Translator Version 2

Upright reason dictates that the recipients of the good, of whatever type and level of beneficence it may be, must show gratitude and blessing to the beneficent person in every way possible, commensurate with the value of the beneficence. And one who has benefited all the people of the world — for example, one who invented a new instrument for the good of the world, or a good book — it is fitting for every discerning person, out of the obligation of love of fellow beings, to at least purchase it, so that the man will profit and his heart will be encouraged thereby to invent yet more good instruments in the world. And similarly, all other wise-hearted people will likewise strive and exert themselves to invent good things and instruments needed for the repair of the world and its perfection.

And therefore, whoever says: "What do I need this new instrument for?" — he does not act well towards the world. For if not for the man who invented it, where would you be? And what would your city do? And more than this, if the man did not exert himself, what would the world do?

— R. Pinchas Eliyahu Hurwitz, *Sefer HaBris HaShalem* (1797)

A note on the work

Tomus V is Clavius's definitive account of the Gregorian calendar reform, which he principally engineered. The *Explicatio Romani Calendarii* expounds the reformed calendar in full — the correction of the solar year and the equinox, the epacts and golden numbers, the lunar cycle, and the reckoning of Easter — with the great computus tables that put it into practice. It is followed by the *Apologia*, Clavius's two-book defence of the reform against Michael Maestlin's attacks, and by an appendix answering further critics (Joseph Scaliger, Georg Germanus, François Viète). The volume is the fullest primary exposition of the calendar that the modern world still uses.

A note on the translation process

This translation was produced with the [translation-pipeline](#). See the linked repository for details on the process.

This text is the product of a highly refined automated translation process. It has undergone only cursory human review and should not be treated as an authoritative or scholarly rendering. It is offered solely as a reference and reading aid — a way to make an otherwise inaccessible work approachable — and any passage of real consequence should be checked against the original source.

CHRISTOPHORI CLAVII BAMBERGENSIS E SOCIETATE IESV OPERVM MATHEMATICORVM TOMVS QVINTVS

**CHRISTOPH CLAVIUS of Bamberg, of the Society of Jesus: MATHEMATICAL
WORKS, VOLUME FIVE**

Containing:

The Exposition of the Roman Calendar restored by Gregory XIII, Supreme Pontiff [ROMANI CALENDARIII à GREGORIO XIII. P. M. RESTITVTI Explicationem], published by order of our Holy Lord **Clement VIII, Supreme Pontiff**.

The Defence of the New Roman Calendar [NOVI CALENDARIII ROMANI APOLOGIAM] against Michael Mästlin of Göppingen [Michael Mästlin], mathematician in the University of Tübingen, set out in two books.

An **Appendix to the Defence of the New Roman Calendar** [APPENDICEM AD NOVI CALENDARIII ROMANI Apologiam], in which Joseph Scaliger [Joseph Justus Scaliger], Georg Germanus [Georg Germanus], and François Viète [François Viète] — who maintained that the calendar ought to have been reformed on other lines — are each refuted separately. There is also added a refutation of Scaliger's *Cyclometria* [Cyclometrica, on the quadrature of the circle].

Diagram. The Jesuit printer's device at the centre of the title page: a square woodcut cartouche with putti at the four corners and a winged cherub head at the top, enclosing a radiant oval medallion. At the medallion's centre stands the monogram **IHS** surmounted by a cross, with three nails below. The oval is ringed by a beaded lettered band, inked and legible throughout, carrying the legend in four segments read clockwise from the lower-left arc:

- Left arc, ascending: LAVDA
- Upper-left arc: BILE
- Upper arc: NOMEN
- Right arc, descending: DOMINI

i.e. **LAVDABILE NOMEN DOMINI** — "Blessed be the name of the Lord" (Psalm 112:2 Vulg.). The band carries no further lettering; the ink ownership inscriptions cross the cartouche frame, not the band.

[Manuscript ownership inscriptions, in a 17th–18th-century hand, written across the device:]

- [Above the device, in ink: "Monast[erij] Schyrenfis." — i.e. of the Monastery of Scheyern]
- [To the right of the device, in a large flourished hand: "Schyrenfis"]
- [To the left of the device, a heavily blotted flourished word, probably the matching "Mon[asterij]" (?) — the letters are obscured by a large ink blot]

MOGVNTIAE [Mainz], at the expense of **Antonius Hierat** [Anton Hierat], printed by **Ioannes Volmari** [Johann Volmar]. With the Grace and Privilege of His Sacred Imperial Majesty.

**TO THE MOST REVEREND AND MOST
ILLUSTRIOUS PRINCE AND LORD, LORD
JOHANN GOTTFRIED**

Bishop of Bamberg, and Provost of the Cathedral Church of Würzburg
[Herbipolensis], etc., his most gracious Lord —

IOANNES REINHARDVS ZIEGLERVS [Johann Reinhard Ziegler] of the Society of Jesus sends warmest greetings.

I was under no illusion, most Reverend and most Illustrious Prince, when Christoph Clavius first offered his Commentaries to the College of Mainz for publication, that if I took charge of the task it would involve — besides immense labour and trouble — a great deal of risk as well. For everything mathematical is by its very nature so constituted that a single accent or a single point overlooked can produce embarrassing errors. And who is so rash as to suppose that, amid such a multitude of figures and numbers, he can guarantee that nothing will ever escape his eye? Who has a mind so tireless that, contending daily with the intolerable negligence — or should I say the incompetence? — of the copyists, he does not sometimes, worn down by labour and weariness, deal too lightly with much that would require closer attention?

For my part, I could see clearly that however scrupulously I discharged every part of my duty, if any fault did occur, then — such being the temper of the ill-disposed — even what no human care could have guarded against would be charged to my negligence. That is why I could easily have been brought round to the view that, however keenly I favoured the mathematical disciplines of my own accord, I ought nonetheless to keep my hands off so risky a business — had not the authority of the Reverend Father Clavius weighed more with me than the magnitude of the risk and the labour. For I understood that he, being now advanced in years, could not cope with a task so genuinely burdensome; and I was willing to try anything rather than have the entreaties of that man carry no weight with me — a man whom the whole world by common consent has held to be the most celebrated mathematician of our time. At the same time it occurred to me how much it mattered to the common good that nothing should ever be lost of all those works which he had published piecemeal and scattered. So I decided I must not allow myself to appear to have failed either his own most honourable wish or the public good of learning.

Accordingly, having begun two years ago, we have at last, with great effort and expense, reached the end — and, unless my judgement deceives me, with better success than I could have hoped for. One thing alone is chiefly wanting to make my joy complete. I wished nothing more than that the Reverend Father Clavius, already set at the very end of his life, should not depart from this mortal course before he had himself seen this offspring of his brought out by us in a more dignified and more elegant form, and — if it seemed good to him — given it his approval. God, best and greatest, willed it to fall out far otherwise. For in this very

year 1612, on the sixth day of February, just as we were putting almost the last hand to the work, that man died — a man most celebrated for the praise of his very great virtues and learning. That distinguished star of mathematicians ceased to shine among men: the glory of his native land, the ornament of our Society, an adornment of the Christian Church.

How splendid an opinion everyone held of him can be seen even from the admission of a certain

man of no mean standing among the learned, who — though he admired himself rather than others — nevertheless conceded so much to Clavius alone that he said he would rather be criticized by him than praised by anyone else. And those who knew him rather more closely, from familiar acquaintance, report that what was most to be admired in him was this: that with so great a reputation for learning and so bright a name, he kept joined to them, unbroken, so remarkable a piety and modesty that he never ranked any man below himself, and ranked himself below everyone else. For these reasons, since God in his great kindness willed him to be rewarded with immortal honours, he called him — weighed down now with years and with merits — out of this life to those seats of the blessed on which he had always fixed his eyes and his heart.

If this event moves you rather deeply, most Reverend and most Illustrious Prince, as I am convinced it does, given your love for Clavius, I should like you to reflect again and again that there can be no doubt of this: the safety of the Church of Bamberg, for which he prayed daily to God while he lived, must now be all the more dear to him, in proportion as the hope of obtaining from the divine Power what he wishes now shines more surely upon him.

As for myself, I shall keep faith with him dead as I gave it to him living, and shall not allow the commentaries which he consecrated by his last will to Your Name to be inscribed with anyone else's title. For from the very beginning [printed *pincipio*; recte: *principio*], when I took charge of this work, besides the other motives I have mentioned above, there was this too: that I was glad to be offered some occasion of serving Your Glory. And so it often happened that when I was worn out by the sheer length of the labour, nothing spurred me on to persevere more than the recollection of Your Name. Thus it has at last been brought about that I bring before the public five substantial volumes, published in print under your favourable auspices — volumes which, unless I am much mistaken, will last for many centuries, both because of the widely acknowledged reputation of their author's learning and because of the excellence of their subject matter, and

which I am confident will carry the memory of Your Name as far as possible into all posterity.

And yet it is a small thing that I should seem to entrust the fame of Your Glory to perishable paper. That fame will endure of itself, and will flourish, stamped on men's minds by the splendid achievements of your virtues. For this is the road by which Christian Princes must strive toward true immortality: that once they have died, they should wish no other monuments of themselves to survive than illustrious examples of things well done. But if our writings do count for something in celebrating the fame of outstanding men among later generations, then I beg you again and again, most Reverend and most Illustrious Prince, to take this our devotion to honouring you in good part, in keeping with your singular goodwill. I hope you will do so all the more if you weigh it kindly and graciously — not by the magnitude of the benefits you confer almost daily upon our Society, and above all upon your College at Bamberg, and therefore by what you could rightly demand of us, but rather by the slenderness of our resources, and so by how little it is that we are able to offer.

It remains only that I pray God, for the easing of Germany's common grief — Germany, which at this very time lies stricken by the all too frequent funerals of her best Princes — to keep Your Highness safe and sound for as long as possible.

Mainz, the 25th day of March, in the year 1612.

[p. 9 — title page of the first work in the volume:]

EXPOSITION OF THE ROMAN CALENDAR RESTORED BY GREGORY XIII, SUPREME PONTIFF

ROMANI CALENDARII A GREGORIO XIII. P. M. RESTITVTI EXPLICATIO

PUBLISHED BY ORDER OF OUR MOST HOLY LORD CLEMENT VIII, SUPREME
PONTIFF

BY THE AUTHOR

CHRISTOPH CLAVIUS OF BAMBERG, OF THE SOCIETY OF JESUS

[Show-through from the following leaf is visible across this page — the reversed text of the next page's heading ("SANCTISSIMO PATRI AC DOMINO ... CLEMENTI

VIII ...) and of its opening paragraphs shows through the paper; it is not printed on this side.]

TO OUR MOST HOLY FATHER AND LORD CLEMENT VIII

CHRISTOPH CLAVIUS OF THE SOCIETY OF JESUS.

How much weight and importance has always been attached, Most Blessed Father [P. B. = *Pater Beatissime*], to keeping the memory of the resurrection of Christ our deliverer at fixed and settled seasons of the year is easy to gather from this alone: that a great many Roman Pontiffs wished many and most serious decrees to stand on the matter. Indeed, they repeatedly guarded it with the severest pronouncement of anathema, so that no one, misled by the error of certain seditious men, should choose the fourteenth moon of the first month for the observance of that most holy day — men who, shamelessly breaking away from the judgment of the whole Church, were for that very reason called Quartodecimans. I could list here many general councils which by their own authority repeatedly ratified what the Roman Pontiffs had once prudently decreed, and which laid down carefully at what times of the year, by what rite, and with what religious observance the most holy Passover of Christ was to be celebrated. But let one council stand for them all: the one first held at Nicaea, famous for the attendance of three hundred and eighteen bishops of the most outstanding character in every department of life, at which the great Constantine was present, and over which the legates of this Apostolic Roman See presided with the fullest authority. For in that assembly, as the most holy and likewise most learned Ambrose, Bishop of Milan [Ambrosius Mediolanensis Antistes — Ambrose of Milan], reports, many things were decreed by the foresight of those most wise Fathers which seemed to bear on establishing or on advancing the Christian religion. Above all, one matter was seen to with the greatest care: that men most expert in mathematics should be called into consultation, and that a nineteen-year cycle [Cyclus decennouennalis] should be established for the correct celebration of Easter.

Once this was done, it could have seemed that a most serious matter had been sufficiently provided for — had not a few small fractions of hours, neglected in the reckoning of the years and of the lunar months, gradually and imperceptibly dislodged the equinox and the new moons from their proper places. The result was that the very thing the Fathers of the Council of Nicaea had meant to serve as

a kind of guide in the celebration of Easter became instead a guide to shameful error and to contradicting the most prudent institutions of our forebears. The Fathers of the Council of Trent, therefore, who not many years earlier had assembled in that city to restore a collapsed discipline and to check the wicked efforts of the enemies of the Christian religion, judged it to belong to no small part of their office that this drawback I have mentioned should be met at the earliest possible moment. Accordingly they entrusted the task of correcting the calendar to the Roman Pontiff, as the supreme overseer and guardian of the sacred ceremonies and of the ecclesiastical rites. Gregory XIII — a man abounding in every kind of virtue — then took it up, and carried it through so praiseworthily that the new calendar was received and approved by the agreement of nearly the whole world.

And although the authority of the Roman Pontiff ought to stand so high with everyone that whatever he has determined all alike are bound to hold as valid — nevertheless, since in past years there was no lack, and there is no lack at present, of men who rashly (to say nothing harsher) dare to condemn the plan of the corrected calendar, and who try to persuade society at large that they alone have seen more in a moment of time than those most eminent and most learned men who for ten years held meetings in Rome on this subject by the authority of the Roman Pontiff — for this reason it was very wisely decided that, lest the matter should appear to have been settled by authority rather than by argument, the rationale of the corrected calendar should be set out. In this way either the handle for further disparagement would be taken away from the malicious, or, if they persisted in their obstinacy, later generations would have a source from which to draw the strongest possible supports for the defence of the New Calendar.

Since, then, a few years ago Your Holiness saw fit to lay this burden on me — on me, that is, who by God's kindness am the one survivor of all of us who took part in restoring the calendar — even though I recognized that I could not bring strength equal to so great a task, if I wished (as indeed seemed only right) to satisfy the wonderfully divergent opinions of learned men about the correction of the year: still I could not fail to serve the zeal of so great a Pontiff, whom I saw

directing all his cares and thoughts to the good of the whole Christian commonwealth. And so, relying on divine help, I have tried to expound the whole matter in such a way that — unless I see nothing at all clearly — anyone can very easily understand that the plan of the corrected calendar which Gregory XIII

followed is in every respect complete, and that no more perfect one could have been established.

For the rest, I must beg and entreat you, Most Blessed Father, by that singular kindness and clemency of yours, that if I have fallen short of the greatness of the subject and of people's expectations, you will judge it pardonable — partly on account of the difficulty of the subject matter, partly on account of my poor health, partly on account of my now advancing age. For my part, if I learn that my willingness to obey Your Holiness — that is, to obey God, whose place you fill — has not been unwelcome, I shall reckon that I have gained the greatest possible fruit of my long labour.

CLEMENS PAPA VIII.

AD PERPETVAM REI Memoriam.

Whatever our predecessors, the Roman Pontiffs, have piously and wisely established and decreed for the common good of the whole Catholic Church — after long study and lengthy deliberation — we are bound not only to defend by every means against the assaults of wicked men, but also, so far as is permitted in the Lord, to confirm by apostolic authority.

Now our predecessor Pope Gregory XIII, of happy memory, restored the Roman calendar and the ecclesiastical year to their original condition with such care and such success that the calendar just named appears never again to be liable to any change. It had, through the neglect of certain small quantities, drifted so far from the truth with the passage of time that, had Gregory not made timely provision, the sacred day of Easter would generally have been presented for celebration outside the lawful period fixed by the holy councils and the Fathers. Yet certain unprincipled men have gone to such lengths of audacity as to attack this work of great labour, completed by the industry and application of such distinguished men, to harass it with slanders, and to presume to raise this objection against it: that it does not always answer exactly to the motions of the heavens — as though a form of calendar could be devised that, one and the same, would agree perpetually with the run of all the years that follow, and would at no time diverge from the celestial motions even in the slightest. In particular, one François Viète has reached such a pitch of impudence that he has dared to publish a calendar of his own composition, full of errors and plainly contrary to the Gregorian, yet titled *Gregorian*; and he has prefixed to it the letters of the said Gregory, our

predecessor, on the emendation and restoration of the calendar, so that under a public show of truth he might instil the poison of his false teaching.

We, therefore, considering that this calendar was restored by our predecessor Gregory with the utmost diligence and care, men most expert in these matters having been engaged upon the work; that it could rightly be entitled *perfect and perpetual*, since it always stands entire in its principal parts; and that it is no cause for wonder if the cycle of our epacts, distributed through the days of the calendar, does not at every point agree with the motions of the heavens in respect of the new moons and the fourteenth Paschal moons, since this must necessarily happen in every cycle, and it is enough that this error — which cannot be avoided — is found to be far rarer in this new calendar than in any other: for these reasons, in order to explain the calendar more fully, and to remove every occasion of attacking it along with the remaining difficulties, we charged our beloved son Christoph Clavius of Bamberg, religious of the Society of Jesus, a man thoroughly versed in this subject, who rendered outstanding service in the emendation of that same calendar under the same Gregory, to publish expositions of the said calendar, both to confirm the reasoning of the calendar and of Gregory, and to break down the fabrications of all its adversaries. After much labour by lamplight he has at last presented us with the book we desired, and has entitled it *An Exposition of the Roman Calendar restored by Gregory XIII, Supreme Pontiff, published by our command*. In it the errors of the adversaries are clearly refuted, and it is shown that this calendar will be perpetual, so that it will never be subject to any change, not even the smallest, so far as the arrangement of the epacts is concerned — although after very many centuries have elapsed another equation of the solar and lunar year may perhaps have to be instituted.

Wherefore we, wishing to provide in good time that nothing further be objected or fabricated against the said calendar, by these present letters approve the exposition of that calendar published by the aforesaid Christoph Clavius. But all other calendars already drawn up by anyone whatever, contrary in any respect to this one — thoroughly faulty calendars that are being forced upon the Church — and especially the one which the said François Viète published on his own authority, which differs from the Gregorian in this among other things: that in it the epact xxx, or the one marked with this sign *, is not written against the first day of January, as it is in the [Gregorian] calendar [?], but is not so entered as it is in the Gregorian, and the year begins with the epact xxix from the eighth day of March, which is a thing unheard of and utterly contrary to the Fathers of the Council of Nicaea — these, and likewise any others that may perhaps be published hereafter in

the whole Christian world, we perpetually abrogate, and we everywhere forbid and prohibit their use. And we decree that this is to be so held by all, and that whatever may be attempted to the contrary in these matters by anyone, on any authority, knowingly or unknowingly, is to be judged and determined null and void by any ordinary or delegated judges whatsoever.

Enjoining, by virtue of holy obedience, upon all our venerable brothers the patriarchs, primates, archbishops, bishops, and other local ordinaries, and upon their vicars general in spiritual matters, that each of them see to it and cause these our present letters to be published and observed in their churches, cities, and dioceses. Notwithstanding any apostolic constitutions and ordinances, statutes and customs — even those confirmed by oath, by apostolic confirmation, or by any other guarantee — and notwithstanding any privileges, indults, and apostolic letters granted, confirmed, or approved in any manner to the contrary of the foregoing, and notwithstanding anything else to the contrary.

We further will that transcripts of these present letters, even printed ones, signed by the hand of a public notary and secured with the seal of some person constituted in ecclesiastical dignity, shall be given exactly the same credit as would be given to the letters themselves if they were produced or shown.

Given at Rome, at Saint Peter's, under the Fisherman's Ring, on the seventeenth day of March, M.DC.III, in the twelfth year of our pontificate.

M. Vestrius Barbianus.

LECTORI S.

[To the Reader, greeting.]

It is now twenty years and more since we saw the Roman calendar — no lightly corrupted by the fault of the times, and then corrected by the work and industry of the most learned men — come to light under the most favourable auspices of Gregory XIII, Supreme Pontiff. The achievement was the more glorious for that wisest of pontiffs because, although everyone had most eagerly pressed for it and many had attempted it with what I may call obstinate labour, it had never been possible to carry it through to a conclusion as intended.

There is no need for me to recall with what unanimity and with what universal approval the restored calendar was received and commended. I say only this: there was no kingdom of the Christian world, no province, no city, no academy of any distinction, that did not acknowledge that so great a matter had been

accomplished with the utmost wisdom and success, and that did not judge that a plan for correcting the calendar, devised almost by divine inspiration, should be embraced with every effort. And if there are certain corners of the earth to the north, or towards the rising sun, that have not yet received the most welcome light of this emendation, we take it as established that this has come about not so much from love of darkness as from hatred of the Roman Pontiff: because heretics and schismatics count him an adversary to their own positions, they find it utterly galling that so great and so singular a benefit should have been conferred on the human race through him. But surely, just as bodies cast the smallest shadows once the sun is high, so we may expect that in time the growing splendour of the corrected calendar will in some measure light up every shore of the earth, however remote — or at the least will dazzle the eyes of treacherous men, willing or unwilling.

[Margin: Why some have not accepted the new calendar.]

Amid all the advantages which everyone admits the restoration of the calendar has brought to the community of mankind, one thing seemed still to be wanting, no less to the sum of its usefulness than of its pleasure: that the plan Gregory XIII followed in this splendid emendation should be set out publicly, as plainly as could be done. When therefore the most holy and equally most prudent Pontiff Clement VIII noticed this, and saw that many years had now passed since the emendation of the calendar while what was most needed had still never been supplied, he judged that he must by all means see to it that, since the calendar had been corrected and emended by the authority of the Roman Pontiff, the plan of the corrected calendar should likewise be established at the command of the Roman Pontiff.

[Margin: That this exposition of the calendar was published by order of Clement VIII.]

Would that Luigi Lilio of Cirò [Aloysius Lilius Hypsichronaeus], a man most worthy of immortality, who was the first author of so excellent a correction and lit the way for others by his own brilliant discoveries, were still alive! Or at least that some one of the other experts in mathematics — those of us who repeatedly met in Rome by the authority of the Supreme Pontiff, so that we might carry the undertaken emendation of the calendar through to completion by joint effort and counsel — still survived at this time. Then one might indeed hope that the plan of the emended calendar could be so expounded as to satisfy the fair-minded and the hostile alike, and wonderfully well.

[Margin: Luigi Lilio, the first author of the new calendar.]

As it is, however, since God has decided otherwise concerning those most learned men, and since it hardly seems possible for anyone to accomplish so great a task who did not take part in the correction of the calendar itself, I understand that I — who by God's favour am still living — must not shirk a burden otherwise far beyond my strength, especially at the command of so great a Pontiff. And although I see that I have already attempted many things in repeated night labours which, in the judgment of many, reveal the plan of the restored calendar clearly enough, still, since most of those writings answer the accusations of detractors and therefore concern the general public less, and since besides there is not a little which — as I do not deny — we have usefully thought out, this new labour had to be undertaken in full. If, as we hope, we find it approved by fair judges of such matters, we shall have reason to give immense thanks to God, the bestower of all good things.

[Margin: Why the burden of writing this was laid upon the author of this work rather than upon others.]

I am well aware, moreover, that in this exposition of ours there are some points that differ somewhat from Lilio's method of inscribing the epacts and from his equation of them. But since we know that in this very matter the Gregorian calendar itself, published in 1582, departed from Lilio's own method — as can be clearly established from the version sent to the Christian princes in 1577 — we have judged that we too are free not to adhere to Lilio's method at every point. We have done this the more readily because we understand that many things have been changed for the better, by which this emendation of the calendar may be rendered more fully explained and more secure against its detractors.

[Margin: Why the author of this work differs from Luigi Lilio in a good many respects.]

For among other things, with no small labour we have devised new procedures, and not a few of them, by which the cycle of the epacts — in which the whole substance of this correction consists — might be made easier and quicker to use, and by which the equation of the epacts might be corrected, since it was set up less than correctly by the author of the calendar. Next, by what route and method the epact for any year whatever, however remote,

[Margin: What the author of this work has principally added to Luigi Lilio's calendar.]

however remote, is to be worked out without much labour, even if the table for the equation of the epacts — which will be discussed in its proper place — does not extend as far as that year. I say nothing for the moment of the many things we have added from the more expert astronomers, by which the advance and the retreat of the equinoxes are explained, so as to make clearer the procedures by which the vernal equinox is kept in its own seat. Nor will I speak of the new rules by which everything belonging to what is called the ecclesiastical computus [Computus Ecclesiasticus] can be found very quickly on the joints of the fingers.

Among those who have tried to overturn the Gregorian calendar — a calendar confirmed by the approval of almost every nation — two stand out for the fame of their name and for their literary learning, and they seemed to some to have said something [?] to the purpose: Joseph Scaliger and François Viète. It therefore seemed appropriate to attach a refutation of both to this work, and of Viète above all. Viète entered on a scheme for restoring the calendar that was as novel as it was false; not only did he fail to grasp the intention of Gregory XIII — though he boasts grandly that he did — but he even fathered on that Pontiff decrees concerning the new calendar which were his own, that is, false ones, so as to prop up his own utterly frivolous inventions with the papal authority that no one fails to hold most sacred.

To this refutation of Viète's calendar there was no lack of people urging me strongly to add a reply to that same man's *Expostulatio* — a most empty piece, to say nothing harsher — which itself appeared to want to be addressed in this book as well, since it came into my sight at the very time when the opening sheets of my book were being struck off, as usual, on the final presses; and indeed it still breathed something of the Lord's [?] anger. For it had been published as soon as its author learned that I had set about routing his false scheme for correcting the calendar with every resource at my command — as though I were acting unfairly in defending against the rashness of a single man a Gregorian calendar long since established by the votes of all princes and all universities.

But I did not allow anyone to persuade me of this. First, because there is nothing in that *Expostulatio* which does not clearly proceed from an agitated mind. Next, because it contains nothing but abuse and insults, which in my judgement have not so much as reached me. Finally, because more than one of my friends has claimed for himself the task of replying, out of goodwill toward me or out of respect for the papal decrees.

I shall therefore be content for the present with what appears in the diploma of His Holiness prefixed to this work: what the supreme and most holy Pontiff

Clement VIII thinks of my labours; what he thinks of the Gregorian calendar, which Viète loudly proclaims that I have wretchedly depraved and corrupted; and what he thinks of Viète's own calendar. And I shall gladly and willingly pardon François Viète for whatever insulting things he has said about me.

One thing seems to remain: since in this whole matter I have been greatly helped by the discussions held at Rome in the assembly of learned men that we often convened while Gregory was still alive, I should acknowledge this publicly. If I kept silent about it, something might perhaps be taken from another's glory.

For the rest, kind reader, if you notice anything accomplished by us that you judge to be joined with some credit for talent or industry, ascribe it to God, since it is wholly a divine gift; if anything has been wrongly stated or explained, ascribe that to me. As for me, relying on the help of God the Best and Greatest, I shall take up the task itself eagerly — not so much in the hope of completing it as with the will to attempt it and to obey. Farewell.

PROOEMIVM

The holy Roman, Catholic, and Apostolic Church celebrates two kinds of feast days. The first keeps a fixed place in the calendar and comprises those feasts that always recur at set times of the year; these are accordingly called immovable. The second has a movable seat, though one enclosed within definite limits of days, and it takes in the solemnities of the day of Easter and of the feast days that depend on it; these are for that reason called movable.

[Margin: That two kinds of feast days are celebrated by the Church.]

For the first kind only the use of solar months is required — unless someone should say that lunar months are also needed, because the Church in choir, by a most ancient and praiseworthy custom, when announcing in the martyrology the solemnities and birthdays of martyrs, confessors, and holy virgins throughout the year, announces together with each day of the solar month the day of the lunar month as well.

[Margin: That for celebrating the immovable feasts only the use of solar months is necessary.]

For the second kind, which of course has come down to us from the ancient institution of the Mosaic Law, the lunar year must necessarily be employed alongside the solar; for in it both the vernal equinox and the fourteenth day of the moon of the first month have to be observed.

[Margin: That for celebrating the movable feasts both solar and lunar months are necessary.]

But since it has been discovered over a long course of time that neither year, the solar or the lunar, keeps its proper and due magnitude, the result has been that from the time of the Council of Nicaea down to our own age the Church has often celebrated Easter and the other movable feasts contrary to [?] their proper reckoning — which I shall make plain in its own place. Therefore, so that feast days of this sort might be duly kept at their own times, both years had to be corrected.

[Margin: Why both years had to be corrected.]

And indeed many supreme Roman Pontiffs, and not a few general councils, and very many men of the greatest weight and most learned in mathematical matters, have attempted to set their hand to correcting the errors of both years.

[Margin: That many Roman Pontiffs and councils desired a correction of the calendar in this respect.]

For 870 years ago and more, the Venerable Bede the Anglo-Saxon [Bede] had detected the errors in the Roman calendar, and after him, 250 years ago or more, the Greek writer Isaacius Argyrus [Isaac Argyros]. Later, when the same errors had slipped further, Campanus [Campanus of Novara] and Johannes de Sacrobosco [Sacrobosco], both very distinguished writers on the ecclesiastical calendar, remarked on them very clearly. On rooting out these same errors from the Church of God, Nicolaus Cusanus [Nicholas of Cusa] and Petrus de Aliaco [Pierre d'Ailly], both cardinals of the Holy Roman Church, and Johannes Regiomontanus [Regiomontanus], easily the foremost mathematician of his time, wrote a good deal.

[Margin: Which writers chiefly detected the errors of the calendar of the Council [?] of Nicaea.]

Most recently, at the time of the Lateran Council held under Leo X, a good many men worked energetically at emending the calendar. Among them are counted Paulus Middelburgensis [Paul of Middelburg], bishop of Fossombrone; Johannes Stoflerinus [Johannes Stöffler]; Albertus Pighius Campensis [Albert Pigge of Kampen]; and a little later Lucas Gauricus [Luca Gaurico], bishop of Civitate; and other most learned men, thoroughly practised in mathematics. All of them, it is true, wrote at sufficient length and with subtlety on the magnitude of the year — not only according to Roman usage but also according to Greek, Persian,

Egyptian, Hebrew, and Arab usage — and likewise on the months, on embolisms, on the change and variety of months and years, on the lunar cycles, and on very many other matters bearing on the restoration of the calendar. Yet none of them (be it said with their leave) fully attained what was chiefly wanted: namely, what road and what method were to be followed so that the solemnity of Easter, together with the other movable festivals, and also the immovable feast days, might be restored to their original seat, and might remain there permanently without appreciable error.

[Margin: That no one before Gregory XIII achieved a complete correction of the calendar, and why.]

For some, by their correction, threw the ecclesiastical rites into confusion — which was in no way to be tolerated. Others, while taking care to keep the equinox in its own seat, drove the moon out of its proper place; and conversely, while providing for the new moons, they forced the equinox to abandon its own home. As a result, others asserted that it could not be done — that a lunar cycle valid in perpetuity could not be written into the calendar while at the same time a firm and settled seat was assigned to the equinox. We shall set out the difficulty of this in its own place.

[Margin: That most men judged that a perpetual lunar cycle could not be written in the calendar, and that a stable seat could not be assigned to the equinox.]

Luigi Lilio of Cirò [Aloysius Lilius Hypsicroneus] alone achieved the thing successfully — and not without the kindness of God the Best and Greatest — when he devised a cycle such that, once written into the calendar, it shows the new moons in perpetuity, even though a day must sometimes be taken out of the year in order to keep the equinox in its seat. This method, then, Gregory XIII of happy memory embraced with the consent of the whole Christian world, and proposed to all for observance. This was indeed a notable and illustrious deed, one that grateful posterity deserves to

[Margin: That Luigi Lilio alone — whom Gregory XIII followed — wrote a perpetual lunar cycle into the calendar and at the same time assigned a stable seat to the equinox.]

consecrate to everlasting memory. For by it the Christian commonwealth has secured that the solar and lunar years should henceforth proceed by an equalized calculation, in agreement with each other, and that the feast days, both fixed and movable, should be duly and lawfully carried through at their own times according to the decrees of the councils, the pontiffs, and the fathers — the

very thing that so many councils and learned men greatly desired but were unable to obtain.

We have undertaken to explain this same method in the present volume, so that everyone may understand where the whole force and rationale of correcting the Roman calendar lies, and why, when the opinions of others were rejected, this one of Luigi Lilio's was retained.

Since both years, the solar and the lunar, have been restored to their original condition, we shall treat the solar year first and the lunar afterwards. But first it seemed worth the effort to set out the *Compendium* of this new method of restoring the calendar, which Gregory XIII, Supreme Pontiff, sent in the year 1577 to Christian kings and princes and to the most celebrated universities. This is partly so that the memory of it may be left to posterity, but chiefly so that it may be clear to all what was changed in it by those to whom the task of emending the calendar was entrusted.

[Margin: The order the author keeps in this work.]

Next we shall append the corrected perpetual Gregorian calendar itself, which the same Pontiff set before the whole Christian world in the year 1582, lest the memory of that too should some day perish through the passage of time — especially since in this book we intend to expound the foundations and rationale of that correction.

After that we shall explain, before anything else, what is prescribed in Holy Scripture concerning the celebration of Passover, given to the Jews by God through Moses, and what was decreed about the same by the holy fathers and the councils; and how it came about that in our own time the truth has so often been missed in that solemnity, and that it has so often been celebrated contrary to the decrees of the fathers and the sanctions of the councils — so much so that it became absolutely necessary to emend the year and the calendar, lest the errors should grow greater day by day and Easter should at last be forced so far out of its place that no observance of it would any longer be lawful.

And since in the year 1588 we published a fairly long *Apologia* for the new calendar against a certain heretic, in which it was necessary to explain nearly all the foundations of this restoration, we shall transfer from it into this volume everything we judge useful and suitable to the present purpose. This is our right beyond dispute; no one, unless I am mistaken, ought to think we are forbidden to insert in its own and most proper place material that had undoubtedly been set in a place not its own.

Finally we shall set out the schemes of others for restoring the calendar and shall refute them; and for the benefit of students we shall add very short and very easy rules for the ecclesiastical computus.

COMPENDIUM OF THE NEW METHOD

of Restoring the Calendar, by Gregory XIII, Supreme Pontiff

SENT TO THE CHRISTIAN PRINCES AND TO THE MOST CELEBRATED
UNIVERSITIES IN THE YEAR OF OUR LORD 1577.

TO EXPERT MATHEMATICIANS.

[Margin: Why Gregory XIII sent this *Compendium* to the princes.]

The correction of the Breviary and the Missal was reserved to the Roman Pontiff by the sacred Council of Trent, and Pius V, of happy memory, saw to its completion in earlier years with all the diligence he could command and published it. Even so, that work did not seem complete and perfect in every respect unless the restoration of the year and of the ecclesiastical calendar were added to it. While Gregory XIII, Supreme Pontiff, was applying himself to that task with his whole mind and thought, a book written by Aloysius Lilius [Luigi Lilio of Cirò] was brought to him, which appeared to propose a way and a method of accomplishing the thing that was neither inconvenient nor difficult. But since this correction of the calendar brings with it many great difficulties — and since, though it had long been demanded by all good men, often deliberated by the most learned mathematicians, and much debated, it still could not be completed and carried through — the most prudent Pontiff judged that all the most expert men in this science should be consulted about the matter, so that a thing which belongs to everyone in common might also be accomplished by the common counsel of all. He had therefore resolved to send that book to all the Christian princes, so that they, calling in the more skilled mathematicians, might either approve it by their own judgment or, if anything seemed to be lacking, might complete and polish the whole of it; and at the same time, if a more suitable method should be discovered anywhere — which he does not despair of — he might, once it was communicated to him, follow that method instead. But since the book has not yet been printed, this would have been laborious and awkward, and perhaps less necessary for the expert astronomers with whom the method has to be shared. He therefore judged it enough to pass over everything else and

to indicate briefly only the chief heads that contain the substance and the ground of the matter.

[Margin: When Passover/Easter is to be celebrated according to the decree of the Council of Nicaea.]

Now the most holy Passover [Pascha] of Christians, which is bound up with the highest religious observance and with the supreme mystery of our redemption, must be celebrated — by the prescription of the divine law and by the decree of the most holy Fathers who assembled at the Council of Nicaea — from the fourteenth day of the moon to the twenty-first of the first month; and that is the moon which falls on the vernal equinox or follows immediately after it. Those Fathers therefore judged it of the greatest importance that fixed and definite days be assigned in the calendar both for the equinox and for the fourteenth moon, so that no disagreement or dissension over its celebration might arise thereafter, as had often happened before.

[Margin: That the seat of the equinox on 21 March was established by the Fathers of the Council of Nicaea.]

At that Council the seat of the equinox was placed and established on the twelfth day before the Kalends of April [21 March], and they persuaded themselves that it would be more or less stable and certain.

[Margin: That the Fathers of the Council of Nicaea laid down that the fourteenth moon was to be found from the golden number.]

The ancient Fathers likewise believed that the fourteenth moon could be found perpetually and easily from the golden number (as they call it), which had been fitted to the calendar.

[Margin: That the equinox has deserted its own seat.]

But the equinox did not easily keep its place. It abandoned its station and wandered by uncertain steps until it reached the fifth, and even the sixth, day before the Ides of March [11 or 10 March]. Unless this error is met in good time, the equinox will one day arrive at the season at which the winter solstice now falls; nor will it stop there, but will go on without limit. Many have written before now how great a disturbance this will bring upon all matters, and above all upon ecclesiastical ones, and the author of that book discusses it subtly and at length.

[Margin: That before the correction the fourteenth moon was falsely indicated by the golden number.]

The fourteenth moon, moreover, so far disagrees with that golden number that, if we follow the golden number, we now often celebrate Easter not between the fourteenth moon and the twenty-first, but — against the divine precept and the institutions of our forefathers — at the twenty-sixth moon. And this evil will creep on unnoticed and spread wider day by day, unless the necessary remedy is at last applied.

[Margin: That several Supreme Pontiffs attempted to correct the error of the equinox and of the fourteenth moon.]

Indeed, ever since Nicholas V of happy memory — in whose age good letters and the study of the liberal arts, long neglected, began to revive and recover — the remedy has been attempted with great care and zeal by the Supreme Pontiffs; yet nothing seemed capable of being settled that did not run into some great difficulty. So far as astronomy is concerned, two obstacles above all seemed to stand in the way.

[Margin: That it is difficult to assign a stable seat to the equinox, because of the uncertain and varying magnitude of the tropical year.]

The first is the true and certain measure of the tropical year itself. Since the most learned and most careful mathematicians have found this to be one value at one period and another at another, it is proved not to be always the same and consistent with itself. Since, then, the Sun runs its course in so wandering and changeable a manner, it was extremely difficult to distribute the intercalations in such a way that the equinoxes would have fixed and settled seats in the calendar for all time to come — especially as, since Julius Caesar, who first introduced this form of the year and this method of intercalation, thirteen days or more now stand ahead of the seat then established.

[Margin: What remedy Lilius devised for fixing a stable seat to the equinox.]

But the author of that little book promises to bring a remedy for this difficulty, and indeed a permanent one. He adopts the measure of the Alphonsine year, which is a mean among the various values and therefore less liable to error; and from it, when the calculations are worked out, it follows that in roughly 134 years the places of the equinoxes anticipate a whole day. On this basis he judges that the thirteen days we have mentioned — or rather (as he thinks more consonant with the dignity of the Church) those ten days that have accumulated since the time of the Council of Nicaea — should be removed by omitting ten intercalations in the forty years next following. And so, with the vernal equinox brought back to the twelfth day before the Kalends of April [21 March], the place at which

it was fixed by that Council, and with all confusion ended in the year of our Lord 1620 — from which the years will begin to proceed under better auspices — he has established this method of intercalation for all future time: that from that point on, the hundredth years, which are all normally intercalary, shall not all be so, but the first three in each set shall be common years and every fourth one intercalary. Thus in 1700, 1800, and 1900 no day shall be intercalated, but in 2000 the intercalation shall be made in the usual and customary way; and so with the remaining years that follow thereafter.

Or else — since others think one should not wait for those forty years to pass before the rest return to their proper reckoning, but hold that the ten days should be removed all at once and the inconvenience swallowed in a single draught — this shall be done in the year 1582, in whichever month shall seem more suitable, and thereafter the order shall be kept that is set out below in the table. Furthermore, for changes of this kind he chooses the hundredth years above all, as being more notable, so that no negligence or forgetfulness of this variation may creep in.

[Margin: The interruption of the cycle of dominical letters, devised by Lilius as part of his method of equating the equinox.]

This method has one drawback: the cycle of the dominical letter, as it is called, can be of no use during these first forty years, which have to be common years; and thereafter it does not return to the same beginning until four hundred years have been completed. But that is of no great consequence, especially since a table of its own has been devoted to the matter.

[Margin: Why the golden number cannot perpetually indicate the fourteenth Paschal moon in the calendar.]

The second thing that seemed to obstruct the restoration of the calendar and the delivery of a true method for Easter is this: no nineteen-year cycle could be found which, when set beside the calendar, could guarantee that the same numbers would perpetually show the new moon, and from it the fourteenth Paschal moon. And the reason is that the Moon does not, as those ancients supposed, complete her courses in the number of nineteen years and return to the same starting point in such a way as to revolve again through the same tracks. Rather, as has been more subtly investigated and detected by others, she governs and completes her orbits and revolutions in such a way that over a span of three hundred years and something more she disagrees by nearly a whole day from the places of the new moon marked in the calendar. The result has been that the golden number

has by now strayed four days and more from the true places, and that — as we said above — we sometimes celebrate Easter at the twenty-sixth moon, to the grief of devout men and the mockery of the ill-disposed.

Since, then, on account of this motion of the Moon one year in three hundred must pass without intercalation, while on account of the other motion, that of the Sun, in the same span of years there is sometimes three times, and sometimes twice, no intercalation at all, no golden number can serve these two equations in such a way that the places of the new moon do not diverge very widely within a few centuries.

[Margin: That a nineteen-year cycle of epacts can perpetually show the fourteenth Paschal moon in the calendar, provided an equation is applied at fixed times.]

But the author of this little book has ingeniously and carefully devised a certain cycle. Because it consists and is composed of the numbers of the epacts, and advances and is equated through a nineteen-year cycle, he himself calls it the *nineteen-year cycle of the epacts* [Cyclus decemnouennalis Epactarum]. Set beside the calendar, it can guarantee this result by a constant method and one that will last through all the ages, provided an equation is applied at fixed times.

It is as follows.

The Gregorian Calendar — January, February, March.

Each month block has, from left to right: an unlabelled narrow column of reference marks; the column of epacts (labelled *Cyclus Epact.* — "Cycle of the Epacts" — at the foot of the block); the dominical letter; the Roman-calendar designation of the day; and the day of the month in Arabic numerals. The column headings at the top of the table are blank; the only printed label is *Cyclus Epact.* beneath each month.

Cyclus Epact. [Cycle of the Epacts]

The perpetual calendar continues with the second quarter of the year: three month blocks set side by side, each with the same five columns — the marker column, the *Cyclus Epact.* (cycle of the epacts), the dominical letter, the Roman-style day designation, and the day-number.

Note printed beneath the three blocks:

When the golden number is 19 and the epact is likewise 19, the new moon of December is completed on the last day of that same month. But when the golden number is any other, while the epact is still that same 19, the new moon will fall on the first day of January.

To make the equation we spoke of easier to apply, he drew up a table of the cycle of the epacts [cyclus epactarum], expanded to thirty lines, and prefixed to them the same number of letters of the alphabet. Above it he set the golden numbers, so arranged that the number 3 — which used formerly to be fitted to the Kalends of January — corresponds exactly to the letter ω, which in this Cycle is assigned to those same Kalends. He also published a small table serving both the equations of the solar year and those of the lunar year taken together with the solar. In it a B,

set on the right-hand side beside the year that is to receive the solar equation, shows the year to be intercalary when it is present, and common when it is absent; the remaining letters serve the equation of the lunar year together with the solar. That equation, moreover, is of more than one kind. One is owed every 300 years, as we said. Another falls at every 2,400, since one day is not owed exactly every 300 years: twelve years and six months are still wanting, and in 2,400 years these make up nearly a third of a day and so carry the equation over into the following hundredth year. Another arises from an intercalation left out which otherwise would have had to be made; for it will sometimes happen that a day which had to be intercalated on the score of one equation is dropped on the score of another. So that these should not stand in the way of obtaining the new moons from this cycle for all time to come, it will have to be noted (*the sentence resumes below the table*) —

Tabula Epactarum expansa Aloysii Lilij, cum tabella æquationis earundem epactarum.

The expanded Table of the Epacts of Luigi Lilio, with the little table of the equation of those same epacts.

(the sentence broken off above resumes) — that the letters prefixed to the expanded table change upward, and the epact number increases, when the equation falls in a centesimal intercalary year; but downward, and the epact number decreases, when the day that was to have been intercalated in the centesimal year is not intercalated. When, however, nothing is subtracted either from the current year or from the lunar year, or when the subtraction falls in that centesimal year in which the lunar year was in need of its equation, one stays on the same letter and the same epact. These tables we append here, and also the others which the author of this book calls tables of the periods, in which are set out the epacts that indicate the new moons for each single year.

The use of these tables is as follows. For the year proposed, the golden number must first be sought from the ordinary table; then, in the little table of the equation, one must see what letter is marked opposite the number of that year, or of the next lower one, and the like letter and the golden number must be looked for in the table of the Epacts; for opposite the two of them will be found the epact numbers, or the signs, which throughout that whole year will show the new moons in the Calendar.

An example set beside it will make this clear. I want to know which number, or which sign, among those placed in the cycle of the Epacts, indicates the new moons in the year 1720. First of all, then, I find from the ordinary table that the golden number of that year is 11; this I note in the upper line of the expanded

table of the Epacts, in which the golden number is written out. Next I look for that same year in the little table of the equation; and since I do not find it expressly, I take the next lower, that is, 1700, beside which stands the capital letter D. I therefore look for the like letter in the first column of that same table of the Epacts, and having found it I move across to the right from it until I come to the column of the number 11 noted before; and I see the number 21 written in the corner common to both. Wherever, then, that number is found in the cycle of the Epacts in that year, it will show the day of the new moon.

Sequuntur tabellæ temporum pro Epactarum vsu. — **There follow the tables of the periods for the use of the Epacts.**

	0	1		3	4		6	7		9		2	3		5	6		8	9

Numeri Epactarum nouilunia indicantes ab anno Domini 1900. vsque ad annum 2199. — Epact numbers indicating the new moons from the year of the Lord 1900 up to the year 2199.

											1	1	1	1	1	1	1	1	1
Aur. Num.	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9
Epactæ	ω	1	2	3	1	2	6	1	2	9	2	1	1	2	4	1	2	7	1
		1	2		4	5		7	8		0		2	3		5	6		8

In the first table of the periods, the golden number 19 and the epact * serve the year of the Lord 1500; but 1 and 12 the year 1501, and so on in turn, these cycles always recurring upon themselves. Let the same be understood of the rest.

