venenosa producant [why they sometimes produce venomous little creatures]	124, a.
Plastica vis quid [what the plastic force is]	7, b. 328, a.
semini innata [innate in the seed]	328, a. 333, b.
in inanimatis est analogia ad vegetabilium & animalium plasticam vim [in inanimate things it is analogous to the plastic force of vegetables and animals]	334, b.
quomodo operetur [how it works]	335, a.
ejus effectus [its effects]	335, b.
Plumbum in cerussam quomodo mutetur ejusque ratio [how lead is changed into ceruse (white lead) and the reason for it]	12, a.
qui in calcem [how into calx]	ibid.
argento est amicum [it is friendly to silver]	219, a.
calcinatum cur gravius [why calcined lead is heavier]	219, b.
qui calcinetur [how it is calcined]	243, b.
nigrum qui candidum & aureum reddatur [how black lead is made white and golden]	301, a.

Lemma [gloss]	Reference(s)
cur dulce [why it is sweet]	401, b.
qui crystallescat [how it crystallizes]	457, b.
Plumbi minera qualis [lead ore, of what kind]	188, a.
scoria [its slag]	207, a.
utilitates [its uses]	218, b.
matrix quænam [what its matrix is]	ibid.
reductio in cuprum [its reduction into copper]	258, b.
in stannum [into tin]	248, q. [recte: a.?] [?]
ad stannum gravitas [its weight relative to tin]	441, b.
vitrum [its glass]	452, b.
calx [its calx]	483, b.
Pluvia ignea qui conficiatur [how a fiery rain is made]	475, b.
Polypodium [polypody (fern)]	139, b.
Poma acida & dulcia in una arbore qui producantur [how sour and sweet apples are produced on one tree]	387, a.
ut imaginem quamvis referant [how they may reproduce any image whatever]	388, b.
ut fiant dulcia [how they are made sweet]	ibid.
ut rubra [how [made] red]	ibid.
eorum calami longe allati quomodo conservandi [how their grafts, brought from afar, are to be preserved]	383, a.
Pompholix quid [what pompholyx (zinc oxide) is]	207, b.
Ponderum mineralium valor [the value (relation) of mineral weights]	288, a.

Lemma [gloss]	Reference(s)
Populi foliorum motus [the motion of poplar leaves]	418, b.
Porrum prodigiosæ magnitudinis qui producat [how a leek of prodigious size is produced]	388, b.
Potosinus tractus olim ob frigus inhabitatus [the Potosí region, once uninhabited because of cold]	208, a.
Pruna sine osiculis ut fiant [how plums are made without pits]	390, a.
Psylli symptomata, cura & remedia [fleawort — symptoms, treatment and remedies]	142
Pthias serpens [the pthias serpent]	144
Pulex unde [whence the flea]	371, a.
quomodo propulsetur [how it is driven off]	377, b.
Pulmo marinus [the sea-lung (jellyfish)]	129, b.
ejus venenum, pulmonibus inimicum [its venom, hostile to the lungs]	ibid.
Pulvis argentum in aurum commutans ab Arabibus confictus [a powder changing silver into gold, devised by the Arabs]	305, a, b.
Pulveris pyrii prima inventio [the first invention of gunpowder]	467.
confectio [its manufacture]	468 & seq.
Purpura qui nascantur [how purples (murex) are born]	345, b.
Putrefactio, quid Chymicis [putrefaction, what it is to the chemists]	248, a. 405, a.
ejus effectus [its effects]	395, b. 409, b.

Lemma [gloss]	Reference(s)
Pygmæi non homines sed dæmones subterranei [pygmies are not men but subterranean demons]	101, b.
nusquam eorum natio reperitur [their race is nowhere found]	ibid.
Pyrites ubi reperiatur [where pyrite is found]	387, a.
ejus fuligo tertiò usti sit incombustibilis [its soot, when burned a third time, is incombustible]	197, b.

Q.