Lilius further completed a wholly finished table for finding the lawful days of Easter and of the movable feasts, as they are called, since those hitherto in common use are not free from uncertainty. He adds several other things bearing on a fuller explanation and proof of this scheme of his own devising, but which do not seem necessary to mention now.

Once, therefore, the vernal equinox has been restored to the place from which it had slipped; once this Cycle of the Epacts — which can be accommodated to any length of the year whatever — has been attached to the Calendar; and once the method of intercalation we have described, together with the equation of that Cycle, has been applied, the years and the months will hereafter agree with the reckoning of the sun and the moon so exactly that no variation or discrepancy can thereafter arise. And should it ever happen, he shows that it can be restored to its proper state most handsomely by this same route. Thus far the author himself.

But if the Alphonsine calculations should seem to anyone too uncertain to be trusted, and he judges that the more recent ones should be followed instead, he will assuredly see that the arrangement and ordering of this ingenious Cycle and of the table of the Epacts devised by Lilius is such that it can be fitted without any trouble to the calculations of Copernicus, or of anyone else, if a table of the equation drawn up from them is substituted for the one we have written in the margin: as for instance

— as, for example, this one, which we have set down by way of illustration and which does not differ much from Copernicus's reckoning.

Come then, you mathematicians, who are drawn on by the contemplation and study of the heavens: throw yourselves wholeheartedly and with every care into this common cause. Weigh the matter diligently, and then either approve what Lilius here proposes, or, if you know anything sounder than these proposals, be so good as to share it openly and communicate it to us. It will be a disgrace to us all if every Christian is left any longer to suffer under a serious error and to remain in ignorance of matters of the first importance.

We shall therefore await the judgments of the princes and of your learned men; and whichever scheme appears more fitting and more suitable to the greater part of them, that one the Supreme Pontiff himself will approve and adopt, as representing something like the consensus of the whole Christian world.

FINIS.

[Left-hand table, p. 12]

Vertical caption: **Table for the equation of the epacts, if ten intercalations should have been omitted over forty years.**

[Margin: Gregory XIII proposed to himself to follow the consensus of the whole Christian world in this business of the correction.]

CALENDARIVM GREGORIANVM PERPETVVM.

Set before the whole Christian world by GREGORY XIII, Supreme Pontiff. In the year M. D. LXXXII.

GREGORIVS EPISCOPVS SERVVS SERVORVM DEI

AD PERPETVAM REI MEMORIAM.

[The bull Inter gravissimas, printed throughout in italic.]**

Among the weightiest cares of our pastoral office, not the least is this: that whatever the sacred Council of Trent reserved to the Apostolic See should be brought, with God's help, to the desired conclusion. The Fathers of that same Council did indeed take up the care of the Breviary along with the rest of their deliberations, but, cut short by time, they referred the whole matter, by decree of the Council itself, to the authority and judgment of the Roman Pontiff. Now the Breviary contains two chief things: one comprises the prayers and divine praises to be recited on feast days and ordinary days alike; the other concerns the annual return of Easter and of the feasts that depend on it, to be measured by the motion of the Sun and the Moon. The first of these our predecessor Pius V, of happy memory, saw completed and published. The second, which of course requires a proper restoration of the Calendar, has long been attempted, and often, by the Roman Pontiffs our predecessors; but it could not be completed and carried

through to its end down to the present time. The reason was that the schemes for correcting the Calendar put forward by those skilled in the celestial motions were neither perpetual, nor did they keep the ancient ecclesiastical usages intact — which was the very first thing that had to be safeguarded in this matter — because of the great and almost insoluble difficulties that such a correction has always involved.

While we too, then, relying on the dispensation entrusted to us by God, unworthy though we are, were occupied with this thought and care, a book was brought to us by our beloved son Antonio Lilio, doctor of arts and of medicine, which his own brother Luigi Lilio had written some time before. In it he shows, by means of a certain new Cycle of the Epacts which he had devised — one governed by a fixed rule of the golden number itself, and adaptable to any length whatever of the solar year — that everything which has fallen into disorder in the Calendar can be restored on a consistent principle, and restored so as to last for all ages, in such a way that the Calendar itself appears never to be liable to any change in the future. This new method of restoring the Calendar, contained in a slim volume, we sent a few years ago to the Christian princes and to the more celebrated universities, so that a matter which belongs to all might also be brought to completion by the common counsel of all. When they had replied in agreement, and just as we most desired, we were moved by the consent of them all to employ upon the correction of the Calendar men most expert in these matters here in the sacred City — men whom we had long before chosen from the leading nations of the Christian world. When they had devoted much time and diligence to that labour, and had compared with one another the cycles both of the ancients and of more recent writers, gathered from every quarter and most carefully weighed, they chose, on their own judgment and on that of the learned men who have written on the subject, this Cycle of the Epacts in preference to all others; and they added to it a number of things which, after careful consideration, seemed to bear most closely on the perfecting of the Calendar.

We therefore considered that, for the right celebration of the feast of Easter according to the enactments of the holy Fathers and of the ancient Roman Pontiffs — especially the first Pius and Victor — and of that great ecumenical Council of Nicaea, and of others, three things must necessarily be brought together and settled: first, a fixed seat for the vernal equinox; next, the right placing of the fourteenth day of the moon of the first month, which falls either on the day of the equinox itself or immediately after it; and last, the first Sunday that follows that same fourteenth day of the moon. We have accordingly taken care not only that the vernal equinox be restored to its original seat, from which it has

by now drifted about ten days since the Council of Nicaea, and that the Paschal fourteenth day of the moon be put back in its place, from which at present it is four days and more distant, but also that a way and a method be handed down whereby it is provided that in future the equinox and the fourteenth day of the moon shall never be shifted from their proper seats.

In order, therefore, that the vernal equinox — which was fixed by the Fathers of the Council of Nicaea at the twelfth day before the Kalends of April — may be restored to that same seat, we order and command that in the month of October of the year 1582 ten days be removed, inclusively, from the third day before the Nones up to the day before the Ides; and that the day which follows the feast of St Francis, customarily celebrated on the fourth day before the Nones, be called the Ides of October, and that on it be celebrated the feast of the holy martyrs Dionysius, Rusticus, and Eleutherius, with the commemoration of St Mark, pope and confessor, and of the holy martyrs Sergius, Bacchus, Marcellus, and Apuleius. On the seventeenth day before the Kalends of November, which follows immediately, let the feast of St Callistus, pope and martyr, be celebrated. Then on the sixteenth day before the Kalends of November let the office and Mass be those of the eighteenth Sunday after Pentecost, the dominical letter being changed from G to C. Finally, on the fifteenth day before the Kalends of November let the feast of St Luke the Evangelist be kept, and from it let the remaining feast days follow in order, as they are set out in the Calendar.

But so that this subtraction of ten days by us may work no prejudice to anyone in the matter of yearly or monthly payments, it shall be the duty of judges, in any disputes that arise over this, to take account of the said subtraction by adding another ten days at the end of each term of payment.

Next, so that in future the equinox may not recede from the twelfth day before the Kalends of April, we decree that the bissextile day must continue to be kept every fourth year, as is the custom — except in the centesimal years. Although these have hitherto always been bissextile, and we wish the year 1600 to be so as well, the centesimal years that follow after it shall not all be bissextile: rather, in every four hundred years the first three centesimal years shall pass without a bissextile, while every fourth centesimal year shall be bissextile, so that the years 1700, 1800, and 1900 shall not be bissextile. But in the year 2000 the bissextile day shall be intercalated in the customary way, February having 29 days; and this same order of omitting and intercalating the bissextile day in every four hundred years shall be preserved perpetually.

Likewise, so that the Paschal fourteenth day of the moon may be rightly found, and so that the days of the moon may be truly set before the faithful people according to the ancient usage of the Church, to be learned each day from the Martyrology, we decree that the golden number be removed from the Calendar and that the Cycle of the Epacts be substituted in its place. This Cycle, governed (as we have said) by a fixed rule of the golden number, brings it about that the new moon and the Paschal fourteenth day of the moon always keep their true places. This is plainly evident from our exposition of the Calendar, in which the Paschal tables are also set out according to the ancient rite of the Church, so that the most holy feast of Easter may be found more surely and more easily.

Finally, since the Cycle of the dominical letters of 28 years, in use in the Roman Church down to this day, must necessarily be broken — partly on account of the ten days removed from the month of October of the year 1582 (which may rightly be called the year of the correction), and partly on account of the three days that are not to be intercalated in the space of every four hundred years — we wish that in its place there be substituted the same Cycle of 28 years, adapted by the same Lilius both to the aforesaid rule for intercalating the bissextile in the centesimal years and to any length whatever of the solar year; from which the dominical letter can be found in perpetuity, by the help of the solar cycle, just as easily as before, as is explained in its own canon.

We therefore, that we may carry out what is proper to the Supreme Pontiff, approve by this our decree the Calendar, now corrected and completed through God's boundless kindness towards his Church, and we have ordered it to be printed at Rome together with the Martyrology, and, once printed, to be published abroad. And so that both may everywhere on earth be preserved uncorrupted and purged of blemishes and errors, we forbid all printers living in territory subject, mediately or immediately, to us and to the holy Roman Church — under penalty of the loss of the books and of a hundred gold ducats, forfeited ipso facto to the Apostolic Chamber — and all others residing in any part of the world whatever, under penalty of excommunication *latae sententiae* and other penalties at our discretion, to dare or presume in any way to print, to offer for sale, or to accept the Calendar or the Martyrology, whether together or separately, without our licence.

Moreover we abolish and wholly annul the old Calendar; and we wish that all patriarchs, primates, archbishops, bishops, abbots, and the other heads of churches introduce the new Calendar (to which the plan of the Martyrology has likewise been adapted) for the recitation of the divine offices and the celebration

of the feasts, each into his own churches, monasteries, convents, orders, military orders, and dioceses, and that they alone use it — they themselves, and likewise all other priests, and clerics both secular and regular of either sex, and soldiers too, and all the faithful of Christ. Its use will begin after those ten days removed from the month of October in the year 1582. But those who inhabit regions so remote that they cannot have notice of these letters before the time prescribed by us shall be permitted to make this change in the manner just now laid down by us in that same month of October of the following year, 1583, or of another year — that is, as soon as these our letters shall have reached them — as will be explained more fully in our Calendar of the year of the correction.

And by the authority given to us by the Lord, we exhort and entreat our most dear son in Christ, Rudolf, illustrious King of the Romans [recte: *Romanorum*; the page prints *Romanorem*], elected Emperor, and the other kings, princes, and republics, and we charge them, that with the same zeal with which they have pressed us ...

might bring so distinguished a work to completion, so now, with the same zeal — indeed with even greater — for preserving concord among the Christian nations in the celebration of the feasts, they too should adopt this Calendar of ours, and see to it that it is devoutly received and inviolably observed by all the peoples subject to them.

But since it would be difficult to convey the present letters to every place in the Christian world, we direct that they be published and posted on the doors of the Basilica of the Prince of the Apostles and of the Apostolic Chancery, and in the open space of the Campo dei Fiori; and we further direct that copies of these same letters — printed copies included, and copies inserted into or prefixed to volumes of the Calendar and the Martyrology, whether subscribed by the hand of a public notary or sealed with the seal of a person constituted in ecclesiastical dignity — shall everywhere, among all nations and in all places, be held to carry exactly the same unquestioned authority that the originals themselves would carry if produced. Therefore let no one whatever be permitted to infringe this page of our precepts, mandates, statutes, will, approbation, prohibition, revocation, abolition, exhortation, and request, or to oppose it with reckless daring. Anyone who presumes to attempt this should know that he will incur the anger of Almighty God and of his blessed Apostles Peter and Paul.

Given at Tusculum, in the year of the Lord's Incarnation 1581 [M. D. LXXXI.], on the sixth day before the Kalends of March, in the tenth year of our Pontificate.

Cae. Glorierius. A. de Alexijs.

In the year from the Nativity of our Lord Jesus Christ 1582, in the tenth indiction, on Thursday the first day of the month of March, in the tenth year of the Pontificate of the most holy Father in Christ and our Lord Gregory XIII, Pope by divine providence: the Apostolic letters transcribed above were published and posted on the doors of the Prince of the Apostles in the City and of the Apostolic Chancery, and in the open space of the Campo dei Fiori, as is customary, by me, Scipio de Octavianis, Apostolic Courier.

Franciscus Baron, Master of the Couriers.

CANONS ON THE PERPETUAL GREGORIAN CALENDAR

[CANONES IN CALENDARIVM GREGORIANVM PERPETVVM.]

Canon I.

ON THE NINETEEN-YEAR CYCLE OF THE GOLDEN NUMBER

[DE CYCLO DECENNOVENNALI AVREI NVMERI.]

The nineteen-year cycle [cylus decennouennalis] of the golden number [numerus aureus] is a revolution of the number 19, running from 1 up to 19; once that revolution is completed, the count returns to unity. For example: in the year 1577 the number of the nineteen-year cycle, which is called the golden number, is 1. In the following year, 1578, it is 2, and so on in the succeeding years, always one greater, up to 19 — a golden number that will fall in the year 1595. After that one must return again to unity, so that in 1596 the golden number is once more 1, in 1597 it is 2, and so on. This cycle of the golden number contains 19 years because, after 19 solar years have elapsed, the new moons [nouilunia] return to the same days of the months — though not entirely exactly, but a small fraction of a day earlier, as the computists show, and as is shown in the book on the new method of restoring the Roman Calendar.

Every year of the golden number ends at the close of the month of December, and at the beginning of the following January another year of the golden number takes its start — just as happens with the years of the Lord, which always end in the month of December and take their beginning from January. Thus in the year of the Lord 1582 the year of the nineteen-year cycle, which is called the golden

number, is 6, and it ends together with that same year of the Lord 1582 in the month of December. In January another year of the Lord begins, namely 1583, and in that same month of January another year of the golden number is likewise taken up, namely 7. The same procedure is to be followed in the remaining years, until the number 19 is completed, from which one must again return to unity — and so on in perpetuity.

Down to the present day the Roman Church has used this nineteen-year cycle of the golden number, distributed through the days of the Calendar, both for finding the conjunctions of the Sun and Moon and — above all — for finding the feast day of Easter and tracking down the other movable feasts. The reason is that the ancients supposed that the new moons, once a span of 19 solar years had passed, returned to precisely the same day and the same hour. That is not true: as has been said, the new moons return to the same position a little sooner than the span of 19 solar years is completed. The result is that the new moons now stand more than four days away from the golden number in the old Roman Calendar, and that by that Calendar's rule Easter is very often celebrated after the twenty-first [xxj.] Moon, contrary to the institutions of our forefathers. So much so that this cycle of the golden number has by now been found altogether useless for indicating the new moons and the movable feasts, and it will grow more and more useless day by day for the future — both because of the ten days to be removed from the month of October of the year 1582, and also because of the three bissextiles to be omitted in every four hundred years — unless it were reduced into 30 series; that is, unless 30 Calendars were constructed, so that from among them one might always select the one that fits a given period. And everyone can see what disturbance and what expense that would entail, especially for churchmen.

To avoid this drawback, there has been substituted in the Calendar, in place of the golden number, the cycle of the epacts [Cyclus Epactarum], consisting of 30 epactal numbers. This is nothing else than the nineteen-year cycle of the golden number equated, so as to stand in place of the golden number distributed through the 30 Calendars just mentioned, as is explained in the book on the new method of restoring the Roman Calendar. The golden number, however, we shall still use hereafter — not indeed for finding the new moons and the movable feasts, as the Church has done down to this day, but only for investigating the epact of any given year, from which the new moons and the movable feasts are then to be found, as we shall teach in the following Canon. So that even now it is altogether necessary to track down the golden number for any year whatever,

even though it has been removed from the Calendar and no longer has a place in finding the new moons and the movable feasts.

THEREFORE, so that the golden number may be found for any year proposed, the following table of golden numbers has been drawn up. Its use begins with the year of the correction, 1582, inclusive, and it lasts in perpetuity. From it the golden number of any year after the year 1582 will be found in the following way.

Table of the cycle of the golden number, taking its start from the year of the correction 1582. [Tabella cycli Aurei numeri initium sumens ab anno correctionis 1582.]

[illegible]

Assign to the year 1582 the first number of the table, which is v_j ; assign the second, which is v_{ij} , to the following year, 1583; and so on without limit, until you reach the year whose golden number you are seeking, returning to the beginning of the table each time you have run through it. For the cell into which the proposed year falls will give the golden number sought.

BUT since it is very laborious and tiresome to count out so many years in that table, and to repeat it so many times until one reaches the year whose golden number is sought — especially if the proposed year is far distant from 1582 — we have constructed this other table that follows, from which the golden number of any year, whether before or after the year 1582, will be found without great labour, by the following technique.

Look for the proposed year in the table under "years of the Lord." If it is entered there, the golden number placed to its right, after unity has first been added (as the head of the table directs), will be the number sought. But if the proposed year is not contained in the table, take the next smaller year that the table does contain, together with its corresponding golden number. Then take, in the same table, the years that remain over, together with the corresponding golden number, and add that to the golden number found before, casting out 19 from the sum if 19 can be cast out. Finally add unity. For in this way the golden number of the proposed year will be made up. But if the years that remained over are likewise not found in the table, one must again take the next smaller year, together with its golden number, which is to be added to the golden number previously found, and 19 is to be cast out of the sum if it can be cast out. The same

is to be done with the remaining years that are left over, until you have found them all in the table. And finally, to the last golden number made up out of the golden numbers found in the table (19 having first been cast out, if it can be cast out, as has been said), unity is to be added. For in this way the golden number of the proposed year will be produced. And if after the addition of unity the resulting number is 19 — so that when 19 is subtracted nothing remains — the golden number will be 19.

Examples will make the matter clearer. Suppose the golden number of the year 700 is to be found. Since this year is found in the table, and the golden number 16 corresponds to it, then if 1 is added to that golden number, the golden number for the year 700 will be 17. Again, let the golden number for the year 1583 be proposed for finding. Since this year does not appear in the table, one must take the year 1000, the next smaller in the table, and its golden number 12. Next the remaining 583 years are to be taken in the table; and since they are not contained in it, one must again take the year 500, the next smaller in the table, and its golden number 6, which added to the golden number 12 found before makes 18. After this, the 83 years that remain are to be taken in the table; but since they are not found there, one must take the year 80, the next smaller in the table, and its golden number 4, which set beside the golden number 18 composed before yields 22 — and if 19 is subtracted from this, 3 will remain. Lastly the remaining 3 years are to be taken in the table, with the golden number 3 that corresponds to them; and when this is added to the golden number 3 just left over, the number 6 is composed. If 1 is finally added to this, as the head of the table directs, the golden number for the year 1583 will be 7. Suppose, finally, that the golden number of the year 1595 is sought. I first take the golden number 12 corresponding to the year 1000, and add it to the golden number 6 that corresponds to the year 500, making 18. Then I add the golden number 14 corresponding to the year 90 to that golden number 18 already found,

Table for finding the golden number of any year whatever. [Tabula ad Aureum numerum cuiuslibet anni inueniendum.]

Each pair of columns runs: years of the Lord | golden number, **Add 1** [*Adde 1*].

An. Dom ini	Aureus Num. (Adde 1)	Anni Domi ni	Aureus Num. (Adde 1)	Anni Domi ni	Aureus Num. (Adde 1)	Anni Domi ni	Aureus Num. (Adde 1)

6	6	800	2	1000 00	3	3000 0000	7
7	7	900	7	2000 00	6	4000 0000	3
8	8	1000	12	3000 00	9	5000 0000	18
9	9	2000	5	4000 00	12	6000 0000	14
10	10	3000	17	5000 00	15	7000 0000	10
20	1	4000	10	6000 00	18	8000 0000	6
30	11	5000	3	7000 00	2	9000 0000	2
40	2	6000	15	8000 00	5	1000 0000 0	17
50	12	7000	8	9000 00	8	2000 0000 0	15
60	3	8000	1	1000 000	11	3000 0000 0	13
70	13	9000	13	2000 000	3	4000 0000	11

An. Dom ini	Aureus Num. (Adde 1)	Anni Domi ni	Aureus Num. (Adde 1)	Anni Domi ni	Aureus Num. (Adde 1)	Anni Domi ni	Aureus Num. (Adde 1)
						0	
80	4	1000 0	6	3000 000	14	5000 0000 0	9
90	14	2000 0	12	4000 000	6	6000 0000 0	7
100	5	3000 0	18	5000 000	17	7000 0000 0	5
200	10	4000 0	5	6000 000	9	8000 0000 0	3

and this produces the number 32; taking 19 away from it leaves 13. To this I add the golden number 5, which corresponds to the year 5, and so make 18. If I finally add 1 to that, I shall have 19 as the golden number of the year 1595.

One is always added to the last number because Christ was born in the second year of this golden-number cycle: in the year of the Lord 1 the golden number was 2, in year 2 it was 3, and so on.

The construction of this table is likewise perfectly straightforward. The first ten golden numbers correspond to the first 10 years. Then, since from 20 onward the table advances by tens of years, and the golden number 10 corresponds to the tenth year — so that every ten years the golden number increases by 10 units — the golden number 10 belonging to year 10 must be doubled, and 19 cast out of the resulting 20, to give the golden number 1 for the year 20. To that golden number 1 the golden number 10 of the tenth year must again be added, to compose the golden number 11 for the year 30. In this way, for the succeeding decades up to 100, the golden number 10 is always to be added to the preceding golden number, and 19 cast out if it can be cast out, so as to obtain the next golden number. After that, since in the table the progression beyond the year 100 runs by hundreds of years, and the golden number 5 corresponds to the year 100, the golden number 5 must be doubled to compose the golden number 10 for the year 200 — seeing that with every 100 years the golden number increases by five

units. To the golden number 10, again, the golden number 5 of the hundredth year must be added, to generate the golden number 15 for the year 300. And so, for the succeeding centuries up to the thousandth year, the golden number 5 is always to be added to the preceding golden number, and 19 cast out whenever it can be cast out, so that the next golden number emerges. By this method you can extend the table to any number of years you like, provided you observe by what interval of years the table advances and which golden number corresponds to the year at which the progression begins. Thus you see that from the year 1000 up to the year 10000 the golden number 12 is always added to the preceding golden number, and 19 discarded whenever it could be cast out; for the progression of years then begins from the year 1000 and proceeds by thousands up to the year 10000, and moreover the golden number 12 corresponds to the year 1000, and so forth.

Further, even without this table the golden number of any year can be found very easily by the rules of arithmetic, as follows. Add 1 to the proposed year of the Lord and divide the sum by 19. The remainder left by the division — no account being taken of the quotient, since that only shows how many revolutions of the golden number have been completed from Christ down to the proposed year — will be the golden number of the proposed year. If nothing remains from the division, the golden number will be 19. For example, suppose the golden number of the year 1584 is wanted. I add 1, divide the sum 1585 by 19, and find that 8 is left by the division; so the golden number for the year 1584 will be 8. Again, if the golden number is wanted for the year 1595: adding one gives 1596, which divided by 19 leaves nothing; the golden number in that case will therefore be 19. Likewise, if 1 is added to the year 1600, the number 1601 results, which divided by 19 leaves 5 as the golden number of the year 1600. And so for the rest.

Canon 2.

DE EPACTIS, ET NOVILUNIIS.

[On the epacts and the new moons.]

The epact is simply the number of days by which the common solar year of 365 days exceeds the common lunar year of 354 days. Thus the epact of the first year is 11, since by that number the common solar year exceeds the common lunar year, and consequently in the following year the new moons fall 11 days earlier than in the first. From this it follows that the epact of the second year is 22: for in that year the solar year again exceeds the lunar by 11 days, which added to the 11 days of the first year make 22, and accordingly, once that year is complete, the

new moons fall 22 days earlier than in the first year. The epact of the third year is 3, because if 11 days are again added to 22 the number 33 results, and if 30 days — which constitute one embolismic lunation — are cast out of it, 3 remain; and so on in succession. For all the epacts advance by a continual increase of 11 days, 30 being discarded whenever it can be discarded. Only when one reaches the last epact, the one corresponding to golden number 19, which is 29, are 12 added, so that when 30 is thrown out of the resulting 41 one has the epact 11 again, as at the beginning. The reason for this is that the last embolismic lunation, while golden number 19 is running, should be only 29 days. For if it contained 30 days, like the other six embolismic lunations, the new moons would not return after 19 solar years to the same days, but would slip toward the end of the months and would fall one day later than 19 years before. On this you will find more in the book on the new method of restoring the Roman calendar. There are, then, nineteen epacts, as many as there are golden numbers, and before the correction of the calendar they were matched with the golden numbers themselves in the arrangement set out in this table.

Tabella Epactarum respondentium Aureis numeris ante Calendarij correctionem. [*Table of the epacts corresponding to the golden numbers before the correction of the calendar.*]

					v	v																

Now since the nineteen-year cycle of the golden number is imperfect — the new moons not returning after 19 solar years exactly to the same places, as has been said — this cycle of 19 epacts will be imperfect as well. We have therefore corrected it in such a way that in future, in place of the golden number and of the said 19 epacts, we use 30 epactal numbers running in order from 1 to 30, although the last epact — the one that stands thirtieth in order — is not marked with a numeral but with this sign *, for the reason that no epact can be 30.

At various periods, however, various sets of nineteen out of these 30 epacts correspond to the nineteen golden numbers, according as the equation of the solar and lunar year requires. These nineteen epacts advance, as they formerly did, by the same number 11, and 12 are always added to the epact that corresponds to golden number 19, so as to obtain the next epact, corresponding to

golden number 1, for the reason just given. The three following tables make this plain. The first of them contains the golden numbers and their corresponding epacts from the year of the correction, 1582, after the removal of the ten days, up to the year 1700 exclusive; in that year the second table is to be taken up, and the third in the year 1900, and so on, one after another, as we shall explain below. All this is set out more fully in the book on the new method of restoring the Roman calendar. And although the common epacts are changed in March, in strict fact they should be changed at the beginning of the year, together with the golden number, in whose place these epacts of ours step in.

Each table takes its beginning from the golden number that is current in the year in which the use of the table begins. And although in these tables different epacts always correspond to the golden numbers, it will nevertheless sometimes happen that the same epacts correspond to the same golden numbers as did formerly, before the correction of the calendar.

So, if the epact is to be found for any proposed year, look for the golden number of that year in the upper row of the table appropriate to the period in which the proposed year falls. Directly beneath the golden number, in the lower row of the table, you will find the epact of the proposed year, or else this sign *. Wherever that epact, or the sign *, is found in the calendar, on that day the new moon will occur. The golden number itself is found either by the preceding canon or from the epact table appropriate to the period in question, by assigning the first golden number of that table to the year in which the use of the table begins, the second golden number to the following year, and so on. In the same way the epact can be found without the golden number, if the first epact of the table is assigned to the year in which its use begins, the second epact to the following year, and so on.

An example. In the year of the correction, 1582, the golden number is 6 — the first of the first table, whose use begins from the Ides of October of the year of the correction, 1582, the ten days having first been removed. The epact will therefore be xxvi, which is placed under golden number 6; and the new moon will fall on 27 October, on 26 November, and on 25 December. Again, in the year 1583, now corrected, the golden number is 7, under which in the same table stands the epact vii; and that epact will indicate the new moons in the calendar throughout that year — thus in January on the 24th, in February on the 22nd, in March on the 24th, and so on. Again, in the year 1710 the golden number is 1, and beneath it, in

the epact row of the second table (which is the one that suits the proposed year), stands this sign *; that sign will show the new moons in the calendar throughout that year — namely in January on the 1st and the 31st; in March (for in February there will then be no new moon, since the sign * is not found in it) on the 1st and the 31st; in April on the 29th, and so on. Lastly, in the year 1916 the golden number is 17, under which, in the epact row of the third table — the one that suits the proposed year — the epact 25 is found, written not in the old numeral, as the other epacts are, but in the common numeral. Wherever, then, in the year 1916 the epact 25 written in the common numeral is found in the calendar, there the new moon falls: as in January on the 6th, in February on the 4th,

in March on the 6th, in April on the 4th, and so on. For whenever the epact 25 corresponds to golden numbers greater than 11 — that is, the last eight, from 12 up to 19 — the epact 25 written in the common numeral is to be taken in the calendar; but when the same epact 25 corresponds to golden numbers smaller than 12 — that is, the first eleven, from 1 up to 11 inclusive — then the epact xxv written in the old numeral is to be taken in the calendar. This happens with the epact 25 alone, and never with any of the others. The purpose of the arrangement is that the lunar years should correspond more exactly to the solar years. For the same reason, in six places of the calendar two epacts, namely xxv and xxiiii, are entered against the same day, so that the lunations may follow one another in such a way that alternately six of them contain 30 days and six others only 29. All of this is explained at length in the book on the new method of restoring the Roman calendar.

If the epacts distributed through the days of the calendar should sometimes indicate the new moons a little later than the facts require, that is no cause for surprise, since they have been arranged so by deliberate design. For since no lunar cycle can answer exactly to astronomical calculation, but indicates the new moons now earlier, now later, careful pains were taken in distributing this cycle of 30 epacts through the calendar so that the epacts should rather show the new moons somewhat late than ever anticipate their proper places — this so that the most holy Easter should not be celebrated, as by the Quartodeciman heretics, either on the fourteenth day of the moon or before it. Indeed, in the matter of celebrating Easter more regard was had to the fourteenth day of the moon, that is, to the full moon, than to the new moon; and it is of no great consequence if occasionally — though this rarely happens — this postponement of the new moon results in Easter being celebrated after the twenty-first day of the moon. That fault is smaller than if it were celebrated before the fourteenth day of the moon, or in the last month, which would be utterly absurd. But there is more on these

matters in the book on the new method of restoring the Roman calendar, where all of this is explained most fully.

But so that you may see where the three preceding tables were drawn from, and by what art others may be constructed, there has been added the following perpetual table of the cycle of the epacts, together with the table of the equation of the cycle of the epacts, from which the epact of any year whatever may be found in perpetuity. As for the rationale of the construction both of the perpetual table of the cycle of the epacts and of the table of the equation of the cycle of the epacts — since it cannot be explained in a few words, and since the letters of the alphabet are drawn from the expanded table of the cycle of the epacts — we refer the reader to the book on the new method of restoring the Roman calendar, where that expanded table is contained.

Both tables are used as follows. Look for the proposed year in the table of the equation, or, if it is not found there, the next lower year; note the letter of the alphabet, capital or small, placed to its left; and work out the golden number belonging to the proposed year. Then in the perpetual table of the cycle of the epacts note the corresponding letter, and assign the golden number *i* to the cell which, counting that letter inclusively, is the third toward the left; assign the next golden number, *ii*, to the following cell to the right; and so on in order, until you reach the golden number of the proposed year, returning to the beginning of the table if you run through the whole of it, and counting also the capital letter **F**, under which the epacts *xxv* and 25 are placed written in different numerals, as a single cell. When this has been duly carried out,

you will at once find the epact of that year in the cell into which the golden number of the proposed year falls. One point, however, must be carefully observed. When the golden number of the proposed year is greater than 11 — as the last eight golden numbers, from 12 to 19, all are — and it falls into the cell of the letter **F**, where two epacts, *xxv* and 25, stand written in different numerals, take the epact 25. Take the other, *xxv*, if one of the first eleven golden numbers, from 1 to 11, all of which are less than 12, falls into that same cell.

Let us make this plain by examples. To the year 1582, after the correction, the capital letter **D** corresponds in the table of the equation, and the golden number is then 6. So if in the perpetual table of the cycle of the epacts you assign the golden number 1 to the cell of the small letter **a** — the third counting from the cell of the capital letter **D** — and the golden number 2 to the next cell to the right, and so on, the golden number 6 of the proposed year 1582 will fall into the cell of the epact *xxvi*, which will show the new moons in the calendar from the Ides of October of that year. Again, in the year 1583, now corrected, the golden number is 7, and the same capital letter **D** corresponds to it in the table of the equation; for since this year is not found in the table, the next lower one must be taken,

namely 1582, to which the capital **D** corresponds. So if in the table of the epacts you assign the golden number 1 to the cell of the small letter **a**, the third from the cell of the capital letter **D**, and the golden number 2 to the next cell to the right, and so on, the golden number 7 of the proposed year will fall into the cell of the epact vii, which will show the new moons in that year.

Likewise, for the year 4218 the letter **I** corresponds in the table of the equation, and the golden number is 1. So if in the table of the epacts you assign the golden number 1 of that year to the cell of the letter **u**, which is the third toward the left from the cell of the letter **I**, you will find the epact xix for that year. Moreover, for the year 1710 the capital letter **C** corresponds in the table of the equation, and again the golden number is 1. So if you assign the golden number 1 of that year to the first cell, that of the capital letter **P**, in the table of the epacts — the cell that is the third from the capital letter **C** — you will find * as the epact of that year. Again, for the year 1912 the capital letter **B** corresponds in the table of the equation, and the golden number is 13. Therefore, if in the perpetual table of the epacts the golden number 1 is assigned to the cell of the capital letter **N**, which is the third from the capital letter **B**, and the golden number 2 to the next cell to the right, and so on, returning to the beginning of the table, the golden number 13 of the proposed year will fall into the second cell. The epact will therefore be xi.

Further, for the year 1715 the capital letter **C** corresponds in the table of the equation, and the golden number is 6. So if you assign the golden number 1 to the cell of the capital letter **P** in the table of the epacts, the third from the cell of the capital letter **C**, and the golden number 2 to the next cell to the right, and so on, the golden number 6 of the proposed year will fall into the cell of the letter **F**, under which two epacts, xxv and 25, are set, expressed in different characters. But since the golden number 6 is less than 12, the former epact, xxv, is to be taken for the year 1715. Finally, for the year 1916 the capital letter **B** corresponds in the table of the equation, and the golden number is 17. For that reason, if in the table of the epacts the golden number 1 is given to the cell of the letter **N**, which is the third from the cell of the capital **B**, and the golden number 2 to the next cell to the right, and so on, returning to the beginning of the table, the golden number 17 of the proposed year will meet that same cell of the letter **F**, under which the two epacts xxv and 25 are set in different characters. And since the golden number 17 is greater than 11, the latter epact, 25, is to be taken for the year 1916. In this way you will find the epact of any year whatever, in perpetuity.

From all this anyone can easily construct, if he wishes, a short table like the three above, containing the epacts that serve certain determinate years. For instance:

For example. For the said year 2200 the capital letter **A** corresponds in the table of the equation, and the golden number is 16. So if we assign the golden number 1 to the cell of the capital letter **M** in the perpetual table of the epacts — the cell that is the third from the cell of the letter **A** — and the golden number 2 to the next cell to the right, and so on, the golden number 16 of the said year 2200 will fall into the cell of the small letter **n**, under which is found the epact *xiii* for that year. Accordingly, the short table of the epacts corresponding to the golden numbers, begun from the golden number 16 and the epact *xiii* of that year, will stand thus.

Aur.num. [golden number]	1 6	17	1 1 8 9	1 1	2 3 4 5	6	7	8 9	1 0	11	1 2
Epactæ [epacts]	xi ii	xxii ii	v x v	xxv iii i	i x i x x x	xxi ii	iii i	x x v x	v i	xvi ii	x xi x
13	14						15				
x	xxi						ii				

But these same epacts can be extracted more easily from the perpetual table of the cycle of the epacts. For the golden number 1 is assigned to the cell of the capital letter **M**; the golden number 2 to the next cell to the right, where the letter **i** stands; the golden number 3 to the next cell to the right, where the capital letter **A** stands; and the golden number 4 to the cell next after that to the right, in which the small letter **a** is written; and so on, as has been said. The epacts, then, are to be written under the golden numbers of this temporary table just as they correspond to the golden numbers in that perpetual table of the cycle of the epacts, as you see done in the example. From this it is easy to see how the three earlier temporary tables of the epacts were composed. Still other ways — and expeditious ones — of finding the epact of any year you will find in the book of the *Explicatio* of the restored Roman Calendar [*Explicatio Romani Calendarii*].

Canon 3.

ON THE SOLAR CYCLE, OR THE CYCLE OF THE DOMINICAL LETTERS, OF 28 YEARS.

The solar cycle, or cycle of the dominical letters, is a revolution of the number 28, from 1 up to 28; and once that revolution is complete it returns again to unity. Every year of this cycle takes its beginning from January, just as was said of the golden number in the nineteen-year cycle. This solar cycle of 28 years arises from the multiplication of 7 by 4: there are seven dominical letters for the seven days of the week, and every fourth year one day is intercalated, so that the order of those seven letters is then interrupted and two dominical letters are taken. By this cycle the dominical letter of any year whatever is found in perpetuity, as we shall teach at the end of the next canon.

So that the number of the solar cycle may be found for any proposed year, the following short table has been drawn up. Its use begins from the year of the correction 1582 and lasts in perpetuity. From it the number of the solar cycle for any current year after the year 1582 will be found in this way.

Short table of the solar cycle, taking its beginning from the year of the correction 1582. [*Tabella cycli Solaris initium sumens ab anno correctionis 1582.*]

2	2	2	2	2	2											1	1	1	1	1	1	1	1						
3	4	5	6	7	8	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7							
18						19						20						21						22					

To the year 1582 assign the first number of the table, which is 23; to the following year 1583 the second, which is 24; and so on without end, until you reach the year whose solar-cycle number you are seeking, returning to the beginning of the table as often as you run through it. The cell into which the proposed year falls will indicate the number of the solar cycle sought.

But it is very laborious and tiresome to count out so many years in that table and to run through it so many times until one reaches the proposed year — especially if the proposed year lies far from 1582. We have therefore constructed this other table, from which the number of the solar cycle for any year, as far before the year 1582 as after it, will be found without great labour, in the following way.

Look for the proposed year in the table under the years of the Lord. If it is set down there, the number placed to its right — after 9 has first been added, as is directed at the head of the table, and 28 cast out after this addition, if it can be cast out — will be the number of the solar cycle sought. But if the proposed year is not contained in the table, take the next lower year that the table does contain, together with the number of the solar cycle corresponding to it. Then take, in the same table, the years that remain over, together with the number of the solar cycle corresponding to them; add that to the number of the solar cycle found before; cast out 28 from the composite number if it can be cast out; and finally add 9. For the composite number, with 28 first cast out if it can be cast out, will be the number of the solar cycle sought. If the years that remained over are likewise not found in the table, again take the next lower year together with its corresponding number of the solar cycle, add that to the number of the solar cycle found before, and cast out 28 from the composite number if it can be cast out. The same is to be done with the remaining years that are left over, until you have found them all in the table. Finally, to the last number of the solar cycle made up out of the solar-cycle numbers found in the table, 9 must be added, and 28 cast out from the sum that results, if it can be cast out. In this way the number of the solar cycle of the proposed year will be produced. And if after the addition of 9 the composite number turns out to be 28, so that after the subtraction of 28 nothing remains, the number of the solar cycle will be 28.

Table for finding the number of the solar cycle of any year. [*Tabula ad numerum cycli Solaris cuiuslibet anni inueniendum.*]

An. Domini [years of the Lord]	Cyclus Solaris. <i>Adde 9</i> [solar cycle; add 9]	Ann i Do min i	Cyclus Solaris. <i>Adde 9</i>	Ann i Do min i	Cyclus Solaris. <i>Adde 9</i>	Ann i Do min i	Cyclus Solaris. <i>Adde 9</i>

9	9	200 0	12	400 000	20	600 000 00	4
10	10	300 0	4	500 000	4	700 000 00	0
20	20	400	24	600	16	800	24

An. Domini [years of the Lord]	Cyclus Solaris. <i>Adde 9</i> [solar cycle; add 9]	Ann i Do min i	Cyclus Solaris. <i>Adde 9</i>	Ann i Do min i	Cyclus Solaris. <i>Adde 9</i>	Ann i Do min i	Cyclus Solaris. <i>Adde 9</i>
		0		000		000	
30	2	500 0	16	700 000	0	900 000 00	20
40	12	600 0	8	800 000	12	100 000 000	16
50	22	700 0	0	900 000	24	200 000 000	4
60	4	800 0	20	100 000 0	8	300 000 000	20
70	14	900 0	12	200 000 0	16	400 000 000	8
80	24	100 00	4	300 000 0	24	500 000 000	24
90	6	200 00	8	400 000 0	4	600 000 000	12
100	16	300 00	12	500 000 0	12	700 000 000	0
200	4	400 00	16	600 000 0	20	800 000 000	16

Let us illustrate the matter by examples. Suppose the number of the solar cycle for the year 1000 is to be found. Since this year is found in the table, and the number 20 corresponds to it, adding 9 gives the number 29; and casting out 28 from that leaves 1 as the number of the solar cycle for the year 1000. Next, suppose the number of the solar cycle for the year 1582 is proposed for investigation. Since this year is not found in the table, take the year 1000, the next lower in the table, and its solar-cycle number 20. Then the remaining 582 years are to be taken in the table; and since they are not contained in it, take again the year 500, the next lower in the table, and its solar-cycle number 24. Adding this to the solar-cycle number 20 found before produces the number 44; and subtracting 28 from that leaves 16. After this the 82 years that remain are to be taken in the table; but since they are not found there, take the year 80, the next lower in the table, and its solar-cycle number 24. Adding this to the solar-cycle number 16 composed before yields the number 40; and subtracting 28 from that leaves 12. Finally the remaining 2 years are to be taken in the table, with the solar-cycle number 2 corresponding to them; and adding this to the solar-cycle number 12 just left gives the number 14. If 9 is added to that at the last, as the head of the table directs, the result is the solar-cycle number 23 for the year 1582.

Lastly, suppose the number of the solar cycle for the year 7075 is to be investigated. I take first the solar-cycle number 0 opposite the year 7000, and add it to the solar-cycle number 14 found opposite the year 70, making the number 14. Then to this number 14 I join the solar-cycle number 5 corresponding to the year 5, producing the number 19. To this I finally add 9, and so produce the solar-cycle number 28 for the year 7075.

Nine is always added to the last number because Christ was born in the tenth year of this solar cycle: in the year of the Lord 1 the solar-cycle number was 10, in the second year 11, and so on.

The composition of this table, too, does not differ from the construction of the table for finding the golden number, except that here 28 is to be cast out and not 19, as there. You can therefore easily extend it to as many years as you wish.

Even without this table, however, the number of the solar cycle will be found for any proposed year quite easily, by the rules of arithmetic, in this way. To the proposed year of the Lord add 9, and divide the composite number by 28. The number left over from the division — no account being taken of the quotient, which indicates only how many revolutions of the solar cycle have been completed from Christ up to the proposed year — will be the number of the solar cycle of the proposed year. And if nothing remains from the division, the number

of the solar cycle will be 28. Suppose, for instance, that the number of the solar cycle for the year 1582 is sought. I add 9, divide the composite number 1591 by 28, and find that 23 is left over from the division. In the year 1582, therefore, the number of the solar cycle will be 23. Again, suppose the number of the solar cycle for the year 1587 is wanted. I add 9, making 1596, divide that number by 28, and find that nothing is left over. In the year 1587, therefore, the number of the solar cycle will be 28. And so for the rest.

Canon 4.

ON THE DOMINICAL LETTER.

The cycle of the dominical letters [cylcus literarum Dominicalium] returns upon itself every 28 years, and the Roman Church has used it down to the present day. That cycle must now necessarily be interrupted — both because of the ten days removed from the month of October in the year 1582, and because of the three bissextiles that are to be omitted in every four hundred years, as was laid down in the book on the new method of restoring the Roman calendar and in the bull of the correction issued by Gregory XIII, Supreme Pontiff. We therefore set out the following table of dominical letters. It will serve for all the years after the Ides of October of the year of the correction 1582 (the ten days having first been removed), down to the year 1700 exclusive.

Table of dominical letters from the Ides of October of the year of the correction 1582 (the ten days having first been removed) down to the year 1700 exclusive.

c	b	A	f	e	d	c	A	g	f	e	c	b	A	g
		g				b				d				f
e	d	c	b	g	f	e	d	b	A	g	f	d		
			A				c				e			

The use of this table is as follows. In the year of the correction 1582, after the Ides of October (the ten days having first been removed), assign the letter c of the first cell; to the following year 1583 the letter b of the second cell; to the year 1584 the letters A, g of the third cell; and so on for the remaining years in order, cell by cell, until you reach the year proposed — returning to the beginning of the table

as often as you have run through it. For the cell into which the proposed year falls, provided that year is earlier than 1700, will give the dominical letter of the proposed year. If a single letter turns up, the year will be a common one; if a double letter, a bissextile. In that case the upper letter will show the Sunday in the calendar from the beginning of the year to the feast of St Matthias the Apostle, and the lower letter from that feast to the end of the year.

For example: suppose the dominical letter for the year 1587 is to be found. Count from the year 1582, which you assign to the first letter c, down to the year 1587, giving one year to each cell (reckoning any pair of letters, upper and lower, as a single cell). The year 1587 will fall on the letter d, which occupies the sixth place in the table. Throughout that year, then, the dominical letter is d, and the year is a common one, since a single letter turns up.

Again, suppose the dominical letter for the year 1616 is to be investigated. Count from the year 1582, as has been said, down to the year 1616, returning to the beginning of the table after you have run through it; you will arrive at the two letters c, b, placed in the seventh position. That year is therefore a bissextile, since a double letter turns up. The upper letter c will indicate the Sunday from the beginning of that year to the feast of St Matthias, and the lower letter b through the remaining part of the year.

[Margin: *Years at which the table of dominical letters begins.* 1582 1610 1638 1666 1694]

But for years that are not far distant from 1700, the counting can be made easier — and you can be spared repeated returns to the beginning of the table — if a certain table of years is composed by this device. To the year 1582, at which the use of the table of dominical letters begins, add 28; then add 28 again to the sum, and so on, but only so far that the last year is less than 1700, to which the use of the table of dominical letters does not reach. Then, if the year whose dominical letter is sought is contained in this table of years, the first letter of the table of dominical letters will be the dominical letter for that year. If it is not contained there, take in the table of years the next lower year, and count from it in the table of dominical letters just described, beginning at the first cell, down to the year proposed. This counting will bring you to the dominical letter without your ever having to return to the beginning of the table.

Suppose, for instance, that the proposed year is 1638, which is found in this table: the dominical letter for that year will be c, which stands first in the table of dominical letters. But suppose the proposed year is 1647, which is not contained

in this table. Then you must count in the table of dominical letters from the next lower year 1638 down to the given year 1647 — assigning, that is, the year 1638 to the first cell, the following year 1639 to the second cell, and so on. In this way the proposed year 1647 will fall into the tenth cell, that of the letter f, which is the third after a bissextile; and f is the dominical letter for that year.

When the year 1699 has run out, at the end of which the use of the table above comes to an end, the following table of dominical letters is to be taken up. Its use begins with the year 1700, and it is perpetual, provided the adjoining table of equation is employed, in this way.

Table of dominical letters from the year 1700 inclusive, perpetual, provided that in every 400 years three bissextiles are omitted.

I				II				III											
d	b	A	g	f	d	c	b	A	f	e	d	c	A	g	f	e	c	b	
c				e				g				b				d			
A		g		e		d		c		b		g		f		e			
		f								A									

Table of equation for the aforesaid table of dominical letters, perpetual from the year 1700.

To find the dominical letter of any year not earlier than 1700: look in the table of equation and see which of the old Roman numerals stands to the left of the proposed year — or, if that year is not entered in the table, to the left of the next lower year — and mark that numeral in the perpetual table of dominical letters. For if you assign to the cell of this old Roman numeral the year taken from the table of equation, the next year to the next cell, and so on until you reach the proposed year (returning to the beginning of the table if need be), you will light upon the cell of the dominical letter you are looking for. If that letter is single, the proposed year will be common; if double, bissextile — with the exception of those centesimal years in which the intercalary day is omitted, which are all those, and only those, that are set out in the table of equation. Since these are common years, only the lower of the two letters found is to be taken, the upper being left aside, because the upper served in the preceding year. In the other, bissextile, centesimal years — that is, all those not entered in the table of equation — both letters found are to be taken, just as in other bissextile years.

Example. To the year 1710 there corresponds in the table of equation the old numeral I; for since that year is not contained in the table, the next lower year 1700 is to be taken, and to it the numeral I corresponds. If, then, starting from the

year 1700 found in the table, you count through the cells of the perpetual table of dominical letters as far as the proposed year 1710 — beginning at the first cell, which is precisely the one above which stands the same old numeral I that was found in the table of equation — you will find the dominical letter e, the second after a bissextile; and the year 1710 will be a common year, the second after a bissextile.

Again, to the year 1912 there corresponds in the table of equation the old numeral III. Counting therefore from the year 1900 found in the table, through the cells of the table of dominical letters, beginning at the ninth cell — the one above which the old numeral III is placed — as far as the year 1912, we shall find the two dominical letters g, f; and that year will be a bissextile.

Further, to the year 1800 there corresponds in the table of equation the old numeral II, to which in the table of dominical letters there correspond the two letters f, e. Of these the lower, e, will serve for that year alone, since the year is a common one, while the upper letter f was the dominical letter in the preceding year 1799.

Lastly, to the year 3600 there corresponds in the table of equation the old numeral III, next to the year 3500, the next lower one. If, then, the cells are counted from the year 3500 in the table of dominical letters, taking the start at the ninth cell of this numeral III, these two letters b, A will be found, and both are to be taken, because that centesimal year is a bissextile, since it is not contained in the table of equation.

[Margin: 3500 3528 3556 3584 3612 3640 3668 3696]

Here too the device described above should be used, to make the counting easier. A table of years is to be constructed, advancing by the continual addition of 28 to the year found in the table of equation. So, in the example just given, to the year 3500, then to the sum 3528, and so on — but only so far that the last sum is less than 3700. For in that year a different old numeral will have to be taken in the table of dominical letters, as is clear from the table of equation. Once this table of years has been composed, we shall know at once from what year the counting in the table of dominical letters is to begin.

On this principle — to stay with the same example — under the old numeral III we shall begin the counting from the year 3584, which in the table of years is the next lower than the proposed year 3600; and 3600 will fall into the cell of the two letters b, A, as before.

Indeed this same table can be adapted to any centesimal year of the table of equation, if in place of the centesimal 3500 any other centesimal is taken. At any centesimal that has the numeral I or II, the counting should begin at that centesimal itself, then at 28, 56, 84 after that centesimal. But at any centesimal that has the numeral III, it should begin at that centesimal itself, then at 28, 56, 84 after that centesimal, and at 12, 40, 68, 96 after the centesimal next following — just as in the table set out here the counting is to begin at the centesimal 3500 itself, which has the numeral III in the table of equation, then at 28, 56, 84 after 3500, and at 12, 40, 68, 96 after 3600, which is the centesimal next following 3500.

The construction of the table of equation, moreover, is perfectly straightforward. It runs through all the centesimal years that are not bissextile, the bissextile centesimals being omitted; for in the former the order of the dominical letters is interrupted, but in the latter it is not. And so after every three centesimals one centesimal year is left out of the table, since that one is a bissextile. Then, as you see, the old numerals I, II, III are repeated in order.

From all this it will not be difficult for anyone to extract from our perpetual table a particular table serving his own time. For if a table of the 28 dominical letters is composed, beginning at the cell of that old numeral which in the table of equation corresponds to any given centesimal year, the result will be a table serving from that centesimal year to the centesimal year which follows next in the table of equation, exclusive — with this proviso, that of the first two letters corresponding to the centesimal year at which the use of the table begins, the lower is to be taken and the upper left aside. By this method the following table has been constructed. Its use begins with the year 1800 and lasts to the end of the year 1899, on this rule: that in the year 1800 the dominical letter is e, the lower of the first two f, e; that in the next year, 1801, the dominical letter is d; and so on.

Table of dominical letters from the year 1800 to the year 1900 exclusive.

f	d	c	b	A	f	e	d	c	A	g	f	e	c	b	A	g	e	d
e				g				b				d				f		
c		b		g		f		e		d		b		A		g		
		A								c								

We shall also find the same dominical letter for any year, perpetually, and quite readily, both before and after the year of the correction, from the ancient solar cycle — that is, the cycle of the dominical letters of 28 years — which the Church has used down to this day. That cycle, together with the table of Equation (which advances through all the centesimal years in such a way that every fourth centesimal is a bissextile, at which point the same old numeral is repeated), stands as follows.

Cyclus Solaris, seu literarum Dominicalium antiquus 28. annorum perpetuus. — The ancient solar cycle, or perpetual cycle of the dominical letters, of 28 years.

First block (cells 1–19). The row *Old numeral* gives the old numeral printed over the bissextile cell; *Letter* gives the upper (or single) letter of each cell; *2nd letter* gives the lower letter, printed only in the bissextile cells.

										1	1	1	1	1	1	1	1	1	1
	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9

To find the dominical letter for any given year, look in the table of equation for the old numeral standing to the left of the proposed year — or, if that year is not entered in the table, of the next lower year — and mark that numeral in the solar cycle. Beginning from it inclusive, count off toward the right (starting again from

the beginning of the cycle, if need be) as many cells of dominical letters as there are units in the current number of the solar cycle, which you will find from Canon 3; you will land on the cell of the dominical letter you are seeking. If that letter is single, the proposed year will be a common year; if double, a bissextile — except in those centesimal years in which the intercalary day is dropped, namely all those, and only those, to which the syllable [*Biss.*] is not attached in the table of equation. In these, since they are common years, the lower of the two letters found is to be taken and the upper left aside, because the upper was the dominical letter in the preceding year. In the other centesimal years, the bissextile ones — all those to which the syllable [*Biss.*] is attached — both letters are to be taken, just as in other bissextile years.

Example. The year 1699 corresponds in the table of equation to the old numeral I, next to the year 1600, the next lower year. Since the number of the solar cycle for 1699 is 28, 28 cells of dominical letters must be counted, starting from the cell above which this numeral I is placed, and running as far as d, which will be the dominical letter of that year, the third after the bissextile. Again, the year 1700 corresponds in the table of equation to the old numeral II, and the number of the solar cycle is 1. In the first cell of dominical letters under the old numeral II, therefore, of the two letters d and c the lower will be the dominical letter of that year, because it is a common year; and the upper letter d was dominical in the preceding year, 1699, as the previous example showed. Lastly, the year 2000 corresponds in the table of equation to the old numeral IV, and the number of the solar cycle is then 21. So if 21 cells of dominical letters are counted, starting from the cell of this old numeral IV, these two letters will be found: b [?], A — both of which will be dominical in that year, since it is bissextile. But the first method is the more convenient, since it does not require the solar cycle.

CANON V.

DE INDICTIONE.

The indiction is a revolution of 15 years, running from 1 to 15; and when that revolution is complete the count returns to unity again. In papal bulls every year of this cycle begins from January, just as we wrote of the nineteen-year cycle of the golden number. And since the indiction is in constant use in diplomas and public documents, we shall easily find the current year of the indiction for any proposed year from the following table. Its use is perpetual, but it takes its start from the year of the correction, 1582.

Tabella Indictionis ab anno correctionis 1582. — Table of the indiction from the year of the correction, 1582.

10	11	12	13	14	15	1	2	3	4	5	6	7	8	9

For if you assign to the year 1582 the first number, which is 10, and to the following year 1583 the second number, which is 11, and so on in order down to the proposed year, returning to the beginning of the table as often as you run through it, the proposed year will fall on the indiction you are looking for.

But since it is tedious and laborious to run through so many years in that table, returning again and again to its beginning until the indiction of the proposed year turns up — especially if the proposed year is far from 1582 — we have drawn up this other table, from which the indiction of any year whatever, whether before 1582 or after it, will be found without much labour, as follows.

Tabula ad Indictionem cuiuslibet anni inueniendam. — Table for finding the indiction of any year.

				00		0000	

Look up the proposed year in the table above, or the next lower year if it is not found there; then the years still left over, together with the indictions set to the right of the years. For if you gather all these indictions into a single sum, in the order we taught in the canon both of the golden number and of the solar cycle, and finally add 3 — always casting out 15 as often as 15 can be cast out — you will have the indiction of the proposed year. And if the final sum, after the addition of 3, comes to 15, so that nothing is left when 15 is cast out, the indiction will be 15. We shall make this clear by an example or two. The year 2000 corresponds in the table to indiction 5; add 3 to it, and there

will be indiction 8 for the year 2000. Again, to find the indiction of the year 1582: take the year 1000, the next lower, with its indiction 10; then, out of the remaining 582 years, the year 500, the next lower, with its indiction 5, which added to the previous 10 makes 15 — and if 15 be cast out of this, nothing is left. After this, out of the remaining 82 years, take from the table the year 80, the next lower, with its indiction 5, which added to the indiction 0 just left over gives the number 5; and if to this be joined indiction 2, answering to the remaining 2 years, the number 7 results. Add 3 to this at last, and indiction 10 is made up for the year 1582. Finally, the indiction of the year 3040 will be found as follows. Add indiction 0, answering to the year 3000, the next lower, to indiction 10, which answers to the remaining 40 years, and the number 10 will be had; add 3 to it, and indiction 13 results for the year 3040.

Three is always added to the last number because Christ was born in the fourth year of the cycle of indictions, so that in the first year of the Lord the indiction was 4, in the second year indiction 5, and so on.

The construction of this table, too, is the same as that of the table for finding the golden number and the number of the solar cycle, except that here 15 is always to be cast out where possible, not 19 or 28 as there.

Even without this table, however, the indiction of any year is very easily found by the rules of arithmetic, in this way. Add 3 to the proposed year of the Lord, and divide the resulting number by 15. The number left over from the division — no account being taken of the quotient, since that merely shows how many revolutions of the cycle of indictions have passed from Christ down to the given year — will be the indiction sought. Thus for the year 1582 I add 3, making 1585; I divide this by 15, and 10 remains from the division as the indiction of the year 1582. Again, for the year 1587 I add 3, and the number 1590 results; I divide it by 15, and nothing is left over. The indiction is therefore 15 in that case.

CANON VI.

DE FESTIS MOBILIBVS.

By decree of the sacred Council of Nicaea, Easter — on which the other movable feasts depend — must be celebrated on the Sunday next following the fourteenth day of the Moon of the first month. (Among the Hebrews that month is called the first month whose fourteenth Moon either falls on the day of the vernal equinox, which occurs on the twenty-first day of the month of March, or follows it more closely.) The consequence is this: find the epact of any given year from Canon 2,

and in the Calendar, from the epact marked between the eighth day of March inclusive and the fifth of April inclusive — for the fourteenth Moon of this epact either falls on the day of the vernal equinox, that is, on 21 March, or follows it more closely — count downward fourteen days inclusive; the next Sunday following that fourteenth day (so that we may not coincide with the Jews, should the fourteenth day of the Moon happen to fall on a Sunday) will be Easter Day.

Example. In the year 1583, now corrected, the epact is vii and the dominical letter b. I therefore look for this epact vii in the Calendar between the eighth day of March and the fifth of April inclusive, and I find it opposite 24 March. Counting downward inclusive from that day through fourteen days, I obtain the fourteenth Moon, which I see falls on 6 April; and after that day the first dominical letter b is found opposite 10 April of the same month. Easter in the year 1583, therefore, had to be celebrated on 10 April. Again, in the year 1585 the epact is xxix and the dominical letter f. Since I find epact xxix set between 8 March and 5 April inclusive, opposite 12 April [?] — and counting downward inclusive from it through 14 days I find the fourteenth Moon on 14 April, which is a Sunday, since the dominical letter f stands opposite it — Easter is not to be placed on that fourteenth day, lest we coincide with the Jews, who celebrate Easter on the fourteenth day; the dominical letter f which follows the fourteenth Moon is to be taken, namely the one that stands opposite 21 April, and so Easter is to be placed on 21 April. Accordingly Easter that year fell on 21 April. Again, in the year 1592 the epact is xvi, and the dominical letter is double, e and d, since that year is bissextile. If, then, from epact xvi, which stands opposite 15 March, and which is set between 8 March and 5 April inclusive, 14 days are counted inclusive, the fourteenth Moon will fall on 28 March. And because the later of the two dominical letters is then current, namely d, which stands after 28 March — that is, after the fourteenth Moon — Easter that year will be celebrated on 29 March.

Once Easter Day has been found, the other movable feasts are easily found. If six Sundays are counted back before Easter Day in the Calendar, the first Sunday of Lent will be had, and the Wednesday immediately preceding it will be the first day of Lent, that is, Ash Wednesday; Quinquagesima Sunday is the Sunday immediately before that, Sexagesima Sunday is celebrated before Quinquagesima, and Septuagesima Sunday precedes Sexagesima. If, on the other hand, five Sundays are counted forward from Easter Sunday in the Calendar, Rogation days follow that fifth Sunday, and the Thursday next after them will be the Ascension of the Lord. The seventh Sunday after Easter will be Pentecost, immediately followed by Trinity Sunday, and on the Thursday next after Trinity the feast of Corpus Christi will be celebrated. On this reckoning, since Easter in

the year 1592 was celebrated on 29 March, the first Sunday of Lent will be celebrated on 16 February, the dominical letter then current being e; Ash Wednesday will be 12 February, and Septuagesima Sunday will fall on 26 January. Rogations will be on 4 May, the Ascension of the Lord on 7 May, Pentecost on 17 May, the feast of Trinity on 24 May, and lastly the feast of Corpus Christi will be celebrated on 28 May. The number of Sundays between Pentecost and Advent is found on this reckoning: count four Sundays before Christmas, for the fourth Sunday before Christmas is the first Sunday of Advent. Therefore, if all the Sundays are counted from Pentecost up to the first Sunday of Advent exclusive, the number of Sundays between Pentecost and Advent will be had — though we shall show a shorter way of finding this number a little further on.

To make all the movable feasts easier to find, two Paschal tables have been drawn up, one of them the old table and the other the new. From the old table the movable feasts are found as follows. In the left-hand margin of the table take the current epact, and in the line of dominical letters take the current dominical letter — but *below* the current epact, so that if the current dominical letter is found on the same line as the current epact, the letter to be taken is the next occurrence of that same dominical letter lower down. For opposite this dominical letter all the movable feasts are set out. Take the same examples as before. In the year 1583 the epact is vij, and the dominical letter is b; the b that occurs in the first place below epact vij will be found opposite the following: Septuagesima Sunday on 6 February, Ash Wednesday on 23 February, Easter on 10 April; the Ascension of the Lord on 19 May; Pentecost on 29 May, and the feast of Corpus Christi on 9 June. The Sundays between Pentecost and Advent will then be 25, and Advent will be celebrated on 27 November — and so with the rest. Again, in the year 1585 the epact is xxix and the dominical letter is f, which in the table is found on the same line as epact xxix. Another f must therefore be taken, the one found next below the epact; opposite it you will find Septuagesima on 17 February, Ash Wednesday on 6 March, and Easter on 21 April, and so on.

Note, too, that just as in a common year, when the dominical letter falls on the same line as the epact in the old table, the next occurrence of that same letter below the epact is used, as we have said, so also in a bissextile year, if either of the two dominical letters then current is found on the same line as the epact, the next pair of like letters lower down must be taken in order to find the movable feasts.

From the new Paschal table the same movable feasts are found in this way. In the cell of the current dominical letter, look for the current epact; for all the movable

feasts will be found directly opposite it. Thus in the year 1585, in the cell of the letter f, then current, on the line of epact xxix, which runs in that same year, one has Septuagesima on 17 February, Ash Wednesday on 6 March, and Easter on 21 April.

But whether we use the old Paschal table or the new one, in bissextile years all the movable feasts must be found by the *later* dominical letter — the one, that is, which runs after the feast of St Matthias the Apostle — so that we may not be in doubt which of the two letters is to be taken for finding this or that feast; with the proviso, however, that when Septuagesima and Ash Wednesday are found to fall in January or February, one day is to be added. The reason is this: before St Matthias's day the earlier dominical letter runs, which in the Calendar always follows the later one; but after the feast of St Matthias in February, although the later letter runs, the intercalary day is then inserted, so that the 24th of February is called the 25th, the 25th is called the 26th, and so on. If, however, Ash Wednesday falls in March, nothing is to be added, since the later letter is then running and the days of the month answer to their proper numbers, the intercalary day having already been added to February. Indeed, unless the search were made by the later letter, Septuagesima would not be found correctly in a bissextile year when epact xxiiiij or xxv is running with dominical letters d, c — as will be clear from the second and third examples, for the years 4088 and 3784. For example: in the bissextile year 2096 the epact will be v and the dominical letters A, g. If, then, the movable feasts are investigated by the later letter, which is g, Septuagesima will be found on 11 February and Ash Wednesday on 28 February. But if one day is added, Septuagesima falls on 12 February, which is a Sunday, and Ash Wednesday on 29 February, which is a Wednesday. Easter and the remaining feasts will fall on the days set out in the table. Again, in the bissextile year 4088 the epact will be xxiiiij and the dominical letters d, c. If, then, the movable feasts are sought by the letter c, which is the later one, Septuagesima will be found on 21 February; and if one day is added, it falls on 22 February, which is a Sunday. Ash Wednesday, however, will fall on 10 March, so nothing is added there, and so on.

Again, in the bissextile year 3784 the epact will be xxv and the dominical letters d, c. So once more, by the later letter c, Septuagesima will be found on 21 February — that is, with 1 added, on the 22nd. If in either of these two years one were to proceed by the earlier letter d, nothing would be achieved, since below epacts xxiiiij and xxv the letter d indicates Septuagesima on 15 February. That would be false, because in that year the later letter c yields Easter on 25 April,

and consequently Septuagesima must be celebrated on 22 February — as is perfectly clear if one counts the Sundays back from Easter Day to Septuagesima.

The Advent of the Lord is always celebrated on the Sunday nearest to the feast of St Andrew the Apostle, that is, from 27 November to 3 December inclusive; so that the current dominical letter, wherever it is found in the Calendar from 27 November inclusive to 3 December inclusive, marks Advent Sunday. For example, if the dominical letter is g, Advent Sunday will fall on the second of December, because that is where the letter g stands in the Calendar, and so on.

The number of Sundays between Pentecost and the Advent of the Lord is found most briefly as follows. See how many Sundays there are after Easter up to and including the feast of St George, which falls on 23 April. That many Sundays are to be added to 24 to give the number of Sundays between Pentecost and the Advent of the Lord. Thus, since when Easter is celebrated on 26 March four Sundays follow up to and including the feast of St George — which in that case also falls on a Sunday — there will be 28 Sundays between Pentecost and the Advent of the Lord. Likewise, since when Easter falls on 3 April two Sundays follow up to and including the feast of St George, there will be 26 Sundays between Pentecost and the Advent of the Lord. If no Sunday follows Easter Day up to and including that feast, or if Easter Day itself falls on that feast, there will be 24 Sundays; and finally, if Easter is celebrated after that feast, there will be only 23 Sundays between Pentecost and the Advent of the Lord.

From all this it is easy to understand how each of the two Paschal tables is constructed.

Before each of the two general Paschal tables there is placed a temporary table covering many years, opposite which all the movable feasts are found more quickly than one can say. This table has been extracted from the Paschal tables, from which countless others can be drawn out for any years whatever.

Furthermore, in the first Paschal table — the old one reformed — we have set the golden numbers to the left of the epacts, in the same order in which they used to be placed before the corrected year, so that the movable feasts might be found by them. We have done this so that anyone may investigate Easter and the other movable feasts from the Council of Nicaea down to the year of the correction, 1582, whenever he pleases or circumstances require. The movable feasts are drawn from the golden numbers, arranged in this way, by exactly the same device as from the epacts. Suppose, for example, we want to find out when these feasts were celebrated in the year 1450. Since in that year the golden number was

7 and the dominical letter d, take the golden number 7 in the left-hand margin, and the first letter d occurring below it; opposite this letter d one finds Septuagesima on 1 February; Ash Wednesday on 18 February; Easter on 5 April; the Ascension of the Lord on 14 May; Pentecost on 24 May; Corpus Christi on 4 June; the Sundays after Pentecost 26; and finally the first Sunday of Advent on 26 November — and so with the rest.

TABVLA PASCHALIS Antiqua Reformata.

(The Old Paschal Table, Reformed)

Column headings as printed, with their English sense:

- **Au. Num.** — golden number [aureus numerus]
- (a narrow unlabelled column, left blank throughout)
- **Cyclus Epactarum** — cycle of the epacts
- **Lit. Domin.** — dominical letter
- **Dominica Septuagesimæ** (sub-head *Ianuar.*) — Septuagesima Sunday, in January
- **Dies Cinerum** (sub-head *Februa.*) — Ash Wednesday, in February
- **Dies Paschæ** (sub-head *Martij.*) — Easter Day, in March
- **Dies Ascensionis** (sub-head *Aprilis.*) — Ascension Day, in April
- **Dies Pentecostes** (sub-head *Maij.*) — Pentecost, in May

- **Corpus Christi** (sub-head *Maij.*) — Corpus Christi, in May
- **Dominicæ post Pentecosten.** — Sundays after Pentecost
- **Prima Dominica Aduentus.** — the first Sunday of Advent

iiij	g	v	25	
iiij	A	iiij	26	
ij	b	iiij	27	
j	c	Prid.K al.	28	

In a bissextile year February has 29 days, and the feast of St Matthias is celebrated on 25 February; "the sixth before the Kalends" is said twice, that is, on the 24th and on the 25th. The dominical letter that was taken up in the month of January is changed to the letter before it: if in January the dominical letter was A, it is changed to the one before it, which is g, and so on.

CANON FOR THE GREGORIAN CALENDAR OF THE YEAR OF THE CORRECTION, 1582

(CANON IN CALENDARIVM GREGORIANVM ANNI CORRECTIONIS MDLXXXII.)

In the year of the Lord 1582 the old calendar, which the Roman Church has used up to the present day, is to be kept as far as 4 Nones of October — that is, up to and including the feast of St Francis. From that point this fragment of the calendar is to be taken up, which contains the last three months. October in it is truncated as well, since it comprises only 21 days. For in order that the vernal equinox may be restored to 21 March, where the Fathers of the Council of Nicaea found it, and from which it has by now slipped some ten days toward the beginning of March, Gregory XIII, Supreme Pontiff, has decreed that ten days be omitted after 4 Nones of October. One must therefore skip at once from 4 Nones of October to the Ides of October, so that, once the festival of St Francis has been celebrated, the following day is called the Ides of October, or 15 October, and on it is celebrated the feast of SS. Dionysius, Rusticus and Eleutherius, martyrs, with a commemoration of St Mark, Pope and Confessor, and of SS. Sergius, Bacchus, Marcellus and Apuleius, martyrs. On the next day, which is 16 October and is called 17 Kalends of November, the feast of St Calixtus, Pope and Martyr, is to be kept. On the day after that, which is 17 October and is called 16 Kalends of November, the office and Mass of the eighteenth Sunday after Pentecost are to be said — that will be the third Sunday of October — the dominical letter being changed from G to C. On the eighteenth day of October, or 15 Kalends of November, the feast of St Luke the Evangelist is to be celebrated; and from that day on, inclusive, the remaining feast days are to be kept as they are set down in the calendar, up to the end of the year 1582. After that, this fragment of the calendar will have no further use; instead the Perpetual Calendar is to be adopted, in which all 12 months are set out complete. Understand the same of the other years in which this correction will be made.

Therefore, after the removal of 10 days from the month of October in the year 1582, the dominical letter will be C, the epact will be xxvi, and the Martyrology letter will be capital G, as is taught in the proper Canons of the Calendar and of the Martyrology. Accordingly, wherever the letter C is found in this fragment of the calendar, Sunday is to be celebrated there. And wherever the epact xxvi is placed, there the new moon, or Moon 1, occurs. Finally, wherever a capital G appears in the Martyrology, the age of the Moon is to be reckoned under it. But in the year 1583, now corrected, the Canons of the perpetual Gregorian Calendar are

to be used; for the dominical letter will then be b, the epact vii, and the Martyrology letter lowercase g.

What is to be done in more remote regions, where the correction cannot be made in the year 1582 but only in 1583, 1584 or 1585, will be stated after the end of this fragment of the calendar.

WHAT IS TO BE OBSERVED IF THE CORRECTION OF THE CALENDAR IS NOT MADE IN THE YEAR 1582.

Exactly the same fragment of the calendar for the year of the correction, 1582, is to be used whatever year the correction is made in, and one must pass straight from 4 Nones October to the Ides of October, as has been said. The feasts falling between St Francis's day and St Luke the Evangelist's day, however, are to be celebrated as follows.

Suppose the correction is set up in the year 1583. Then the day following the feast of St Francis is to be called the Ides of October, that is, 15 October, and on it the feast of SS. Dionysius, Rusticus and Eleutherius, martyrs, is to be celebrated, with a commemoration of St Marcus, Pope and Confessor, and of SS. Sergius, Bacchus, Marcellus and Apuleius, martyrs. On the next day, which is 16 October and is called 17 Kalends November, the office and Mass are to be those of the twentieth Sunday after Pentecost — which will be the third Sunday of October — the

dominical letter being changed from F to B. On the day after that, which is 17 October and is called 16 Kalends November, the feast kept is that of St Calixtus, Pope and martyr. On 18 October, that is 15 Kalends November, the feast of St Luke the Evangelist is to be celebrated; and from that day inclusive the remaining feast days are to be kept as they are set out in the calendar. And so in the year 1583, after the removal of the ten days from the month of October, the dominical letter will be b, the epact vii, and the letter of the Martyrology g, lower case.

Suppose instead that the correction is set up in the bissextile year 1584, in which the dominical letters are E and D. Then the first day after the feast of St Francis is to be called the Ides of October, that is 15 October, and on it the feast of St Marcus, Pope and Confessor, is to be celebrated, with a commemoration of SS. Sergius, Bacchus, Marcellus and Apuleius, martyrs. On the next day, which is 16 October and is called 17 Kalends November, the feast kept is that of SS. Dionysius, Rusticus and Eleutherius, martyrs. On the day following, which is 17 October and is called 16 Kalends November, the feast of St Calixtus, Pope and martyr, is to be celebrated. On 18 October, that is 15 Kalends November, the feast of St Luke the Evangelist is to be celebrated. On the next day, the 19th — that is, 14 Kalends November — the office and Mass are to be said of Friday of the seventeenth Sunday after Pentecost, which is the second Sunday of October. On the day after that, that is 13 Kalends November, the office and Mass of the Blessed Virgin are to be said, as is customary on a Saturday. On 21 October the office and Mass are to be said of the eighteenth Sunday after Pentecost, which will be the third Sunday of October, the dominical letter being changed from D to G, together with a commemoration of St Hilarion, Abbot, and of SS. Ursula and her companions, virgins and martyrs, and so on. And so in the year 1584, after the removal of the ten days from the month of October, the dominical letter will be G, the epact xviii, and the letter of the Martyrology t.

Now suppose the correction is set up in the year 1585. Then the first day after the feast of St Francis is to be called the Ides, or 15 October, and on it the feast of St Marcus, Pope and Confessor, is to be celebrated, with a commemoration of SS. Sergius, Bacchus, Marcellus and Apuleius, martyrs. On 16 October the feast kept is that of SS. Dionysius, Rusticus and Eleutherius, martyrs. On 17 October the feast of St Calixtus, Pope and martyr, is to be held. On the 18th the feast of St Luke the Evangelist is to be celebrated. On the 19th the office and Mass are to be said of the Blessed Virgin, since it is a Saturday. On the 20th the office and Mass are to be those of the nineteenth Sunday after Pentecost, which will be the third Sunday of October, the dominical letter being changed from C to F, and so on. And so in the year 1585, after the removal of the ten days from the month of October, the

dominical letter will be F, the epact xxix, and the letter of the Martyrology N, upper case.

From these cases it will be easy to understand what must be done in any other year in which the correction is made, provided one carefully observes the Sunday and the dominical letter that has to be adopted. In the year following the year of the correction, the *Calendarium Gregorianum Perpetuum* is to be used, together with the Canons belonging to that same calendar.

FINIS.

EXPOSITION OF THE ROMAN CALENDAR RESTORED BY GREGORY XIII, SUPREME PONTIFF, PUBLISHED BY ORDER OF CLEMENT VIII, SUPREME PONTIFF.

BY CHRISTOPH CLAVIUS OF BAMBERG, OF THE SOCIETY OF JESUS.

CHAPTER ONE.

What Holy Scripture lays down concerning the celebration of Easter, and what the Holy Fathers and the Councils have decreed about it.

Now that the *Compendium of the New Method of Restoring the Calendar* has been sent out to the Christian princes, together with the perpetual Gregorian calendar, let us come to the explanation of the reasons for the calendar itself as emended and corrected. First let us set out precisely what Holy Scripture prescribes about the celebration of Easter, and what the Holy Fathers and the Councils decreed about it. For a good many people, because they did not understand this matter well enough, have not shrunk from attacking the Gregorian correction without any cause at all.

[Margin: Scripture's precept concerning the celebration of Easter.]

The Phase, or Passover, is therefore prescribed to the Hebrews in Exodus chapter 12, in these words: *The Lord also said to Moses and Aaron in the land of Egypt: This month shall be to you the beginning of months; it shall be the first among the months of the year. Speak to the whole assembly of the children of Israel, and say to them: On the tenth day of this month let every man take a lamb by his families and houses. And a little further on: And you shall keep it until the fourteenth day of this*

month, and the whole multitude of the children of Israel shall sacrifice it in the evening. And a little after: For it is the Phase (that is, the Passing) of the Lord. And below: And you shall keep this day as a memorial, and you shall celebrate it as a feast to the Lord in your generations with an everlasting observance. And shortly after: In the first month, on the fourteenth day of the month in the evening, you shall eat unleavened bread until the twenty-first day of the same month in the evening.

Then Leviticus chapter 23: *These therefore are the holy feasts of the Lord, which you must celebrate in their seasons. In the first month, on the fourteenth day of the month in the evening, is the Phase of the Lord; and on the fifteenth day of this month is the solemnity of the unleavened bread of the Lord.*

Likewise Numbers chapter 9: *The Lord spoke to Moses in the desert of Sinai, in the second year after they had gone out of the land of Egypt, in the first month, saying: Let the children of Israel keep the Phase at its proper time, on the fourteenth day of this month in the evening, according to all its ceremonies and its ordinances. And somewhat later: And the Lord spoke to Moses, saying: Speak to the children of Israel. A man who is unclean by reason of a soul, or is on a journey far off among your people, let him keep the Phase to the Lord in the second month, on the fourteenth day of the month in the evening.* In Numbers chapter 28 as well these words are found: *But in the first month, on the fourteenth day of the month, shall be the Phase of the Lord, and on the fifteenth day the solemnity.*

[Margin: When the Jews used to celebrate the Passover by divine precept.]

From all these passages it is clear that God had commanded the Hebrews to celebrate the Phase, or Passover, on the fourteenth day of the first month, in the evening.

[Margin: Which is the first month of the Jews.]

2. Now this month is a lunar month — for the Hebrews used lunar months — and the first month is the one whose fourteenth day of the Moon (counting in the day of the new moon, or Neomenia, itself) falls either on the day of the spring equinox or after the equinox

— the equinox that first occurs. This can be gathered clearly enough from the older and more learned Hebrews, who consistently handed down that the Passover was to be celebrated, according to the lunar cycle, on the fourteenth day of the Moon falling on the equinox itself or on the one next following it. The

richest witness to this is Josephus the Jew, in Book 3 of the *Jewish Antiquities*, chapter 13, where he writes:

In the month of Xanthicus, which we call Nisan, and which is the beginning of the year, on the fourteenth day of the Moon, with the Sun opposite in Aries — the month in which we were freed from the servitude of the Egyptians — he commanded us to offer each year, and to celebrate, the sacrifice which our fathers offered when they went out of Egypt (the sacrifice called the Passover); and we do indeed celebrate it by our tribes, keeping back nothing of what has been offered until the next day.

By these words Josephus plainly teaches that the fourteenth day of the Moon of the first month, on which the Jews used to celebrate the Passover, is the one that either falls on the day of the equinox or next follows the equinox — that is, when the Sun is either at the beginning of Aries or in some degree of Aries.

Anatolius, bishop of Laodicea in Syria, who flourished around the year of the Lord 280, some 45 years before the Council of Nicaea, teaches in the clearest terms that Philo — the most learned of the Jews — and other older Jews held the same view. After showing (as Eusebius reports, *Ecclesiastical History* VII, chapter 29) that the year, so far as the celebration of the Passover is concerned, must begin from the spring equinox, he adds this:

And therefore we say that those go seriously wrong who think the Passover should be celebrated before the beginning of this new year (that is, before the spring equinox). Nor does this reckoning take its first beginning from us: it is shown to have been approved by the ancient Jews and observed before the coming of Christ, as Philo and Josephus clearly teach, and, older than these, Agathobulus and his pupil Aristobulus of Paneas, who was one of the seventy elders sent by the high priests to Ptolemy, king of Egypt, to translate the books of the Hebrews into Greek; and they answered many questions on the traditions of Moses when the king put them and inquired of them. When, then, they were expounding the questions of Exodus, they said that the Passover must not be sacrificed before the spring equinox had passed. Aristobulus added this further point as well: that on the day of the Passover one must see to it not only that the Sun has crossed the spring equinox, but the Moon also. For since there are two equinoxes, of spring and of autumn, separated by equal intervals, and since the festival is fixed for the fourteenth day of the first month after evening, when the

Moon is found standing opposite the Sun from the other quarter of the sky — as one may verify with one's own eyes — the Sun is in every case found occupying the region of the spring equinox, and the Moon, on the contrary, that of the autumn equinox. I have read in their books, and in many others, much set out with the strongest arguments on these matters, which show plainly that the solemnity of the Passover must in every way be celebrated after the equinox.

This is what Eusebius reports of Anatolius.

From all this it is clear that the most ancient and the more expert Hebrews took from the tradition of Moses that the fourteenth day of the Moon of the first month is the one that either falls on the equinox or next follows it — so that a fourteenth day of the Moon preceding the equinox was always rejected as useless, and as belonging rather to the last month of the year than to the first. So much, then, is laid down in sacred and divine Scripture and by the more learned Hebrews concerning the Mosaic Passover.

[Margin: Why the Church preferred Easter to be movable rather than fixed.]

3 Now in the age of grace, after the Mosaic Law, the Catholic Church was not bound by those ceremonial precepts, since everything belonging to the Law ceased and lost its force through the death and resurrection of Jesus Christ, as the holy Doctors agree. Even so, she willed that the Christian Easter — of which the Hebrew Passover was the figure and shadow — should likewise be variable and movable rather than fixed and stationary, and that in celebrating it the same things should be observed as the Hebrews observed: namely the spring equinox and the fourteenth day of the Moon of the first month. This was on account of the sacramental sense and the hidden mysteries contained in celebrating the Easter of the Lord's resurrection in this way, as St. Augustine sets out at length in Book 2 *On the Inquiries of Januarius*, chapters 1 and 2. Therefore we should not listen to those who think — and in our own day there have certainly been men of that mind — that the Church ought to keep the solemnity of Easter always on a fixed day, like the other festivals that are called fixed and immovable, with no account taken of the Moon of the first month; their chief argument being that the Church would thereby free and disentangle herself completely from the difficulties and controversies that regularly arise among writers over the Paschal new moons. We should not, I say, listen to those who hold this view — even though the Church could freely do it by her own right, and no one could fault her for it, since that precept about the Passover is ceremonial and has now ceased, as has been said — because the Catholic Church has never used that manner of celebrating

Easter. In celebrating it she has always observed the motion of the Moon and of the Sun; this was so decreed by the most ancient and most holy Roman Pontiffs, and was moreover confirmed by the Council of Nicaea and by a great many others, as I shall shortly say. For that reason a custom so venerable seems in no way to be broken without some grave cause.

[Margin: The Christian Easter is to be celebrated on the first Sunday after the fourteenth day of the Moon of the first month.]

4 In one respect, however, the Church departed from the Jewish practice: she ordered Easter to be celebrated not on the fourteenth day of the Moon of the first month itself, as the Hebrews did, but on the Sunday that next follows the fourteenth day of the Moon of the first month, because the Lord rose from the dead on the first Sunday after the Jewish Passover. And so, just as the Jews celebrated the Passover on the fourteenth day of the Moon because of the sacrifice of the lamb, which prefigured the death of Christ, so we in our Easter celebrate the memory of Christ's resurrection, which took place on the Lord's Day. Whenever, however, the fourteenth day of the Moon of the first month falls on a Sunday, the Church directs that the solemnity of Easter be transferred to the following Sunday, on which the twenty-first day of the Moon of the first month falls. Two reasons above all are given for this by the Fathers and by other writers. First, so that the Lenten fast should not be broken on the fourteenth day of the Moon; or — if it is not broken then but on the [xiii]. [?] — printed thus; the sense requires the fifteenth] day of the Moon, as the ancient Fathers wished — so that we should not be compelled to fast on a Sunday along with the Manichaeian heretics and then begin the Easter festival on the following Monday. That it was not permitted to break the fast before the fourteenth day of the Moon of the first month is plain from Eusebius, *Ecclesiastical History* V, chapter 23, where he says:

In the provinces of Asia no small question arose, deriving as it were from an ancient custom of theirs, in that they thought Easter must at all costs be celebrated on the fourteenth day of the Moon, that is, when the Jews are commanded to sacrifice the lamb — maintaining as a necessity that on whatever day of the week the fourteenth of the Moon fell, the fast had to be broken; although such a custom had never been observed in any other churches whatever.

Blessed Ambrose teaches the same in his letter to the bishops of Aemilia, in these words:

Hence, if it should happen — as it will happen shortly — that the fourteenth day of the Moon of the first month falls on a Sunday, then, since we ought neither to fast on a Sunday nor to break the fast on the thirteenth day of the Moon, when it falls on a Saturday (a day on which the fast is above all to be kept, as the day of the Passion), the festival of Easter is to be deferred to the following week.

The Venerable Bede also writes as follows on the same matter, in his book *On the Reckoning of Time*, chapter 57:

It is therefore fitting to attend carefully, so that whenever the fourteenth day of the Moon falls on a Sunday, we defer the Paschal feast-day to the following week, for two reasons. First, so that we do not break the fast on the [?] day of the Moon when it is found to fall on a Saturday, which is not consistent and which the Law itself does not command; and second, so that we are not forced to fast on a Sunday when the Lord's Day [?] falls on the fourteenth day of the Moon, thereby doing something unseemly and unlawful.

And so on. Then, so that we may never celebrate Easter together with the Jews, nor agree with the Quartodeciman heretics, who taught that the Mosaic Law was to be observed alongside the Gospel.

5 That Easter must be celebrated on a Sunday — and on the first Sunday after the fourteenth day of the Moon of the first month, that is, after the Jewish Passover — can be established from many authorities of the holy Fathers and from the decrees of councils. First, that it is not to be celebrated on the fourteenth day of the Moon along with the Jews, but on a Sunday, was laid down by St. Pius, pope and martyr, tenth from blessed Peter, around the year of the Lord 159, in a decretal letter, in these words, as given in *De Consecratione*, distinction 3, chapter *Nosse*:

We would have you know that the Lord's Passover is to be celebrated yearly on a Sunday.

And a little later:

Hence we too establish by apostolic authority that all are bound to keep the same, because we ourselves keep it; nor may you in any way depart from the head.

[Margin: Decree of St. Pius, pope and martyr, on celebrating Easter on a Sunday.]

St. Victor, likewise pope and martyr, fourteenth from blessed Peter, around the year of the Lord 198, in his letter to Theophilus, bishop of Caesarea, which is found in *De Consecratione*, distinction 3, chapter *Celebritatem*, lays down still more clearly that Easter must be celebrated not on any Sunday whatever, but on the one that follows the fourteenth day of the Moon of the first month. He writes:

That the festival of holy Easter is to be kept on a Sunday our predecessors have already laid down, and we have directed that it be solemnly celebrated on that same day; for it is not fitting that the members should disagree with the head, or act otherwise. And let that same festival be celebrated from the fourteenth day of the Moon of the first month up to the twenty-first of that same month.

[Margin: Decree of St. Victor, pope, on celebrating Easter on the Sunday after the fourteenth day of the Moon of the first month.]

Besides this, the same has been confirmed and sanctioned by various councils. For in the first council after the Apostles — held at Caesarea in Palestine at the urging of St. Victor, the supreme pontiff just mentioned, by a number [?] of bishops, and presided over by Theophilus, bishop of that city, Narcissus, bishop of Jerusalem, and Cassius, bishop of the church of Tyre — the decree ran as follows, as we read in Eusebius, *Ecclesiastical History* V, chapter 23:

Let assemblies of bishops and councils be convened throughout each of the provinces, and, letters having been exchanged between them, let them all together confirm one single doctrine of the Church: that it never be lawful to celebrate the Lord's Paschal mystery except on the Sunday on which the Lord rose from the dead, and that on that day alone the Paschal fast is to be broken.

Concerning this decree the same Theophilus writes as follows in his synodal letter, where he explains more openly that Easter falls on the Sunday after the fourteenth day of the Moon:

It was established in that synod that Easter should be observed from the eleventh day before the Kalends of April to the twelfth before the Kalends of May, and that no one has leave to cross those limits either before or after. Likewise let the divine precept concerning the Moon be kept: the command given through Moses was laid on you, from the fourteenth day of the Moon to the twenty-first. It is agreed, then, that these seven days of the Moon were consecrated for keeping Easter in like manner. Whenever, therefore, within that limit — from the eleventh

before the Kalends of April to the twelfth before the Kalends of May — there falls a Sunday together with one of those seven hallowed days of the Moon, it is fitting for us to observe Easter, as is right, in Christ Jesus our Lord.

From this constitution it is clear that in that period Easter was regularly celebrated from 22 March to 20 April; to which span five further days were afterwards added, since the reckoning [?] necessarily required it, so that Easter can be celebrated up to and including 25 April. For the first month is not the one in which the Sun traverses the whole of Aries — as the Fathers in that synod of Caesarea seem to have wished — but the one whose fourteenth day of the Moon falls on one of the days from 21 March inclusive, on which the equinox falls, up to 18 April inclusive. From this it follows that Easter can be duly celebrated on 25 April, as I shall say a little further on.

[Margin: Decree of the Council of Caesarea in Palestine on celebrating Easter after the fourteenth day of the Moon of the first month.]

Next, in that most famous synod of Nicaea — three hundred and eighteen bishops distinguished for holiness and innocence of life, with the legates of the Apostolic See sent there by Pope Sylvester present, and Constantine the Great, at whose expense it was held — the same thing was decreed with solemn rite, or rather confirmed and renewed, by the common consent of all. On this matter, in the letter sent by that synod to the church of Alexandria and to the brethren living in Egypt, Libya, and the Pentapolis, these words occur, as Socrates reports in *Ecclesiastical History* I, chapter 6, and Theodoret in *Ecclesiastical History* I, chapter 9:

As to the common agreement about celebrating the most sacred feast of Easter, know that by your prayers the controversy raised on that matter has been prudently and satisfactorily settled: so that all the brethren who live in the East, and who used formerly to imitate the custom of the Jews in observing that feast, will henceforth follow with one accord, and zealously, in celebrating it, the Romans, ourselves, and all of you who from the earliest times have held the same practice in keeping it that we hold.

The Emperor Constantine the Great himself also wrote an elegant letter on the same subject to the churches, and it is reproduced by the same writers in the passages cited.

Finally, the same was afterwards confirmed and enjoined under pain of anathema in the synod of Antioch, and in the Council of Chalcedon of 630 bishops, held under Leo the Great, and in a great many other councils.

[Margin: The decree of the Council of Nicaea on the celebration of Easter is confirmed by the Council of Antioch, by Chalcedon, and by others; the Council of Nicaea confirmed rather than instituted it.]

Now although those words of the Council of Nicaea do not explicitly state on what day the most holy Easter is to be celebrated, but seem only to indicate that it is not to be kept along with the Jews, it can nevertheless be understood from them clearly enough that the custom of the Roman Church, and the enactment of the Roman pontiffs Pius and Victor — by which Easter is directed to be celebrated on a Sunday from the fourteenth to the twenty-first day of the Moon — were confirmed and renewed. For the letter plainly indicates that all the Easterners, who had previously celebrated Easter with the Jews on the fourteenth day of the Moon, had with one accord embraced the Roman practice, which perpetually keeps it on the Sunday after the fourteenth of the Moon. That this was the mind of that great council concerning the celebration of Easter — indeed that a canon was issued on the matter in that same council — has been taught by almost innumerable writers on ecclesiastical matters. Among them the Venerable Bede confirms it in explicit terms in many places, and especially in Book 3, chapter 25, of the *Ecclesiastical History of the English People*, where, in a debate about the right celebration of Easter, he brings in a certain Wilfrid, who, ordered by the king to speak, began thus.

[Margin: Bede's view: that the Council of Nicaea renewed the ecclesiastical decree on celebrating Easter on the Sunday after the fourteenth day of the Moon of the first month.]

The Easter that we keep (he is speaking of celebrating Easter on the Sunday after the fourteenth day of the Moon, as is clear from what follows) we have seen kept by all at Rome, where the blessed Apostles Peter and Paul lived, taught, suffered, and were buried; and so in Italy, and so in Gaul, and so on.

Then a little later:

But Peter, when he was preaching at Rome, mindful that the Lord rose from the dead on the first day of the week and brought the world the hope of resurrection, understood that Easter was to be kept in such a way that, following the custom and the precepts of the Law, he always

waited, just as John did, for the fourteenth day of the Moon of the first month to rise toward evening; and when it had risen, if the Lord's Day (which was then called the first day after the Sabbath) was to come on the following morning, he began on that very evening to celebrate the Lord's Easter, just as we all do today. But if the Sunday was not to come on the next morning after the fourteenth day of the Moon, but on the sixteenth, or on any other day of the Moon up to the twenty-first, he waited for it, and on the preceding Saturday evening began the sacred solemnities of Easter; and so it came about that the Sunday was kept only from the fifteenth day of the Moon to the twenty-first. And this evangelical and apostolic tradition does not abolish the Law but rather fulfils it, in which it was commanded that Easter be observed from the fourteenth day of the Moon of the first month at evening up to the twenty-first day of the Moon of that same month; and to the keeping of this observance all the successors of St. John in Asia after his death, and the whole Church throughout the world, were converted. And that this is the true Easter, and that this alone is to be celebrated by the faithful, was not newly enacted by the Council of Nicaea but confirmed, as ecclesiastical history teaches.