Lemma [gloss]	Reference(s)
Quajacum ubi nascatur [where guaiacum grows]	119, a.
ejus variæ vires [its various powers]	401, b.
Qualitates specificæ quid differant à manifestis [how specific qualities differ from manifest ones]	111, a.
elementares an sympathiam & antipathiam constituere possint [whether elementary qualities can constitute sympathy and antipathy]	112, a.
quatuor elementa sunt earum vehicula [the four elements are their vehicles]	137, a.

R.

Lemma [gloss]	Reference(s)
Radix comedendi facultatem tollens [a root that takes away the faculty of eating]	413, a.
Ranæ unde oriantur [whence frogs arise]	119, b. 345, b. 372, b.
Ranæ fossiles [fossil frogs]	86, a.
earum origo intra saxa [their origin within rocks]	87, a.
Raphanus quomodo dulcis reddatur [how the radish is made sweet]	288, a, b.

Lemma [gloss]	Reference(s)
Reges sepeliendi mos apud veteres [the custom of burying kings among the ancients]	67, a.
Regio subterranea Sole non illuminatur [the subterranean region is not illuminated by the Sun]	99, b.
nova in Hispania detecta [a new one discovered in Spain]	100, a.
quomodo in phiala repræsentetur [how it is represented in a flask]	432, a.
Remora utrum in rerum natura extiterit [whether the remora has existed in the nature of things]	259, a.
Reptilia quæ venenosa [which reptiles are venomous]	109, a.
Reubarbarum quomodo bilem trahat [how rhubarb draws off bile]	112, b.
ejus extractum parandi ratio [the method of preparing its extract]	248, a.
Reverberatio quid [what reverberation is]	245, b.
Rhododendri lignum accensum pestiferum [the kindled wood of the rhododendron is pestilential]	126, a.
Geor. Riphæus [George Rhiphaeus]	245, b.
Risogallum venenum atrox [risigallum (realgar), a dreadful poison]	148, a.
Rochetæ qui componantur [how rockets are composed]	474 & seq.
Rosæ qui variis coloribus imbuantur [how roses are imbued with various colors]	387, b.
qui incorruptæ servantur [how they are kept uncorrupted]	388, b.
Ros salis species est [dew is a kind of]	332, b.

Lemma [gloss]	Reference(s)
salt]	
Roseæ crucis fratres magi [the brothers of the Rosy Cross, magicians]	280, a.
eorum dogma [their doctrine]	280, b.
Rota in aëre versatilis qui repræsentetur [how a wheel revolving in the air is displayed]	480, a.
Rubetæ symptomata & remedia [the toad — symptoms and remedies]	144
Rubinus qui conficiatur [how the ruby is made]	457, a. 460, b.
Rubigo ferrum consumit [rust consumes iron]	220, a.
contra eam remedium [a remedy against it]	ibid.
Rupicissa impostor [Rupescissa, an impostor]	273, a.
ejus de auro Alchymistarum iudicium [his judgment on the gold of the alchemists]	276, a.

S.

Lemma [gloss]	Reference(s)
Sal cur fœcundum dicatur [why salt is called fruitful]	331, b.
ubiq; provenit [it occurs everywhere]	ibid.
animalia conservat [it preserves animals]	332, a.
ei sulphur & mercurius insunt [sulphur and mercury are within it]	333, a.
crystallinum quid [what crystalline salt is]	249, a.

running header: "& VERBORUM"

[Continuation of letter S]