[Margin: The view of St. Ambrose on the celebration of Easter from the decree of the Council of Nicaea.]

Blessed Ambrose likewise writes as follows about the same Paschal solemnity in Letter 83, to the bishops of Aemilia:

That it takes no ordinary wisdom and understanding to determine the Paschal reckoning, both divine Scripture instructs us and the learning of our forefathers, who, meeting at the synod of Nicaea, among those decrees of the faith as true as they are admirable, also gathered together the most expert calculators concerning the festival in question and drew up a reckoning of nineteen years, establishing a kind of cycle, so that the pattern for future years should not fluctuate. This cycle they called the [Greek: ἐννεαδεκά-τηρίδα (enneadekatērida, "nineteen-year period") — small italic type, printed with a line-break hyphen after ἐννεαδεκά-], following the principle that we ought not to fluctuate about such a festival on some empty opinion, but that, the true reckoning once ascertained, the devotion of all should so concur that on one and the same night everywhere the sacrifice may be offered for the Lord's resurrection.

Further on, expounding more clearly what was decreed in the synod of Nicaea, he adds:

Two things are to be observed in the solemnity of Easter: the fourteenth day of the Moon, and the first month, which is called the month of new things.

And somewhat later, having shown that Easter is to be celebrated on a Sunday, he says again:

The month begins not according to common usage, but according to the practice of the experts, from the equinox, which is the twelfth day before the Kalends of April, and so on.

In this letter St. Ambrose declares two things chiefly. First, that by the decree of the Council of Nicaea Easter is to be celebrated on the Sunday after the fourteenth day of the Moon of the first month, and that the first month begins from the equinox. By these words he explains that the first month is the one whose fourteenth day of the Moon falls on the equinox — that is, on 21 March — or next follows it. For when he says that the first month begins from the equinox and not before, he does not mean that the new moon of the first month must be taken from the equinox, but the fourteenth day of the Moon. Otherwise Easter could never have been celebrated before 4 April, since on that reckoning the earliest of all the Paschal fourteenth days of the Moon would fall on 3 April — whereas in the same letter he plainly teaches that in his own time, on the ruling of the Council of Nicaea, Easter was celebrated in the month of March. And that he meant the Sunday after the fourteenth day of the Moon is to be taken, is quite clear. For in the same letter he asserts that Easter is to be deferred to the following week when the Sunday falls on the fourteenth day of the Moon, as I set out above from this same letter of Ambrose. In the second place he teaches that the Fathers of the Council of Nicaea decreed that the fourteenth day of the Moon of the first month should be sought by means of the nineteen-year cycle of the golden number, since they entrusted the arrangement of it in the calendar to men most expert in the art of calculation — namely to Eusebius, bishop of Caesarea, and to the Alexandrians of Egypt.

[Margin: The care of the cycle of the golden number was entrusted by the Council of Nicaea to Eusebius of Caesarea and to the Alexandrian Egyptians.]

Bede states the same thing more plainly in his book *On the Reckoning of Time*, chapter 42, where he writes in these terms:

Eusebius, bishop of Caesarea in Palestine, was the first to draw up the scheme of the nineteen-year cycle, for finding the fourteenth days of the Moon of the Paschal feast and the day of Easter itself, since the Moon of any given age returns after that span of time to the same day of the solar year: not that Egypt, or the rest of Christ's Church throughout the East, had until then been unable to find the Moon's course or the Paschal day correctly, but because the results, which in those times were worked out year by year with labour and sent out through the world, used more often to come into question, whereas once a cyclical rule had been fixed for good they could be learned more easily and observed always without any scruple of doubt.

To this may be added that the same Bede, in his book *On the Reckoning of the Computus*, chapter 16, teaches that Eusebius, bishop of Caesarea in Palestine, was the first to draw up the scheme of the nineteen-year cycle; and he repeats the same in Book 5, chapter 22 [?], of the *Ecclesiastical History of the English People*, from the letter of Abbot Ceolfrid to King Nechtan, where these words occur:

And so, by the equinoctial rising of the Sun, after the completion of the fourteenth day of the first month — all of which we have received as to be observed from the Law — we further await, at the Gospel's prompting, the time of the Lord's Day in that same third week; and only then do we celebrate the votive feasts of our Easter, to show that we do not now venerate the shaking off of the ancient yoke of Egyptian servitude, but that we honour with devout faith and love the redemption of the whole world, prefigured in the liberation of God's ancient people and completed in Christ's resurrection, so as to signify that we rejoice in the most certain hope of our own resurrection also, which we believe will come to pass on that same Lord's Day.

Now this computus of Easter which we set before you to follow is contained in the nineteen-year cycle, which long ago — that is, in the very times of the Apostles — began to be observed in the Church, especially at Rome and in Egypt, as I said above; but through the industry of Eusebius, who takes his surname from the blessed martyr Pamphilus, it was more distinctly set in order, so that what until then used to be sent out through all the churches each year by the bishop of Alexandria could thereafter, once the series of the fourteenth days of the Moon had been gathered into order, be known very easily by everyone.

From all these testimonies it plainly follows that by the Church's precept Easter is to be celebrated on no other day than the first Sunday after the fourteenth day of the Moon of the first month.

[Margin: That the practice of celebrating Easter on the Sunday after the fourteenth day of the Moon of the first month began in the times of the Apostles, and is an apostolic tradition.]

6. Moreover, that this is no new decree of popes and councils, but that from the very beginning of the infant Church this practice flourished continuously at Rome and in most other churches — that Easter should be celebrated not with the Jews on the fourteenth day of the Moon but on a Sunday — and indeed that it was so handed down by the Apostles, seems clear enough from several of the authorities I have adduced. For the letter of the Council of Nicaea states in explicit terms that the Romans, the Alexandrians, and the Egyptians had held that manner of celebrating Easter from the earliest times. It is understood still more clearly from the passages of Bede, since he says that blessed Peter, when he was preaching at Rome, understood that Easter was to be kept in this way; that this practice is an evangelical and apostolic tradition; and further that it began to be so observed in the Church in the very times of the Apostles, especially at Rome and in Egypt.

Abbot Ceolfrid [Ceolfridus Abbas] affirms the same thing in the plainest terms, in the same Bede, book 5 of the *Ecclesiastical History of the English People*, chapter 22, where the passage runs as follows: *If then it could be brought about that Sunday always fell on the fifteenth day of the first month — that is, on the fifteenth Moon — we could celebrate Easter at one and the same time with God's ancient people, though distinguished from them in the kind of sacraments, just as we hold one and the same faith. But since the day of the week does not run on the same track as the Moon, apostolic tradition decreed — the tradition preached at Rome by blessed Peter and confirmed by Mark the Evangelist, its interpreter, at Alexandria — that when the first month has come, and within it the evening of the fourteenth day, Sunday should further be awaited, from the fifteenth day to the twenty-first of that same month.*

[Margin: That Easter has always been celebrated, and ought to be celebrated, on the first Sunday after the fourteenth Moon, even if that Sunday falls on the fifteenth Moon: against certain people who deny it.]

EUSEBIUS too, in book 5 of the *Ecclesiastical History*, chapter 22, testifies that all the other churches scattered throughout the whole world, the Asian churches excepted, kept the custom of breaking their fasts on no other day than the one on which the Saviour rose from the dead. Furthermore, St Cyril, Patriarch of Alexandria, in all his festal letters [sermones Heortistici] — which are very numerous, and in which he announced to the people each year the solemn Lenten fast, the feast of Easter, and Pentecost — declares in every case that Easter is celebrated on such a day of the month, on a Sunday, in accordance with the evangelical or apostolic traditions. Again, the same St Cyril, in his letter to Pope Innocent I (cited by Johannes Stöffler [Ioannes Stoflerinus] in the *Calendarium Romanum*, proposition 32, near the beginning, and by Albert Pigge [albertus Pighius] in his book on the reckoning of the celebration of Easter and the restitution of the calendar, proposition 8), says this: *The holy mystery of Easter and its sacred solemnity would have remained inviolate, just as it was handed down by our Saviour and by the Apostles, had not the perversity of certain foolish men defiled it, along with the other sacraments of the faith, etc.* And there is no room for doubt that he is speaking of an Easter celebrated on a Sunday after the fourteenth Moon of the first month, since he consistently maintained that it must be so celebrated, on the teaching of Theophilus, his uncle and predecessor in the see of Alexandria — as is clear from the festal letters, in which he invariably sets before the people that Easter is to be celebrated on a Sunday.

FINALLY, this is confirmed beyond question by the letter of Proterius [Protherius], Bishop of Alexandria, to blessed Pope Leo I, who had arranged through the Emperor Marcian [Martianus] that the Bishop of Alexandria should expound Theophilus's Paschal cycle more exactly. The passage in that letter reads as follows — as Venerable Bede reports in his book *On the Reckoning of Time*, chapter 42, and at the very beginning of his little book on the equinox addressed to Wicthed [Vuichenredum], and as Johannes Stöffler and Albert Pigge also report in the places cited: *The letters of your affection gladdened me, which our brother and fellow bishop Victorius brought in dutiful service. For it was fitting that such writings should be sent to the Apostolic See by the bishop of the Church of Alexandria — writings that would show that it was by the teaching authority of the blessed Apostle Peter that the Egyptians learned the computation of the Paschal feast from the beginning, through blessed Mark his disciple; and it is agreed that the Romans learned it in the same way, etc.* It is perfectly clear that in this letter the words concern the celebration of Easter after the fourteenth Moon of the first month, since that is how it has always been celebrated at Rome and at Alexandria. Therefore, when Proterius says that the Romans learned this from St

Peter and the Alexandrians from St Mark, it is plain that he is asserting that Easter must be observed in this way by apostolic tradition.

BUT to leave the point still better established — that Easter has always been celebrated, especially in the Roman Church, and ought to be celebrated, on the Sunday next after the fourteenth Moon of the first month, even if that Sunday falls on the fifteenth Moon (which some people in our own day, obstinately and on I know not what principle, have dared to deny) — we set out the following authorities for consideration. Venerable Bede, in his book *On the Reckoning of Time*, chapter 58, after teaching that the Sunday which falls after the fourteenth Moon is the Paschal day of the Lord's Resurrection, adds a little later: *And if it could be brought about that in every year the fourteenth Moon fell on a Saturday, the time of our Paschal observance would differ in nothing from the Legal one. For we too, like them, according to the ordinances of the Law, would sacrifice at evening on the fourteenth Moon of the first month, and eat the flesh of the spotless lamb, and sprinkle its blood on our doorposts to drive off the destroyer — that is, celebrating the solemnities of Baptism and of the Paschal Masses, we would pass over spiritual Egypt; and at the dawning of the morning, on the fifteenth Moon of the same month, we would enter upon the first day of Unleavened Bread; and we would complete with due reverence the seven lawful days of that same festival, from the morning of the fifteenth day to the evening of the twenty-first of that month — that is, from Easter Sunday to the Sunday of the octave of Easter. But since the same day of the Moon rolls round onto different days of the week, the result is that we, who on account of the Resurrection of our Redeemer are taught to reserve the beginning of Easter for Sunday, sometimes have our festival take its start on the seventh day after the beginning of the Legal unleavened bread. Do those who hold the contrary not see that in this passage Bede teaches in the plainest terms that Easter Sunday can fall on the fifteenth Moon — and that Easter is then celebrated entirely correctly?*

THE SAME author states it most clearly in chapter 60, where he says: *For whereas in the Old Testament the Paschal season was prescribed to be observed by three indications drawn from the arguments — namely, that it be celebrated after the equinox, in the first month, and in the third week of that month, that is, from the evening of the fourteenth Moon, which is the beginning of the fifteenth, to the evening, that is, to the limit of the twenty-first — a fourth rule in the observance of it has been laid upon us from the time of the Lord's Resurrection: that when, the equinox being past, we have seen the fourteenth Moon of the first month rise in the evening, we should not leap at once to keeping Easter, but should await the Lord's Day, on which he deigned by rising again to accomplish the Pasch itself, that is, the*

passage from death to life, from corruption to incorruption, from punishment to glory; and then at last on that day celebrate the Paschal solemnities as is fitting. And a little later: Whenever, then, we have Sunday immediately upon the coming of the fourteenth Moon, our Paschal season is in no way out of tune with the Legal one, although we keep the solemnities of the same Pasch with other kinds of sacraments. But whenever that same Sunday falls on the second, third, fourth, fifth, sixth, or seventh day from that point, not even then do we abolish the Law or the prophets; rather we fulfil them with the sacraments of evangelical grace. This custom of the Church he confirms from Theophilus, Bishop of Alexandria, as well; and he repeats and drives the same point home in chapters 61 and 62 and often elsewhere. Moreover, in book 4, chapter 5 of the *Ecclesiastical History* he records that it was decreed in a certain English council, in the king's presence, that Easter should be celebrated on the Sunday after the fourteenth Moon of the first month. And that decree was observed not only then, but in every age thereafter.

BLESSED ISIDORE of Seville, who flourished about the year of the Lord 630, shows the very same thing in book 1 of *On the Ecclesiastical Offices*, chapter 31, when he says: *Easter is celebrated in the third week of the Moon, that is, on whatever day falls as Sunday from the fifteenth to the twenty-first.* See how openly he teaches that Easter is to be celebrated on the day of the fifteenth Moon, if that is a Sunday. For if anyone should be so shameless as to maintain that, on Isidore's view, Easter is to be celebrated on the Sunday after the fifteenth Moon up to the twenty-first Moon, he will be forced to admit that in a year in which Sunday falls on the fifteenth Moon there is either no Easter at all — since up to and including the twenty-first Moon no other Sunday occurs — or

else that Easter must be celebrated on the twenty-second Moon, which blessed Isidore does not allow, since he does not extend Easter Sunday beyond the twenty-first Moon.

NEXT, Hrabanus [Rabanus], Archbishop of Mainz, who lived about the year 855, in book 2 of *On the Instruction of the Clergy*, chapter 39, repeats those very words of Isidore exactly, and enumerates all the Paschal limits which we see observed in the Church to this day as received from the Council of Nicaea, in these words: *The beginning of the first month is to be observed from the eighth day before the Ides of March to the day of the Nones of April; but the fourteenth Moon of Easter is to be sought from the twelfth day before the Kalends of April to the fourteenth before the Kalends of May. Further, Easter Sunday runs from the eleventh before the Kalends of April to the seventh before the Kalends of May, and this from the fifteenth Moon to the twenty-first. It can therefore never happen that the fourteenth*

Moon of the first month falls before the vernal equinox, which occurs on the twelfth day before the Kalends of April. Do you see that Hrabanus teaches that Easter can be kept on the eleventh day before the Kalends of April — that is, on 22 March — after the first Paschal fourteenth Moon, which he places on 21 March, and therefore on the fifteenth Moon? And a little further down the same Hrabanus quotes those words of Venerable Bede which we reviewed a moment ago from the book *On the Reckoning of Time*, chapters 58 and 60.

RUPERT [Rupertus], Abbot of Deutz, who wrote about the year 1124, in book 6 of *On the Divine Offices*, chapter 27, speaking of the Easter of Christians, has these words: *For it is of divine authority, and handed down from the ancient Law of Moses, that it should not be celebrated before the full moon of the first month — that is, where the full Moon first occurs after the vernal equinox.* Here he excludes from the celebration of Easter only the fourteenth Moon of the first month, and not the fifteenth Moon, that is, the full moon.

WILLIAM DURAND [Gulielmus Durantus], in the *Rationale of the Divine Offices*, book 8, chapter 12, carefully expounds all 29 Paschal fourteenth Moons, teaching not once but repeatedly, and not in one way but in several, that in the Church the first Paschal fourteenth Moon is the twelfth day before the Kalends of April and the last the fourteenth before the Kalends of May, and that after these Easter must always be celebrated on a Sunday. There too he affirms in explicit terms that the Easter of the Hebrews is always celebrated on the fourteenth Moon, and that our Easter falls on the following Sunday. He therefore never excludes the fifteenth Moon, if it is a Sunday, from being the day on which Easter may be kept. In book 6, chapter 78 as well, he asserts that by the Lord's command Easter is to be celebrated at the full moon — that is, not indeed before the full moon, but on some one of the seven days of the third week, which begins after the fourteenth Moon of the first month, on the fifteenth Moon or full moon.

FINALLY, all the computists, as many as have written on the celebration of Easter, consistently maintain this very thing by common consent: for instance Johannes de Sacrobosco in the *Computus Ecclesiasticus*; Johannes Stöffler in the *Calendarium Romanum*; Campanus in the *Computus Maior*; and Paul of Middelburg [Paulus Middelburgensis], Bishop of Fossombrone, in his *Paulina* (for so he entitled that immense volume on the correct celebration of Easter and on the true day of Our Lord's Passion) — in many places, but especially not far from the beginning of book 12, where he writes as follows: *We therefore, in the computation of the Paschal Moon, shall call the day of the opposition of the luminaries the fifteenth Moon; and if it falls on a Sunday, we shall note that Easter*

is to be celebrated on that same day, in accordance with the canon established by the holy Fathers in the Synod of Nicaea, by which Easter is ordered to be celebrated on a Sunday from the fourteenth Moon to the twenty-first — that is, on the first Sunday after the fourteenth Moon. What could have been said more clearly than this? For since he calls the opposition of the luminaries, or full moon, the fifteenth Moon, it is clearer than the light of the Sun that he does not call the fourteenth Moon the full moon. Let those who try to exclude the fifteenth Moon from the Paschal solemnity observe how great the agreement is among the Fathers and the other writers. In none of them will they find that Easter is to be celebrated on the Sunday after the fifteenth Moon of the first month; it is always after the fourteenth Moon. And will there be anyone who supposes that these few adversaries — not to call them detractors — have seen more than all those most learned men who, from the first beginnings of the infant Church down to our own times, most diligently preserved the teaching on the celebration of Easter as if handed on from hand to hand from the Apostles? As for Campanus, who alone of all the writers on the computus calls the Paschal fourteenth Moon the full moon, he does so because the end of the fourteenth Moon — when the Jews were commanded to eat the lamb — is the beginning of the fifteenth Moon, or full moon; or else because the fourteenth Moon as found from the cycle usually falls on the day of the full moon, for the reason that the cycle ought to indicate the first or new Moon one day after the true new moon in the heavens. This last point we took the greatest care to observe in the Roman Calendar, so far as the cycle allows. The proof is that Campanus then goes on to testify and teach openly that Easter is to be celebrated on the Sunday after the fourteenth Moon reckoned from the new moon of the cycle.

FROM all this, then, it is established that Easter can rightly and lawfully be celebrated — indeed, that by the decrees of the Fathers it must without qualification be celebrated — on the fifteenth Moon, that is, at the opposition of the luminaries, if that day is a Sunday. And we see that this custom has always been preserved in the Church, in the East as much as in the West. For down to our own age Easter has always been celebrated on the first Sunday after the fourteenth Moon; and how often this was done from the times of the Council of Nicaea up to the Gregorian correction we shall review a little further on.

7 BUT in fact all the authorities we have adduced are to be understood of the fourteenth Moon reckoned from the new moon of the cycle, as Campanus teaches (for this is the only refuge left to our adversaries, that they should say the fourteenth Moon must be counted after the day of the new moon which the cycle supplies). This is plainly established from the golden number inscribed in the

ecclesiastical calendars by Abbot Dionysius [Dionysius Exiguus], which the Church always used down to the year 1582, when the calendar was corrected; and from the prescribed Paschal limits, all of which fall on the fourteenth day of the Moon reckoned inclusively from the golden number of the year proposed. Thus between the golden number xvi, which was set against the eighth day of March (below, in chapter 9, where we treat of setting out the golden number in the calendar, you will find the old calendar with its golden numbers, which the Church used before the year of the correction), and the 21st day of the same month, on which by the Church's usage the fourteenth Moon of that golden number falls, you see that 12 days are interposed; and that from the 8th day inclusive to the 21st day inclusive 14 days are counted. The same reckoning holds for the other golden numbers. Who, then, will be so reckless in his daring as to prescribe — by a new fashion and a new institution — that 15 days be counted from the new moon of the cycle to the Paschal limit? That this is against the canons, the decrees of the Popes, and the teaching of the Fathers is proved most manifestly by this consideration: since from the Council of Nicaea down to these times the first Paschal new moon has been assigned to the eighth day of March, as the unbroken usage of the Church shows, then if Easter had to be celebrated after the fifteenth Moon reckoned from the new moon — as the adversaries contend — it could never have been celebrated on 22 March, since that day is the fifteenth from that new moon; whereas in fact, from the Council of Nicaea down to the correction

of the year, ten Easters were celebrated on 22 March, out of the one hundred and seventy-five that were celebrated on the fifteenth Moon, as I shall show shortly. Nor can they say that the first Paschal new moon ought to be placed on 7 March, since no one ever maintained this, and in fact no golden number was ever affixed to the seventh day so as to mark a new moon there. Again, since the last Paschal new moon in the Church's usage has always fallen on 5 April, if fifteen days were to be counted from it, the Paschal limit of that year would have to be fixed at 19 April, and consequently, if that were a Sunday, Easter would have to be moved to 26 April — which is unheard of and unprecedented. You see, then (I appeal to you, our new lawgivers), that when the fourteenth Moon anticipates the full moon by one day, and that full moon falls on a Sunday, Easter is celebrated by the Church at the full moon itself; and you will be convinced that this was never forbidden. On the contrary, you will find that it was done very frequently from the Council of Nicaea down to the Gregorian correction.

You could easily have learned this too from the old table of movable feasts. For since that table prescribes that Easter be celebrated on the nearest dominical

letter under the golden number — the golden number that indicates the fourteenth Moon, or the Easter of the Jews — who does not see that, if the dominical letter is found next below the golden number (which happens not infrequently), Easter is celebrated on the fifteenth Moon, that is, at the full moon? And so that not the slightest scruple may remain in anyone's mind, and that the whole matter may be clearer than daylight, I have collected in a table, which I shall subjoin presently, 157 years in which Easter was celebrated immediately after the fourteenth Moon reckoned from the new moon. Among these you will find a few years in which Easter preceded the full moon, especially near the times of the Council of Nicaea — namely the years 326, 330, 346, 350, 370, 441, 475, 495, all of them within a span of 170 years, as I shall show below in chapter 18, number 5, when we come to speak of the fourteenth Moon.

Nor indeed did the Church trouble itself greatly over errors of this kind, however they arose, although it was aware of them. It took care of only one thing: that the canon of the Council should be observed uniformly everywhere on earth, the canon by which Easter is prescribed to be celebrated after the fourteenth Moon — even if occasionally, though rarely, on account of the arrangement of the cycle, it was kept before the full moon. From this it follows that the cycle must, so far as possible, be so ordered in the calendar that the Paschal fourteenth Moons anticipate the full moon by one day only, and never by two, save most rarely (since no cycle can avoid that, as I shall show in the proper place). This the cycle of the epacts in the Gregorian calendar achieves with the utmost exactness: for in it, over the 551 years to be counted after the correction of the year 1582 — namely in the year 2133 — Easter is celebrated before the mean full moon only once, and in 3418 years only fifteen times, as we shall set out in chapter 18, number 7, and chapter 22, number 4, where we shall write on this matter more fully. In the cycle of the golden number of the Council of Nicaea, by contrast, this very thing happened eight times in a span of 170 years, as I said a little earlier, and that indeed close to the times of that Council, when the cycle was approved — although four of those years did in some manner reach the mean full moon on the day of Easter, since it occurred before sunset, as is clear from the little table which we shall set out in chapter 18, number 5. That this is not absurd, since no cycle can avoid it, we shall show in chapter 22, number 4.

BUT here are the 175 years for you, in which Easter was celebrated on the fifteenth Moon, so that you may learn by example as well how rashly you have tried to tear up the settled state of the Christian Easter, which you could not budge. And so that no one may have any doubt about the reliability of this table, it has been put together from the great Dionysian cycle of 532 years and from the

old table of movable feasts. I have moreover set beside those same years the corresponding golden numbers and dominical letters, so that it may be plain to anyone that Easter was indeed celebrated on the fifteenth Moon in accordance with the canons. The letter A, further, signifies April and M March, written next to the day of Easter.

Table continues.

Continuation of the table of years in which Easter fell on the fifteenth day of the Moon. Each printed page carries two side-by-side panels, each with four headed columns — Anni Domini. / Aurei numeri. / Literæ Dominicales. / Pascha. — transcribed below as columns 1–4 and 5–8 of a single table. Rows are grouped in fives by horizontal rules. In the Pascha columns the day-number and the month letter (A = April, M = March) are separate printed sub-fields, joined here by a space. Leap years carry two dominical letters.

End of the table. Parsing notes: the left panel's last group holds only three rows and the right panel's only two; the remaining cells are blank on the page.

NOR was this practice peculiar to the Latin — that is, the Western — Church: to celebrate Easter immediately after the fourteenth day of the Moon reckoned from the new moon, whenever the next following day is a Sunday. The Eastern Church has always kept the same custom and keeps it still, as is clear from the tables and

rules for finding the movable feasts that the Orientals use — the very tables Ignatius, Patriarch of Antioch, brought to Rome in the time of Gregory XIII and laid before all of us who had been assembled to correct the calendar. Consider, then: does anyone fail to see (as I said a little earlier) that if Easter could not be celebrated on a Sunday falling on the full moon, that is, on the fifteenth day of the Moon, it would have to be celebrated on the twenty-second day of the Moon? And that if 19 April were a Sunday falling on the Paschal full moon, the feast would have to be put off both to the twenty-second day of the Moon and to 26 April? Yet this was never heard of, and it is flatly contrary to the canons, as what I have said makes plain. Those who assert that Easter cannot be celebrated at the full moon are therefore wrong by the whole breadth of the sky.

8 THESE points settled — that Easter is to be celebrated on the Sunday after the fourteenth day of the Moon of the first month — it must now be explained rather more carefully that the first month is the one whose fourteenth day of the Moon falls on the day of the equinox or next follows it, as I maintained above. For there is no shortage of people who think the first month should be defined otherwise; and I take this to have slipped from them through carelessness rather than as a view they would defend tooth and nail. They call that month the first whose new moon is nearer to the day of the equinox. But they are very much mistaken. Since it can happen that two new moons are equally distant from the day of the equinox, one before it and one after, it would be doubtful — and rightly so — which of the two should be chosen for the celebration of Easter. Suppose, for example, the equinox set on 21 March. If the mean full moon, that is, the mean opposition of the luminaries (for in this business the Church uses the mean motions rather than the true, as I shall show in chapter 4), falls at noon on 21 March, then the mean new moon that precedes the day of the equinox will be as far from noon of the 21st as the mean new moon that follows that same day is from it — since each is distant from the mean full moon by about 14 days, 18 hours, 22 minutes, 2 seconds, as I shall set out in its proper place. Hence anyone could quite rightly be in doubt which of those two new moons belongs to the first month. This is seen still more clearly from the nineteen-year cycle of the golden number, which the Catholic Church used from the Council of Nicaea down to this correction of the calendar. In that cycle golden number 8 was set both against 6 March and against 5 April. Since each of these days is equally far from the 21st — for 14 days lie between 6 and 21 March just as between 5 April and 21 March — it will be ambiguous whether the new moon of 6 March is the Paschal one, or rather the one that occurs on 5 April.

[Margin: The error of certain writers in defining the first month.]

THE SAME thing appears from the cycle of the epacts of the new calendar, which I shall later show to be correctly distributed through the days of the months. For since the ordinary epact 25 is likewise placed both against 6 March and against 5 April, the same ambiguity about choosing the first Paschal month will necessarily arise; and the difficulty will be greater when epact 24 is in use, because its new moon, falling on 7 March, is nearer to the equinox — that is, to 21 March — than the new moon of the same epact that falls on 5 April, since only 13 days are interposed between 7 March and the 21st, while 14 days lie between 5 April and 21 March. On the view of those who hold that the first month is to be measured from the new moon, the new moon of 7 March would be the Paschal one, and the other, falling on 5 April, would have to be rejected as not Paschal. That is altogether false, and contrary to the most ancient practice of the Catholic Church, which rejects the new moon of 7 March and establishes the following one, falling on 5 April, as the Paschal new moon — for no other reason than that the fourteenth day of the earlier one falls on 20 March, before the equinox, and must therefore be referred to the last month of the year.

MORE CORRECTLY, then, the first month is described by that fourteenth day of the Moon which either falls on the day of the equinox or next follows it. This is what I have done, and it was approved before me by a good many ecclesiastical writers — above all by the Venerable Bede [Bede], who was thoroughly practised in this matter, both elsewhere and in the few passages I have thought worth bringing forward to confirm my view. In *De temporum ratione*, chapter 49, writing against a certain Victorius who computed the first month and the Paschal fourteenth Moons differently, he says: *We know that the Egyptian discipline of calculation, which both in your judgment (he is addressing Victorius) and by the consent of the universal Church appears truer, is to be followed by all: namely, that the beginning of the first month runs from the eighth day before the Ides of March to the day of the Nones of April; that the fourteenth Moons of Easter run from the twelfth day before the Kalends of April to the fourteenth before the Kalends of May; and further, that Easter Sunday is to be sought from the eleventh before the Kalends of April to the seventh before the Kalends of May, and this on the fifteenth day of the Moon up to the twenty-first.* By these words Bede plainly places the earliest Paschal fourteenth Moon on the day of the equinox and the latest on 18 April; and he accordingly holds that the first month — that is, the Paschal month — is

the month whose fourteenth day of the Moon either falls on the day of the equinox or next follows it. He states the same more openly in chapter 43 of the same book, in these terms: *Both kinds of year (that is, common and embolismic) take their start, as was said above, from the opening of the first month, which the*

Hebrews call Nisan — that is, from the kindling of the Paschal Moon. The beginning of that month must be governed by this rule: that the fourteenth Paschal Moon never precede the vernal equinox, but proceed as lawful either on the equinox itself, that is, on the twelfth before the Kalends of April, or after it has passed. Hence it comes about that the first beginnings of the lunar year are to be sought from the eighth day before the Ides of March to the day of the Nones of April. That fourteenth Moon itself, occurring at earliest on the twelfth before the Kalends of April and at latest on the fourteenth before the Kalends of May, makes the day of the Paschal feast to be sought from the eleventh before the Kalends of April to the seventh before the Kalends of May. He repeats the same in chapter 57, in these words: For the Sunday that occurs after the fourteenth Moon is itself the Sunday of the Paschal Resurrection; and that fourteenth Moon shows its advance over the earth at earliest at the equinox, that is, on the twelfth before the Kalends of April, and at latest on the twenty-ninth day from then, that is, on the fourteenth before the Kalends of May, at evening. Finally, in chapter 60 he speaks in this way: Of this first month, and of its seven days of unleavened bread, the rule is now such that the fifteenth Moon which occurs after the equinox is to be understood as belonging to the first month, and that this Moon, taking whichever Sunday of the seven days it may up to the twenty-first, yields a day fit for the joys of the Paschal feast.

9 SINCE, THEN, as I have said, the Roman and Catholic Church observes three things, laid down by the decrees of the Holy Pontiffs and of the Councils, in the right celebration of Easter, on which the other movable feasts depend — the vernal equinox, the fourteenth day of the Moon of the first month, and the first Sunday after that fourteenth Moon — it must now be explained what method the Church has followed so that the sacred solemnity of Easter should be carried out by the faithful everywhere at the same time: that is, so that those three requisites of its celebration should be determined by everyone in the same way, with no discrepancy whatever between them.

[Margin: The three things to be observed in the celebration of Easter, from the decrees of the Pontiffs and the Councils.]

10 FIRST, then, so that no one should be left free to go astray in fixing the equinox, the fourteenth day of the Moon of the first month, and the Sunday for celebrating Easter, the Fathers of the Council of Nicaea laid down that 21 March be assigned to the vernal equinox, since the equinox then occurred on or about that day. It follows that any fourteenth day of the Moon which precedes 21 March is reckoned to belong to the last month of the year and not to the first, and is therefore unfit for the celebration of Easter; whereas the fourteenth day of the

Moon that falls on 21 March — or, if it does not fall on that day, the one that occurs first after 21 March — is the lawful one for celebrating Easter. From this it is clear that all the new moons occurring from 8 March to 5 April inclusive, and only these, are Paschal. They are 29 in number: 24 in the last 24 days of March, and 5 in the first 5 days of April. This holds even though, before the restoration of the year, the Church made use of only nineteen new moons within those 29 days, because the nineteen golden numbers it employed occupied only 19 days. Now, however, after the emendation of the calendar, the epacts show that a new moon can occur on each one of those 29 days. That all 29 of these new moons, and only these, are Paschal is perfectly certain: for of those 29 lunar months not one has its fourteenth day of the Moon before 21 March, on which the equinox has been fixed; rather, the fourteenth day of each follows the day of the equinox I have named — except for the first new moon, whose fourteenth day falls on the 21st itself. By contrast, the fourteenth day of any other new moon earlier than 8 March anticipates the equinox; and finally, in the case of any new moon following 5 April, another Paschal fourteenth day of the Moon will already have preceded it, as is evident.

Since this is so, it is clear that Easter can and must always be celebrated on some day from 22 March to 25 April: so that the first and earliest Easter can be celebrated on 22 March, and the last and latest on 25 April. The whole Paschal solemnity thus has a range of 35 days, of which the first 10 belong to the end of March and the remaining 25 to the beginning of April. For when 21 March is a Saturday and the fourteenth day of the Moon which is the first Paschal one falls on it, the solemnity of Easter will fall on the following Sunday, that is, on 22 March; and Easter cannot lawfully be celebrated before this day, nor has it ever been celebrated on this day since the Council of Nicaea. Likewise, when 18 April is a Sunday and the fourteenth day of the Moon which is the last Paschal one falls on it, Easter will be celebrated on the next following Sunday, namely 25 April; and after this day Easter cannot be celebrated without scandal, by decree of the Council of Nicaea. These Paschal limits we have received as established by the authority of the Council of Nicaea, and they follow necessarily from the placing of the equinox on 21 March, as I have said.

[Margin: On how many days of the year, and on which, Easter may be celebrated, by the decree of the Council of Nicaea.]

11 NEXT, so that no further dissension should arise among Christians over the new moons — and so over the fourteenth days of the Moon — such as had occurred from the Council of Nicaea down to about the time of the Emperor

Justinian, but that all should declare the first day of the Moon on the same days, the 19 golden numbers received from the Alexandrians were distributed through the days of the calendar by the abbot Dionysius [Dionysius Exiguus] by this device: each was set against that day of any given month on which the new moon fell in the year in which that golden number was in use. So while golden number 1 was current, the new moon occurred throughout that year on the day of each month against which golden number 1 was set. While golden number 2 was current, the new moon occurred on the day that had golden number 2 set against it, and so on for the rest — so that the new moons always fell on different days of any given month, just as all 19 golden numbers were assigned to different days of the months, until 19 years had run out; after which the golden number was again 1, and the new moons therefore returned to the same days, and so on. But you will find more on this subject where I discuss the lunar year.

[Margin: That the new moons were investigated by means of the golden numbers distributed through the calendar before the correction of the year, so that everyone might celebrate the neomenias on the same days.]

LASTLY, so that it should be plain to all when Sunday fell, the cycle of the dominical letters was instituted, containing 28 years, so that once the dominical letter of any year was known there should be no divergence among Christians in the observance of Sunday and therefore in the celebration of the Paschal solemnity.

[Margin: That the cycle of the dominical letters was devised so that there should be no dissension over celebrating on the Lord's Day.]

CAPVT II.

Why the calendar had to be corrected, and in what its correction consists.

EVERYTHING that we have said the faithful must observe in the celebration of Easter was rightly and wisely settled by the authority of the Council of Nicaea, and confirmed by other councils and by the supreme pontiffs. But the vernal equinox in our own day no longer fell on 21 March, but on about the 11th; and the new moons, likewise, were not correctly indicated by the golden numbers set out in the calendar, but four days and more later than they should have been (I shall explain the cause of this in its proper place). The result was that Easter has again and again, right down to the present, been celebrated contrary to the enactment of the Council of Nicaea.

[Margin: That the equinox and the new moons, at the time when the calendar was being corrected by Gregory, did not fall on the same days on which they occurred in the time of the Council of Nicaea.]

For since, as we said above, the first lunar month — and so the Paschal month — is the one whose fourteenth day of the Moon either falls on the day of the vernal equinox or next follows it, and since the vernal equinox in our own day, before the correction of the calendar, fell around 11 March, it follows that every fourteenth day of the Moon from 11 March to the 20th was, by the prescription of the Council of Nicaea, Paschal — that is, belonging to the first month. Yet the Church always rejected these, as though they belonged to the last month and preceded the equinox, because along with the Council of Nicaea she had fixed the vernal equinox to 21 March. Hence it came about that whenever the fourteenth day of the Moon fell after 10 March and before the 21st — which happened whenever one of these golden numbers was in use: 3, 6, 8, 11, 14, 19 — Easter in our own day, before the restoration of the calendar, was celebrated in the second month. And this error, creeping on imperceptibly day by day, would have gone further still as time advanced, had no remedy been applied through the correction of the year — so far that in the course of time every Paschal fourteenth day of the Moon would have been rejected as useless, and Easter would always have been celebrated in the second month, indeed at last in the third, the fourth, and so on, and even in high summer. That would have been utterly absurd and altogether contrary to the decrees of the Fathers. And this would have come about with the passage of time because the equinox climbs perpetually toward the beginnings of the months by one day in the space of 134 years, as I shall show shortly. For this would have brought it about that, when the equinox had receded 29 days from 21 March or more — that is, after the year 4100 — no Easter at all would have been celebrated in the first month.

[Margin: Which lunations[?] declared Paschal by the Council of Nicaea would have been rejected as non-Paschal before the correction of the calendar, on account of the error in the equinox.]

[Margin: When Easter was celebrated in the second month before the correction of the calendar, on account of the error in the equinox.]

2 NEXT, on account of those four days and more by which the new moons, as we said, were indicated later by the golden numbers in the calendar than the facts required, it often happened that Easter was celebrated on the 25th day of the Moon — namely when the fourteenth day of the Moon found by the golden number, which was in truth the eighteenth, fell on a Sunday, and Easter was

accordingly deferred to the following Sunday. But this plainly conflicts with the decrees of the supreme pontiffs and of the Council of Nicaea, which insist again and again that Easter must be celebrated from the fourteenth day of the Moon of the first month exclusive up to the twenty-first inclusive. Indeed, from the year 1500 to the year 1582, in which the calendar was corrected — that is, in the space of 83 years — 54 Easters were not properly celebrated, and only 29 properly. And had the calendar not been restored, in the remaining 17 years up to the year 1600 Easter would have been wrongly celebrated twelve times and correctly only five. Moreover this sort of error, had no remedy been brought against it, would have grown greater thereafter: it would have come about that the most holy feast of Easter was celebrated on the 30th day of the Moon, and indeed at the new moon itself, or on the 1st and 2nd day of the Moon, on the 4th, and so on. And no one fails to see how great an inconvenience this would have brought with it, and how discordant and absurd — not to say ridiculous — the outcome would have been.

[Margin: Had the calendar not been corrected, it would have come about that for a good many years Easter would always be celebrated in the second month, then the third, the fourth, and so on, because of the equinox's ascent toward the beginnings of the months.]

3 FROM this error in the vernal equinox and in the fourteenth day of the Moon it has come about that in this century Easter has very often been celebrated 7, or 28, or 35 days later than the decrees of the Fathers prescribe. This happened in the years 1565, 1568, 1576, and 1579; and the same would have happened, had the calendar not been emended, in the years 1595, 1598, 1603, 1606, 1614, and in a great many others — in all of which the celebration of Easter would have been in error by 35 days and more, to say nothing of the years in which an error of either twenty-eight or seven days would have been committed. All this will be plainly evident from chapter 22, where we have computed the feasts of Easter and the other movable feasts for the 3,401 years from the year 1600 to the year 5000, together with the errors that would have been committed according to ecclesiastical practice if the old calendar had been retained. From all of these, only 265 Easter feast-days are found to be legitimate according to the old calendar, while 3,136 would have been celebrated contrary to the decrees of the Fathers: 581 of them with an error of 35 days, 881 with an error of 42 days, and 49 with an error of 49 days — leaving aside those Easters with an error of 7, 14, and 28 days, which are very numerous. Indeed — and this is the more absurd — after the year 2698 no legitimate Easter at all is found; and this error would in the course of time have swollen to still more days, had the calendar not been corrected.

[Margin: When Easter was celebrated on the 25th day of the Moon before the correction, on account of the error in the new moons found by means of the golden numbers.]

4 BESIDES these drawbacks and absurdities in the keeping of the feast of Easter, many others in other matters would have followed had the emendation of the calendar not been undertaken. For in the first place, the birthday of our Redeemer, which the earliest Fathers celebrated near the winter solstice, would have slipped to the vernal equinox; the day of his Incarnation, which has always been celebrated on 25 March, near the vernal equinox, would have left the vernal equinox behind and slipped to the summer solstice; and finally the birthday of St John the Baptist, which the ancients celebrated near the summer solstice, would have slipped to the autumnal equinox. All of this is absurd and discordant. For that the forerunner of the Son of God was born at the time of the summer solstice, and that the Son of God himself willed to take flesh at the time of the vernal equinox and to be born near the winter solstice, must not be thought devoid of mystery: it is altogether to be judged that this was so ordained from eternity by divine disposition. Many of the holy Fathers affirm this,

[Margin: Had the calendar not been corrected, it would have come about that Easter was celebrated on the 2nd or 3rd day of the Moon and so on, because of the error in the new moons, which were sought by means of the golden numbers.]

[Margin: That because of the error in the equinox and in the fourteenth day of the Moon found from the golden numbers, an error of 7, or 28, or 35 days often occurred in the celebration of Easter before the emendation of the calendar.]

[Margin: That after many years an error of 42 days and more would have been committed in the celebration of Easter, had the calendar not been corrected.]

[Margin: The damage to histories, to chronology, and to the principal celebrations of the year, if the calendar had not been emended.]

and teach it elegantly. The solemnities, therefore, which the Catholic Church has instituted in memory of these events must be kept at the same seasons of the year at which they were foreordained by the divine will. But in our own age, before the calendar was corrected, they were kept at quite different times: for all the feast-days that we call immovable had receded ten full days from the places in which the earliest Fathers had set them — that is, by exactly the number of days by which the equinoxes and solstices had run ahead of their positions in the calendar between the Council of Nicaea and our own time.

TO this must be added that in our times, before the restoration of the year, the new moons and the age of the Moon were never correctly announced in the churches, on account of the imperfection of the golden number — a thing not to be tolerated, since in the primitive Church great account was always taken of the lunar months. Indeed, in the Martyrology it was customary to announce, along with the day of the solar month, the day of the lunar month as well — a practice still commendably preserved in the Church.

LASTLY, because of the imperfect length of the solar year that the Church has always used, all the months were retreating in the calendar: that is, the portion of the year now understood under the name of the month of June, and containing the summer solstice, was creeping little by little toward the month of May, so that, as June retreated, the summer solstice would in the course of time have fallen in May; the dog days, now found in July, would have fallen in June; spring, now in March, in February; and the winter solstice, which now falls in December, in November. Then, with that same error still continuing, the summer solstice would have slipped into April, the dog days into May, spring into January, and the winter solstice into October; and so, step by step, all these would have moved on into month after month. From this it would follow not only that the celebrations of the several feasts were dislodged from their proper places, as we have said, but also that the whole ecclesiastical order hitherto observed in the performance of the divine offices was subverted and altered in an astonishing way. For the divine offices are so ordered and distributed that at fixed seasons of the year certain fixed lessons and histories from Holy Scripture are recited in the canonical hours, and these are assigned to certain months as well. Since, then, all the months were migrating from one part of the year into another and yet another, with no moment of time's intermission — as has been said — if the calendar had remained uncorrected and unemended, who does not see that the lessons and the histories from Holy Scripture would have had to be recited at a different season of the year from the one for which they were instituted? And this must be said much more emphatically of certain prophecies, above all those read at the Ember days in the most holy sacrifice of the Mass. I pass over the fact that, had the calendar not been restored, the histories both of divine and of human affairs and the chronologies would have been thrown into obscurity — works composed by our forebears with such care and diligence, and the knowledge of which usually brings no small help and advantage both to the public and to private persons. No less would those things be disturbed which are written in the books of the ancients on agriculture and navigation. For it is often prescribed that this is to be done in such a month and that in another, that a voyage is to be undertaken on these or those days of the year, while on others sailing is dangerous. None of this

would any longer hold good once the months, as has been said, had changed places among themselves — since they are all referred to the equinox, which used to fall in March. By the same reasoning the sixth month from March would be wrongly named Sextilis, and likewise those that follow, September, October, November, and December: for they would no longer preserve that order reckoned from the vernal equinox, which belongs to the first month and which would have receded from March.

5 THEREFORE, in order that all these drawbacks and absurdities we have listed might be avoided, and that posterity might not fall into greater ones, it was altogether necessary that the year and the calendar be emended — that is, that the vernal equinox be restored to its original seat assigned to it by the Fathers of the Council of Nicaea, namely 21 March, and that the new moons be shown by the numbers set out in the calendar in such a way that their full moons (for the Church takes more account of full moons than of new moons, on account of the feast of Easter, as will be said in its place) should not, so far as can be managed, differ from those which astronomical calculation yields according to the mean motion. But since the equinox could not be restored to its seat except by removing a certain number of days, it followed necessarily that the solar cycle, or cycle of the dominical letters, in use in the Church of God down to this time, had to be interrupted — as will also happen whenever a day is taken from the year in order to keep the equinox in its place. It was necessary, then, to renew this cycle as well, in such a way that by it the dominical letter proposed for any given year could be found after the correction of the calendar just as before, even though a day is sometimes removed from the year. And so the whole business of the correction of the calendar consists in three things: the restoration of the equinox and its retention in its proper seat; the emendation of the new moons; and the renewal of the solar cycle. That these were rightly set in order by Gregory XIII, and by what method it was done, we shall make plain in what follows.

[Margin: The necessity of correcting the calendar.]

[Margin: That the correction of the calendar consists in three things, and what they are.]

CAPVT III.

Why the vernal equinox was recalled to 21 March in particular, and by what method.

AMONG those who have written on the emendation of the calendar, opinions about the restoration of the equinox varied. Some judged that it should be left on the day on which it was found at the time of the correction, namely 11 March. Others maintained that it should be recalled to the 25th of that month, that is, to the day of the Lord's Incarnation, because they held that the Incarnation of the eternal Son of God took place at the vernal equinox. Most, finally, on more prudent counsel, argued that it should be restored to 21 March, where it was found to fall, near enough, at the time of the Council of Nicaea. And Gregory XIII rightly embraced their opinion, inasmuch as it

[Margin: The various opinions about the restoration of the equinox.]

involves less novelty and change — as will be evident from the drawbacks of the other opinions. For if the equinox had been left around 11 March, where it stood before the correction, or had been recalled to 25 March, or to any other day whatever different from 21 March, the Church would have had to alter all the Paschal limits established by the authority of the Council of Nicaea, and to renew all the breviaries and missals — since all these are arranged and ordered as though the vernal equinox fell perpetually on 21 March. No one doubts how great a disturbance this would have brought upon the faithful, had they seen Easter and the other movable feasts celebrated on different days now from those on which the ancient Fathers celebrated them; and especially since it would have brought no small loss upon churchmen, on account of the waste of very nearly innumerable ecclesiastical books, and the immense expense that would have been required for buying new books used in the worship of God. For most churches and monasteries have libraries of such books valued at many thousands of gold pieces, and all of these would have been rendered useless. To this must be added that, since all the Eastern churches — which are numerous, and of which the greatest account had to be taken — most religiously observe the canon on the celebration of Easter confirmed at the Council of Nicaea, the vernal equinox could not be recalled to any day with greater convenience for all the churches than to 21 March, where it stood at the time of the Council of Nicaea. For in this way the decree on the celebration of Easter enacted by the Fathers in that council has remained wholly intact and unimpaired. Finally, since the greater part of the martyrs, doctors, confessors, and virgins whose feasts the Church devoutly venerates in grateful memory flourished around the time of the Council of Nicaea — the martyrs a little before, under Decius and Diocletian, those most cruel persecutors of the Church of God, and the confessors at the very time of the council or a little after, in the days of Basil, Gregory of Nazianzus, John Chrysostom, [John] Damascene, Ambrose, Augustine, Jerome, Leo, Gregory the

Great, and when the deserts of Egypt and Palestine were crowded with a countless multitude of monks and anchorites under Paul, Antony, and Hilarion, those most holy hermits — the equinox could not be recalled to a more suitable time than to the time of the Council of Nicaea, so that the feast-days of the saints should recur and be celebrated each year at seasons that fit, that is, not far from those on which they lived on earth and illuminated the Catholic Church by their example and their teaching. For if it had been carried back to the time of the Lord's Incarnation, or retained in the place where it was found before the correction, the dates of all those saints would have been thrown into confusion and disorder.

[Margin: Which opinion Gregory XIII followed in restoring the equinox.]

[Margin: The drawbacks of the other opinions about the restoration of the equinox.]

2 THE equinox, moreover, was restored by Gregory XIII, Supreme Pontiff, to 21 March by the removal of ten days from the month of October in the year 1582 (which for that reason will be called the year of the correction, and will stand as the most celebrated of years among posterity), in such a way that after the fourth day of October, which is sacred to St Francis, the fifteenth was immediately taken up in place of the fifth, the ten days lying between being wholly omitted for that year. For by this means it came about that the vernal equinox fell, in the following year 1583, and will fall in the years thereafter, ten days later than before this correction; and so, whereas it previously occurred around 11 March, it is now seen to fall near the 21st, just as in the times of the Council of Nicaea.

[Margin: By what method the vernal equinox was restored to 21 March.]

[Margin: That the year 1582 is to be called the year of the correction, because in it the correction of the calendar was carried out by Gregory XIII.]

3 THIS restoration was also made by the removal of ten days from a single month, namely from October, and not by the omission of ten intercalary days over 40 years, nor by the subtraction of those same 10 days from 10 months, taking one day away from each month — which some would have preferred. This was partly because much could have occurred in 40 years to impede the correction, especially on account of the frequent change of supreme pontiffs over so many years; and partly also because the cycle of the dominical letters would have had to be interrupted more often, which would have been an inconvenience — whereas in our present restoration it has been interrupted only once, and that of necessity.

[Margin: Why ten days were removed all at once from the year 1582, and not one by one in single years or months.]

IF anyone should further ask how it came about that the equinox abandoned its original seat, that is, 21 March, and climbed to the 11th of that month, let him understand that the cause of this is that Julius Caesar, whom the Roman Catholic Church has followed, assigned more than was right to the length of a single year. For he made the solar year 365 days and 6 hours. And because in the civil and political year, which comprises only whole days (for the hours left over beyond the days cannot be written into it, or the beginning of the year would always be shifting), he left out those six hours which in four years make up a whole day, he decreed that in every fourth year one day, made up of 24 hours, should be intercalated, and that the year should then be one of 366 days — which they called bissextile. But the true solar year, which they call the tropical year, is not so long: it is shorter by several minutes of an hour, comprising, according to the Tables of Alfonso, King of Spain, 365 days and only 5 hours 49 minutes 16 seconds. This length of year is in a way midway between the greatest and the least length of the year. For, as we shall say more fully in chapter 6, the more skilled astronomers have observed that the solar years are unequal: they affirm that the year was greatest in the times of Hipparchus and Ptolemy, least in the age of al-Battānī [Albategnius], and in a way intermediate around the times of King Alfonso, and that it has now again reached very nearly its greatest length. And so the Roman year, which is in use in the Church, exceeds the Alphonsine year — which we have said is roughly midway between the greatest and the least — by 10 minutes and 44 seconds of an hour. From this it comes about that by just so many minutes and seconds the equinoxes and solstices run ahead of their places in every Julian year; for when the Sun, by its own motion, according to the Alphonsine tables, returns to the same equinoctial or solstitial point from which it departed, there are still lacking, to complete the Julian year, those 10 minutes and 44 seconds of an hour which we have mentioned. Accordingly, by the same tables, the equinoxes and solstices run ahead of their places by one full day in about 134 years, and by about three days in 402 years. But if the length of the year that the Church uses agreed in every respect with the annual motion of the Sun, no anticipation of the equinoxes and solstices would be observed, but they would recur on the same days of the year.

[Margin: Why the equinox anticipates[?] its seat in the calendar.]

[Margin: The length of the year according to Julius Caesar and the Church.]

[Margin: The length of the year according to the Alphonsines.]

[Margin: When the year was greatest and when least, and when it was of middling measure.]

[Margin: By how much the Roman year exceeds the Alphonsine year.]

[Margin: In how many years the equinox anticipates one day, according to the Alphonsines.]

IF anyone should also wish to know why that removal of ten days was made from the year 1582, in the month of October, and not rather from some centesimal year, or from some other bissextile year, and not in October but in some other month whatever — for this might well trouble an inquisitive reader — the explanation is ready to hand. Those ten days could indeed have been removed from any year whatever, and from any month as well, but the year 1582 was chosen in particular because

[Margin: (continued from the preceding page) Why the correction of the calendar was set in the year 1582, and in October rather than in another month.]

— because at that point everything necessary for the correction had at last been settled and completed. The replies of the Emperor, of all the kings, princes, and republics, and of the principal universities had already been delivered to the Supreme Pontiff and examined with the greatest care by the mathematicians convened for the reform. And so, to keep the restoration of the calendar — which all the Christian princes and states had praised and approved so warmly — from being deferred any longer, the Supreme Pontiff decided to assign the year 1582 to the correction that had been so long desired.

AS for its being done in October rather than in some other month, there was no other reason, and no further mystery is to be looked for here: that month was simply judged the fittest for the business, since it has more days free of saints' feasts. The result was that removing ten days from it caused less disturbance and confusion for churchmen in the discharge of the divine offices. Admittedly few saints' feasts are celebrated in February, March, and April either; but because Septuagesima, Lent, and the Paschal season fall in those months, it was judged that they should not be deprived of ten days, so that those seasons, which the Church observes with the deepest devotion, might run their course in unbroken sequence. There was a further consideration: if, for example, Septuagesima had then been kept on 14 February by the new calendar, with the ten preceding days omitted, there would have been only four Sundays after Epiphany, and the remaining two could not have been inserted before Advent, since in that year there would have been only twenty-four Sundays after Pentecost.

[Margin: Why in the year 1583, in the more remote regions, the correction was ordered to be made in February rather than in another month.]

6 SINCE some provinces had not yet removed the ten days from October of the year 1582 — copies of the new calendar could not be conveyed to them so quickly — it was very wisely decided that in the following year, 1583, without waiting for October, the ten days should be taken out of February, so that those peoples should not remain any longer at odds with the Roman Church in the numbering of the days. For although in that year those who had not yet reformed the calendar would have kept Easter on the same day as we did, they would still have differed in the number of the day, since we would have kept Easter on 10 April and they on the last day of March. There is therefore no reason for anyone to be troubled or anxious in searching out why the Supreme Pontiff wished the restoration of the calendar to take place in the year 1582 in particular, in the month of October, and in the year 1583 in the month of February.

[Margin: If the new calendar had been corrected in February of the year 1582, it would have given Easter more correctly than the old one did.]

7 THERE are nevertheless some who think themselves more intelligent and more knowledgeable than everyone else, and who — in order to find some fault with this Gregorian correction — do not scruple to assert that the ten days were removed from October of 1582 and not from February because, if the calendar had been restored in that year before Easter, Easter would have been celebrated contrary to the decrees and enactments of the Fathers; and that the reform was postponed to October precisely so that this should not be noticed by everyone at the very outset of the correction. In this they are wonderfully mistaken, and (as the saying goes) miss the whole sky. For if the new calendar had begun before Easter, Easter would have been kept lawfully according to the canons, whereas by the old calendar it was kept contrary to the decrees of the Fathers. In the year 1582 the golden number was 6, which would have given the epact 26 if the ten days had been taken out of February; and that epact places the Paschal term, that is, the fourteenth day of the Moon, on 17 April — on a Saturday. Hence, the following Sunday falling on the 18th, Easter would have been celebrated after the full moon, both mean and true; for the mean full moon by the tables of Giovanni Antonio Magini [Magini] occurred then on 17 April at about hour 8 after noon, and the true one on the same day at about hour 15 after noon — all of which agrees with the canons. But in that very year, before the correction, Easter was kept on the twenty-second day of the Moon, that is, in the fourth week, contrary to the enactments of the Fathers and the councils; whereas by the new calendar it

would have fallen on the fifteenth day of the cycle's Moon, that is, at the beginning of the third week, in which alone Easter can lawfully be kept, as we have said.

CAPVT III.

Ecclesia cur posthabitis motibus veris apparentibusue, medios tantum, siue æquales, aut potius cyclos in mobilium solemnitarum celebratione vsurpet.

(Why the Church, setting aside the true or apparent motions, uses only the mean or uniform motions — or rather cycles — in the celebration of the movable feasts.)

[Margin: That the Church considers only the mean motions, for many reasons.]

NOW that the equinox has been restored to its original seat, where the Fathers of the Council of Nicaea found and fixed it, a method and a means also had to be laid down for keeping it in that seat so far as this is possible, so that it should not, as before, abandon its place and creep forward little by little toward the beginnings of the months, and so throw the calendar back into the same errors. To make that method clearer, it must first be explained rather carefully which motions the Church takes into account and applies in the observance of the movable feasts. Once this has been set out, it will be perfectly plain how rashly and groundlessly certain men have tried to introduce the true motions into the Church. For the Church sets aside the true motions of the Moon and the Sun — these belong rather to astronomers — and considers only the mean and uniform motions, or rather cycles, which advance in a steady and even order. Many reasons can be given for this.

[Margin: 1st reason. Because the mean motions are equal and uniform, and therefore suited and convenient to ordinary people's grasp; whereas the true motions are unequal and irregular.]

FIRST, because the true motions are unequal, now faster, now slower, whereas the mean motions are always equal and uniform, and can therefore easily be reduced to a cycle, which the true motions cannot. Since, then, easy rules had to be handed down for finding the equinox, the new moon, and the Paschal full moon — rules that anyone, even one wholly untrained in and ignorant of astronomy, could grasp and hold without great labour and without any knowledge of astronomical tables (for the whole people cannot be compelled to master astronomy, which would be something new and unheard of, and in fact quite impossible) — the mean motions had to be adopted rather than the true, especially because error can more easily creep into the true and apparent

motions than into the mean and uniform ones. Nor does it much matter that the true motions really exist in the heavenly bodies, while the mean ones have been devised by astronomers only in thought and by art,

so that they may investigate the true motions through the mean. For the Church is not bound, and never has been, by the exact laws and motions of the stars; it is enough for her if she can follow the motion of the Sun or the Moon with what is called a "rough-and-ready wit" [pingui Minerua], provided it does not depart far from the truth. This is clearly demonstrated by the most ancient practice, continued and carried on from the primitive Church down to our own age.

[Margin: 2nd reason. Lest a perpetual seedbed of quarrels and discords be stirred up in the Church, if the true motions were observed, on account of the variety of the astronomical tables.]

2 NEXT, because if the Church chose to use the true motions, there would be a perpetual seedbed of discord and quarrelling among the faithful of Christ over the celebration of the most holy Easter, on account of the variety and disagreement of the astronomical tables and the differing hypotheses of the motions, some contending that these tables should be followed, others those — just as today we see some using the Alphonsine tables and others the Prutenic tables, drawn from the doctrine of Nicolaus Copernicus, in investigating the motions of the stars. The result would be that different people would observe different equinoxes and new moons, and so would not celebrate Easter at the same time — which would be thoroughly discordant and absurd, not to say ruinous.

[Margin: 3rd reason. Because to this day no tables have existed[?] that would exhibit[?] the true motions[?] without error over many years.]

3 THIRD, because down to this day no tables have been drawn up by astronomers by which the true motions of the stars can be ascertained and known with certainty and without any error for every period; rather, everyone has always compiled tables agreeing with the observations of his own time, which after a long lapse of time were found to fall away from the truth — and this because no one has yet known and explored the periods of the celestial motions exactly and thoroughly. Ptolemy, the leader and prince of astronomers and a most skilful investigator of the celestial motions, compiled some 1470 years ago, more or less, tables agreeing with his own observations, by which at that time the motions of the heavens were computed with complete certainty and beyond doubt. Then, since experience had shown that these no longer presented the celestial motions

accurately, other tables succeeded them, called Alphonsine because they were drawn up by astronomers about 360 years ago at the expense and by the care and diligence of Alfonso, King of Spain; by these the motions were found more surely in that age than by Ptolemy's tables. Into their place there have now been substituted, in our own time, the tables of Nicolaus Copernicus, commonly called the Prutenic, because by the consensus of nearly all astronomers they agree with the celestial phenomena far more exactly than the Alphonsine. And so perhaps, after many centuries, our descendants will detect other periods of the celestial motions from their own observations, and will accordingly frame new hypotheses, and so substitute other new tables for the Prutenic ones.

[Margin: Why the Prutenic tables, which everyone uses today, may be judged uncertain.]

For who would dare affirm for certain that the Prutenic tables will agree with the motions of the heavens at every period, when he sees that the tables of Ptolemy — a most excellent astronomer, and one deservedly set before all others — are now defective and imperfect, though in those times they were the most perfect of all? And this all the more since the Prutenic tables rest on hypotheses that are highly uncertain, indeed absurd and repugnant to the common opinion of mankind, and against which all natural philosophers argue. There is this too: not one complete period of the anomaly of the precession of the equinoxes — on which Copernicus founds the whole inequality of the solar year — has yet been finished and completed; so that one may reasonably doubt the truth of tables built on that anomaly, and whether, when one period is complete, the next will correspond to the preceding one in every respect.

Since this is so, who will be so shameless and bold as to wish to bind the Church of God to such uncertain and deceptive precepts and tables of the astronomers? Surely no one, I think — unless someone should care to say that the Church ought to embrace now these tables, now those, according as she notices that at this or that time they agree with the motions of the heavens. But that would be nothing else than to call everything into doubt, since astronomers themselves could scarcely agree which tables were the more to be trusted. So too in our own age we see that there are most excellent mathematicians who hold that, in the motion of the Sun and the Moon, the Alphonsine tables are more to be believed than the Prutenic.

[Margin: That the equinox was rightly[?] restored to 21 March by the removal of ten days is confirmed by the observations of a certain[?] very accurate mathematician.]

I RECALL indeed that a distinguished mathematician found, by his own observation with exquisite instruments and with careful diligence, that in the year 1586 the vernal equinox — that is, the entry of the Sun into Aries — occurred on 10 March at hour 9 minute 2 after noon by the old calendar; whereas the Alphonsine tables give it nearly six hours earlier, and the Prutenic about 13 hours later. Here it plainly appears that the Alphonsine calculation comes closer to the observation just mentioned than the Prutenic or Copernican does. By the new calendar that same observed equinox falls on 20 March at hour 9 after noon, and so is assigned[?] to the following day, the 21st. From this it is also plainly evident that this correction of the calendar was excellently managed in removing ten days from the year 1582 in order to restore the equinox to 21 March. The same mathematician affirms, in book 1 of his *Progymnasmata* of astronomy to be restored [*Astronomiae Instauratae Progymnasmata*], that from the findings of Hipparchus and of other still older men it can be gathered that the exact length of the equinoctial year, taken universally, is 365 days 5 hours 49 minutes or thereabouts — just as the Alphonsine authors assert.

SO in order that this dissension and discord among astronomers might be removed, the Church has, by a most prudent counsel, always rejected the tables of the true motions, leaving them to the curiosity of astronomers, and has judged that the mean motions, which are equal and uniform — or rather cycles that agree very closely with the mean motions — should be used for the solemnities of the movable feasts.

[Margin: That the astronomical tables are of great value, even though they cannot last for a long time.]

I HAVE not brought all this forward because I think the astronomical tables should be rejected altogether as false and worthless. On the contrary[?], I have always judged astronomers worthy of praise, who in various ages have observed the motions of the stars with the greatest labour and study, and with admirable industry have worked out various tables for computing those motions easily — not indeed with perfect exactness, yet so as to fall little short of the truth — and have handed them down to posterity. I contend only this: that the Church should not be tied to the astronomers' fastidious subtleties, since the same tables cannot last long, but different ones must be used from age to age, as we have said. Nor does this detract at all from the dignity and excellence of astronomy, a most noble science; rather it commends it wonderfully, that it has set so great a variety of motions before our eyes so accurately that we come as close as possible to the truth itself.

[Margin: Where the inconstancy of the astronomical tables comes from.]

And what wonder is it that astronomers cannot perfectly grasp by understanding the motions of the heavens, which lie at so great a distance from us, when philosophers have not yet been able to attain complete knowledge of even one substance, however small, here in this lower world?

AND it certainly seems to me that God, best and greatest, the most wise architect of the heavens and the stars, deliberately willed the motions of the planets

[Margin: 4th reason. Because even if the astronomical tables were entirely perfect, the true motions would still be applied in vain, on account of the variety of meridians.]

and the stars to be wrapped in such great difficulties that no mortal could unravel and explain them by his own wit. For who, from the founding of the world down to our own time, has been found so excellent in astronomy as to define the periods of the celestial motions in such a way that after some centuries of years they should not depart at all from the truth — given the small quantities in every planet's period, in excess or in defect, which over a long interval of time introduce no slight error? The purpose, surely, was that we should always find in so admirable a workmanship of the noblest bodies, and in so constant a harmony and concord of their motions, something to marvel at, and should celebrate their creator and mover with unending praise. It is above all on account of the immense mass of the heavens, and their order and motions — in which there always seems to remain something for the most skilful investigators of celestial things to search out with the utmost diligence — that one may judge those words of Ecclesiastes, chapter 3, to have been written: *And he has delivered the world to their disputation*; namely, lest, if men understood perfectly the number, order, and motion of the heavens, they should cease to inquire into and admire the works of God, and their minds, deprived of the exercise, should in a manner grow torpid through inaction.

[Margin: But the true motions would be applied in vain, on account of the variety of meridians.]

4 FOURTH, the Church neglects the true motions and takes up the mean ones, or rather cycles, because even if astronomical tables existed that were absolutely perfect and wholly purged of every error, so that they were free of any fault, it would still be pointless — and without any necessity or usefulness — to employ, in the celebration of the movable feasts, that exact and fussy computation of hours and minutes according to the true motions. For however accurately both

the vernal equinox and the Paschal full moons were computed from the true motions, the variety of regions and meridians would still make that labour useless and vain. When, for instance, the vernal equinox falls at Rome at noon on 21 March, it will fall for certain more easterly peoples on the same 21st at sunset, for others at the middle of the following night — and so will have to be assigned to the next day, the 22nd, and so on. Likewise, if the true full moon then occurs at Rome on 22 March about noon, the same will happen among the nearer eastern peoples about sunset, and among the more distant about midnight, and so on. Hence, if in that year 22 March were a Sunday, Easter would indeed be kept at Rome according to the enactments of the Fathers and the councils; but among the more easterly peoples, especially the more remote, if they must attend to the true motion, it could not be kept, because for them the equinox falls on the 22nd and the time of the full moon has not yet come.

[Margin: 5th reason. Because it is the Church's most ancient custom to observe the mean motions and not the true ones — a custom that ought not to be changed without pressing cause.]

But it is established from the decrees of the Fathers that Easter cannot lawfully be kept on the very day of the equinox, but that the day of the equinox must have gone before; nor before the full moon, lest it be kept on the fourteenth day of the Moon or before the fourteenth. And since it was ordained in the Council of Nicaea that all should celebrate Easter in the month and on the day on which the Roman Church observes it — the same being afterwards confirmed in the Council of Arles and the fourth Council of Carthage, and asserted most clearly and at length by St Ambrose in his letter to the bishops established throughout Aemilia — it plainly follows that the Church cannot take account of the true motion of the luminaries in the celebration of Easter.

[Margin: That it does not much matter, so far as the Paschal feast is concerned, if the equinox does not always fall on 21 March.]

5 FIFTH, on account of the most ancient custom by which the mean motions, or rather cycles, have always been in use in the Church, the true motions being set aside — a custom that ought not to be changed without some pressing necessity. That the Church has not observed the true equinox according to the true motion is clearly demonstrated from the decree of the holy Fathers issued in the Council of Nicaea, in which they laid down for the whole world that the equinox was to be observed on 21 March. But it is obvious that the equinox cannot be tied and bound to a single day, either by the true motion or by the mean. For if in the year immediately preceding a bissextile year it falls on the 21st, it must in the

following bissextile year fall on the 20th, on account of the intercalary day added to February. Again, if in a bissextile year the equinox occurs about noon on some day, the same must necessarily occur in the year immediately following the bissextile at sunset of that same day, and in the second year after the bissextile at sunrise of the next day, on account of those six hours which are omitted in each common year — since in those years only 365 whole days are counted, although nearly six hours are left over in each year. From this it is clearly concluded that the decree can be referred neither to the true nor to the mean motion, but only to 21 March, on which the equinox generally occurred at that period, even though by astronomical calculation it was usually found to fall sometimes before that day and sometimes a little after. The point was that the equinox should not be observed by some on the 21st and by others on another day, if they chose to consult astronomical tables, and Easter accordingly be celebrated at different times — which would be absurd.

[Margin: That God, through Moses, prescribed the observance of the first month, and of the tenth day, and of the fourteenth, in a rustic or simple manner, adapted to the understanding of the whole people of Israel.]

NOR does it much matter, so far as the Paschal solemnity is concerned, whether the equinox falls on 21 March itself, or before it, or after it, provided it is not far from that day. For the Church has never been bound by such precise and subtle rules of the astronomers — since not even the Hebrews themselves, for whom everything was ceremonial, were commanded to observe the true or the mean equinox in the solemnity of the Passover, but only the season at which, by the judgement of the senses, the days become equal to the nights: a period which usually covers three or four days without any great difference.

THIS is gathered plainly enough from Holy Scripture. For God, through Moses, commanded the celebration of the Passover in these words, Exodus 12: *Mensis iste vobis principium mensium primus erit in mensibus anni, &c.* [This month shall be to you the beginning of months; it shall be the first among the months of the year, etc.] And a little later: *Et servabitis eum vsque ad quartam decimam diem mensis huius* [And you shall keep it (the lamb, that is) until the fourteenth day of this month]. Here the words *iste* ("this") and *huius* ("of this") are insisted on again and again; by which God seems to signify that he did not wish to alter the customary form and numbering of the Hebrews' year and months, but only the change of the seventh month into the first — as though it were said: this month, which hitherto in Egypt you have reckoned and named the seventh according to the common usage of the year and not according to astronomical calculation, shall

henceforth be for you the first of the whole year, and in it you shall celebrate the Passover.

[Margin: That the Church is not to be very anxious about true or mean new moons and full moons, since in investigating them she has always used cycles.]

Nor can it be said that Moses, instructed by God, was then ignorant of the true magnitude of both years, solar and lunar, for that would be ridiculous. Rather it should be said that Moses spoke to the understanding of ordinary people, who know no astronomy, since he was addressing the whole assembly of the children of Israel; and that he named the first month not in the astronomical way — namely, when the Sun enters the first point of Aries — but in a quite common and plainly rustic fashion, that is, *Abib* in Hebrew and [Greek: ἀ[?]ιβ — the printed form does not resolve; the month-name Abib transliterated into Greek] in Greek, which in Latin means "the month of the new produce," or "of the crops," since in spring the new crops are gathered in Egypt.

NOW as to investigating the new moons and full moons, the Church does not take much trouble over the true or the

or the mean motion. This is clear from the fact that, in investigating them, she has from the very beginning always used lunar cycles — that is, nineteen-year cycles — which can in no way agree in every respect with the true or the mean motions. For according to the cycles the lunations comprise whole days, whereas according to both the true and the mean motion they contain, over and above whole days, a number of hours and fractions of hours. Add to this that in bissextile years the lunations in the cycle fall one day later after the intercalary day, and no account can be taken of this until a good many years have elapsed, as will become clear below when I set out the theory of the nineteen-year cycle of the golden number. And indeed, so far as the lunar cycle is concerned, the Church in this matter follows not only the Hebrews, the Alexandrians and the Romans, but also the Chaldeans, the Arabs, the Athenians, and the peoples of virtually every age — all of whom, both long before the coming of Christ and afterwards, used lunar cycles for finding the new moons. Paulus de Middelburgo [Paul of Middelburg] sets them all out in Book 2 of his *Paulina*.

[Margin: That in adopting the lunar cycle the Church follows the common practice of antiquity.]

6 SIXTHLY, the same point is confirmed by the authority of many astronomers, and of all who have written from the Church's own usage on matters pertaining to the Roman calendar. Chief among these is Campanus [Campanus of Novara],

who states at the beginning of his larger *Computus*: "The computus is the science of the numbering and division of times" — I use his own words — "according to common observances." And at chapter 15 he teaches that "the computists, leaving the true lunations to the astronomers because of their intractable variability, have concerned themselves only with the mean lunations, on account of their uniformity."

[Margin: 6. Reason. Because various writers and computists testify that they do the same.]

JOHANNES Stoflerinus [Johannes Stöffler] likewise, in his *Calendarium Romanum*, proposition 34, capital letter Z, teaches that the universal Church, from the Council of Nicaea down to the present day, has used for the celebration of Easter the cycle of the golden number taken over from the Alexandrians, who had used it earlier. A little further on he affirms that the golden numbers written in the calendar indicate the days of the mean conjunctions of the luminaries, and so forth. And somewhat later he writes that the orthodox Church, and especially the Latin Church, used the customary lunar cycle instituted by Julius Caesar for finding the fourteenth day of the Moon for Easter even before the Council of Nicaea. He repeats the same thing in many other places.

PAULUS de Middelburgo, Bishop of Fossombrone, likewise writes as follows in his *Paulina*, Book 10, about the middle, a little before the table of equinoxes, after a long discussion of the varying and unequal length of the year: "This variation in the length of the solar year does not, however, hinder our own operation of drawing up a rule for the Paschal solemnity, since the Roman Church in the Paschal computation does not observe the varying motions, or the extreme ones, on account of their variability, but only the mean and uniform ones. Now the mean length of the year, between the greatest and the least, is 365 days, 5 hours, 49 minutes, 16 seconds." And he immediately adds: "Therefore, setting aside this scruple about the equation of the solar year, which is necessary for astrologers, we shall here describe the vernal equinoxes for the first month, suited to the Paschal rule, according to the computation derived from the Alphonsine tables, etc."

7 From all this I believe it is sufficiently established that neither the day of the vernal equinox nor the Paschal fourteenth days of the Moon need be examined by means of ephemerides and astronomical tables of true or mean motion — as some people, relying on I know not what authority, vainly contend — but that it is enough for them to be found by popular rules, easy to grasp and still in use in the Church, such as the cycles are. I would not, however, deny that mean motions

drawn from astronomical tables — not true ones, since the latter are unequal while the former are equal — are of the greatest use in deciding which of all the cycles set out in the calendar most correctly exhibits the Paschal fourteenth days of the Moon. What has been set out in this chapter refutes and overturns all the arguments that are commonly raised against the new calendar by people with little training in the ecclesiastical computus, since all of those arguments test the calendar by true or mean motions, which is beside the point.

[Margin: That the mean motions are useful for deciding which of several cycles more correctly exhibits the fourteenth days of the Moon in the calendar.]

CAPVT V.

Quæ intercalandi ratio adhibita sit, vt æquinocmium prope diem 21. Martij, ad quem est reuocatum, retineatur.

What method of intercalation has been adopted, so that the equinox may be kept near 21 March, the day to which it has been recalled.

So that the vernal equinox may not, with the passage of time, again desert 21 March, the day to which it has been restored, and move back toward the beginning of the month as it did before the correction of the calendar, this method of intercalation has been established: the customary practice of intercalating one day every fourth year is indeed retained, but not all centesimal years are henceforth to be bissextile (although by the usual rule for bissextile years they all ought to be). Rather, the first three centesimal years after 1600 are to be common years — that is, of only 365 days — namely 1700, 1800 and 1900; while the fourth following centesimal year, that is 2000, remains bissextile, of 366 days. Likewise the next three centesimal years, 2160, 2200 and 2300, become common in the same way, and the next fourth centesimal year, 2400, remains bissextile. And so on thereafter, the same order always being kept.

[Margin: 1. What method of intercalation has been adopted, so that the equinox may be preserved near 21 March.]

The rationale of this intercalation, since it is sharply attacked by a good many people — even by some who are not merely ordinary experts, but who consider the matter less [?] carefully than they should — must be explained here somewhat more fully, especially since it is one of the chief points of this correction. My aim is that everyone should understand that no more convenient method of intercalation could have been devised, and that it is therefore criticized unjustly by certain people. To make this plainer, a few things must first

be said about the varying length of the year as determined by astronomers at different periods. To begin from this point, then: the solar year is of two kinds, astronomical and civil.

The ASTRONOMICAL year is the interval of time in which the Sun by its own motion runs through the whole zodiac from west to east, beginning from some fixed point — for instance from the first point of Aries — until it returns to that same point. This interval of time comprises, over and above 365 whole days, 5 hours and some further minutes of an hour, as is sufficiently clear from the astronomers' observations, and as I shall show shortly.

[Margin: What the astronomical year is.]

3 The CIVIL year consists only of whole days: sometimes of 365, and then it is called a common year; sometimes of 366, and then it is called bissextile or intercalary. Nor can the civil year be reckoned in any other way than by whole days, with the hours and fractions of hours disregarded, since it was instituted for the use of the people at large, who do not grasp a reckoning of the year by days with hours and minutes of hours. Such a reckoning of the year could not be laid out in a calendar, nor would it be suitable or adapted for conducting trade and other civil business, or for keeping feast days and duly performing the sacred ceremonies of the Church — because a year counted in that way begins now from noon, now from sunset, now from midnight, now from sunrise, and now from some other moment of the day; whereas in the calendar neither hours nor minutes of hours are entered, but only whole days.

For example: the year 1600, if hours and minutes are taken into account, begins according to the ephemerides of Giovanni Antonio Magini on 20 March at 8 hours 49 minutes 33 seconds after noon. The next year, 1601, begins on the 20th at 14 hours 45 minutes 36 seconds after noon; the year 1602 on the 20th at 20 hours 41 minutes 20 seconds after noon; the year 1603 on the 21st at 2 hours 37 minutes 20 seconds after noon; and finally the year 1604 begins again on 20 March at 8 hours 33 minutes after noon. Here you see that the year never begins at the same moment of time — a state of affairs that can in no way suit the use of the people, unless we want everyone to be trained in astronomy, which is both ridiculous and altogether impossible.

[Margin: What the civil year is.]

[Margin: That the astronomical year does not always begin at the same moment of the same day.]

4 But although this division into days, hours and fractions of hours cannot, as I have said, be carried over into common use, knowledge of it is nevertheless necessary, so that the civil year, consisting of whole days, can from time to time be equalized — now by adding, now by subtracting a single day, made up out of the omitted hours and their fractions — in order that it may agree as far as possible with the astronomical year, and that the Sun may bring about the equinoxes and solstices at roughly the same seasons of the year.

[Margin: That knowledge of the astronomical year is necessary, so that the civil year may be equalized.]

It is for this reason that the Church, following the institution of Julius Caesar, adds one intercalary day to the year every fourth year, making it 366 days, while the other three preceding years comprise only 365. For since the Church, following Julius Caesar's widely accepted rule, sets the astronomical year at 365 days and 6 hours, while the civil year takes in only 365 days, it comes about that in the first civil year 6 hours are lacking to complete the astronomical year, in the second 12, in the third 18, and in the fourth 24 — which make up one natural day. Every fourth year, therefore, must be made 366 days, so that those 24 hours are not neglected. Otherwise the equinoxes and solstices would fall one day later than they are marked in the calendar; after another four years, two days later; and so on, so that in 120 years they would slip toward the end of the year by a whole month, that is by a full 30 days, and would not return to their former seats until after 1460 years. In that span of time the vernal equinox would run in a circle through every month and indeed through every day. Who does not see what confusion of the seasons this would bring?

[Margin: Why every fourth year is bissextile.]

[Margin: That the equinox, if all years were common, would run through all the days of the year in 1460 years.]

5 But since the solar year has been observed by astronomers to be somewhat less than 365 days and 6 hours, the result is that every fourth year more is intercalated than ought to be, since the hours and fractions by which the astronomical year exceeds the civil do not add up to one whole day in four years. Unless, therefore, account is taken of those fractions which in each four-year period fall short of completing a whole day — so that, when they have grown to a whole day, one day is removed from the year, that is, the intercalation is omitted once — the equinoxes and solstices will gradually move forward toward the beginnings of the months, as happened before the correction of the calendar. To

prevent this happening in future, this remedy has been devised: that some year which ought to be bissextile is made a common year of only 365 days, and not an intercalary one of 366, as will be said more fully below.

I cannot sufficiently wonder what came into the mind of the historian Dio when, in Book 43, about the middle, he says that if intercalation is made every fourth year, it is necessary to intercalate one day out of the regular order in the space of 1461 years. For this is not true unless the year is set at 365 days, 6 hours, 0 minutes, 59 $\frac{3}{7}$ seconds — a length of the year which I do not recall having read in any author.

But in order to determine in how many years' space the fractions of hours which in each astronomical year fall short of completing six hours make up one whole day — and therefore in how many years one intercalary day ought to be omitted — we must consider attentively and carefully what has been recorded about the length of the year from the observations of the more famous astronomers.

[Margin: That the intercalation of one day every fourth year is greater than it ought to be; and why.]

[Margin: What is to be done so that the equinox is not anticipated.]

6 Leaving aside, then, the more ancient astronomers: Ptolemy, about the year 130 after the birth of Christ, found by his own observations that the length of the year was 365 days and 6 hours less a three-hundredth part of a day — that is, over and above the whole days, 5 hours 55 minutes 12 seconds.

AL-BATTĀNĪ, about the year of the Lord 880 — that is, 750 years after Ptolemy — found that the year contains 365 days, 5 hours, 46 minutes, 24 seconds.

The ALPHONSINE tables, which were compiled about the year of the Lord 1250, lay down that the year consists of 365 days, 5 hours, 49 minutes, 16 seconds.

[Margin: The length of the year according to Ptolemy.]

[Margin: The length of the year according to al-Battānī.]

[Margin: The length of the year according to the Alphonsine tables.]

These are the most celebrated opinions about the length of the solar year, and from them it is clear that the solar year is now longer, now shorter, since it has been observed differently, and variously at various periods, by the most skilled astronomers. The ancient astronomers were indeed led by a highly probable conjecture to suspect that the solar year cannot always be of the same length,

both because of the unequal and irregular apparent motion of the Sun and because of the irregular motion of the eighth sphere [sphaera octava]; but since this matter cannot be fully known until many centuries have passed, they left us nothing certain about the inequality of solar years.

7 One man alone within human memory, Nicolaus Copernicus, the outstanding mathematician of our age, comparing his own observations most carefully with those of Hipparchus, Ptolemy, al-Battānī and the Alphonsine astronomers, ventured with great skill — using new hypotheses — to demonstrate the increase and decrease of the solar year, and to reduce the year's inequality to a fixed and definite rule. By a calculation drawn from his own hypotheses he found that the solar year, when it has grown to its greatest length, is a little longer than the one Ptolemy determined, namely 365 days, 5 hours, 55 minutes, 57 seconds, 40 thirds; while when it has diminished to its least, it is a little shorter than the one al-Battānī found, that is, 365 days, 5 hours, 42 minutes, 55 seconds, 7 thirds — so that the length of the Alphonsine year is very nearly midway between

[Margin: Copernicus's observations on the inequality of the year.]

the greatest and the least length of the year. On this inequality of the years I shall write more in the following chapter.

8 Since this was the state of the question, it was genuinely difficult for Gregory XIII, that most prudent pontiff, to determine what method of intercalation he should prescribe in order to keep the vernal equinox on 21 March or near it. For the length of the Ptolemaic year required that roughly every three-hundredth year one intercalary day should be omitted, because that year is shorter by a three-hundredth part of a day than the Julian or ecclesiastical year of 365 days and 6 hours, and therefore over a space of three hundred years the equinox moves forward by one day from the seat assigned to it in the calendar toward the beginning of the month. But according to al-Battānī's year, roughly one intercalary day would have to be omitted every hundredth year, since in that span of years the equinox, according to the length of his year, anticipates its own seat in the calendar by about one day. Finally, if the Alphonsine year were taken as the measure, the intercalation of one day would have to be omitted once in about every 134 years. And this variation in intercalating would grow daily, as the varying length of the year lay between the greatest and the least year. Where, then, was the pontiff to turn? What path was he to set before himself to follow?

[Margin: In how many years an intercalary day would have to be omitted according to Ptolemy.]

[Margin: In how many years, according to al-Battānī's year, the intercalation would have to be suspended.]

[Margin: In how many years the Alphonsine year requires the omission of one intercalary day.]

9 Two paths above all were proposed to him by the distinguished astronomers in charge of the business. The first was that, in accordance with the inequality of the solar year, one intercalary day should be removed now at a longer interval of years, now at a shorter, according as the year turned out longer or shorter by Copernicus's calculation (for they judged that his was to be preferred to the others). The second was that, setting aside the inequality of the year, the method of intercalation should be fitted to the Alphonsine year, which is in a way midway between the greatest and the least. Both paths were sent out in the year of the Lord 1577, in the *Compendium of a new plan for restoring the calendar*, to the Christian princes, the commonwealths and the more famous universities, so that after careful and long and thorough consideration it might be deliberated which of the two seemed the more apt and suitable, in order that the supreme pontiff might approve it by his authority as representing the consensus of the whole Christian world. That *Compendium*, of which I have spoken, we have set out at the beginning of this work in exactly the same words in which it was sent to the princes, with nothing altered, both because frequent mention of it must be made and so that its memory may not perish. When the *Compendium* had been read through and maturely considered, all — with at most one or two exceptions — left the whole matter to the pontiff's judgement; and he at length chose the second method, on the advice of the astronomers, chiefly for the following reasons.

[Margin: The two paths of intercalation proposed to Gregory XIII for keeping the equinox on 21 March.]

[Margin: Which method of intercalation was chosen.]

10 FIRST, because in the celebration of Easter the Church must follow something regular and uniform and fixed, and not far from the truth, rather than an exact astronomical computation, since the measurements of years, months and other periods of time must be adapted to the understanding of ordinary people. The first path of intercalation, therefore, seems on no account to be adopted, because it is uncertain, irregular and unequal, seeing that on it the intercalary day would at one period have to be omitted after more years and at another after fewer. And what else would that be than to cast the whole Christian people into inextricable

snare, since they would be perpetually doubtful and uncertain as to when the intercalary day was to be omitted? Nor can it be said that the Church ought to put before the people a table of intercalation in which the years are set down in which intercalation is not to be used; for a conflagration of disagreements and intolerable seditions would be kindled among the astronomers, since each would press his own calculation as the one to be followed in this business — inasmuch as, on the one hand (as I said in the preceding chapter), one man maintains that these tables are to be adopted, and another those.

For what other reason, I ask, did so many disputes and contentions over the celebration of Easter arise between Greeks and Latins from the Council of Nicaea down to the time of the Emperor Justinian, except that in that council those most holy Fathers did not lay down some fixed cycle for the whole Church to observe, but entrusted that care to Eusebius, bishop of Caesarea, and to the Alexandrians? For this is how it came about that the Latins contended that Easter was to be celebrated according to one cycle and the Greeks according to another, until in the time of Justinian the Elder Dionysius Exiguus, the Roman abbot, inscribed the Alexandrian cycle in the Roman calendar, which thereafter all the churches followed with one accord — as was in fact done by the Eastern Church as well as the Western, right down to this Gregorian correction.

If, then, Gregory XIII, that most prudent pontiff, had not prescribed some even and regular formula of intercalation, but had left that care to the astronomers free and unrestricted, so that they might draw up tables from the true motion listing the years in which intercalation was to be suspended — who does not see that there would have been perpetual quarrels and dissensions among the astronomers, each pressing his own calculation upon the Church? But I think I have already shown, in the preceding chapter, more than adequately that true motions are not necessary to the Church.

One definite length of the year, therefore, had to be chosen, so that a rule might be established according to it by which the intercalation would be suspended at some fixed interval of years. For in this way both the common and unlearned people are better provided for, and every occasion of discord among the astronomers is entirely removed.

[Margin: 1. Reason. Why in the correction of the calendar the mean length of the year was adopted.]

[Margin: That an unequal year is not suited to establishing a rule of intercalation.]

THEREFORE, since the year is unequal — greatest, least, and middling or mean — the greatest cannot be adopted for this purpose, because the intercalation would be omitted too rarely, that is, only once every three hundredth year. And although this rule would answer exactly to the Sun's motion at the period when the year had grown to its greatest length, it would nevertheless be very far from the truth when the same year had reached its least length.

For the same reason neither can the least year be suitable for the matter, because it would demand too frequent an omission of the intercalary day, and would answer to the Sun's motion only at the period when the year was running at its least.

[Margin: Why the greatest year is not suited to the equation of the solar year.]

[Margin: Why the least year is not suited to the equation of the solar year.]

The only year fit for this office, therefore, is the one midway between the greatest and the least — such as the Alphonsine is. For whether at some period the year is found to be longer or shorter than the middling one, we shall be able to depart little from the truth if we set up the omission of the intercalary day according to the length of that middle or middling year, since then the intercalary day is removed neither too rarely nor too frequently, but a certain mean rule is always preserved. Indeed, this method of intercalation corrects and amends itself: for when at one period the intercalary day is omitted more often than is fair, this error is compensated at another period, when the intercalary day is removed more rarely, and conversely.

[Margin: Why the mean year — that is, the Alphonsine — is alone suited to equalizing the solar year.]

[Margin: How the rule of intercalation established on the mean year amends itself.]

This will be plain from the calculations of a number of years at the end of chapter 6, where it will appear clearer than daylight that an even equation can be established only on the middling year, and not on the least or the greatest: seeing that

seeing that the equations of those years drive the equinox, after a certain number of years, very far from its own seat and station, whereas the equation of that other year — the mean year, that is — keeps it near 21 March, which is its proper seat, so that it cannot stray far from it even over many thousands of years.

Nor can any other drawback (if it can even be called a drawback) follow from this omission of the intercalation established on the mean length of the year, except this: in a maximum year we take away the intercalary day sooner than is needed, and so the equinox retreats a little from 21 March toward the end of the month, and the ecclesiastical equinox, fixed to the 21st, comes before the true one; whereas in a minimum year we omit the intercalary day later than is fair, and so the equinox leaves 21 March and moves toward the beginning of the month, so that the ecclesiastical equinox falls after the celestial, or true, one. That this is not absurd, but on the contrary thoroughly in keeping with the Church's practice, will be understood from what follows.

[Margin: No drawback of any consequence follows from the intercalation established on the mean year.]

11 Next, this second method is the more approved because — as we proved in the preceding chapter with several arguments — the Church has always used mean motions, or rather cycles, in investigating the new moons and the fourteenth days of the Moon for the correct celebration of Easter, leaving true motions to the more exacting researches of the astronomers. Mean motions are always equal and uniform; true motions are unequal and irregular, now greater than the mean, now less. It seems fair, then, and consistent that for keeping the equinox in its seat the Church should likewise use the length of year that lies midway between the greatest and the least, since the case appears the same on both sides. For just as the mean conjunctions of the luminaries sometimes come before the true ones and sometimes after them, so too the equinox yielded by a year midway between the greatest and the least will at one time come before the true equinox, which then follows [?], while at another time it will fall after the true one, as we said a little earlier.

[Margin: 2. Reason. Why the length of the mean year was adopted in the correction of the calendar.] [Margin: The likeness between the mean conjunctions of the luminaries and the equation established on the mean year.]

But suppose someone objects as follows. Since the true equinox does not always fall on 21 March, where the Church has placed it, but sometimes before it and sometimes after, it necessarily follows that some fourteenth days of the Moon which belong to the first month and are Paschal by the decrees and enactments of the Fathers and of the Council of Nicaea are nevertheless rejected as non-Paschal and treated as belonging to the last month — and this because those fourteenth days occur before 21 March, the day on which the Church supposes the equinox to fall, even though they may land on the very day of the equinox (which then

perhaps precedes the 21st), or even follow it. And conversely, some fourteenth days of the Moon which by those same decrees and enactments of the Fathers and of the Nicene Council are not Paschal and belong to the last month are nevertheless reckoned by the Church as legitimate for celebrating Easter and as of the first month, because they fall on 21 March, the day set aside for the equinox, or follow it, even though they come before the vernal equinox, which then perhaps occurs after the 21st. Both results seem absurd, since the former fourteenth days of the Moon push Easter out of the first month into the second, while the latter set it to be celebrated in the twelfth and last month, before the first.

[Margin: The difficulty that Easter is sometimes pushed into the second month, and sometimes anticipates the first month, if the equation is established on the mean year.]

If anyone, I say, raises this objection, the answer is that this is neither absurd nor new in the Church of God. For the equinox cannot be confined within one day; it demands two. Suppose that in some leap year it falls, say, on 20 March about midday: in the following year it will fall six hours later, namely on the 20th about sunset, on account of those six hours that are dropped in every year after the leap year. Then in the next year it will fall on the 21st about midnight, and in the year following that on the 21st about sunrise; and finally in the next year, which is again a leap year, it will go back to the earlier day, the 20th, about midday, because of the intercalary day added to that year. Since, therefore, the equinox requires two days, while the Church has always assigned it a single day, namely 21 March, so that all the faithful of Christ may everywhere celebrate Easter on the same day — that is, on the Sunday next after the fourteenth day of the Moon which falls either on the day given to the equinox, 21 March, or immediately after it, but never before, as we showed above — it was impossible at any period, even in the days of the Council of Nicaea itself, when the Paschal canon was first confirmed and issued by a general council, to prevent Easter from sometimes being celebrated in the last month or in the second. I shall make this plain as follows.