Lemma [gloss]	Reference(s)
Sal Ammoniacum producendis serpentibus multum prodest [sal ammoniac is very useful for producing serpents]	122, a.
Salis Ammoniaci mira vis [the wondrous power of sal ammoniac]	246, a.
sublimatio [its sublimation]	246, b.
menstruum [its menstruum]	435, a.
in aquam reductio [its reduction into water]	438, a.
Sal Naturæ quid [what the Salt of Nature is]	6, b.
omnia fixat [it fixes all things]	169, a.
ex quibus constet [of what it consists]	328, b.
quotuplex [how many kinds]	380, a.
ejus mira vis [its wondrous power]	167, b.
Salis mira proprietas [the wondrous property of salt]	226, b.
in crystallum versi effectus [the effects of its being turned into crystal]	229, b.
diversitas [its diversity]	402, a.
Salifodinæ ubi reperiuntur [where salt-mines are found]	224 & seq.
quotannis novo sale replentur [they are replenished with new salt each year]	225, b.
Tyrolenses [those of the Tyrol]	227, b.
Burgundiæ [of Burgundy]	228, a. & seq.
Salomon novit fibras unicuique plantarum inserendarum aptas [Solomon knew the fibers fit to be implanted into each [kind] of plants]	408, b.
Salamandra quid Alchymistis [what the salamander is to the alchemists]	315, b.
ejus symptomata & remedia [its symptoms and remedies]	144
Sandaster quid [what the sandaster is]	22, b.
Sanguisuga [the leech]	144

Lemma [gloss]	Reference(s)
ad quid utilis [for what it is useful]	376, a.
Sapor unde [whence flavor]	401, b.
Saphyrus quomodo conficiatur [how the sapphire is made]	456, b. 461, b.
in adamantem qui convertatur [how it is converted into a diamond]	463, a.
Sargasso herba unde [whence the sargasso weed]	342, a, b.
ejus crista venenosa [its venomous crest]	ibid.
Saturnus chymice plumbum denotat [Saturn, in chemistry, denotes lead]	165, a.
Satyrion unde [whence the satyrion (orchid)]	108, b. 348, a.
cur sic dictum [why it is so called]	349, a.
Saxifodinæ Tiburtinæ [the stone-quarries of Tivoli]	41, b.
Scabies unde [whence scabies]	136, a.
Scajola quid [what scagliola is]	458, a.
Scalarum mira fabrica [the wondrous construction of staircases]	209, 210, a.
Scammonium quomodo bilem trahat [how scammony draws off bile]	112, b.
Scammoneæ symptomata, cura & remedia [scammony — symptoms, treatment and remedies]	142
Scarabei capite equi [beetles from a horse's head]	96, a.
unde [whence]	364, b.
monocerotes unde [whence the single-horned ones]	365, b.
ad quid utiles [for what they are useful]	37, b.
Scolopendræ symptomata, cura & remedia [the scolopendra (centipede) — symptoms, treatment and remedies]	144

Lemma [gloss]	Reference(s)
Scoria metallorum [the slag of metals]	206, a.
argenti [of silver]	206, b.
æris & ferri [of copper and iron]	ibid.
plumbi [of lead]	207, a.
Scorpio pestis remedium [the scorpion, a remedy for the plague]	121, a.
ex ocymo natus [born from basil]	252, a. 368, a.
ex cancro [from a crab]	353, a.
quid & unde [what and whence]	367, b.
ubi reperiatur [where it is found]	368, a.
artificio qui producat [how it is produced by artifice]	368, b.
ad quid utilis [for what it is useful]	376, a.
Scossacavallo herba [the scossacavallo herb]	412, a.
Selenites qualis [the selenite, of what kind]	67, b.
Semen quid producat [what the seed produces]	8, b. 327, a.
quid sit in massa Chaotica [what it is in the chaotic mass]	328, b.
Mundi quid [what the seed of the World is]	329, a.
universale quomodo gradus acquirat [how the universal [seed] acquires degrees]	329, b.
metallorum non est animatum [the seed of metals is not animate]	329, a.
Naturæ omnia trahunt [the seeds of Nature draw all things]	330, b.
est sal animatum [it is an animate salt]	332, a.
universale quid [what the universal [seed] is]	332, a. 333, a.
in quo constat [in what it consists]	333, b.
est vegetabile [it is vegetable]	332, b. 372, a.
prolificum quid [what the prolific [seed] is]	ibid.
individuatur pro ratione matricum [it is individuated according to the matrices]	336, b.

Lemma [gloss]	Reference(s)
in vegetantibus quid operetur [what it works in growing things]	378 & seq.
quomodo attrahatur [how it is drawn]	379, a.
in emphyteutica arte quid præstet [what it accomplishes in the emphyteutic (planting) art]	386, a.
Seminis facultas duplex [the twofold faculty of the seed]	328, a.
vis radiativa [its radiative force]	334, a.
pars quota [what proportion]	379, b.
Seminarium rerum quid proprie sit [what the seed-store of things properly is]	6, a.
duplex [twofold]	6, b.
naturæ quid [what the seed-store of Nature is]	164, b.
matrici quomodo inseratur [how it is implanted in the matrix]	356, a.
Sendivogius [Sendivogius]	266, b.
Seps serpens [the seps serpent]	144
Serpentes unde [whence serpents]	119, a. 372, b.
quomodo hominem interimant [how they kill a man]	120, a.
cur in Australibus partibus venenosiores quam in Borealibus [why in southern parts they are more venomous than in northern]	121, b.
quando in diferentes serpentes degenerent [when they degenerate into different serpents]	122, a.
ubi reperiantur [where they are found]	ibid.
ciconiis in cibum sumpti cur non noceant [why, eaten by storks, they do no harm]	132, a.
qui artificiose producantur [how they are produced artificially]	373, a.
quomodo fugentur [how they are driven away]	377, a.
Siccitatis gradus difficilioris indaginis [the degree of dryness is of more difficult]	400 & seq.

Lemma [gloss]	Reference(s)
investigation]	
Smaltum varii generis quomodo præparetur [how enamel of various kinds is prepared]	455, b.
Smaragdus qui conficiatur [how the emerald is made]	457, a. 462, a.
Soda præstans ad vitrum [soda excellent for glass]	451, a.
Sol aurum denotat chymice [the Sun denotes gold in chemistry]	165, a.
Romanus cur noceat [why the Roman sun is harmful]	125, a.
Philosophorum quid [what the Sun of the Philosophers is]	317, a, b.
ejus vigorem explorare [to test its vigor]	447, b.
Solani symptomata, cura & remedia [nightshade — symptoms, treatment and remedies]	142
Solventia quid præstent [what solvents accomplish]	434, a, b.
Sonus quid operetur [what sound effects]	114, a.
Spagyrica ars quid [what the spagyric art is]	233, a. 238, b.
quomodo licita [how it is permissible]	308, a.
SpermatICA corpuscula quænam [what the spermatic corpuscles are]	379, a.
omnibus insunt [they are within all things]	338, a.
Spicæ farris e naribus natæ [ears of spelt grown from the nostrils]	344, a.
Spiritus salis figit materiam tartaream [spirit of salt fixes tartareous matter]	136, b.
spermaticus quid [what the spermatic spirit is]	379, a.
acidus quid operetur [what the acid [spirit] effects]	434, b.
Spodium quid [what spodium is]	207, b.
Stannum potabile qui conficiatur [how potable]	430, a.

Lemma [gloss]	Reference(s)
tin is made]	
quomodo vitrescat [how it vitrifies]	452, b.
qui crystallescat [how it crystallizes]	457, b.
quomodo calcinetur [how it is calcined]	483, a.
Stellæ an concurrant ad metallogenesis [whether the stars concur in metal-generation]	165, a.
earum radii terram non penetrant [their rays do not penetrate the earth]	165, b.
Stibium. Vide Antimonium. [stibium — see Antimony]	
Stramonii symptomata, cura & remedia [thorn- apple (stramonium) — symptoms, treatment and remedies]	142
Struthio camelus qua vi ferrum digerat [the ostrich, by what force it digests iron]	112, a.
Stuppæ pyrotechnicæ qui præparentur [how pyrotechnic tow is prepared]	473, a, b.
Sublimatio quid [what sublimation is]	246, b.
Subtiliatio quid [what subtiliation is]	246, a.
Succinum quid [what amber is]	74, b. 75, a.
quomodo Borussi piscentur [how the Prussians fish for it]	75, a.
quid præstet [what it accomplishes]	76 & seq.
qui animalcula contineat [how it contains little creatures]	75, b. 76, a.
quomodo componatur [how it is composed]	466, b.
Succus petrificus unde [whence the petrifying juice]	45.
quid sit & quotuplex [what it is and how many kinds]	46, a.
ex nitro & sulphure saxum durissimum facit [from niter and sulphur it makes a most hard stone]	47, a.