[Margin: The solution of the difficulty: it is nothing new that Easter should sometimes be celebrated either in the second month or in the last, on account of common and leap years.]

Suppose, then, that around the time of the Council of Nicaea the equinox — which the Fathers fixed on 21 March — actually fell on 21 and 22 March, as the tables of Nicolaus Copernicus, that is, the Prutenic Tables, show us. From them we find

that in the leap year AD 324 the equinox fell on 21 March about midday, and therefore in the third year after the leap year, namely 327, on the 22nd about sunrise. On this supposition, whenever in that third year after the leap year the fourteenth day of the Moon fell on 21 March (which, while golden number 16 was running, always happened before the correction of the calendar), Easter was celebrated in the last month, since that fourteenth day of the Moon had preceded the equinox; and Easter would have fallen on the equinox itself, if the 22nd happened then to be a Sunday. Next let us suppose that around the same time of the Nicene Council the equinox occupied 20 and 21 March, which agrees better with the Alphonsine Tables, since they place the equinox in the leap year 324 on 20 March at about 22 hours before midday [?]. If we accept this, I say, then whenever at that period the fourteenth day of the Moon in a leap year fell on 20 March, Easter was pushed into the second month, although that fourteenth day of the Moon was truly Paschal, seeing that it fell either on the equinox or after it; and yet the Church rejected it as belonging to the last month, for no other reason than that it came before the 21st, the day assigned to the equinox. The same must now necessarily happen after the correction as well, whenever epacts xxiv and xxiii are in use. For when the equinox falls on 20 March and epact xxiii is running, the fourteenth day of the Moon of that epact, seated on 20 March, would be Paschal by the decrees of the Fathers and of the Nicene Council; and yet it is rejected, and another, belonging to the second month, is accepted instead. And when the equinox falls on 22 March and epact xxii is running, the fourteenth day of the Moon of that epact, falling on the 21st, is [?] taken as Paschal, although by the decrees of the Fathers it belongs to the last month, since it stands before the equinox.

[Margin: Easter had necessarily to be celebrated sometimes in the second month and sometimes in the last, even in the days of the Council of Nicaea itself.]

[Margin: The Church does not conflict with the decrees of the Fathers, even though it sometimes celebrates Easter either in the last month or in the second, since this can in no way be avoided.]

12 From all this it plainly appears that it is nothing new in the Church for Easter to be celebrated either in the last month or in the second, because the equinox is tied to a single day when it requires two. Nor is the Church to be thought to depart in this from the decrees of the Fathers and of the Council of Nicaea. Those decrees are not to be taken so strictly as to mean that the Church must determine the equinox from astronomical tables; they are to be understood only as directing that in the celebration of Easter the Church must observe the day ascribed to the equinox,

even if the equinox sometimes comes before that day or after it, provided it does not recede far from it.

13 It can therefore rightly be said that the equinox is taken in two senses: in one, as it truly exists in the nature of things and is considered by astronomers; in the other, as it is fixed in the calendar to some determinate day and used by the Church for the due celebration of Easter. Let the first be called the astronomical or true equinox, the second the ecclesiastical or civil [politicum] equinox. And although this ecclesiastical equinox ought to be referred, so far as possible, to the astronomical and true one, there are nevertheless just causes for which the one may differ from the other. The most just cause of all, why the ecclesiastical equinox sometimes differs from the natural and true one, is the concord and consent of the faithful. For the sake of that concord the Church ascribed the equinox to one single day, so that throughout the whole Christian world all might keep the most holy day of Easter on the same day and with united hearts. That concord could scarcely — or rather not even scarcely — be preserved if the equinox, reckoned by the true motion, were tied to two or even more days, as is clear from what we have said. And so, although in the celebration of Easter the Church freely and of its own accord sets itself to observe the equinox and the course of the Moon (for it is bound by no law to do so, as we said above in chapter 1), and does so in order to bring out more fully the mysteries contained in the most holy Passion and in the Lord's Resurrection, still the peace and concord of the faithful is dearer to its heart. So much so that if in some case a loss must be incurred either in the equinox and the motion of the Moon or in the concord of the faithful, the Church would rather that Easter be celebrated by all on the same day, even if the equinox and the course of the Moon are not perfectly kept, than that the least agreement of the faithful in celebrating it be broken or disturbed. For who could justly blame the Church, or charge it with error, if it departs somewhat from the perfect observance of the equinox and of the fourteenth day of the Moon in order to preserve quiet and peace among the faithful in keeping Easter, the most celebrated of all the feasts of the faithful? The equinox and the fourteenth day of the Moon it considers in this business freely, and only for the sake of a certain congruity and likeness with the Passover of the Hebrews, as we showed in chapter 1; but the peace and concord of believers it is bound by divine command to protect and preserve.

[Margin: The equinox is twofold: astronomical, that is, true, and ecclesiastical, that is, civil.] [Margin: Why the ecclesiastical equinox differs from the astronomical one.] [Margin: That the Church observes the equinox and the fourteenth day of the Moon freely in the solemnity of Easter, and why it observes

them.] [Margin: That the peace of the faithful in the celebration of Easter is dearer to the Church than the exact observance of the equinox and of the course of the Moon.]

14 Finally, the Church followed the mean year in this matter above all for the following reason. Suppose that, because of the omission of the intercalary day established on the mean length of the year, it should happen after the lapse of some centuries that the equinox no longer stood on 21 March, but was found by new observations to have slipped toward the end of the month or moved forward toward its beginning. We do not deny that this can happen, given the uncertainty and changeableness of the astronomical tables. (Just as the tables of Ptolemy and of King Alfonso have by now been found to have deviated somewhat from the true motions — although in the times when they were composed they presented those motions most exactly — so we cannot guarantee the perpetuity of the Prutenic Tables drawn from the teaching of Copernicus.) Even if, I say, the equinox were found to have moved from its seat, it could be brought back to the 21st without any trouble: by decree of the Roman Pontiff one day, or two, or even more if need be, could be intercalated out of the ordinary course in some year, if the equinox were found to have slipped toward the end of the month; or one or more days could be taken away from some year, if it had moved toward the beginning of the month — according, of course, to the number of days by which the equinox was observed to have receded from the 21st. By this means it would be restored to the 21st day, and nothing on that account would have to be changed in the epacts of the calendar; only the equations of the expanded table of epacts would have to be arranged a little differently. How that should be done we shall explain in its own place, when we come to speak of the equation of the epacts.

[Margin: 3. Reason. Why the mean length of the year was adopted in the correction of the calendar.] [Margin: The equinox, if after some centuries it should have departed [?] from 21 March, by what means it can be recalled to that same day.]

15 And in this consists the excellence and perpetuity of the Gregorian calendar: that it can be fitted to any form of intercalation whatever — that is, to any length of the year — without any change being made in the cycle of the epacts in the calendar. This is something that can suit no other lunar cycle, since when the rule of intercalation is changed the arrangement of the cycle in the calendar must necessarily be changed too, as we shall explain at length below when we treat of the expanded table of the epacts. Not understanding this, most people rashly and

thoughtlessly attack the perpetuity of the Gregorian calendar. For the Gregorian calendar is not called perpetual, and subject to no change ever, in the sense our adversaries falsely put upon it — as though a formula of intercalation were prescribed in it by which the equinox would be so held on 21 March that it never moved from that day. We never said this; and indeed it cannot be brought about by any means, if the civil year is to consist of whole days and the manner of intercalation is to be easy and regular, as it should be, and if what is set before an untrained people is not to be the astronomical year made up of days, hours, and fractions of hours, with an irregular form of intercalation. For who could be so stupid and dull — provided he has even the slightest tincture of astronomy — as to persuade himself of such a thing, when daily experience teaches us that the equinox cannot stand on the same day even over an interval of four years, because of the six hours dropped each year? We called this new calendar perpetual and subject to no change for this reason instead: that even if posterity should perhaps discover a different length of the year, and a different rule of intercalation should accordingly have to be established to match it (which we frankly admit may happen, given that the length of the year is uncertain and unequal — this indeed was why two formulae of intercalation were laid before the Christian princes and the mathematicians in the *Compendium* of the restoration of the calendar), the calendar itself, so far as concerns the arrangement of the epacts, will remain wholly untouched. This would not be the case if the golden number had been left in the calendar, arranged over the days in whatever manner, as some wished. For not only would a different intercalation have to be established for different lengths of the year, but even keeping always the same form of intercalation, according to the Alphonsine year which we have proposed, the golden number would have had to be altered in the calendar thirty times; and therefore thirty different calendars would have had to be composed — which would be intolerable — because of the anticipation of the Moon, as will be clear below in chapter 15.

[Margin: The perpetuity and perfection of the Gregorian calendar: in what it consists.] [Margin: That the new calendar is not called perpetual as though the equinox could never recede from 21 March.] [Margin: That it is impossible for the equinox to remain on the same day, because of the six hours dropped each year.] [Margin: Why the new calendar is called perpetual.]

16 And so, since in this business of correction the length of the Alphonsine year has been chosen — the year according to which the form of intercalation for keeping the equinox on the same day is to be established, as being more uniform and better suited to the common understanding — let us now explain how the

omission of the intercalary day in every hundredth year after the year 1600, every four hundredth excepted (of which something was said at the beginning of this chapter), squares with this length of the year. For since, as we showed in chapter 1, the equinox anticipates by nearly one whole day in 134 years, so that if it now clings to the 21st it will after 134 years have moved forward to the 20th, it follows

that if in any given 134th year after the year 1600 the intercalary day is omitted — making now the 132nd, now the 136th year (since the 134th is not a leap year) a common year, of 365 days, and not a leap year as it ought to be if the Julian, or greater ecclesiastical, year were neither longer nor shorter than 365 days and 6 hours — it follows, I say, that the equinox returns to the 21st, just as by the omission of ten days made in the year 1582 it was restored to that same 21st, from which it had drifted toward the beginning of March. But since this variation, by which the intercalation would have to be omitted now in any 132nd year, now in any 136th, could easily be forgotten — such years being marked by no conspicuous sign — the hundredth years were chosen instead for this purpose, since they are more prominent, and negligence or forgetfulness cannot so easily creep in with them; especially since all the hundredth years are dedicated to jubilees, and are therefore best known to the sons of the Catholic Church, and most eagerly awaited. For since in 134 years, as has been said, the equinox anticipates by one day, it will in the space of 402 years get ahead of its seat in the calendar by three days.

[Margin: Why the hundredth years were chosen for equalizing the solar year.]

[Margin: By what reasoning the omission of the intercalary day in the hundredth years, every four hundredth excepted, squares with the Alphonsine year.]

17 Therefore, if in each space of four hundred years three intercalations are omitted, in this order — that the first three hundredth years after the year 1600 (for the year 1600 does not yet need an equation, since at that point, because of the nearness of the year 1582 in which the calendar was corrected, the equinox could not yet anticipate a whole day, but still falls on the 21st [?]) be common years and not leap years, while every four hundredth year is a leap year — then the equinox will be kept near 21 March exactly as if the intercalary day were omitted in every 134th year.

And so, although in future every fourth year (with three left between) is still to be a leap year as usual, yet these years 1700, 1800, 1900 will not be counted as leap years (although they are contained in the number of the leap years) but as common years, while the year 2000 will be a leap year. In the same way the years

2100, 2200, 2300 will be made common, and the year 2400 a leap year, and so on continually, the same order being kept, until it is found that the equinox has so far departed from 21 March that it cannot return to it unless an intercalation is made out of the ordinary course by decree of the Supreme Pontiff, or one or more days are omitted in some year, as we showed above. Nor should anyone be surprised that we have neglected those two years which remain over and above the 400: for in many thousands of years — namely in 26800 — they can scarcely produce an error of one day, even if no account is taken of them; and that error, when it has grown to one day, will easily be corrected by an extraordinary intercalation of one day in some common year, since the day then to be restored to the year is one that was removed without necessity. We judged, however, that no account should be taken of those two years, lest the rule of intercalation be made more obscure — especially since posterity, after the year of the Lord 28400, that is, about the year 26800 after the correction (if the world lasts so long), will easily restore the equinox to its seat, as we have said. Add to this that our rule of intercalation is established on the Alphonsine year, of which we cannot be certain whether over so long a time it will always keep the middle place between the greatest and the least year. We therefore rightly leave this care to posterity, that they may consider in good time what equation is then to be established, if by chance a different length of the year has been discovered. This number of 26800 years is arrived at as follows. If in 134 years one intercalary day is omitted, then in 2 years there ought to be omitted $\frac{2}{134}$ [?] — that is, $\frac{1}{67}$ — of a day; and it is by this small amount that we anticipate the omission of the intercalation in 400 years. Therefore, if $\frac{1}{67}$ of a day demands 400 years, one whole day will require 26800 years. And this is true, of course, provided the year really is 365 days, 5 hours, 49 minutes, 16 seconds. But on this matter see also what we wrote in chapter 14, number 1.

18 Further, it seems worth noting that this rule of intercalation established in the hundredth years is very like the customary formula of intercalating in every fourth year, and so can easily be kept in memory by ordinary people. For just as every fourth year after the birth of Christ has always been and will be a leap year (with certain hundredth years excepted), while all the rest are common years, so after the year 1600 every four hundredth year will be a leap year, and all the other hundredth years common. Again, just as among the non-hundredth years those alone are leap years which the number four measures — such as the years 4, 8, 12, 16, 20, 24, 28, 32, 1588, 1592, 1596, 3416, 3420, 3424, and so on — so too after the correction, of the hundredth years those alone will be leap years whose number of hundreds the number four measures: such as the years 1600, 2000,

2400, 3600, 9200, and so on. For the number four measures all these numbers of hundreds — 16, 20, 24, 36, 92 — as is evident.

[Margin: The likeness between the intercalation in every four hundredth year and the customary intercalation in every fourth year.]

But someone will say (and in fact not a few are persuaded of this): this omission of the intercalary day in the hundredth years is indeed excellently suited to the grasp of ordinary people and to memory, but it seems less fit for keeping the equinox on 21 March. For since, to keep the equinox on the same day, one intercalary day must be omitted every 134 years, according to the length of the Alphonsine year, as was shown above, the result is that in an equation which proceeds by hundredth years, the omission of the intercalary day forestalls the just and lawful equation by 34 years in the first century, by 68 years in the second, and by 102 years in the third. And this seems not to keep the equinox in its seat, but rather to drive it out of it.

[Margin: The difficulty that the equation seems not rightly applied in the hundredth years, since it ought to be made in every 134th year.]

Yet if anyone will consider the matter a little more attentively, he will certainly understand that by this equation of ours — supposing the length of the year to be exactly what the Alphonsine Tables give us — the equinox is more correctly kept in its seat than if the equation were made in every 134th year. This will be made plain as follows. Let us suppose that in some year the equinox falls on 21 March six hours before sunrise, that is, at the midnight preceding. On this supposition, after 33 1/2 years it will run ahead of that midnight by six hours, and will fall about sunset of the 20th, since in 134 years it anticipates by one day, and therefore in 33 1/2 years by a quarter of a day, that is, by six hours. After 67 years, for the same reason, it will be found at midday of the same 20th day; and after 100 1/2 [?] years, at sunrise of that same 20th. So that after the space of 100 years the equinox will have receded from the 21st, its assigned seat, toward the beginning of the month by three quarters of a day, that is, by 18 hours. But if in that hundredth year the intercalary day is not removed, and instead the 134th year is waited for — as pleases some who do not weigh the matter rightly — this recession toward the beginning of the month will grow to 24 hours, and the equinox will fall before the 20th day, at midnight,

[Margin: The solution of the foregoing difficulty.]

will fall before the 20th day, at midnight, before the day is removed in the 134th year; and this will happen in every interval of 134 years. But if the intercalary

day is subtracted in the first centesimal year — even though the anticipation of the equinox has not yet grown to a full day but only to 18 hours — the equinox will be carried back from sunrise of the 20th to sunrise of the 21st. It will then stand six hours toward the end of the month from the point first assigned to it, and not 18 hours toward the beginning of the month. Next, in the second centesimal year, once the equinox has reached midday of the 20th, the subtraction of the intercalary day will restore it to midday of the 21st, and it will stand 12 hours from its first seat. In the third centesimal year, when the equinox has already reached sunset of the 20th, the removal of a second day will bring it back to sunset of the 21st, and it will stand 18 hours from its first seat. From then on this distance will gradually shrink, until in the fourth centesimal year it has diminished by 18 hours — since in each centesimal year the equinox runs ahead of its seat by 18 hours — and so the equinox will once again be in its first seat, that is, at midnight before the 21st, because in that fourth centesimal year the intercalary day is not omitted but intercalated in the usual way.

YOU SEE, then, that if one day were taken out every 134th year — which, as we said, not a few have thought expedient — the equinox would always recede toward the beginning of the month from the seat assigned to it, so that this recession would grow to nearly a whole day at about the 134th year; and this would happen three times in the space of four hundred years. But under our equation, established at the centesimal years, the distance of the equinox from its first seat can never amount to 24 hours, but at most to 18 — and that only once in the whole space of four hundred years. Therefore the equinox is kept at the 21st day more accurately if the equation is made at the centesimal years than if the 134th year is waited for.

[Margin: The equation applied at the centesimal years preserves the equinox on the same day in the same way that it is preserved by intercalation every fourth year.]

19. ADD to this that our equation, applied at the centesimal years, not only conforms to the customary four-yearly rule of intercalation, as was said above, but that the reasoning in the two cases is exactly the same as regards keeping the equinox in the same seat. For just as in the first year after a bissextile the equinox slips six hours toward the end of the month, in the second 12 hours, and in the third 18 hours — because of the six hours dropped in each common year — and then in the fourth year, thanks to the intercalation of one day near the beginning of the year, it is restored to the same seat without waiting for the full 24 hours to elapse: exactly so it

happens in any space of four hundred years, if the first three centesimals are made common and the fourth intercalary, as is plain from what has been said. Therefore this arrangement cannot rightly be faulted without condemning the other along with it.

[Margin: The equation applied at the centesimal years is very like the Arabs' equation in the lunar year.]

20. AND consider, too, that the Arabs follow much the same rule of intercalation in the equation of the lunar year. They never wait until a whole day is made up out of the hours dropped; rather, whenever a number of those hours greater than 12 has accumulated, they establish an intercalary year, adding one day to the lunar year of 354 days — a year they call *embolismic* [embolismus]. On this subject one should read Campanus in the *Computus maior*, and Paul of Middelburg [Paulus Middelburgensis], book 2 of his *Paulina*. But so that it may be seen still more plainly that no more convenient or more truthful way of making the equation could have been taken than the one we have set out in this chapter, we shall bring forward the arguments — or rather the quibbles — that certain people raise against this method of equating the solar year. First, though, the next chapter must set out somewhat more carefully the whole period of the anomaly of the equinoxes and of the inequality of the years, according to the hypotheses of Nicolaus Copernicus, since these are the ones more widely accepted by astronomers today. From that it will appear with the greatest clarity both that the prescribed formula of equation is entirely apt, and that our opponents, whoever they may be, are wasting their time in attacking it.

CAPVT VI.

De periodo anomalie Aequinoctiorum, & inæqualitatis annorum, ex Nicolai Copernici doctrina.

[On the period of the anomaly of the equinoxes and of the inequality of the years, from the doctrine of Nicolaus Copernicus.]

SINCE, with a view to overturning root and branch the formula for equating the solar year expounded in the last chapter, certain men who advertise themselves as distinguished astronomers rashly assert that, if that formula is used, the vernal equinox will slip from 21 March all the way to the 27th within no very great number of thousands of years and will never return to the 21st again; and since

they add that the mean equinox at present falls on 23 March, and that the true equinox can depart from the mean by a full four days, now advancing, now falling back — I think it worth my while, in order to expose the ignorance of these prophets, and in keeping with the plan of this work, to set out briefly in this chapter both the true and the mean equinoxes for the whole period of the anomaly of the equinoxes, together with the inequality of the solar years, out of the Prutenic Tables, which by now are almost the only ones anyone values, and out of which our opponents fabricate and draw all their arguments. In this way their slanders — which they employ to attack the equation of the equinoxes prescribed in the new calendar — will be made plain to everyone; and it will be made clear that the vernal equinox, with our formula of intercalation applied, will not recede from the 21st day by anything like the interval that these men falsely and rashly prophesy it will depart.

2. AND since Nicolaus Copernicus, on whose doctrine the Prutenic Tables were constructed, laid down that the period of the anomaly of the precession of the equinoxes is completed in the space of 1717 Egyptian years — which make 1717 [?] Julian years, the years we now use, and 302 days — we shall divide this whole circuit and revolution into 8 principal parts: first into 4 quadrants, and then each quadrant into two equal parts, so that the time of any one of these 8 equal parts comprises 214 years, 174 days, and 15 hours.

[Margin: When the period of the anomaly of the equinoxes would have begun before the birth of Christ. The root [radix] of the period of the anomaly of the equinoxes.]

3. THIS revolution of the anomaly had its beginning 63 completed years, 227 days, 20 hours and 42 minutes before the birth of Christ, because in that interval of time the equal or mean motion of that anomaly completes the arc assigned by Copernicus for the epoch, that is, for its root, at the beginning of the years of the Lord — which root contains Sign 0, Degrees 6, Minutes 40, Seconds 27, Thirds 28, Fourths 6. If, therefore, to the 63 years, 227 days, 20 hours and 42 minutes elapsed before the birth of Christ we add the 1715 years and 302 days of the whole circuit and revolution — or, what comes to the same thing, if we subtract that time before the birth of Christ from this entire revolution (much as if someone wished to add 10 days to a point three days before the beginning of the year, and so made up 7 days of the year, subtracting 3 from 10) — we shall find that the same anomaly begins its revolution afresh in the course of the year of the Lord

1653, on 25 March by the new calendar, whereas the beginning of the previous revolution had fallen on 18 May, had the Julian year then been in use.

[Margin: In what year of Christ the period of the anomaly of the equinoxes will begin again.]

Hence, by continually adding 1715 years and 302 days, one obtains the years in which the same revolution returns to its head. And by continually adding 214 years, 174 days and 15 hours, one obtains the years in which the same revolution occupies those eight equal parts of the whole period — as has been done in the table below, in which two whole revolutions are set out. The first has its beginning from the year 63 completed before the Nativity of Christ, and ends in the course of the year of the Lord 1653; from that year the second period begins and ends in the course of the year of the Lord 3369. In these we have also entered the days of the months in which the anomaly occupies roughly each of the eight parts of the whole revolution.

[Margin: When the true and the mean equinox occur together, when they differ most from each other, and when their difference is middling.]

4. THE true and the mean equinox do not differ from one another but occur simultaneously at the same moment when the anomaly is both at the beginning of its revolution and at the end of the second quadrant — that is, at the beginning of the first quadrant and of the third — because then the equation of the precession is nil. The greatest difference between the two equinoxes occurs when the anomaly holds the end of both the first and the third quadrant in its revolution, because then the equation of the precession is at its maximum. Finally, the difference between the two equinoxes is middling at the middle of each quadrant, because then the equation of the precession stands at its mean value. So it comes about that in a whole period of the anomaly the two equinoxes occur together twice, twice differ from one another by the greatest amount, and four times have their difference settled at a middling value.

[Margin: When the tropical year is greatest, when least, and when middling.]

AGAIN, the tropical or turning year is greatest when the anomaly is both at the beginning of its revolution and at the end of it — that is, at the start of the first quadrant and at the end of the fourth. It is least when the same anomaly is set at the middle of its revolution, that is, at the end of the second quadrant or the beginning of the third. At all the other places of the anomaly it is middling. The reason for this variation is that the precession of the equinoxes for a single year — which must always be subtracted from the equal sidereal year (which contains 365 days, 6 hours, 9 minutes, 39 seconds, on the view of Thābit [Thebitius] and Copernicus) so that the magnitude of the tropical year is left — is slowest both at the beginning of its revolution and at the end, and swiftest at the middle; while at all the other places it stands midway between the slowest and the swiftest motion. And so in the whole period of the anomaly of the precession of the equinoxes the year is once greatest, once least, and more often middling — yet in such a way that the magnitudes of two years always equally distant on either side from the least year are equal to each other. All of this is contained in the following table, where

the time of the true and of the mean equinox, at the moments when the anomaly stands at those eight places of the whole revolution begun in the year 1653, has been computed, together with the magnitude of the turning year. The computation has been made for the bissextile years nearest to the years in which the anomaly stands at those eight places (except for the year 1653, which is the

beginning of the revolution and to which the calculation was carried back, although it is not a bissextile), because in bissextile years less variation is observed in the Sun's entry into the first degree of Aries. The calculation has also been adapted to the equation of the restored calendar, which proceeds by 400 years. We have, however, disregarded the hours in the equinoxes, since it seemed enough for the day of the vernal equinox to be recorded together with the time before or after midday or midnight, the hours being left out.

Anno 1653. quando reuolutio anomaliae præcessionis æquinociorum incipit. [In the year 1653, when the revolution of the anomaly of the precession of the equinoxes begins.]

Æquinocium [The equinox]	fiet [will fall]
verum [true]	20. Martij post med. noct. [20 March after midnight]
medium [mean]	20. Martii post med. noct. [20 March after midnight]

Annus tropicus continebit dies 365. hor. 5. min. 55. sec. 37. ter. 40. — The tropical year will contain 365 days, 5 hours, 55 minutes, 37 seconds, 40 thirds. This was also the magnitude of the year in the year 63 before the birth of Christ our Lord; and on that magnitude the equinox anticipates by one day in about 329 years.

Anno 1868. cum anomalia erit iuxta medium primi quadrantis suæ reuolutionis. [In the year 1868, when the anomaly will be near the middle of the first quadrant of its revolution.]

Æquinocium [The equinox]	fiet [will fall]
verum [true]	21. Martii post med. noct. [21 March after midnight]
medium [mean]	20. Martii circa ortum Solis. [20 March about sunrise]

Annus tropicus continebit dies 365. hor. 5. min. 53. sec. 52. — The tropical year will contain 365 days, 5 hours, 53 minutes, 52 seconds. This magnitude of the year also suits the time around the year of the Lord 151; and on it the equinox anticipates by one day in very nearly 231 years.

Anno 2080. obtinente anomalia finem ferme primi quadrantis, & principium secundi suæ reuolutionis. [In the year 2080, the anomaly holding roughly the end of the first quadrant and the beginning of the second of its revolution.]

Æquinoctium [The equinox]	fiet [will fall]
verum [true]	21. Martij circa occasum Solis. [21 March about sunset]
medium [mean]	20. Martii post mer. [20 March after midday]

Annus tropicus erit dierum 365. hor. 5. min. 49. sec. 16. ter. 29. — The tropical year will be of 365 days, 5 hours, 49 minutes, 16 seconds, 29 thirds. This magnitude of the year also fits the time around the year of the Lord 366; and on it the anticipation of the equinox by one day requires about 134 years.

Anno 2296. cum anomalia circa medium secundi quadrantis suæ reuolutionis versabitur. [In the year 2296, when the anomaly will be moving about the middle of the second quadrant of its revolution.]

Æquinoctium [The equinox]	fiet [will fall]
verum [true]	21. Martii post merid. [21 March after midday]
medium [mean]	20. Martii sub occasum Solis. [20 March toward sunset]

Annus tropicus erit dierum 365. hor. 5. min. 44. sec. 46. ter. 59. — The tropical year will be of 365 days, 5 hours, 44 minutes, 46 seconds, 59 thirds. This magnitude of the year also obtained around the year of the Lord 580; and on it the equinox anticipates by one day in about 94 years.

Anno 2512. quando anomalia erit iuxta finem secundi quadrantis, & in principio fere tertij, videlicet in medio totius reuolutionis. [In the year 2512, when the anomaly will be near the end of the second quadrant and almost at the beginning of the third — that is, at the middle of the whole revolution.]

Æquinoctium [The equinox]	fiet [will fall]
verum [true]	21. Martij ante merid. [21 March before midday]
medium [mean]	21. Martii ante merid. [21 March before midday]

Annus tropicus est dierum 365. hor. 5. min. 42. sec. 55. ter. 7. — The tropical year is of 365 days, 5 hours, 42 minutes, 55 seconds, 7 thirds. This magnitude of the

year also obtained around the year of the Lord 795; and on it about 84 years are required for the equinox to anticipate by one day.

Anno 2724. anomalia occupante medium ferme tertij quadrantis suæ reuolutionis. [In the year 2724, the anomaly occupying nearly the middle of the third quadrant of its revolution.]

Æquinoctium [The equinox]	fiet [will fall]
verum [true]	20. Martii post med. noct. [20 March after midnight]
medium [mean]	21. Martii circa occasum Solis. [21 March about sunset]

Annus tropicus erit dierum 365. hor. 5. min. 44. sec. 46. ter. 59. — The tropical year will be of 365 days, 5 hours, 44 minutes, 46 seconds, 59 thirds. This magnitude of the year also obtained around the year of the Lord 1009; and it requires nearly 94 years for the equinox to anticipate by one day.

Anno 2940. versante anomalia in fine prope tertij quadrantis suæ reuolutionis, & principio fere quarti. [In the year 2940, the anomaly standing near the end of the third quadrant of its revolution and almost at the beginning of the fourth.]

Æquinoctium [The equinox]	fiet [will fall]
verum [true]	19. Martii post med. noct. [19 March after midnight]
medium [mean]	21. Martij circa ortum Solis. [21 March about sunrise]

Annus tropicus erit dierum 365. hor. 5. min. 49. sec. 16. ter. 29. — The tropical year will be of 365 days, 5 hours, 49 minutes, 16 seconds, 29 thirds. This magnitude of the year fits the period around the year of the Lord 1224 as well, and it requires about 134 years for the equinox to anticipate by one day.

Anno 3156. cum anomalia erit fere in medio quarti quadrantis suæ reuolutionis. [In the year 3156, when the anomaly will be nearly at the middle of the fourth quadrant of its revolution.]

Æquinoctium [The equinox]	fiet [will fall]
verum [true]	20. Martii circa occasum Solis. [20 March about sunset]
medium [mean]	21. Martii circa merid. [21 March

Æquinoctium [The equinox]

fiet [will fall]

about midday]

Annus tropicus erit dierum 365 hor. 5. min. 53. sec. 52. — The tropical year will be of 365 days, 5 hours, 53 minutes, 52 seconds. This magnitude of the year also occurred around the time of the year of the Lord 1438; and on it nearly 231 years are required for the equinox to anticipate by one day.

Anno 3368. quando anomalia tenebit fere finem totius reuolutionis, hoc est, in fine quasi quarti quadrantis versabitur. [In the year 3368, when the anomaly will hold nearly the end of its whole revolution — that is, it will stand almost at the end of the fourth quadrant.]

Æquinoctium [The equinox]

fiet [will fall]

verum [true]

21. Martii circa merid. [21 March
about midday]

medium [mean]

21. Martii circa merid. [21 March
about midday]

Annus tropicus erit dierum 365. hor. 5. min. 55. sec. 37. ter. 40. — The tropical year will be of 365 days, 5 hours, 55 minutes, 37 seconds, 40 thirds. This magnitude of the year suits the period around the year of the Lord 1653, and also around the year 63 before the birth of Christ. It requires nearly 329 years for the equinox to anticipate by one day. And if the year always had this magnitude, the customary bissextile intercalation would have to be omitted every 329th year.

From all this one can easily gather how great a confusion would arise throughout the whole Christian world if the equation of the equinox had to be established according to the true motion. It would have to be changed very frequently within the space of 1715 years, in step with the varying magnitude of the year, which over that span grows and shrinks continuously in a remarkable way. This would throw all the churches into great anxiety, since they would be perpetually in doubt whether the intercalary day should be dropped in this bissextile year or in that, and would be forced to canvass the opinions of astronomers on the question every year. That would be wholly absurd, and unheard of down to the present day.

[Margin: Confusio inter Christianos, si æquatio æquinoctij ad motum verum institueretur. — Confusion among Christians, if the equation of the equinox were established with reference to the true motion.]

5 It is likewise clear that no equation of the solar year which prescribes that the intercalary day be dropped at fixed and always settled times — such as ours is, which lays down that in every four hundred years three intercalary days be removed — can square in every respect with the true motion of the Sun, so as to keep and preserve the equinox perpetually on 21 March. The reason is that according to the true motion, sometimes more years are required and sometimes fewer for the equinox to advance by one day in the calendar toward the beginning of the month. It is therefore pointless for some to attack this equation of ours on the ground that it does not answer exactly to the true motion, since this cannot possibly be achieved by any equation that is regular and uniform — the kind the Church ought to institute, and the kind ours is, as is evident from what has been said.

[Margin: *Æquationem vniformem frustra à nonnullis impugnari. — That a uniform equation is attacked by some to no purpose.*]

6 It is clear, further, that throughout the whole of the period next to come — which begins in the year 1653 and will end in the year 3369 — the vernal equinox will depart from its seat by not much more than the space of one day in either direction, even if the intercalation-equation of the new calendar is applied; provided that the magnitude of the Alphonsine year, which is in a way midway between the greatest and the least, has rightly been taken as the basis from which the formula of intercalation is prescribed. For that formula is both regular and uniform, and perfectly suited to ordinary people's grasp; and it holds the equinox around 21 March, where its seat has been fixed, in such a way that it cannot recede far from that day, but sometimes precedes it, sometimes follows it, and sometimes falls on the 21st itself.

[Margin: *Æquinocetium secundum æquationem noui Calendarij non longe à die 21. Martij recedere, ideoque merito eam esse institutam ad annum Alphonsinum, qui medius est. — That under the equation of the new calendar the equinox does not recede far from 21 March, and that the equation was therefore rightly framed on the Alphonsine year, which is the middle one.*]

7 Finally, it follows from what we have said that in one entire period of the anomaly of the equinoxes the difference between the true and the mean equinox never grows to two whole days — indeed, not even to a day and a half. Yet certain people slanderously assert that it can amount to a full four days; and in this they clash most plainly with the teaching of Copernicus, which they nevertheless make a great parade of. This too will be made plain as follows. The true and the mean equinox occur together at the same moment of time (as was said above at

Number 4) whenever the equation of precession is nil, which happens when the anomaly of precession holds the beginning, or the middle, or the end of its circuit and revolution. They stand furthest apart from each other when that same equation is greatest, and in the Prutenic Tables it then comes to 1 degree 11 minutes 22 seconds 30 thirds; this happens whenever the anomaly stands at the beginning of the second quadrant of its revolution, or of the fourth. Moreover, when these two equinoxes differ from each other, the mean goes first and the true follows — that is, the mean equinox occurs before the true — whenever the equation of the precession of the equinoxes is subtracted from the mean precession in order to obtain the true precession; and that happens whenever twice the anomaly is less than a semicircle, that is, when the anomaly of the equinoxes has not yet completed the second quadrant of the whole period. The mean equinox follows and the true goes first — that is, the true equinox occurs before the mean — whenever the equation of the precession of the equinoxes is added to the mean precession in order to make up the true precession; and that comes about whenever twice the anomaly is greater than a semicircle, that is, when the anomaly of the equinoxes has already passed the second quadrant of the whole period. The one equinox precedes or follows the other by just so much time as suffices for the Sun by its true motion to run through the arc of the equation of the precession of the equinoxes. Now since the greatest equation of the equinoxes never exceeds, as has been said, 1 degree 11 minutes 22 seconds 30 thirds, and since the daily motion of the Sun is at no time less than 0 degrees 56 minutes 46 seconds, it follows that the interval between the true and the mean equinox never exceeds 1 day and 6 hours, or a little more — even at the time when the Sun's motion is slowest and the equation of the equinoxes greatest. So I am utterly astonished at what can have come into the heads of certain people when they said, as if dreaming, that the difference between the two equinoxes can grow to a full four days, and that in this century the mean equinox falls on 23 March; whereas in fact, from the year of Christ our Lord 1653 to the year 3368 — one entire revolution of the anomaly — it scarcely ever passes beyond the 21st, as is evident from the calculation above.

[Margin: *Differentiam inter verum ac medium æquinoctium non attingere diem vnum cum semisse.* — That the difference between the true and the mean equinox does not reach one day and a half.]

[Margin: *Æquinoctium medium quando antecedit, aut sequatur verum.* — When the mean equinox precedes, and when it follows, the true.]

[Margin: Quantum sit maximum discrimen inter verum ac medium æquinoctium. — How great the maximum difference between the true and the mean equinox is.]

8. But I think I see the cause of these mathematicians' error. They have reasoned, I suppose, about the mean and the true equinox as we habitually do about the mean and the true conjunction or opposition of the luminaries. For they supposed that the equinox becomes mean only when the line of the Sun's mean motion is joined with the point of the mean equinox — just as the mean conjunction or opposition of the Sun and Moon occurs when the lines of the mean motions of the Sun and Moon are joined or opposed. From this it follows that, if the point of the mean equinox then lies between the point of the true equinox and the Sun's body, the true equinox will be distant from the mean by a greater interval than the prosthaphaeresis, or equation of the precession of the equinoxes, requires. Yet even so this distance could not reach a full four days, since the equation of the Sun, or of its orb, never amounts to two whole degrees.

[Margin: Quid deceperit nonnullos, vt putauerint æquinoctium medium à vero abesse posse toto quatrduo. — What deceived some, so that they thought the mean equinox could be four whole days distant from the true.]

But these lynx-eyed mathematicians have gone astray. For the case of the mean equinox is one thing, and that of the mean conjunction or opposition of the luminaries another. The mean equinox occurs as soon as the Sun reaches the point of the mean equinox, as astronomers teach. For Erasmus Reinhold [Erasmus Reinhold], that most skilled astronomer, writes as follows in Precept 22 of the Prutenic Tables which he constructed: *Non dubium est, Solem conficere vernum æquinoctium, cum tanto interuallo adhuc præcedit primam stellam Arietis, quantum interiectum est inter ipsam vernam sectionem vtriusque circulorum, æquinoctialis, atque obliqui, & eandem stellam.* [There is no doubt that the Sun makes the vernal equinox when it still precedes the first star of Aries by just such an interval as lies between that vernal intersection of the two circles, the equinoctial and the oblique, and the same star.] That this is to be understood of the mean vernal intersection as much as of the true is gathered from Precept 10, where he calls the difference between the mean and the apparent equinox the prosthaphaeresis, or equation of the equinoxes, whose maximum is 71 minutes and 22 seconds together with half a second. The same is taught much more clearly by Giuseppe Moletti [Giuseppe Moletti], the famous astronomer, in the

Gregorian tables he published, at Canon 13, where he says: *Fit æquinocmium apparens,*

[Margin: *Æquinocmium medium quando fiat.* — When the mean equinox occurs.]

apparens, quando Sol ingreditur punctum sectionis Eclipticæ, & Æquatoris apparentis: medium vero, quando Sol intrat punctum sectionis Æquatoris medij, & Eclipticæ. Et ideo æquinocmium verum fit, quando Sol antecedit primam Arietis stellam tanto spatio, quanta est vera præcessio æquinocmiorum ad datum tempus: Medium autem, quando Sol antecedit tanto interuallo primam Arietis stellam, quantus est arcus mediæ præcessionis. Differentia inter hæc duo æquinocmia est tempus respondens Prosthaphæresi æquinocmiorum. [The apparent equinox occurs when the Sun enters the point of intersection of the ecliptic and the apparent equator; the mean, when the Sun enters the point of intersection of the mean equator and the ecliptic. And so the true equinox occurs when the Sun precedes the first star of Aries by as great a space as the true precession of the equinoxes amounts to at the given time; the mean, when the Sun precedes the first star of Aries by as great an interval as the arc of the mean precession. The difference between these two equinoxes is the time answering to the prosthaphæresis of the equinoxes.]

The mean equinox will therefore not occur when the line of the Sun's mean motion occupies the point of the mean equinox, as these new mathematicians wrongly seem to want, but when the Sun itself holds that point, as we have set out from the doctrine of the astronomers. For if the equinox became mean when the Sun by its mean motion holds the mean vernal intersection, the true and the mean equinox would not always occur together when the prosthaphæresis of the equinoxes is nil — since it is very rarely the case that the Sun's true motion then fails to differ from the mean. But this conflicts with all the astronomers, since they all teach that the mean equinox occurs together with the true whenever the prosthaphæresis of the precession of the equinoxes is nil.

[Margin: *Æquinocmium medium non fieri, quando linea medij motus Solis cum puncto medij æquinocmij coniungitur.* — That the mean equinox does not occur when the line of the Sun's mean motion is joined with the point of the mean equinox.]

9 But let us carry the calculation forward to some later years, so that it may appear how rash and thoughtless one of these mathematicians has been in this matter too, when he most ineptly asserted that the equinox would slip back to 27 March before the year of the Lord 15000, if the method of equating the solar year

prescribed in the new calendar is kept. He asserted this, I believe, on no astronomical calculation, but out of that false opinion of his — namely, that the mean equinox falls on 23 March, and that either equinox can be distant from the mean by a full four days. For it is from this, and from nothing else, that one gathers that the true equinox will at some point slip back to 27 March, and will advance as far as the 19th. But that this is fictitious and false, the calculation of the years set out below plainly demonstrates.

[Margin: Quare quidam Astronomus putauerit æquinocmium verum prolapsurum ad diem 27. Martij. — Why a certain astronomer supposed that the true equinox would slip back to 27 March.]

Aequinocmium ergo verum fiet.

[The vernal equinox, then, will fall:]

Anno Domini [In the year of the Lord]	Die [on day]	Martii [of March]
4709	21	post med. noct. [after midnight]
5084	21	ante med. noct. [before midnight]
5209	23	circa med. noct. [about midnight]
6004	23	sub occasum Solis. [toward sunset]
10020	23	post med. noct. [after midnight]
15002	21	post med. noct. [after midnight]
15004	20	circa med. noct. [about midnight]
15102	21	post med. noct. [after midnight]
15202	21	post med. noct. [after midnight]
15604	22	post med. noct. [after midnight]

Anno Domini [In the year of the Lord]	Die [on day]	Martii [of March]
15804	23	circa med. noct. [about midnight]
20004	20	post merid. [after midday]
20005	20	post med. noct. [after midnight]

Where, I ask, is the equinox on 27 March in these thirteen years, right up to the year 20005? I certainly find that it is not more than two or three days, and a little more, away from the 21st — even when the true equinox is computed from the Prutenic Tables with the equation-formula of the Gregorian calendar always applied. But evidently that sharp mathematician, a simple soul born to slander what has been rightly done, supposed that no one would go on counting into future centuries to sift his prophecy about the equinox slipping back to the 27th.

And if, after so vast an interval of years (supposing the world is to last so long), it were established that the Prutenic Tables still agreed with the motions of the heavens, who does not see that our method of intercalation — framed on the mean magnitude of the year and running in periods of 400 years — is the most suitable of all, granted that something regular and uniform must be set before ordinary people in the ecclesiastical computus for determining the movable feasts from the motions of the heavens (which we have amply shown to be altogether necessary in chapter 4 and in other places)? For with this formula of intercalation applied, the equinox returns of its own accord to 21 March, even though, on account of the unequal magnitude of the solar year, or on account of the unequal precession of the equinoxes, it is apt now and then to stray a little to one side or the other of the 21st. And so with the fullest right this equation of ours can be said to keep the equinox around 21 March.

[Margin: *Calendarium nouum esse perfectum, etiamsi tabulæ Prutenicæ veris motibus adhuc consentirent post annos 20000. — That the new calendar is sound, even if the Prutenic Tables should still agree with the true motions after 20,000 years.*]

10. One point, however, must not be passed over here. If our equation, framed on the Alphonsine or mean year, is applied, the equinox follows 21 March more often than it anticipates it, and recedes from that same 21st by a greater interval toward the end of the month than toward its beginning.

For since, as has been said, the least year requires 84 years for the equinox to anticipate by one day, while the Alphonsine or mean year calls for 134 years and the greatest for 329, it comes about that the speed with which we forestall the equation due to the greatest year is greater than the slowness with which we defer the equation answering to the least year. Hence when the year is nearly at its greatest, the equinox will indeed roll forward to the later days of the month, because more intercalary days are dropped by our equation of the mean year than the case demands; and when the year is nearly at its least, the equinox will retreat to the earlier days of the month — yet not with the same swiftness with which it slipped toward the end of the month, because the number of intercalary days retained by our equation of the Alphonsine year, which on account of the least year ought to have been omitted, is not as great as the number previously omitted which the greatest year prescribed should be retained. But this matter ought not to be reckoned of such moment that another equation should on that account be established

[Margin: Cur æquinoctium per æquationem noui Calendarij frequentius post diem 21. Martij contingat in cœlo, quam ante diem 21. — Why, under the equation of the new calendar, the equinox occurs in the heavens more often after 21 March than before the 21st.]

and maintained — since no other can be devised so easy that it would keep the equinox in the same seat as well as ours does, especially since under our equation the equinox returns of its own accord to the 21st day, and is held there more correctly than under any other equation whatsoever.

To make this plain, and to show still more clearly that the Alphonsine year — the mean year — necessarily had to be adopted if a fixed and determinate equation was to be prescribed, and not the least or the greatest year (as we set out in chapter 5), we have computed the equinox of, for example, the year 5084, applying the equation first at intervals of 84 years (the span the least year requires for the equinox to anticipate by one day), and then at intervals of 329 years (the span we said the greatest year demands for the equinox to anticipate one day). If the first equation is used, then in the year 5084 a total of 51 days will have been dropped (counting in the ten that were removed in the year of the correction), and the equinox will fall on about 7 April — that is, 17 days after 21 March. If the second equation is applied, only 21 days in all will have been dropped, and the equinox will fall on about 7 March, roughly 14 days before 21 March. But with our own equation applied, 36 days will have been omitted by

that year, and the equinox will occur on 21 March, shortly before midnight, as is clear from the calculation of the preceding 13 years just given.

You see, then, that under the equation of the least year the equinox recedes from 21 March toward the later months by far too great an interval, while under the equation of the greatest year it slips back much too far from that same 21st toward the beginning of the month; whereas the equation of the mean year keeps and guards it quite suitably about that same 21st day.

In the same way the calculation will show that an equation framed to any other year than the mean drives the equinox from the proper seat we fixed for it on 21 March further than it should. This is evident from the year-length of 365 days 5 hours 53 minutes 2 seconds 37 thirds, which requires nearly 207 years for an anticipation of one day, and which might therefore seem apt for having an equation prescribed to it, since 207 years holds almost the middle place between the 84 and the 329 years which, as we said, the least and the greatest year require for the equinox to anticipate one day in the calendar. Let us see, then, whether this equation preserves the equinox at the 21st as well as ours does. The calculation shows that in the year 2940, for instance — when 18 days in all will have been dropped by this equation — the equinox falls on 18 March at sunrise, that is, 3 days and more before 21 March; while in the year 10020, with the same equation applied, 51 days in all will have been dropped, and the equinox occurs on 1 March, again at sunrise, that is, 20 days and more before 21 March. Now let us compare these equinoxes with the equinoxes of the same years under our own equation. We shall find that ours does not force the equinox so far from its proper seat — even though the 134 years in which, on our reckoning, the equinox anticipates one day do not hold the middle place between the 84 and 329 years that the least and the greatest year demand for an anticipation of one day: for in the year 2940 it puts the equinox on 19 March after midnight, and in the year 10020 it throws it back to 23 March after midnight.