Lemma [gloss]	Reference(s)
ex pyrite & vitriolatis quid efficiat [what it effects from pyrite and vitriolated substances]	ibid. & b.
terræ venenosus animalibus venenosis loco nutrimenti servit [the venomous juice of the earth serves venomous animals in place of nourishment]	121, a.
Sulphur virtute omnes colores habet [sulphur has all colors in potency]	14, b.
cum nitro coctum in lapidem abit [cooked with niter it passes into stone]	47, a.
generat quatuor species [it generates four species]	115, b.
cur θεῖον dictum [why it is called θεῖον (theion, "divine" — the Greek word for sulphur)]	145, a.
dividitur in ἄπυρον & πεπυρωμένον [it is divided into ἄπυρον (apyron, "unfired") and πεπυρωμένον (pepyrōmenon, "fired")]	ibid.
ubi fodiat [where it is dug]	ibid. b.
quid sit [what it is]	146, a.
est minerale & philosophorum [it is mineral and [the sulphur] of the philosophers]	ibid.
idem fere cum bitumine [almost the same as bitumen]	156, a.
rubrum ubi [red sulphur, where]	189, a.
quomodo vitrificetur [how it is vitrified]	245, b.
difficulter domatur [it is tamed with difficulty]	252, a.
fixum quomodo aurum exaltet [how fixed sulphur exalts gold]	294, b.
qui Lunam in Solem tingat [how it tinges silver into gold]	295, a.
fixum quid [what fixed sulphur is]	438, b.
Sulphuris mineralis origo [the origin of mineral sulphur]	46, b.
flores, lac, oleum [its flowers, milk, oil]	147, a.

Lemma [gloss]	Reference(s)
virtutes [its powers]	147, b.
balsamum plumonis vitia curat [its balsam cures defects of the lung]	174, b.
vis auri purificativa [its power of purifying gold]	187, a.
sidera [its stars]	189, a.
flores conficiendi ratio [the method of making its flowers]	246, a, b.
fixi saluti ad volatilitatem præparatio [the preparation of fixed [sulphur] for safe restoration to volatility]	294, a.
oleum reale non datur [a real oil is not to be had]	436, b.
oleum qui præparetur [how the oil is prepared]	468, a, b.
Surculi quomodo inserendi [how grafts are to be inserted]	382, b.
Sympathia quid [what sympathy is]	111 & seqq.
venenorum ad certa membra [of poisons toward particular members]	130, a.
ferri cum plantis [of iron with plants]	220, b.
auri cum plumbo [of gold with lead]	206, a.
ocymi cum scorpione [of basil with the scorpion]	368, b.

T.

Lemma [gloss]	Reference(s)
Talcum quid [what talc is]	67, b.
quomodo in oleum reducatur [how it is reduced into oil]	436, a.
Talpæ non sunt cæcæ [moles are not blind]	87, b.
earum origo [their origin]	ibid.
Tapulæ qui nascantur [how tapulæ are born]	345, b.
Tarantulæ virus [the venom of the tarantula]	129, a.
Tartarum quid [what tartar is]	136, a.

Lemma [gloss]	Reference(s)
causat horrendos morbos [it causes dreadful diseases]	136, b.
quomodo solvatur [how it is dissolved]	435, a.
Taxus ubi nascatur [where the yew grows]	119, a.
ejus umbra noxia [its harmful shade]	125, b.
Tellinæ qui producantur [how cockles are produced]	373, b.
Terra halitibus aquam & aërem inficit [the earth infects water and air with its exhalations]	128, a.
quotuplex [how many kinds]	399, a.
foliata quid [what foliated earth is]	265, a.
alba quid [what white earth is]	ibid.
Tetragonismus nondum repertus [the squaring [of the circle] not yet found]	233, b.
Thapsiæ symptomata, cura & remedia [thapsia — symptoms, treatment and remedies]	142
Thus ubi nascatur [where frankincense is produced]	119, a.
Tineæ qui nascantur [how moths are born]	356, b.
Tithimalli symptomata, cura & remedia [spurge (tithymalus) — symptoms, treatment and remedies]	142
Tinctura colorum in vegetabilibus [the tincture of colors in vegetables]	19, a.
in gemmis quid operetur [what it effects in gems]	20, a.
quid sit [what it is]	262, a.
auri multiplicativa an detur [whether a gold-multiplying [tincture] exists]	268, b. 425, a.
argentum in aurum convertens [converting silver into gold]	294, a.
argenti ejusque vires [the tincture of silver and its powers]	429, 430, a, b.