[Margin: That any equation other than the one framed to the Alphonsine year drives the equinox from its proper seat further than it should.]

From this it follows that no one can justly find fault with our equation, since none more apt can be produced — unless someone should say that an uneven and irregular equation, varying with the varying length of the year, ought to be applied at different times; and that we long ago ruled out by the practice and custom of the Church.

[Margin: That the equation framed to the mean year cannot justly be faulted.]

CAPVT VII.

Soluuntur dubitationes variae de aequali anni Solaris formula in Calendario nouo praescripta.

Various doubts concerning the uniform formula for the solar year prescribed in the new calendar are resolved.

Although everything that can be brought against the Gregorian correction of the year — so far as concerns the restoration of the equinox to 21 March and its preservation there — can be refuted without difficulty from what we wrote in the two preceding chapters, still, so that the truth may appear more clearly, it will not be useless to set out here, and to resolve, a number of the difficulties which either those who oppose this correction with all their energy commonly raise, or which might occur to someone else.

First, then, in order to overturn this new calendar from its foundations, not a few anxiously and uneasily ask themselves which astronomical tables this Gregorian emendation of the calendar follows — the Alphonsine, the Prutenic, or some others. And whichever it may finally approve, the first foundations of the new calendar seem to them to totter, because, they say, the calculation of no tables published to this day agrees exactly with the heavens: the tables are uncertain and need some vigorous restorer. This, they assert, is the common complaint of all mathematicians. From this they conclude that the new calendar is in no way perfect or perpetual, and therefore will not last through all ages without some change, since its foundation is anything but firm.

[Margin: 1. An argument against the new calendar.]

The answer is that in this work of correction the Prutenic tables were used, as being the more celebrated and more probable in our age. This is why — since those tables teach that sometimes more than 134 years are required for the equinox to anticipate one day in the calendar, and sometimes fewer — the equation of the solar year was framed to the mean length of the year, exactly as if the equinox advanced one day toward the beginning of the month in each interval of 134 years, so that by this mean the excessive slowness of the greatest year and the swiftness of the least might in some measure be balanced against one another.

[Margin: Solution. That the Prutenic tables were used for restoring the calendar.]

Nor does the variety and inconstancy of the astronomical tables tell against the durability or the constancy of the calendar. For as we said in chapter 5, the perfection and perpetuity of the calendar does not consist in this, that it should answer to the motions of the heavens

exactly at every time, and that the equinox should be so fixed and settled on 21 March that it could never be moved from it, whatever equation — ours or any other — were applied. That cannot possibly be done: partly because of the mutability of the tables, whichever we may in the end choose to follow, but most of all because a middle and even path has to be chosen, one that is regular and suited to the grasp of ordinary people, as reason demands and as has been observed in the corrected calendar. The excellence and perpetuity of the calendar consists rather, as was said above, in this: that the cycle of epacts is arranged in it with such art that nothing in it will ever have to be altered in future ages, but the calendar will remain wholly untouched — even if, by the intercalation or the omission of one day, or even of several, by decree of the Supreme Pontiff, the equinox has to be recalled to 21 March, should it be found to have slipped so far from it that it cannot return there of its own accord without this remedy. We shall treat this perpetuity and excellence of the calendar more fully later, when we explain the equation of the lunar year; and there we shall also show by what means the new moons and full moons too can be corrected, if need be, with no change at all made in the cycle of epacts inscribed in the calendar.

[Margin: (continuing) ...astronomical tables does not damage the perfection and perpetuity of the calendar.]

To this may be added what was said in the last chapter: that on our equation and on the Prutenic tables the equinox returns to 21 March even after 20000 years — a point most worthy of observation, for it wonderfully commends the excellence of the new calendar — even though in the meantime it may have strayed now to the 23rd, now to the 19th day. There is nothing absurd in this, since no even and uniform equation of the solar year can be devised that would preserve and hold it perfectly and exactly on the 21st itself; nor is the Church, in the political and civil year, compelled to pursue astronomical niceties, even if that year sometimes diverges from the true motions of the heavens, as we showed in that same preceding chapter. It is enough that she prescribe one day for the political or ecclesiastical equinox, to which the equinox may at set times be restored by the authority of the Roman Pontiff, if it ever departs too far from it — and the calculation of past years shows very clearly that this happens exceedingly rarely.

[Margin: What the perfection of the calendar consists in.]

Next, it seems to tell against the perfection of the new calendar that not even in the present years in which we now live do the equinoxes fall on 21 March, so that the omission of 10 days appears not to have brought the equinox back to 21 March at all. For in our own time it falls, in every intercalary year, not on the 21st but on 20 March. Thus in 1584 it was on the 20th, at about 10 hours after noon; in 1596 it was on the 20th at 9 hours after noon; in 1612 it will be at 8 hours after noon on that same 20th day, and so on in sequence. Moreover, after the year 1640 the equinox will climb to that same 20 March not only in the intercalary years but also in the years that are first after the intercalary ones. For in 1645, which is not bissextile but the first year after a bissextile, the equinox will fall on 20 March at 12 hours 24 minutes after noon; and in 1697, which is likewise the first year after a bissextile, it will fall on 20 March at 9 hours after noon. So from the year 1640 onward the equinoxes of all the bissextile years, and of the years next following them, will fall on 20 March, right up to the year 1700. And although some part of this will be set right by the omission of the intercalary day in 1700, that restoration (as one of our opponents objects, by way of calumny) seems to be no more than paying one debt by contracting another. For the equinoxes of the bissextile years and of the first years after them will indeed be brought back to 21 March by striking out the intercalary day of 1700; but by that very means the equinoxes of the second and third years after the bissextiles will be shifted to 22 March. And this exchange and alternation seems impossible to remove, until at last, after no small number of years, the equinoxes of all the bissextile years, as well as of the three years following, desert 21 March altogether.

[Margin: 2. An argument against the new calendar.]

This doubt must be met by showing that our opponents argue wrongly and maliciously when they use it to prove that the equinox, after the removal of 10 days and under our equation, does not fit the present years. For the years 1584, 1596, 1612, which are cited as examples, are all bissextile. It is no wonder, then, that in them the equinox moves from the 21st toward 20 March, because of the added intercalary day — though it could with perfect justice be assigned to the 21st, since in all those years it occurs after sunset, namely at 10, 9, and 8 hours after noon. And every astronomer knows that at least two days must be allowed to the equinox, on account of common and bissextile years, even if the intercalation made every fourth year agreed most exactly with the solar year — that is, even if the year were truly of 365 days 6 hours. From this too it appears plainly that our adversaries are cunning old hands rather than fair judges of the matter, and that they are looking (as the proverb has it) for a knot in a bulrush, since they cavil at what has been done perfectly rightly. For as far as the present

years are concerned, the equinox has been rightly restored to 21 March, seeing that in intercalary years it climbs to the 20th — which is just what the principle of intercalation requires. And that after the year 1640 the equinox will move further and further toward the beginning of the year, falling on 20 March even in the years that are first after the bissextiles, wonderfully confirms the omission of the intercalary day to be made in 1700 — namely, that in this way the equinox may be drawn back to 21 March in the years after the bissextiles.

[Margin: Solution.]

[Margin: That the restoration of the equinox to 21 March by the omission of the intercalary day in the year 1700 is not paying one debt with another, as certain people allege by way of calumny.]

Nor indeed is this restoration by way of the intercalary day of the year 1700 merely paying one debt with another, as one of our adversaries maliciously charges. For although in the years following 1700, because of that very removal of a day, the equinox of the years that are second and third after the bissextiles will be transferred to 22 March, and long afterwards even to the 23rd, this cannot be charged as a fault against our equation, but against the inequality of the solar year. For since, as was shown above, the equation of the year must be even and regular, so that it may be easily grasped by all peoples, while the length of the year is unequal, now greater, now less, it follows that if an equation is applied that answers to the mean length of the year — the only one that is even and uniform, as the practice of the Church requires — the equinox cannot remain permanently on 21 March, as we showed in the last chapter, but will now slide down to the 22nd and 23rd, now climb up to the 20th and 19th. It will slide down to the 22nd and 23rd when the length of the year is at its greatest, and therefore more than 134 years are required for an anticipation of one day — as happens in our own century, and will happen continuously until the year 2080, because throughout that whole time the tropical year will be greater than the Alphonsine, as is clear from the preceding chapter. But from there it will return to 21 March when the tropical year becomes less than the Alphonsine, since then the equinox needs fewer than 134 years for an anticipation of one day. And on the other hand it will move forward from the 21st to the 20th and the 19th of March when, after it has come back to the 21st because of the least length of the year, as we said, the year is found smaller still than the Alphonsine year.

[Margin: That because of the inequality of the year the equinox recedes from 21 March in both directions.]

[Margin: When the equinox slides down from the 21st to the 22nd and 23rd, and when it returns to the 21st.]

But as soon as the year becomes greater, the equinox will draw back to the 21st from the 19th and the 20th. Thus 21 March, the day assigned to the equinox, holds in a manner the middle place between the 23rd and the 19th, the limits out to which the equinox so runs that it can scarcely run beyond them, not even in the space of very many centuries, but returns from there step by step and of its own accord to the 21st, as was shown in the last chapter. So either this is no borrowing-to-pay at all, or, if it can in any way be called such, it must be reckoned the borrowing not of a bankrupt bent on ruin, but of a prudent householder settling his estate, for a time.

[Margin: Likewise, when it recedes from the 21st to the 20th and 19th, and when it returns from there to the 21st.]

[Margin: That 21 March, the day assigned to the equinox, holds the middle place between the 23rd and the 19th — the limits out to which the equinox can run, since from there it returns of its own accord to the 21st.]

But suppose someone presses the point and urges that from this excursion of the equinox to 23 March and to the 19th (which we assert cannot be avoided) it follows that Easter may be celebrated both in the last month and in the second — which seems absurd. I answer, first, that this can happen only very rarely. For even if the equinox slides down to the 22nd or the 23rd, Easter will nevertheless never on that account be celebrated in the last month unless epact xxij or xxij is in use; and that rarely comes about, since epact xxij or xxij does not come into use in every nineteen-year cycle of epacts, but only in eight of all the 30 cycles of epacts, of which we shall speak later. For in the remaining 22 cycles epact xxij is found alone in 11 cycles, and epact xxij in the other 11, as will appear below from the expanded table of epacts. Add to this that this error, if it ever arises from the nature of the cycle, is very often removed by the dominical letter, so that Easter is celebrated after the equinox and therefore in the first month, even though those epacts are in use and throw their fourteenth moons into the twelfth month. By the same reasoning, although the equinox moves forward to 20 or 19 March, Easter will nevertheless never on that account be thrown into the second month unless epact xxiiij or xxv is running — which likewise will happen very rarely.

[Margin: That Easter rarely falls in the last or in the second month.]

Next, suppose both do happen: even so, this is nothing new or unheard of in the Church of God, since the very same thing must necessarily have occurred in the

days of the Council of Nicaea itself, when the decree on the lawful celebration of Easter was framed — or rather confirmed — as we demonstrated above in chapter 5. Indeed, even if the solar year needed no equation at all, but the equinox were fixed permanently to 21 and 20 March, and the old calendar were retained, Easter would still necessarily be thrown into the second month whenever, with the equinox falling on 20 March (which we showed above can necessarily happen in bissextile years), the fourteenth moon fell on that same 20 March. Nor will anyone justly blame the Catholic Church in this, for sometimes celebrating Easter in the first or in the second month, when the reckoning of the cycle, or the day fixed for the equinox, so requires: since it cannot be avoided in any way, it by no means deserves to be called an error — and all the more so because the Church has been freed from the yoke of the Mosaic law. For was not Easter, before the correction of the calendar, and above all in this century (to say nothing of other past years), very frequently thrown into the second month, and beyond that into the fourth week [?] of that second month [?] — and yet no one dared to condemn her on that account? It is enough that the Church celebrate Easter according to the decrees of the Fathers and of the councils, keeping a certain fixed day of the equinox (even if the equinox does not always fall on it), and using the lunar cycle to find the fourteenth moons, even though these too sometimes differ from the true motion. The only thing that made the minds of astronomers uneasy and anxious before the correction was that they saw this error growing greater day by day, and that it would never be removed unless the year were corrected.

[Margin: That it is nothing new for Easter sometimes to fall in the last or in the second month.]

[Margin: That it ought not to be called an error that Easter is sometimes celebrated in the second month, since this cannot be avoided, on account of the two days that the equinox requires, whether the new calendar is adopted or the old one retained.]

For my own part, together with other most learned men and very many of great weight, I was always of this opinion: that the equinox ought not to have been corrected by the Church, and indeed that she would not have corrected it — although it had run out as far as 11 March — if it had checked its excessive course and begun of its own accord, with no equation applied, to return to 21 March. So far is she from being over-anxious about the true day of the equinox, even if now and then, when that day is not observed, Easter runs into the last or the second month, provided that the day she has prescribed for the equinox holds the middle

place between the limits within which the equinox wanders to and fro. How much more, then, ought we now to be content with the equation that has been made — to be applied in each interval of 400 years according to the mean length of the year, the easiest of all, and one that allows the equinox to be moved from its appointed seat, that is, from 21 March, by an interval of no more than two, or at most three, days? Certainly hardly anyone could establish another even and uniform manner of equating that would do as much. This can be confirmed by the testimony of all who took part in this work of correction: no other, even after a long and prolonged inquiry lasting nearly a whole decade, could occur to them.

Now if it should happen — and I certainly cannot deny that it may happen after many thousands of years, nor did any of those summoned by the Pontiff to correct the year deny it, on account of the uncertain permanence of the astronomical tables — that the equinox should at some time desert 21 March altogether, moving either toward the end of the month or toward its beginning, so that it cannot return to the seat appointed for it (which one of our adversaries has prophesied to us), it has already been said more than once by what means the equinox is to be restored to the 21st, by an extraordinary intercalation or omission of a few days, by edict of the Supreme Pontiff. And this, as we have said, is not inconsistent with the perpetuity of the calendar.

[Margin: That the correction of the calendar would not have been called for, if the equinox had begun to return to 21 March of its own accord.]

Furthermore, it does not seem right to conceal that this advance and retreat of the equinox has place only in the Prutenic tables, and that it was foreseen long beforehand by those who emended the calendar at the command of the Supreme Pontiff — as may be gathered from the *Compendium of the new method of restoring the calendar* sent to the Christian princes, in which both the even and regular equation, adapted to the mean length of the year, and the uneven and irregular one drawn from the doctrine of Copernicus, are described. The former was retained (the latter rejected) as easier and better suited to the use of the Church, as was said above. But if perhaps the Prutenic tables should prove not so reliable as to be able to last long, and the Alphonsine should answer better to the motion of the Sun — as most astronomers seem to affirm — then this advance and retreat of the equinox will have no place at all: the equinox will remain through a long series of centuries in the seat assigned to it, to which it must again be restored if it ever departs from it, just as we said above. This being so, certain people inveigh in vain, so bitterly and abusively, against the restoration of the

new calendar, since they bring and object nothing against it that was not foreseen before the calendar was published.

[Margin: That the retreat of the equinox from the 21st has place only in the Prutenic tables.]

3 It also seems to not a few that this method of equating the solar year, bounded within four hundred years, is

[Margin: 3. An argument.]

[Margin: ... against the new calendar.]

faulty and imperfect, because when it is carried back to earlier ages it does not answer to the motions of the heavens. Ten days were removed all at once in the year 1582, so that the equinox might be restored to 21 March, where it is believed to have stood at the time of the Council of Nicaea. This equation, then, if it had been applied, ought certainly to have offered ten days for removal — and that seems false, since it yields only nine. For since the year 1600 remains bissextile, the years 1200, 800 and 400 would have remained bissextile as well, and the intercalary day would have had to be dropped only in the years 1500, 1400, 1300, 1100, 1000, 900, 700, 600 and 500. Only nine days, therefore, ought to have been removed, and not ten; and consequently the equinox in the time of that Council would have fallen on 20 March, and not on the 21st — which is not true.

[Margin: Solution.]

STILL, the answer must be this: our equation is not obliged to answer to every past year, just as it cannot agree exactly with every future year either, as we said above — and for the same reason: the equation is even and uniform, whereas the year is uneven. Hence it comes about that when the year is at its greatest, the intercalation ought not to be suspended as often as our equation prescribes, whereas when the year is at its least, the intercalary day ought to be dropped more often, as was said above. And since at roughly the midpoint between the birth of Christ our Lord and the year of the correction, 1582 — that is, around the year 880, when al-Battānī lived — the length of the year was found to be the least of all, and therefore the anticipation of the equinox at its swiftest, it is no wonder that our equation does not agree exactly with the times of the Council of Nicaea, since around al-Battānī's time the intercalary day would have had to be dropped more frequently than once in every 134 years. In the same way, for the years now immediately ahead, since the year is at present nearly at its greatest, the intercalary day would have to be dropped more rarely, if the equation had to

answer strictly to the true motion. Since it does not do so, because our equation is uniform, it necessarily follows that, on account of the too frequent removal of the intercalary day in 1700, 1800 and 1900, the equinox will slip from 21 March towards the end of the month, as we showed above.

[Margin: That the equation of the new calendar answers exactly for a number of past and future years, though not for all — which is enough.]

It is enough that the equation should exhibit an equinox not far from the true equinox, whether it be fitted to past years or to future ones, provided only that it now and then agrees with years both past and to come. This the equation of the new calendar performs admirably. For it answers wonderfully to the times of Ptolemy, who flourished around the year of our Lord 130, since it then places the vernal equinox on 22 March, on account of the 11 days that would have been removed up to the year of the correction, in the years 200, 300, 500, 600, 700, 900, 1000, 1100, 1300, 1400 and 1500 (for the remaining centesimal years, 400, 800 and 1200, would have stayed bissextile) — if our equation had then been in use; and it was on about that very day that Ptolemy observed it to occur. Again, the same equation keeps the equinox on 21 March with great exactness for a number of years to come, namely around the years of our Lord 1653, 2080, 2296, 2512, 2724, 3156, 3368 and 15004[?], at which times we made it plain in the preceding chapter that the equinox falls about 21 March. Our equation, therefore, is rightly to be said to agree with both past and future years, since its equinox stands, so to speak, in the middle of the advance and retreat of the true equinox — that is, it falls now before the true equinox, now after it, and now coincides with it, just as the mean new moons do when compared with the true new moons.

[Margin: How the equation of the new calendar, carried back to the times of the Council of Nicaea, yields ten days for removal.]

WHAT is more, it is not even entirely true, as our opponents assert, that the equinox falls on 20 March at the time of the Council of Nicaea if the equation is fitted to years past. For if our equation is properly carried back to earlier years, we shall find that it offers ten days for removal down to the time of that Council. For in the year 300 — from which the year of that Council was not far distant — one further day would have had to be removed, if this equation had then been in use, and accordingly the equinox would be shown around that time on 21 March. So our equation agrees not only with the years in which Ptolemy lived, but also with the times of the Council of Nicaea, which was held not long after Ptolemy's day. Our opponents therefore act maliciously and slyly when they carry our

equation back only as far as the year 500, whereas they ought to carry it back to the year 300, which was nearer to the Council than the year 500 was.

[Margin: How, if the equation of the new calendar had begun at the Council of Nicaea, it yields ten days for removal down to the year 1600.]

SUPPOSE our opponents press the point: granted that the equation, applied backwards, removes ten days down to the year 300 inclusive, which was close to the Council of Nicaea, nevertheless if the same equation had begun at the time of the Council of Nicaea and been carried forward to our own times, it would remove only nine days, as the third argument maintained. The answer is that this is not absurd, for the reason given just above — namely that in the intervening period the year was at its least. It can also be said that the four-hundredth years would then have had to be arranged differently. For since the equinox then fell on 21 March — in the year 300, that is, and at the time of the Council — the intercalary day would have had to be dropped in the year 400, so as to hold the equinox in its place; and therefore, down to the year 1600 inclusive, ten days would have had to be removed in these centesimal years: 400, 500, 600, 800, 900, 1000, 1200, 1300, 1400 and 1600 — every fourth centesimal year remaining bissextile, as 700, 1100 and 1500 would have been.

[Margin: That the removal of ten days was necessary if the equinox was to be restored from the 11th to the 21st, whether or not the equation offers ten days for removal down to the Council of Nicaea.]

BUT however that may be — whether or not our equation answers to the year of the Council of Nicaea — it is certain and settled in everyone's judgement that ten days had absolutely to be removed, so that the equinox might be called back from 11 March, to which it had advanced, to the 21st; just as, if it had been necessary to call it back to the 25th, the day of the Lord's Incarnation (which not a few desired), fourteen days would have had to be removed — even though from the Incarnation of the Lord down to our own times the equinox has not moved forward from its place by that many days; for it is clearly established from Ptolemy's observations that at the time of the Incarnation of the Word of God the equinox fell on 23 March.

[Margin: A general reply to all the arguments that can be brought against the equation of the equinox.]

4 AND let this be our answer to the arguments that might seem to shake, by some middle course, the equation of the new calendar. To these, however, and to all others whatever that can in the end be brought forward, it will be possible to

reply by saying that all the arguments are drawn from the true motion, and that from the Prutenic tables — a motion which is highly uneven and irregular, cannot be fitted to any cycle, and is therefore unsuited to overturning our equation. For our equation rests on the mean motion, which is uniform; so that by its steadiness and uniformity it finely and neatly compensates for the uneven and irregular advance and retreat of the true equinox over many thousands of years, and never lets the equinox depart from the true one by more than two days at most, or a little more, sometimes running ahead of it, sometimes lagging behind. And that is quite enough for the due celebration of Easter according to the decree of the Church, which in the reckoning of time employs and considers mean and regular motions — or rather cycles — by very ancient custom, leaving the true and uneven motions to the curiosity and diligence of astronomers.

[Margin: How it is to be understood ...]

WHEN, however, we say that our equation agrees with the mean equinox and not with the true one, the "mean equinox" is not to be understood

[Margin: ... that the equinox of the new calendar agrees with the mean equinox.]

as astronomers understand mean motions, but as the equinox of the mean, or Alphonsine, year — which, once our equation is applied, will almost always cling to 21 March.

5. IF perhaps, after a long interval of time, it should happen (and we frankly admit that it can happen, because of the unsteadiness of the astronomical tables) that the equinox of the new calendar departs unduly from the true equinox, it will have to be restored, as has often been said, to 21 March, by an intercalation, or by an omission of intercalation applied out of the regular order; and thereafter either the same rule of equating is to be retained as before, or else another better suited to that age is to be prescribed on the astronomers' judgement — yet in such a way that no change is made in the calendar so far as the arrangement of the epacts is concerned. On this reckoning, even though the equinox may at some time need restoration, or the plan of the equation need changing, the calendar itself is nonetheless called perpetual in the Bull of Gregory XIII, and is of such a kind that it can be adapted to any length of the year whatever by interrupting or varying the equation, while it meanwhile remains, together with the epacts, untouched, stable and wholly unchangeable — as will be explained more plainly below, in dealing with the equation of the Moon.

[Margin: Why the new calendar is called perpetual by the Pontiff.]

THEREFORE what argument can be devised at last that would have any force against the calendar as being perpetual in the sense stated? For although the equation of the solar year does not preserve the equinox on the 21st day over a long stretch of time so well as to need no emendation, the calendar is not on that account to be judged faulty or imperfect, since with nothing in it altered the equinox can be corrected without any trouble, by varying the equation in some way, if that seems good. And certainly no calendar can be constructed in any other way than the one described that would be either perpetual or long-lasting, since everything the astronomers have subtly and acutely handed down about the length and the unevenness of the solar year is uncertain and doubtful — so that of no equation of the year, whether framed to the mean motion or to the true, can we promise ourselves a steady, perpetual or long-lasting truth.

[Margin: That no calendar can be built in any other way than that in which the Gregorian is built.]

6. IF, then, some equation of the solar year is set up together with a lunar cycle laid out through the days of the calendar, and so contrived that nothing in the calendar ever has to be altered, even should some error be detected in keeping the equinox at its appointed seat, so that the equation of the solar year has to be changed in the way we set out above — then at last the business of the calendar will have been splendidly managed, and it can rightly and with the best justice be reckoned perfect and complete. Of just this kind is the new calendar published by Gregory XIII, Supreme Pontiff, in the year 1582, as is partly clear from what has been said, and will appear partly — and indeed far more evidently — from what remains to be said. If those who think less well of the new calendar would weigh this with a sincere and untroubled mind, they would surely not pour out so many words and insults against the new calendar so rashly and thoughtlessly.

[Margin: What is required for a calendar to be called complete and long-lasting.]

And indeed anyone can gather all this without any difficulty from the *Compendium of the restoration of the calendar* sent to the Christian princes, where it is most plainly declared that the cycle of the epacts can be adapted to any length of the year — so much so that, once that cycle has been set out in the calendar, and once the rule of intercalation at every four-hundredth year has been applied (as has been explained), together with the equation of that cycle, which we shall discuss below, the years and months will thereafter so agree with the reckoning of the Sun and Moon that no further discrepancy or disagreement

of any consequence can arise. And if it should ever happen that some discrepancy does arise, the same *Compendium* clearly testifies that everything can be restored to its proper state by a very easy method. For that reason a twofold table of the equation of the epacts is constructed in it: one agreeing with the Alphonsine year, which is mean and uniform, the other answering to the year of Copernicus, which is uneven and irregular. So no one can justly object that we failed to foresee what might be urged against the calendar, or failed to understand in what sense it can be called perpetual and never liable to any change.

BUT enough has been said here about the exposition of the new calendar so far as the equinox is concerned. That our equation, proceeding by four hundred years, surpasses all others that can be devised may be established clearly enough from what has been said so far; but it will appear more clearly from chapter 22, where we shall subject it to astronomical calculation from the year 1600 to the year 5000. There it will appear plainly enough that this equation of ours for the solar year, together with the equation of the lunar year (of which later), does not depart from the decrees of the Councils and of the Pontiffs — something that can hold of no other equation that might be set up, as will be clearly established if any other equation whatever is examined by astronomical calculation. Let us therefore now turn to the exposition of the lunar year, where the nature of the nineteen-year cycle of the golden number must be laid open, together with the cycle of the epacts, and the reason why, once the golden numbers were removed from the calendar, epacts were substituted in their place. Then we must treat of the solar cycle, or the cycle of dominical letters, and of finding the movable feasts. Finally, at the end, we shall briefly set down certain easy rules bearing on the ecclesiastical computus.

CAPVT VIII.

How the nineteen-year cycle of the golden number equalizes 19 solar years.

1

THE lunar year, like the solar year of which we spoke in chapter 5, is of two kinds: the one civil or political, the other astronomical. The civil year consists of whole days and is of two sorts, common and embolismic. The common year contains sometimes 354 days, sometimes (which rarely happens) 353; the former is usually called full, the latter hollow or defective, and each comprises 12 lunations. The embolismic year, for its part, generally contains 384 days, but

sometimes (though more rarely) 383; the first is likewise called full, the second hollow; and each is made up of 13 lunations. Nor

[Margin: What the civil lunar year is, of how many kinds, and how long.]

[Margin: What the lunar year, both common and embolismic, full and hollow, is.]

can the civil lunar year be arranged or reckoned in the calendar otherwise than by whole days — no more than the solar year can, the reason for which we gave fully in chapter 5. For the same relation of the solar year holds good for the lunar year.

[Margin: What the astronomical lunar year is and how long, both the common and the embolismic.]

2 THE mean or uniform astronomical lunar year (for of the true one, which is highly uneven and variable and belongs to the astronomers, nothing need be said here) comprises, besides whole days, a number of hours and fractions of hours. Thus the common year of 12 lunations, by the Prutenic tables, which are today held the more reliable, contains 354 days, 22 minutes of a day, 1 second, 35 thirds, 19 fourths — that is, 354 days, 8 hours, 48 minutes, 38 seconds, 7 thirds, 36 fourths. The embolismic year of 13 lunations contains 383 days, 53 minutes of a day, 51 seconds, 43 thirds, 16 fourths — that is, 383 days, 21 hours, 32 minutes, 41 seconds, 18 thirds, 24 fourths.

[Margin: The length of the astronomical lunar month according to the mean motion.]

A single lunation, or lunar month, taken according to the mean course — that is, the interval of time from one mean new moon to another — comprises 29 days, 31 minutes of a day, 50 seconds, 7 thirds, 57 fourths; that is, 29 days, 12 hours, 44 minutes, 3 seconds, 10 thirds, 48 fourths. The size of the lunar month is nevertheless set a little larger by Ptolemy and by Nicolaus Copernicus, and a little smaller by the Alphonsines and by most computists. Ptolemy indeed puts it at 29 days, 12 hours, 44 minutes, 3 seconds, 12 thirds; the Alphonsines make it 29 days, 12 hours, 44 minutes, 3 seconds, 2 thirds. For my own part, by dividing the whole circle of 360 degrees by the Moon's elongation from the Sun in one day, which in the Prutenic tables is 12 degrees, 11 minutes, 26 seconds, 41 thirds, 29 fourths, 57 fifths, 49 sixths, 37 sevenths, I find the lunar month to be 29 days, 12 hours, 44 minutes, 3 seconds, 10 thirds, 38 fourths, 9 fifths, 20 sixths, 5 sevenths. But in what follows we shall adopt the former value, which is larger than this by 10

fourths. That, perhaps, is why the Prutenic tables chose the intermediate quantity, as the more likely.

[Margin: How great the half and the quarter of the lunar month are.]

From this it follows that half a lunar month comprises 14 days, 45 minutes of a day, 55 seconds, 3 thirds, 58 fourths — that is, 14 days, 18 hours, 22 minutes, 1 second, 35 thirds, 24 fourths; and a quarter of the same lunar month, 7 days, 22 minutes of a day, 57 seconds, 31 thirds, 59 fourths — that is, 7 days, 9 hours, 11 minutes, 0 seconds, 47 thirds, 36 fourths. And although this reckoning of the lunar month by days, hours and fractions of hours cannot be written into the calendar, which contains only whole days, knowledge of it is nonetheless indispensable if the civil or political lunar months are to be so established that they can agree with the solar year. Let us now explain by what method this is done by means of the nineteen-year cycle of the golden number.

[Margin: Meton the Athenian, the inventor of the nineteen-year cycle of the golden number.]

3 AMONG the most ancient astronomers who concerned themselves with the course of the Moon and its harmony with the solar years, then, Meton the Athenian is found, who flourished about the 86th Olympiad, roughly 431 years before the birth of Christ. He announced that in 19 solar years 235 lunar months are completed. From this the whole of that span of time embracing 19 solar years was called the great year, [Greek: ἐννεαδεκάτηρις(?)] (enneadekatēris, "nineteen-year period" — the printed form is compressed and its ending does not resolve with certainty)], that is, the Metonic nineteen-year period.

[Margin: The Metonic nineteen-year year.]

This number won such favour that it was set up in the marketplace at Athens and in other notable cities, and was called golden by the Romans; and it remained in common use right down to the Gregorian correction, because men judged that by it the beginnings and ends of the months stood in a fixed order. And since in 19 years four bissextile years are contained, with three years left over; in 38 years, nine bissextiles, with two years left over; and in 57 years, fourteen bissextiles, with one year in excess; while in 76 years there are exactly nineteen bissextiles — Hipparchus adopted this span of 76 years (a number produced by multiplying 19 by 4), who flourished about 128 years before Christ our Lord, in the 162nd Olympiad; and for that reason the same span was called by Ptolemy and other writers the Callippic period, in which 940 lunar months are completed.

[Margin: The Callippic period of 76 years.]

But neither the Metonic year nor the Callippic period agrees exactly with the solar years, as will be clearly established from what we shall presently add.

[Margin: The length of the civil lunar month.]

4 IN the nineteen-year cycle the civil lunar month is fixed at 29 days and 12 hours only, the fractions of the hours being left aside. But since hours cannot be written in the calendar, the numbers of the nineteen-year cycle are laid out for finding the new moons by this device, through the days of the year: the lunations, that is, the lunar months, contain 30 and 29 days alternately.

[Margin: Why the lunations in the calendar run alternately of 30 and 29 days.]

For thus it comes about that the 12 hours granted in excess to the preceding lunation of 30 days are taken away again by the following lunation of 29 days; that two lunations comprise 59 days; and that twelve lunar months make 354 days, which constitute the civil lunar year. And therefore the common civil lunar year differs by 11 days from the common solar year of 365 days. From this it results that the new moons of the following year generally fall (for sometimes this order is interrupted, the nineteen-year cycle requiring it, as we shall say in the following chapter 9) 11 days earlier than the new moons of the year before; so that if, for example, some new moon falls on the 29th of any month in a given year, in the following year it will fall on the 18th of the same month; in the third year, on the 7th; and so on in turn, until 19 years are completed, after which that new moon falls again on the 29th day.

[Margin: Why the new moons in any given year generally fall 11 days earlier than in the year immediately preceding.]

The reason is that all the lunar months contained in 19 solar years comprise nearly as many days and hours as make up 19 solar years. For 19 solar years (if you assign to each, following the institution of Julius Caesar, 365 days and 6 hours) contain 6939 days and 18 hours, in which 235 lunations and a little more are completed according to the Moon's mean course; and just so many civil lunations are included in the same 19 solar years. For 235 mean lunations require 6939 days and, over and above, 16 hours only, 32 minutes, 27 seconds, 18 thirds, 0 fourths — so that the 19 solar years exceed the 235 mean lunations by 1 hour, 27 minutes, 32 seconds, 41 thirds, 0 fourths.

[Margin: How many days 19 solar years contain.]

[Margin: In 19 solar years there are 235 lunations.]

Hence it comes about that the mean new moons, when 19 solar years have passed, do indeed fall on the same days of the months on which they fell 19 years before, but not at exactly the same hours: somewhat earlier, by just the amount of excess we have stated. So small is the interval of time by which the Moon runs ahead of the seats appointed to it in the calendar over 19 years.

[Margin: How great the difference is between 19 solar years and 235 mean lunations.]

From this it follows that in 76 years — that is, in four nineteen-year cycles — the Moon anticipates those same seats by 5 hours, 50 minutes, 10 seconds, 44 thirds, 0 fourths; and at length, in $312\frac{1}{2}$ years, by almost a whole day. Computists with Hipparchus would have it that the Moon runs ahead of its seats by one day in 304 years, because they make one lunation smaller than we do, as we have said. But more truly, as we have shown, the Moon anticipates its seats by one day in $312\frac{1}{2}$ years. For according to the quantity of a single lunation given above, in $312\frac{1}{2}$ years it runs ahead of its seats by 23 hours, 59 minutes, 52 seconds, 49 thirds, which fall short of a whole day by only 0 hours, 0 minutes, 7 seconds, 11 thirds; and to anticipate these there are still required 23 days and 17 hours — so that the Moon truly anticipates one day in $312\frac{1}{2}$ years and 23 days 17 hours. I say this against certain people who stubbornly contend, with Hipparchus, in defence of

[Margin: How great the Moon's anticipation is in 19 years, and how great in 76.]

[Margin: The lunations anticipate one day in $312\frac{1}{2}$ years, and not in 304 years, as some would have it.]

the Moon anticipates one day in 304 years. Yet in chapter 11, in the table of the equation of the epacts, we do anticipate the Moon's equation — which we set at $312\frac{1}{2}$ years — by 23 days 17 hours. Still, these neglected days and hours barely amount to 100 years in 481436 years, and so they scarcely produce an error of 8 hours in the lunations, as we shall point out in the same chapter 11, Num. 11. This is why the new moons, from the Council of Nicaea down to our own age, have run forward by four days and more toward the beginnings of the months.

5. Now I shall make it plain that 235 **civil** lunations as well are contained in 19 solar years. Since in any given year there are 12 lunations, alternately of 30 and 29 days, making up 354 days, in 19 years there will be 228 lunations, and over and above them 209 days, made up out of the 11 days by which — as we said above — the solar year exceeds the lunar. Out of these 209 days

there are formed 7 extraordinary lunations, which are called embolismic: six of them of 30 days each, and one of 29 days, as we shall say below. These 7 extraordinary lunations, added to those 228, make up the number of 235 lunations. The lunar cycle is therefore rightly said to comprehend 19 solar years, since in that stretch of time 235 lunations are completed — precisely as many as can occur in the same interval according to the Moon's mean course, except that there still remains the difference we mentioned, of 1 hour, 27 minutes, 32 seconds, 41 thirds, 0 fourths.

[Margin: That 235 civil lunations are contained in 19 years.]

6. But let me teach the matter somewhat more exactly: how the 235 civil lunations comprehended in 19 solar years fill out the time of the same number of astronomical lunations reckoned by the mean motion. For since in the civil lunations the fractions of an hour are dropped — namely 44 minutes, 3 seconds, 11 thirds, nearly a whole hour, in each lunation — the civil lunations do not appear capable of being made equal to the astronomical ones. Nevertheless, you may learn from what follows how beautifully those discarded fragments are compensated by the bissextile days and by the 7 extraordinary lunations. The 235 civil lunations which we said are contained in 19 solar years, if $29\frac{1}{2}$ days are assigned to each — that is, if we make them alternately of 30 and 29 days (which we affirmed the Cycle requires) — make up 6932 days and 12 hours. But the same number of astronomical lunations make 6939 days, 16 hours, 32 minutes, 27 seconds, 18 thirds, 0 fourths. To fill out this span, then, the 235 civil lunations fall short by 7 days and $4\frac{1}{2}$ hours and a little more; and this deficit is made good as follows. In the whole nineteen-year cycle, over and above the whole days of the solar years, there remain 114 hours, gathered from the 6 hours dropped in each year, which make 4 intercalary days and 18 hours. Those 4 days, in the 4 bissextile years, are assigned to four lunations of February that have 29 days, so that they may contain 30. For on account of the added day, which is not marked in the calendar, that lunation which includes the said intercalary day is increased by one day, so that if it was of 29 days it becomes one of 30; but if it had 30 days it becomes one of 31 — contrary to the nature and condition of lunations, which nevertheless cannot be avoided, as will be said later in chapter 17. The civil lunations have therefore now been increased by four days, so that they fall short only by 3 days and $4\frac{1}{2}$ hours and a little more; and this deficit too we make good in the following way. Of the 7 embolismic or extraordinary lunations, we assigned 3 days to the first six, when we made

each of them 30 days, so that all six exceed six ordinary lunations of $29\frac{1}{2}$ days by six times twelve hours — that is, by three days. There will now be lacking to us only $4\frac{1}{2}$ hours and a little more. Indeed, since to the seventh and last extraordinary lunation, which in the Cycle contains only 29 days, we gave 12 hours which it does not have (for we made it, like the others, of $29\frac{1}{2}$ days, when we said that all 235 civil lunations comprehend 6932 days and 12 hours), there will be lacking $16\frac{1}{2}$ hours and a little more. These are restored by those 18 hours which, over and above the 4 intercalary days, we said were left over in the 19 years; and there will remain that same difference of 1 hour, 27 minutes, 32 seconds, 41 thirds, by which 19 solar years exceed 235 mean lunations. Aptly and neatly, then, the Moon's nineteen-year cycle agrees with 19 solar years, since the 235 civil lunations comprehended in them fill out very nearly the time of the same number of mean astronomical lunations, as we have explained.

[Margin: How the 235 civil lunations contained in 19 years fill out the time of the same number of mean lunations, even though in each of them 44 minutes, 3 seconds, 11 thirds of one hour are dropped.]

Perhaps the point will be grasped more clearly and distinctly in this way. The 228 civil lunations comprehended in 19 solar years, if we assign to each year 12 lunations alternately of 30 and 29 days, make up 6726 days. If to these are added the 209 days gathered from the 11 days which are left over, beyond the 12 lunations, in each solar year, the sum of days will come in all to 6935. If in turn there are added to these the 4 intercalary days and the 18 hours contained in the 19 solar years, the result will be 6939 days and 18 hours — as many as are found in the solar years. And so, even though the 235 lunations, each being set at $29\frac{1}{2}$ days (except the last, which has only 29 days), make up only 6932 days, there are nevertheless inserted and added out of the regular order, over the whole compass of the nineteen-year cycle, the remaining $7\frac{3}{4}$ days. These are collected partly from the 4 intercalary days and 18 hours, partly from the 3 days which we assigned over and above their due to the six extraordinary lunations, so that the number of 6939 days and 18 hours may result — which is about what is required to complete 235 mean astronomical lunations. For this span of 235 lunations differs from that of the 19 solar years by only 1 hour, 27 minutes, 32 seconds, 41 thirds, as was said above. And these $7\frac{3}{4}$ days, grafted in out of the regular order, make up very nearly those 44 minutes, 3 seconds, 10 thirds, 48 fourths of one hour which are dropped in each civil lunation, and also the 12 other hours which we subtracted from the last extraordinary lunation — since we made that one of only 29 days, whereas all the others contain $29\frac{1}{2}$ days, apart from the six earlier

extraordinary ones, each of which consists of 30 days. For 44 minutes, 3 seconds, 10 thirds, 48 fourths, multiplied into 235 lunations, yield 7 days, 4 hours, 32 minutes, 27 seconds, 1 third, 20 fourths. If to these are joined those 12 hours dropped in the last extraordinary lunation, the number of days becomes 7 days, 16 hours, 32 minutes, 27 seconds; and this differs from the figure of 7 days 18 hours by only 1 hour, 27 minutes, 32 seconds, 58 thirds, 40 fourths — very nearly the difference which we said above holds between 235 astronomical lunations reckoned by the Moon's mean course and 19 solar years. For we defined that difference as 1 hour, 27 minutes, 32 seconds, 41 thirds, so that the discrepancy is only 0 hours, 0 minutes, 0 seconds, 17 thirds, 40 fourths — which is of no consequence.

[Margin: How in 19 years the 44 minutes, 3 seconds, 11 thirds dropped in each civil lunation are made good, together with the 12 hours taken away from the last extraordinary lunation.]

This, then, is the reckoning of the 19-year lunar cycle, or golden number, so much celebrated by everyone — which Meton of Athens is said to have devised, with truly admirable ingenuity, around the 86th Olympiad, so that it has deservedly been adopted among almost all nations for finding the new moons.

CAPVT IX.

How the golden numbers are arranged in the calendar; and why, once they were removed, the epacts were substituted in their place.

1

Since the ancients had found that the new moons return to the same days after 19 years have run out, they wrote down in the calendar the same number of numerals, from 1 through 19, which they called "golden" (perhaps from their usefulness in tracking down the new moons, or — as others prefer — because they were marked in gold letters), setting them beside those days on which, in the space of any of the 19 years, the new moons fell. Thus they prefixed 1 to the day on which, with golden number 1 current, the new moon occurred; 2 to the day on which the new moon fell with golden number 2 current; and so on for the rest. In doing this, however, they carefully saw to it that the lunations should be alternately of 30 and 29 days, and that the new moons of one year should anticipate the new moons of the preceding year, generally by 11 days — on account of those 11 days by which the common solar year of 365 days exceeds the common lunar year of 354 days.

[Margin: The setting-down of the golden numbers in the calendar.]

2. From this setting-down of the golden numbers there emerged among them an order and sequence of the following kind: in the calendar they do not keep the natural order of the numbers, but the larger number generally precedes the next smaller one by 11 days, on account of those 11 days by which the solar year exceeds the lunar. Thus, if (for example) golden number 1 is placed near some day of any month, the next larger golden number, 2, runs ahead of it toward the beginning of the month by eleven days — that is, with ten days interposed — because in the following year the new moon of the same month precedes the previous year's new moon by eleven days. In the same way golden number 1, which in the natural series of numbers follows immediately after golden number 19, precedes golden number 19 in the calendar, toward the beginning of the month, by eleven days. And the same principle holds for the rest of the golden numbers. Very rarely does the larger precede the next smaller one by only ten days, and far more rarely by twelve — though this does happen from time to time, the nature of the nineteen-year cycle requiring it.

[Margin: What order there is among the golden numbers in the calendar.]

3. From this it comes about that in the calendar each following golden number is produced by the addition of eight to the preceding golden number — casting out 19, however, if the sum turns out to be greater than 19 — or (what comes to the same thing) by the subtraction of 11 from the preceding golden number, with 19 first added if the preceding golden number was not greater than 11, so that the subtraction can be performed. Conversely it follows that each preceding golden number is in turn formed by the addition of 11 to the following one, casting out 19, however, if the sum turns out to be greater than 19; or (and this comes to the same) by the taking away of 8 from the following golden number, with 19 first added if the following number was not greater than 8.

[Margin: How the following golden number is generated from the one immediately preceding, and conversely. In the calendar a smaller golden number generally follows immediately after a larger preceding one, whereas a larger does not follow immediately after a smaller.]

4. From the same arrangement of the golden numbers in the calendar there follows this sort of linkage among them: the following number, if it is smaller than the preceding one, follows immediately after it; but if it is

larger, it does not follow immediately, but in the third place, with one day left empty. In certain places of the calendar, however, this is not observed; occasionally, though rarely, a larger number does follow immediately after a smaller one, the nineteen-year cycle necessarily requiring this — namely, that the lunations be made roughly alternately of 30 and 29 days. And so, once you know the golden number written at the beginning of January (whether it stands on the first day or on the second — at the time of the Council of Nicaea golden number 3 was set against the first day of January; but now, after the correction of the calendar, if the golden numbers were to be written into the calendar, golden number 9 would have to be prefixed to the second day), all the other golden numbers that follow will be formed from it by the addition of 8 or the subtraction of 11, as has been said, this order being kept: that a smaller follows a larger immediately, but a larger does not follow a smaller immediately — with a few places in the calendar excepted, of which we shall say something shortly. Likewise, once you know the golden number that is the last one in December (whether it occupies the last day or the next-to-last), all the other preceding golden numbers will be formed from it by the addition of 11 or the subtraction of 8, and so on. But since no single rule can be given for those places in which a larger number follows a smaller immediately — because it is not always the same golden number that is placed at the beginning of January or at the end of December, but one succeeds another until all the golden numbers have occupied the beginning of January, the equation of the Moon requiring this, as we shall say below — we shall more easily arrange those same golden numbers in the calendar by means of the epacts written in the calendar, whose arrangement is both very easy and unchanging, as we shall show a little later.

[Margin: On what principle all the rest are written into the calendar from the first golden number of the calendar, or from the last.]