Lemma [gloss]	Reference(s)
corallorum quomodo solvatur [how the tincture of corals is dissolved]	435, b.
essentialis ex antimonio extrahi non potest [the essential [tincture] cannot be extracted from antimony]	436, b.
gemmarum varia [the various tinctures of gems]	465 & seq.
Topazius qui conficiatur [how the topaz is made]	457, a. 462, b.

[End of the Index of Subjects and Words of the Second Volume.]

To the Reader

[AD LECTOREM — printer's note to the reader]

If, in the varied subject-matter of this Work, any errata [Greek: σφάλματα (sphalmata, "errors, slips")] should occur as to the type and the engravings — or if

(as for the most part happens in works of the greatest difficulty) the Reader should meet with anything obscure, distorted, or with a gap in it — he, with that prudence which is his, will not disdain to amend it himself, to take it in good part, and so to discharge the office of the absent Author (to whom recourse was not always possible) out of his own kindness, mindful of that saying: *Even good Homer sometimes nods*.

FINIS.

Mundus Subterraneus — End-leaves

These four PDF pages are the back-matter end-leaves and binding material of the volume. The book's main text, the *Index Rerum & Verborum*, the *Ad Lectorem* errata note, and "FINIS" all concluded in the prior batch (printed p. ~492). No printed text appears on any of these four pages; they carry only blank paper, a vellum binding board, and modern library/archival pencil markings.

Reading order. No printed page numbers, signatures, or catchwords are present on any of these leaves, so the original printed reading order cannot be reconstructed from them — there is nothing printed to order. The pages are taken in PDF sequence (993, 994, 995, 996), which corresponds to the physical end of the bound volume (final blank fly-leaves followed by the inside of the rear vellum cover).

blank rear fly-leaf

Blank end-leaf. The page shows aged, foxed paper with faint show-through (bleed-through) of text from the preceding printed leaves, but **no printed or written text of its own**. A crease/fold runs across the lower-right corner. No printer's device, colophon, signature, or date.

blank rear fly-leaf (verso)

Blank end-leaf. No printed text. Faint show-through from adjacent leaves is visible. At the **lower-left corner**, two modern archival/library shelf markings are written by hand in pencil:

- [Archival mark: ALPH 1885040] [?]
- [Archival mark: 02-35465]

These are modern cataloguing annotations added by a holding library, not part of Kircher's printed book. No printer's device, colophon, or date.

blank fly-leaf / pastedown

Blank leaf. No printed text. The image shows the page within the binding's framing border (the impression of the vellum turn-ins). At the **upper-right corner**, a modern pencil shelf/inventory note is written by hand:

- [Archival mark: 3446 p. 24] [?]

The reading of this pencil annotation is uncertain. No printed text, printer's device, colophon, or date.

inside of rear cover (vellum binding board)

This is the inside face of the rear cover: a limp-vellum binding board, showing staining, scuffing, and the sewing-station holes along the spine edge. It bears **no printed or written text** — only faint scratches and binder's marks. No printer's device, colophon, or date.

Summary. The volume ends with blank fly-leaves and the rear vellum binding board. There is no terminal printer's device, advertisement/book-catalogue, privilege, imprimatur, colophon, signature, or date on these final four pages — all such matter (FINIS, errata, index) concluded earlier. The only non-blank content is modern library pencil shelfmarks, transcribed above as [Archival mark: ...]. This completes the volume.