5. Still, the arrangement of the golden numbers in the calendar should not be passed over — the arrangement the Church used before the Gregorian correction, and would now use after the correction if golden numbers, and not epacts, had to be set out in it — so that it may be understood in what places a larger golden number follows immediately after a smaller. Suppose, then, that the number 3 is set against the first day of the year, as was done in the time of the Council of Nicaea. All the other golden numbers will be formed by continual addition of 8, always casting out 19 when the sum turns out greater than 19, and by placing the smaller immediately

under the larger, but the larger not immediately under the smaller — with these few places excepted, so that the lunations may be alternately of 30 and 29 days. On 3 February let the number 19 be written immediately under the smaller number 11; and on 6 April, 4 June, and 2 August, the number 16 immediately under the smaller number 8. Likewise on 3 October and 1 December, the number 13 immediately under the smaller number 5. Finally, once all the golden numbers have been arranged in this order, let golden number 19 be moved up in July, and in all the other five months that follow to the end of the year, to the day above, so that it may be placed immediately under the smaller number 11; and in the same months let the smaller number 8 be written not immediately under 19, but with one day left empty. I am well aware that Campanus and some others put the number 13 in December not against the first day but against the second, together with golden number 2. But since everyone else objects to this — on the ground that it is absurd for two new moons within one nineteen-year cycle to fall on the same day, such as those indicated by golden numbers 13 and 2 — since on Campanus's

[Margin: In what places a larger golden number follows immediately after a smaller in the old calendar.]

arrangement these fall on 2 December; indeed, since the very rationale of the lunations teaches the contrary, as we shall explain a little below in this same chapter, Num. 9, we have preferred, with the other computists, to write the number 13 against 1 December, immediately under the smaller number 5, which is attached to the last day of November. In this way, then, the golden numbers were placed in the calendar according to the mind of the Council of Nicaea before the correction.

6. But at the present time, after the correction, they would have to be placed thus, if we wished to use them for finding the new moons. With golden number 9 written against 2 January, all the others would be formed by continual addition of 8, as before, with these places excepted on account of the alternating lunations of 30 and 29 days. Against 5 February, 5 April, 3 June, 1 August, 29 September, and 27 November, golden number 14 would have to be written, immediately after the smaller golden number 6. Likewise on the last day of December golden number 19 would have to be set, immediately under the smaller number 11. But come — so that this difference may appear more clearly, let us set both calendars before our eyes, with the golden numbers arranged in the way we have described.

[Margin: In what places a larger golden number follows immediately after a smaller in the new calendar of our own time, if golden numbers were to be written into it.]

SEQVITVR CALENDARIVM ECCLESIASTICVM, QVO ECCLESIA A CONCILIO NICÆNO vsque ad anni correctionem à Gregorio XIII. factam vsa est.

There follows the ECCLESIASTICAL CALENDAR which the Church used from the Council of Nicaea down to the correction of the year made by Gregory XIII.

Ianuarius. [January]

[p. 110 — printed 94]

[Margin: The first golden number of January is not formed by adding 8 to the last golden number of December.]

[Margin: The golden numbers written into the calendar do not follow the pattern of the cycle.]

In this calendar you can see for yourself that each golden number is set down twelve times — exactly as many times as there are lunations in a common lunar year — apart from those seven numbers which are repeated in a thirteenth position after 20 December, and which also occupy the first days of January. I want to warn you of this, so that you will not think the golden numbers are laid out in the calendar in the manner of a cycle: that is, that the golden number for the first day of January is formed from the last golden number of the year by adding 8 to the golden number above it, the one that stands last in December. For this generation of the succeeding golden numbers by adding 8 to the golden numbers above them stops entirely at the end of the year, and begins again at the start of the year from the same golden number it began from before, with no account taken of the golden number that stands last in the month of December — because the golden numbers written into the calendar cannot preserve the pattern of the cycle. Precisely the same thing can be seen in the calendar that

follows, where the golden numbers are so arranged that they indicate the new moons from the year of the restoration up to the year 1700, exactly as the epacts show those same new moons in the new calendar.

SEQVITVR CALENDARIVM ECCLESIASTICVM, QVO POST ANNI CORRECTIONEM A GREgorio XIII. factam Ecclesia vti deberet vsque ad annum 1700. si aurei numeri pro Epactis in eo descripti essent.

THERE FOLLOWS THE ECCLESIASTICAL CALENDAR WHICH, after the correction of the year made by Gregory XIII, the Church would have had to use up to the year 1700, if golden numbers had been written into it in place of epacts.

[31 day-rows counted against the month length.]

7 THE REASON why the following golden number is formed from the preceding one by adding 8 or subtracting 11, and likewise the preceding one from the one that follows by adding 11 or subtracting 8; and why the golden numbers are not written in the Calendar in an unbroken series, but nearly always with single empty days left between each pair — that reason is this. Eight solar years, assigning 365 days 6 hours to each, comprise 2922 days, and in that span very nearly 99 lunations occur. The last lunation alone falls short by 1 day 12 hours 41 minutes 15 seconds 9 thirds, since 99 lunations according to the Moon's mean motion require 2923 days 12 hours 41 minutes 15 seconds 9 thirds. The lunations after eight elapsed years therefore do not begin on the same days on which the new moons occurred eight years before, but a day and a half later. This is why, after any given golden number, a golden number eight units greater is written in the Calendar: to signify that after eight years the new moons do not fall on the

days to which the preceding golden number is assigned, but on those before which the following golden number, formed from the preceding one by the addition of 8, is set. And since, if the following golden number came immediately after the preceding one, the lunation of the following golden number would be anticipated by 12 hours and more, the next golden number after that must be written not immediately after the first, but with one empty day left between, so that its lunation is not anticipated by a whole day and more. Thus this golden number, the third from the first — from which it is formed by adding 16 — is written in the third place after it, just as its lunation likewise begins about three days later than the lunation of that first number. This is the reason why the following golden number is composed by adding 8 to the preceding one; why they are set down two at a time; and why single empty days are left between each pair — apart from a few golden numbers which interrupt that order because of the lunar equation, which is necessary.

[Margin: Why the following golden number is formed from the preceding one by adding 8 or subtracting 11; and the preceding one from the one that follows by adding 11 or subtracting 8. And why the golden numbers are not written in the Calendar in an unbroken series.]

8 AS FOR why a smaller golden number should follow immediately upon a larger one, rather than a larger upon a smaller — a thing that could equally well have been done — this seems to have come about by a kind of accident. For since the Moon on any given day of the year is 11 days older than on the same day of the year before, on account of those 11 days by which the solar year exceeds the lunar, it follows that any golden number in the Calendar is preceded by the golden number of the following year by 11 days: that is, the Moon is reckoned new 11 days earlier than in the preceding year. Hence it came about that the smaller golden number was generally written immediately beneath the larger, while the larger was not immediately beneath the smaller — which seems attributable rather to that arrangement of the golden number and to some chance circumstance than to any fixed reason compelling the smaller to be written immediately beneath the larger rather than the larger beneath the smaller, since the reckoning of the lunations would hold good either way. So much, then, for the reason why the following golden number is formed from the preceding one by adding 8, and why the golden numbers do not keep an unbroken order.

9 LET US NOW also explain the reason why the preceding golden number is formed from the one that follows by adding 11. It is this. Eleven solar years

contain 4017 days and 18 hours, in which 136 lunations are completed, with 1 day 14 hours 8 minutes 47 seconds 4 thirds left over; for 136 lunations require only 4016 days 3 hours 51 minutes 12 seconds 56 thirds. The new moons after 11 completed years therefore do not fall on the same days on which they occurred 11 years earlier, but very nearly a day and a half earlier. This is why, before any given golden number, a golden number eleven units greater is placed in the Calendar: to signify that after 11 years the new moons do not fall on the same days on which they occurred 11 years before, but begin earlier — namely on those days before which the preceding golden number, formed from the following one by adding 11, is written. From this it follows that Campanus and some others were wrong to set these two golden numbers, 13 and 2, against 2 December. For if, after 11 years, with golden number 2 current, the new moon falls on 2 December, that same new moon must necessarily occur about a day and a half earlier, as has been said. Since, then, it is now established that any following golden number is eight units greater than the preceding one, and that any preceding number is eleven units greater than the one that follows, it plainly follows that the following number can be formed from the preceding one either by adding 8 or by subtracting 11, and the preceding one from the one that follows either by adding 11 or by subtracting 8. This is why the ancient writers divided the nineteen-year cycle — which they called ἐννεαδεκαετηρίδα[?] [Greek: "nineteen-year period"; the reading of the middle of the word is uncertain, and the standard form is ἐννεακαιδεκαετηρίς] — into an ὀγδόαδα [Greek: "octad," a group of eight] and an ἐνδέκαδα [Greek: "hendecad," a group of eleven], seeing that its whole progression and order in the Calendar is constituted by adding or subtracting 8 or 11, as we have set out. The ὀγδόας [octad], together with the 11 days by which the solar year exceeds the lunar, makes up the whole nineteen-year cycle, while the ἐνδεκάς [hendecad], together with the nineteen-year cycle, completes a full lunation of 30 days.

10 ONCE the 19 golden numbers had been disposed in the Calendar by the technique we have described, it was not hard to find the time of the new moon in any month — that is, the day on which the Moon was to be called "first." For the Moon was declared new, or the new moon was said to occur, on the day before which the golden number current in the proposed year stood; and from this the Paschal fourteenth Moon was found, and from that Easter with the other movable feasts.

[Margin: How the new moons are found from the golden numbers disposed in the Calendar.]

11 ALL THIS which we have transmitted concerning the arrangement and use of the golden number was devised by the ancients with great subtlety and great ingenuity; but more accurate astronomical observation has found it not to be true in every respect. For the new moons, when 19 solar years have run out, do not return to exactly the same places, but a little earlier, so that in each span of 19 years they anticipate their former places by 1 hour 27 minutes 31 seconds 55 thirds; in the span of four nineteen-year cycles, that is 76 years, by 5 hours 50 minutes 7 seconds 40 thirds; and finally, in 312½ years, by almost a whole day, as was shown in the preceding chapter. Consequently, from the time of the Council of Nicaea down to our own age they have moved forward towards the beginnings of the months by four days and more. Hence it came about that, in order to find the new moons by the golden numbers of the Council of Nicaea (golden number 3 being of course placed at the beginning of January), one had, before the correction of the Calendar, to count upward from the place of the golden number current in the proposed year as far as the fifth day inclusive. Some indeed used to do this by these five syllables: IN COELIS EST HIC; or by these, HIC NOVA LVNA; or by these, IN COELO LVNA.

[Margin: By how much the new moons had anticipated from the time of the Council of Nicaea down to the year of the correction.]

[Margin: How the golden numbers in the old Calendar would have had to be altered, so that they might indicate the new moons both before the correction and after it.]

12 AND SO, if the golden numbers were to indicate the new moons correctly before the correction, they would all have had to be advanced by five days, three empty days being left between the old places and the new, so that golden number 19, which before the correction occupied 5 January, would have had to be assigned to the first day, and so with the rest — keeping nevertheless to the rule that the lunations be made alternately of 30 and 29 days, as was done before the emendation of the Calendar in the Breviaries and Missals corrected by Pius V. In this way the golden numbers so disposed would have correctly indicated the new moons for the years immediately preceding the restoration. But once the golden numbers had been advanced

in this way towards the beginnings of the months, if they had had to be retained in the Calendar after the correction — that is, after the removal of the 10 days — they would have had to be moved back again towards the ends of the months by ten days, so that 9 days would be left empty between the golden numbers advanced before the correction of the year and the same numbers set back after

the correction, the same alternating lunations of 30 and 29 days being preserved. By this method the golden numbers would, after the restoration of the year, have correctly shown the new moons according to the mean motion. In the preceding Calendar, however, we have for the most part pushed those same golden numbers down eleven days from the places into which they would have been advanced by the syllables *In coelis est hic*; for since the golden numbers indicated the new moons too early in the time of the Council of Nicaea, as we shall say in chapter 11, number 5, and since, when advanced in that way, they would have shown the same thing in the same manner, they had to be pushed back by 11 days, so as to give the new moons in the way the practice of the Church makes more correct, that is, later. This has not, however, been observed everywhere, on account of the alternating lunations of 30 and 29 days.

[Margin: That the golden numbers corrected in the Calendar cannot show the new moons perpetually, or even for long; and why.]

13 BUT the golden numbers thus corrected and restored to their proper places, although they would indicate the new moons correctly for a while, could not do so perpetually or for a long time, for two reasons. First, because whenever the intercalary day is taken away from some centesimal year — that is, whenever some centesimal year is made a common year, so that the equinox may not recede from 21 March, as was said above — all the new moons would occur one day later than they would be indicated by the golden numbers. Hence, as often as a common year is made out of a centesimal year which by its own nature is bissextile, so often would all the golden numbers have to be moved down by one day in order to show the new moons correctly. Secondly, because, as we showed in the preceding chapter, number 4, the new moons in $312\frac{1}{2}$ years anticipate their places in the Calendar by one day; whence it follows that after every $312\frac{1}{2}$ years the golden numbers would have to be advanced one day towards the beginnings of the months in order to indicate the new moons — provided that the intercalary day were not then to be omitted. But by what rule this advancing of the golden numbers by one day downward is to be corrected, when some centesimal year is made common, we shall teach in chapter 12, number 10.

[Margin: If the golden number had to be retained in the Calendar, 30 Calendars would have to be made.]

14 AND ON THIS PRINCIPLE 30 Calendars would have to be made, so that the arrangement of the golden numbers would have 30 varieties, each one being moved up and down through 30 days — as many, that is, as are contained in one lunation of 30 days, as will be clear from chapter 15. But since this would be

extremely inconvenient and troublesome, it was very wisely decided that the golden numbers should be removed from the Calendar and other numbers put in their place, which would show the new moons perpetually in a single Calendar, whether the new moons move forward towards the beginnings of the months or slip back towards their ends, with no change made in the Calendar — as we shall say in the next chapter.

THESE numbers are the 30 epacts, from i to xxx, or to *. The last epact, xxx, is marked with this sign * rather than with the number xxx, because, if we wish to speak properly, no epact can be xxx, since every epact must be less than the time of a whole lunation. For the epacts are the numbers of days that remain over in December after the last lunation of the year. Thus, if the last lunation of the year ends on the last day of December, so that no day remains over, the epact of the following year will be 0; if it ends on the second to last, that is on the 30th day, the epact will be i, because of the one day remaining; if on the third to last, that is on the 29th day, the epact will be ii; and so with the rest, until we come to the lunation that ends on the Kalends of December, so that 30 days remain over. For then that lunation is not the last but the second to last, since those 30 surplus days constitute the last lunation, and so the epact will then be 0 or xxx, which we express by the sign *. And this is the reason why there can be 30 epacts in all, from i to xxx or 0 or *, on account of the days 1, 2, 3, and so on up to 30 or 0, which can remain over after the lunation that ends in the month of December. And although, when some lunation ends on the first day of December or on the last, the epact of the following year is xxx or 0, that epact xxx or 0 must nevertheless be marked with some sign, namely with this *, so that by it the new moons of the following year may be investigated, and so that it may be understood that two lunations were then completed in December — one on the last day, so that no day remained over, and the other on the first day, so that after it 30 days were left. But it sometimes happens that the epact of some year is one unit greater than the number of days remaining after the last lunation of the preceding year. When this occurs will be stated in chapter 12, number 14, where we shall treat of finding the epact of any given year.

[Margin: Why every epact must be less than 30.]

[Margin: What the epacts are, and why they are 30.]

THIS same number of 30 epacts is likewise gathered from the 11 days by which, as we have said, the lunar year is exceeded by the solar. For if in the first year 11 days remain over, in the second there will be 22, and in the third 33; and casting out 30, which make one lunation, the remainder gives epact iii. And so on in turn,

always adding 11 and casting out 30 if the sum is greater than 30, all 30 epacts will be made up, so that the first is xi and the last xxx or 0 or *, after which xi is again generated by the addition of 11, as appears here.

xi	xxii	iii	xiiii	xxv	vi	xvii	xxviii	ix	xx	i
xii	xxiii	iiii	xv	xxvi	vii	xviii	xxix	x	xx	ii
										i
xiii	xxiiii	v	xvi	xxvii	viii	xix	xxx	vel 0.	vel	*

IT SOMETIMES HAPPENS that 12, not 11, must be added to the preceding epact in order to form the following epact. When this occurs will be stated below in chapter 12, numbers 12 and 13, in which chapter we shall teach how to find the epact of any year whatever.

THESE 30 numbers are called *epacts*, from a Greek word which in Latin means the same as "added days," or "supplementary" or "inserted" days. For they are joined on at the end of the last lunar month to fill out the number of days of the solar year, and to begin the first lunation of the following year. In what way epacts of this kind, once placed in the Calendar, can indicate the new moons perpetually with no change made in the Calendar will be clear from what follows; but in the first place we must show by what technique and care they are disposed through the days of the Calendar.

CAPVT X.

Quo Artificio Epactæ in Calendario describantur. [By what technique the epacts are set out in the Calendar.]

ALTHOUGH the epacts could be written in the Calendar in the natural order of the numbers, from 1 up to xxx or to *, as I shall show a little further on (for there is no lack of people who deny that this can be done), it nevertheless seemed more expedient that they be written in retrograde order, starting from xxx or *, proceeding through xxix, xxviii, and so on down to 1 — both so that they may be distinguished from the number of the days of the same Calendar, and so that they may show the new moons more naturally, as will be clear from what follows. Beginning, then, from epact * at the start of January, epact xxix is written against the second day, xxviii against the third, and so on in turn in retrograde order until 1 is reached, which epact is set before 30 January; after which all thirty epacts are repeated in the same order to the end of the Calendar, so that they are

all inscribed in the Calendar only twelve times — except for these eleven, *, xxix, xxviii, xxvii, xxvi, xxv, xxiiii, xxiii, xxii, xxi, xx, which are repeated a thirteenth time on the last eleven days of December. Epact 19 is also excepted, being marked with a different character or colour; for it too is attached to the last day, alongside epact xx, as we shall say below.

[Margin: Why the epacts have been disposed in the Calendar in retrograde order.]

2 BUT in order that the epacts may indicate the new moons correctly, this precaution must be observed in setting them out. In the second placement of the thirty epacts (that is, once all 30 have been written down a first time), and likewise in the fourth, sixth, eighth, tenth and twelfth, the two epacts xxv and xxiiii must be written together against the same day — namely 5 February, 5 April, 3 June, 1 August [printed *Agusti*], 29 September and 27 November, the days on which epact xxv falls according to the arrangement set out above. The effect of this is that after the twelfth inscription of the epacts, 11 days are left over in December; against these are again set the epacts *, xxix, xxviii, xxvii, xxvi, xxv, xxiiii, xxiii, [xxii, xxi ?] xx, which are of course the ones assigned to the first 11 days of January. All 30 epacts, inscribed twelve times, thus occupy only 354 days, the number we have said is contained in a common lunar year — with the result that the epacts in the Calendar cannot preserve the reckoning of the cycle in such a way that the epact of the first day of January is the next smaller than the one assigned to the last day of December, which of course precedes the first day of January; rather their retrograde order ceases at the end of the year and begins again at the beginning of the year from epact *, as before.

[Margin: That the epacts disposed in the Calendar do not preserve the reckoning of the cycle.]

3 NOW if two epacts were not attached to the same day in six places of the Calendar, but each followed the next singly in retrograde order right to the end of the year, all 12 lunations of every epact would be of 30 days, and all the epacts, repeated twelve times, would occupy 360 days — a number that exceeds the common lunar year by six days, which is absurd and contrary to the nature and condition of the lunations. Therefore, in order that the lunations may be alternately of 30 and 29 days, it is necessary to place two epacts together in six places. For in this way it will come about that the lunations are constituted alternately of 30 and 29 days. For when epact xxiiii, together with the others that follow it, has risen in February, for example, one day above its natural place towards the beginning of the month, on account of the two epacts xxv and xxiiii

assigned to the same fifth day, the result is that the lunations which begin from the 30 epacts preceding epact *xxiiii* — the one written against the same day as epact *xxv* — namely from the epacts *xxv*, *xxvi*, *xxvii*, *xxviii*, *xxix*, ***, *i*, and from the rest of the month of January up to epact *xxiiii* inclusive, contain only 29 days. And we mean the same to be said of the lunations of those same 30 epacts which in the other five places of the Calendar precede epact *xxiiii*, written against the same day as epact *xxv*.

[Margin: Why in six places of the Calendar two epacts are written against the same day.]

[Margin: That the lunations are made alternately of 30 and 29 days because two epacts are attached to the same day in six places of the Calendar.]

4 NEXT, since it sometimes happens that within one and the same nineteen-year cycle both of these epacts, *xxv* and *xxiiii*, are in use, as will appear below, epact 25 will have to be written in a different character or colour, next to epact *xxvi*, in those six places in which the epacts *xxv* and *xxiiii* are placed together. In the other places, however, this same epact 25 must be written next to epact *xxv*, again in a different character or colour. For unless this is done, it will happen that in one and the same nineteen-year cycle, in which both epact *xxv* and epact *xxiiii* are in use, two lunations will six times in the year fall on one and the same day, and two golden numbers will be assigned to the same day — namely those which, in the expanded table of which we shall speak in the next chapter, stand above those two epacts. That is absurd, and contrary to the principle of the nineteen-year cycle, since the new moons, as we showed above, cannot return to the same days except after 19 years have elapsed.

[Margin: Why epact 25 must be written in a different character or colour above the other epact *xxv* in six places of the Calendar.]

5 THIS drawback is entirely avoided by means of epact *xxv/25* written twice in six places of the Calendar, in different characters or colours, against different days. For whenever, in some nineteen-year cycle, epact *xxv* runs together with a golden number greater than 11 — such as are the last eight golden numbers, 12, 13, 14, 15, 16, 17, 18, 19 — epact *xxiiii* will indeed be in use in that same cycle as well; but if in that case the epact 25 is taken which is marked with a different character or colour, and which in those six places is placed opposite epact *xxvi*, then two golden numbers, or two new moons, cannot fall on the same day, since epact 25 marked with that different character or colour, and epact *xxiiii*, always occupy two different days in each month. When, however, in some nineteen-year

cycle epact xxv runs together with a golden number not greater than 11 — such as are the first eleven golden numbers, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 — it will never happen that epact xxiiii is in use together with xxv in the same cycle. Therefore the epact xxv is then to be taken which, in those six places, is written against the same day as epact xxiiii; for since epact xxiiii is not then in use in that cycle, there can be no danger of a new moon falling twice on the same day within the same nineteen-year cycle. In the same way, even if epact 25, marked with a different colour or character, is placed in six different positions opposite epact xxvi against the same day, two new moons will nevertheless not fall on that same day before 19 years have passed; because while epact xxv runs together with a golden number greater than 11 (the only time at which that epact 25 of a different colour or character is used, as we have said), epact xxvi will never be employed in the same cycle to indicate the new moons. And all this

[Margin: That because epact 25 is written in a different colour or character, two new moons cannot fall on the same day in the same nineteen-year cycle.]

the expanded table of epacts [tabula expansa Epactarum], which I shall treat in chapter 11. There, in the eight lines prefixed with the capital letters N, E, B and the small letters r, n, k, e, b (each line of that table, as will be understood later, presents a single nineteen-year cycle), you will find epact 25, marked with a different character or colour, under these eight larger golden numbers 12.13.14.15.16.17.18.19; whereas you will find epact xxiiii under these eleven smaller ones, 1.2.3.4.5.6.7.8.9.10.11 — but never epact xxvi. In the other 22 lines, by contrast, where epact xxv is written under the smaller eleven golden numbers, you will indeed sometimes find epact xxvi as well; yet you will never see epact xxiii [?: three minims are printed; the argument requires xxiiii] occurring alongside it at the same time. Therefore, if one takes now the epact xxv that is placed opposite epact xxiiii, and now the epact 25 of the other character or colour, which is placed opposite epact xxvi (due account being taken, of course, of the smaller or larger golden number with which it runs, as I said a moment ago), it becomes altogether impossible for two new moons to fall together on one and the same day within the same nineteen-year cycle — even though in the six places enumerated above the epacts xxv and xxiiii are set opposite the same day, and epact 25 of the other colour or character is likewise assigned to that same day together with epact xxvi.

[Margin: Why in the same cycle epact xxiiii is not used, when epact xxv and a golden number not greater than 12 run together. Likewise why epact xxvi is not

in use in the same cycle, when epact 25 and a golden number greater than 11 run together.]

6 THAT epact xxiiii cannot be in use when epact xxv runs with some golden number smaller than 12, or not greater than 11, but only when it runs with a golden number greater than 11; and likewise that epact xxvi is not employed when epact 25 of a different colour or character runs together with a golden number greater than 11 — all this is also gathered very clearly from the arrangement of the golden numbers and of the epacts in the Calendar. For since, as I said above, a larger golden number follows a smaller one in the Calendar not immediately but with one day left between, it follows that if in January, say, opposite the 6th day, where epact xxv is placed, any golden number smaller than 12 is written, and epact xxv is supposed to run together with it, then the next larger golden number must be written against 8 January, leaving the 7th vacant — so that in that nineteen-year cycle no new moon can fall on the 7th. Hence in that same cycle epact xxiiii, which is placed immediately below xxv, cannot possibly be in use; otherwise a new moon would fall on 7 January. Again, since in the Calendar a smaller golden number follows immediately upon a larger one, as was said above, it follows that if opposite that same 6 January, to which epact xxv is prefixed, any golden number greater than 11 is written, and epact 25 is supposed to run with it, then the following golden number must be placed at 7 January, immediately after that larger one, so that in that cycle a new moon can fall on the 7th. Therefore in the same cycle epact xxiiii, placed immediately below 25, will indicate a new moon and will accordingly be in use. But since a smaller golden number precedes a larger one not immediately but with one day left vacant, it follows that the golden number preceding that larger one, with which epact 25 is supposed to run, must be placed at the 4th day, so that on the 5th no new moon then occurs. For that reason epact xxvi, assigned to the 5th day, can in no way be in use at that time, lest a new moon in that cycle fall on 5 January.

[Margin: That epact 25 of a different colour or character, placed opposite epact xxvi, does not disturb the lunations.]

7 Moreover, this anticipation of epact 25 of the other colour or character, in those six places of the Calendar, is so far from disturbing the lunations that it rather restores them to their correct order. For since every lunation that ends on one of the first 30 days of January is the first lunation of the whole year, as I shall say later, it comes about that, while that epact 25 is running, the first lunation of the year, ending on 5 January, is made 30 days long; the second, ending on 3 February, only 29 (though it too would be 30 days if the epact xxv below epact

xxvi were taken); the third then becomes 30 days again, and the fourth 29, and so on, as the order of alternating lunations of 30 and 29 days requires. The thirteenth and extraordinary lunation of that year (for when epact 25 is in use the lunar year is embolismic, as will be said later) likewise becomes 30 days, whereas while epact xxv was running — the one assigned to the same day as xxiii — it would be only 29. Finally, there are just as many lunations of 30 days while epact 25 of the different colour is running as are found when the other epact xxv is in use; for there are 7 in the one case as in the other, although they proceed differently in the one case and in the other. Add to this that the Paschal lunation investigated by means of epact 25 of the different colour or character corresponds for the most part more exactly to the mean motion of the Moon. This will become plain if the lunations indicated by golden numbers greater than 11 are carefully compared with the calculation of the Moon's mean motion. For we shall generally find that those shown by golden numbers greater than 11 come out a little later than the Moon's mean motion requires. Therefore, since the Paschal lunation beginning on 4 April — the one shown by epact 25, marked with a character or colour different from the rest, which, as I said above, always runs with some golden number greater than 11 — begins one day earlier than it would if it were indicated by epact xxv assigned to 5 April, it plainly follows that the Paschal lunation which that earlier epact 25 begins agrees better with the Moon's mean motion than the one indicated by epact xxv placed at 5 April, running with the same larger golden number with which the former runs; for the latter begins one day later. But suppose someone objects: then the other epacts running with golden numbers greater than 11 which have not been anticipated — such as xxvi, xxvii, xxviii and so on — will make the Paschal lunations begin later than the mean motion requires. The answer is that this is generally true, but that it is to be put down to the nature of the cycle (for no cycle can avoid every disadvantage, as I shall say later); and that it is better to correct at least one lunation — namely the one that the anticipated epact 25 shows — than to leave them all uncorrected. Nor indeed does any error in the solemnity of Easter arise from this postponement of the lunations, except very rarely, as will appear later from the calculation of a great many years.

[Margin: Why the equation of the lunar months was made through the epacts xxv, xxiii *[so printed; the body text has xxiiii]* set together rather than through others.]

8 BUT someone may ask why, in the equation of the lunar months — that is, in the placing of two epacts against one and the same day in six places of the Calendar, so that the lunations may be constituted alternately of 30 and 29 days

— these two, xxv and xxiii, were adopted (set opposite 5 February; 5 April; 3 July; 1 August; 29 September; and 27 November) rather than two others, since it could equally well have been done with any two epacts whatever, and especially with the epacts * and xxix, which are placed at the end of January and the beginning of February — so that this equation would have been established, that is, after the completion of the first lunar month of 30 days, as we read was done by Julius Caesar in the cycle of the golden number, as Paul of Middelburg testifies in book 2 of the *Paulina*, where he sets out the Roman Calendar with Julius Caesar's lunar cycle, in which we see the equation applied at the end of January and of March, at the golden numbers 1 and 9. And the same was done by Luigi Lilio, the first author of this new Calendar, as is clear from the *Compendium* of the new plan for restoring the Calendar, sent in the year 1577 by Gregory xiii to the Christian princes, which I placed at the beginning of this work. For there the equation of the Moon is made on the last day of January, the last of March, 29 May, and so forth — on which days these two epacts ☉ [*the Compendium's circular epact-mark, distinct from the asterisk * used in the new Calendar*] and xxix are written together, of which ☉ signifies epact xxx, or 0

— or 0 (just as, in the new Calendar, epact * does); and above those same days, opposite epact j, is placed epact *, which in that *Compendium* signifies the same thing as ☉ and differs only in its figure. In just the same way, in the new Calendar epact 25, formed with a different character or colour, is written opposite epact xxvj, above the epacts xxv and xxiiij which are placed against the same day; and the upper epact 25 differs from the lower xxv only in figure or in colour. If, I say, someone asks this, let him know that these two epacts xxv and xxiiij were chosen for the equation of the Moon in preference to others because in this way the lunations reckoned by the cycle of 30 epacts — and especially (which is more to the point) the 30 Paschal lunations — are made to agree better with the lunations of the golden numbers of the Council of Nicaea, whose decrees and enactments we have retained in everything, so far as could be done and as was fitting. For we see that the equation of the Moon was made at practically the same places by the golden numbers of the old Calendar as it is made in the new Calendar by the epacts xxv and xxiiij.

[Margin: Why not all the Paschal lunations in the new Calendar are of 29 days, as in the old one.]

9 NEXT, just as in that cycle of the golden number all 19 Paschal lunations contain only 29 days, the first beginning on the eighth day of March and the last on 5 April, so too in the new cycle of the epacts (once the equation of the Moon has

been made through the epacts xxv, xxiiij) all 30 Paschal lunations are closed by the same limiting days — that is, 8 March and 5 April — and each contains 29 days, with the exception of the two lunations of the epacts 25 and xxiiij, when nevertheless 25 (which happens rarely) runs together with one of the last eight golden numbers, those greater than 11. For these two alone are of 30 days; which ought not to seem surprising. For since the Fathers of the Council of Nicaea assigned 29 days to the Paschal new moons — those counted from 8 March to 5 April — the 19 golden numbers could easily be arranged in them on the rule that each should make up a lunation of 29 days. But since there are 30 epacts, they cannot all be arranged in those same 29 days unless two of them are placed together on some one and the same day, as was done on 5 April. From which it follows that the lunation of epact xxiiij, and consequently also that of epact 25 placed above xxiiij, is made 30 days long.

[Margin: Why the equation of the epacts proposed in the Calendar of the *Compendium* was rejected, and another established in the new Calendar.]

10 NOW if the equation of the Moon were established at the end of March, as was indicated in the *Compendium* of the new plan for restoring the Calendar, seven Paschal lunations of 30 days would result, as is plainly evident in that Calendar. Therefore, in order that the Paschal new moons of the new Calendar might be confined within the same limits within which they were constrained from the Council of Nicaea down to the new Calendar, and that only two Paschal lunations should comprise 30 days, and that we should accordingly depart less from the ancient practice of the Church, we rejected the equation described in that *Compendium* and chose the one I have set out. For according to it all the new moons — and the Paschal ones especially — are found to have fallen at the time of the Council of Nicaea on exactly the same days on which the golden numbers of the old Calendar show them to have fallen; which by no means happens with the other equation of the *Compendium*. And this [recte: manifestum] will be evident to anyone who resolves into golden numbers the epacts both of the new Calendar and of the one described in that *Compendium*; how this is to be done I shall teach in chapter 15, no. 2. In the whole circuit of the year, out of the new moons of all the epacts (the Paschal ones excepted), only 12 are found to differ from the new moons indicated by the golden numbers at the time of the Council of Nicaea, if our epacts are resolved into the golden numbers of that period. On this matter I shall write more in its proper place [recte: suo loco], namely after I have set out the 30 Calendars of the golden numbers in chapter 15, the 30 tables of all the lunations in chapter 16, and the account of the embolisms in chapter 17.

[Margin: Why epact 19 is placed in the Calendar in another colour or character at the last day of December, opposite epact xx.]

11 IN addition, at the end of December, next to epact xx, epact 19 must also be placed, in a character or colour different from the others, to show the new moon on the last day of December when epact xix and golden number 19 run together. This will happen only once in many thousands of years — that is, once in the thirty nineteen-year cycles of the expanded table, when its eighth line, prefixed with the capital letter D, is in use, as is the case at present from the correction up to the year 1700 exclusive. For in that line alone is epact xix written under golden number 19. That epact 19, affixed to the last day of December, must at that period necessarily indicate a new moon (as happened in the year 1595, and will happen again in 1614, 1633, 1652, 1671, 1690, and thereafter will not occur again until after the year 8200) will become plain as follows. Since to an epact running with golden number 19 — whichever it may be — 12 must be added (whereas to the others only 11 is added) in order to form the epact of the following year, just as from the year 1400 up to the correction of the Calendar 12 was likewise always added to the last epact xxix, which always concurred with golden number 19, so that the first epact xi might be composed again — since the lunar cycle necessarily requires this, as I shall show below in chapter 12, nos. 12, 13 and 14 — it comes about that when epact xix runs with golden number 19, the epact of the following year is j, because adding 12 to 19 gives 31, and casting out 30 leaves j as the epact of the following year. Therefore, since the use of epact j begins in January, where it is assigned to the 30th day, then unless epact 19 were repeated at the end of December, so that a new moon might begin from it again before January (the December lunation then containing only 29 days), the lunation beginning on 2 December, where epact xix is written, would take in 59 days — as many, that is, as are counted from 2 December up to 29 January inclusive — because in December no other epact xix is found, apart from the one which I said must be assigned to the last day, from which a new moon could begin, nor in January any other epact j before the 30th day that could show the beginning of a new moon. The scheme of the lunations investigated by the nineteen-year cycle therefore necessarily requires either that epact 19 be repeated on the last day of December, so that the lunation of epact xix begun on 2 December contains only 29 days, and another begins on the last day from that same epact 19 and comprises 30 days — as many as are counted from the last day of December up to 29 January inclusive; or that epact j be assigned to the first day of January opposite epact *, so that the lunation of epact xix beginning on 2 December is made 30 days, and another, beginning on the first day of January from epact j, takes in only 29; or else that epact 1 be put back at the last day of December

opposite epact xx, in place of epact 19, so that the lunation beginning from it contains 30 days, while the preceding lunation, begun from epact xix assigned to 2 December, is made only 29. But since we began the distribution of the epacts in the Calendar from the first day of January, it does not seem fitting that right at the beginning of the lunations this equation should be made by two epacts, * and j, affixed to the same first day; and so that equation was thrown back onto the preceding day, that is, onto the end of December, where by the natural order epact j would have to be placed if the year did not begin from January — just as in the other months too epact j is set above *. But since epact j is also found next to 20 December,

it did not seem right to repeat it so soon at the end of December, especially since it does not immediately follow, in the retrograde order, the epact xx set at the end of December; and above all because the use of epact j first begins in the following year. I therefore judged that epact 19 should be written next to that xx, since these two epacts, xx and 19, follow one another in the correct order in the natural series of the epacts. Indeed, the calculation of the mean lunations confirms admirably that, when golden number 19 and epact xix concur, the new moon falls more correctly on the last day of December than on the first of January of the following year. This is plainly apparent in the years 1595, 1614, 1633, 1652, 1671, 1690, in all of which the golden number is 19 and the epact likewise xix. For the mean new moon in the year 1595 occurs on 30 December, 18 hours after midday; in the year 1614, on the 30th, nearly 11 hours after midday; in the year 1633, on the 30th, 3 hours after midday; in the year 1652, on the 29th, 20 hours after midday; in the year 1671, on the 30th, 12 hours after midday; and in the year 1690, on the 30th, 5 hours after midday.

[Margin: That because of epact 19 set at the last day of December opposite epact xx, two new moons cannot fall on the same day in the same nineteen-year cycle.]

NOR does it follow from this placing of epact 19 next to epact xx that two new moons fall on that same day within the space of 19 years. For in the cycle in which epact xix runs with golden number 19, epact xx is not in use, as is clear from the line of the expanded table which you will find in the next chapter, the one prefixed with the capital letter D. For in that line alone epact xix is indeed written under golden number 19, but epact xx is not found among the 19 epacts of that cycle.

AND this is the natural arrangement of the cycle of thirty epacts through the days of the months in the Calendar — and indeed the only one — showing the new moons and full moons, and the age of the Moon on any day at any time proposed;

although the new moons are sometimes forced to move upward in the Calendar on account of the equation of the Moon that must necessarily be applied, or on account of the intercalary day to be omitted in each space of four hundred years. For this cycle of the epacts, thus arranged in the Calendar, is perpetual, and can be adapted to any length of year whatever, provided that the due equation is applied at its proper times, as will be explained in chapters 11 and 12.

BUT I set out the new Calendar, with the epacts arranged through the days of the months in the manner I have explained, at the beginning of this work; there everyone will clearly see that only two Paschal lunations are of 30 days — namely those shown by epact 25 of a different character or colour and by epact xxiiij — whereas in the Calendar of the *Compendium*, which I also displayed at the beginning of this book, seven Paschal lunations contain 30 days, namely those indicated by the epacts *, xxix, xxviii, xxvij, xxvj, xxv and xxiiij.

[Margin: How the new moons of ecclesiastical use are investigated from the epacts arranged in the Calendar.]

12 NOW that all 30 epacts have been described, repeated over and over in the Calendar in the order I have set out — the order that appears in the Gregorian Calendar placed at the beginning of the book — the first day of the Moon, that is, the new moon of ecclesiastical use, will be declared to fall, in any proposed year and month, on those days to which the epact of that year is assigned; just as before the correction the new moon was said by the Church to occur, in any year and month, on those days to which the golden number of that year was attached.

[Margin: On what principle the epacts can indicate the new moons perpetually.]

AND these 30 epacts will indicate the new moons in perpetuity, with no alteration whatever made in them in the Calendar, even though on account of the omission of the intercalary day in the centesimal years the new moons run downward, that is, toward the end of the months; or move upward, that is, toward the beginnings of the months, after each period of $312\frac{1}{2}$ years. The golden numbers cannot do this unless they are arranged in the Calendar in various ways — that is, shifted now downward, now upward, as I said above. For whenever the new moons descend by one day toward the ends of the months, they will be indicated by the lower epact, the one next smaller than the higher. Thus if in some year the new moons are indicated, say, by epact xx, and it happens that the intercalary day is then omitted, after the omission of the day they will be indicated by epact xix, which is placed one day below epact xx in the Calendar. If on the other hand the new moons ascend by one day, they will be traced by the higher epact, the one

next greater than the lower. Thus if in some year the new moons are to be found by that same epact xx, and it happens that they have then moved upward by one day because $312\frac{1}{2}$ years have elapsed, they will have to be sought by epact xxi, which is written one day above epact xx in the Calendar. But when a smaller or a larger epact is to be taken for finding the new moons I shall set out fully below, when I show how the epact of any year is to be found, in chapter 12, no. 5 and following.

[Margin: That the epacts have rightly taken the place of the golden numbers, and are suitably arranged in retrograde order in the Calendar.]

13 THAT the 30 epacts have been substituted with excellent judgement for the golden numbers in the Calendar, and rightly distributed through the days of the whole year in retrograde order, anyone can easily recognize from this: that if all the days of the month of December which remain after the end of the lunation ending in that same month of any given year are carefully counted, that number of days not only gives, for the most part, the epact of the following year — that is, the very days by which the solar year exceeds the preceding lunar year, as was said above — but moreover the lunations of the whole following year begin on those days beside which is placed the epact of just as many units as there were days left over in December after the end of the lunation ending in that month; so that the superfluous days furnish the epact that points to the new moons of the following year.

[Margin: The days of December that remain after the last lunation of the year generally exhibit the epact of the following year.]

For example: if the end of some lunation in any year falls on 26 December — which happens while epact xxiiij is running (since a new lunation takes its start from the 27th, to which epact xxiiij is assigned) — 5 days of December will be left over, and these exhibit epact v of the following year, which by the arrangement of the epacts described above is placed next to 26 January, the day on which the new moon will fall in that year; because the 25 days of January preceding epact v, together with those 5 days that were left over in the month of December, make up a full lunation of 30 days, which is the number of days that any lunation ending in the month of January usually contains. Sometimes, though rarely, it comprises only 29 days — and then almost always when the golden number is j, as will be clear from what follows. So too, when a lunation ends on 8 December — which happens when epact xij is in use — 23 days of December remain, and for the following year these exhibit epact xxiiij, assigned to 8 January, the day on which the new moon will fall in that year. And the same reasoning holds for the rest.

14 NEVERTHELESS, when the golden number of some year is 19, a unit must be added to the days remaining after the lunation ending in the month of December, in order to obtain the epact of the following year — provided that epact xviiij or xix is not then in use. For while epact xviiij is running with golden number 19, the last lunation of the year ends on the final day of December, and no day is left over, because that lunation is only 29 days, whereas it ought to be 30 days and to end on the first day of January, as it does when epact xxiiij runs not with golden number 19 but with others. Therefore, since the following lunation then begins from epact

* is set against the first day of January, the epact of the following year will be * or 0, so that no unit is to be added to the 0 days of December that were left over after the last lunation. Likewise, when epact xix and golden number 19 run together, the last lunation of the year ends on the second-to-last day of December and one day is left over, since the next lunation begins on the last day, from the epact 19 written in the margin, as I said above. That one surplus day will give epact j of the following year without the addition of a unit, because that lunation then contains only 29 days — whereas in other years, when epact xix does not coincide with golden number 19, it comprises 30 days and closes on the last day of December. Why these two lunations then turn out to be only 29 days long will be explained below in chapter 16, on the embolismic months. As for why, on the other days that are left over after any lunation ending in December, a unit is added while golden number 19 is running, I explained that in the immediately preceding chapter.

5 BUT let me now show that the thirty epacts can be written into the Calendar in the natural order of the numbers, from j up to xxx (or up to *), for the purpose of indicating the new moons; and I shall make this clear as follows. In the Calendar the epacts are indicators of the new moons, so much so that any other signs whatever could be put in their place — just as before the correction the same new moons were shown by the golden numbers. Therefore, take our present practice: when the epact is xiiij, the new moon falls on 18 March, and in the following year on the 7th, with epact xxiiij running, which the table of epacts for the current century indicates. In the same way, if the epacts were arranged in the forward order, so that they did not differ from the days of the months, then the table of numbers showing the new moons would offer us, for epact xiiij, the number xviiij — and so again the new moon would fall on 18 March. Then in the following year the same table would give us, for epact xxiiij, the number viij, which is of course eleven units less than xviiij, the preceding year's number — just as epact xxiiij is eleven units greater than epact xiiij of the year before. In fact a Calendar was

proposed here at Rome to the Calendar commission by a certain skilled mathematician, in which the 30 numbers of the epacts were written out in the forward order, and they indicated the new moons perfectly correctly, no differently from our own epacts arranged in the retrograde order. But because in those numbers the increase of the epacts by 11 units is not preserved, as the nature of the epacts requires, but rather a decrease of 11 units, I preferred the retrograde order, so that the new moons should be indicated by the epacts more naturally — which is what I have shown in this chapter. It is clear, then, that the epacts can run through the Calendar in the forward order, even though they would not then observe the principle of the epacts but would merely be signs of the new moons: which some people denied could be done.

[Margin: That the 30 epacts can be arranged in the forward order in the Calendar.]

CAPVT XI.

Constructio tabulæ Expansæ Epactarum, & tabulæ æquationis earundem Epactarum, ex auctoris Calendarij sententia.

The construction of the expanded table of the epacts, and of the table of the equation of those same epacts, according to the mind of the author of the Calendar.

SINCE the new moons return to the same days of the months after 19 solar years have run out — though not to exactly the same hours, as was said in chapter 8 — it follows that out of the 30 epacts written into the Calendar only 19 are to be taken up, within one century or within several, corresponding to the 19 golden numbers one by one, and by these the new moons of those years are to be found. For these 19 epacts will indicate the new moons (just as the 19 golden numbers once did) for as long as the conjunctions of the two luminaries are found to return always to the same days after 19 completed years. But as soon as the new moons have shifted by about one day, whether toward the beginning of the month or toward its end — which must necessarily happen, both because of the common, that is, non-bissextile, centesimal years, and because of the $312\frac{1}{2}$ years in which the lunations anticipate by one day in the Calendar — then another 19 epacts must be adopted, corresponding to the same 19 golden numbers: some of them not found among the preceding 19 epacts, others already in use among them. Thus, when the new moons have moved up one day toward the beginnings of the months, the 19 epacts to be taken, corresponding to the same 19 golden numbers, are those which exceed by a unit, one by one, the other 19 that had

been in use up to that time; but if they have moved down one day toward the ends of the months, then the 19 epacts to be chosen are those which are one unit less, one by one, than the immediately preceding 19 epacts. For in this way it will come about that the first set of 19 epacts indicate in the Calendar that the new moons generally occur one day earlier than the earlier set did, and the second set about one day later. Accordingly I must now set out the method by which we may know which 19 epacts out of all 30 correspond to the 19 golden numbers at any given time, and when another 19 are to be called in. From this we shall learn without any trouble — as I shall write in the following chapter — by what technique the epact by which the new moons are shown may be drawn out, for any proposed year, from the known golden number of that same year. For this purpose a table of the epacts must be constructed, which I call the *Expanded* table, because it contains 30 lines, each of which embraces 19 epacts corresponding to the 19 golden numbers, so that every variation is displayed that can ever be found between the various sets of 19 epacts and the 19 golden numbers, which are always the same. Next, another table must be drawn up, the table of the equation of the epacts, by which we may know which line of epacts out of those 30 is to be taken at this or that time. The construction, then, of the expanded table of the epacts is as follows.

[Margin: Out of the 30 epacts only 19 are used, in one or in several spans of a hundred years, for showing the new moons.]

[Margin: When the 19 epacts to be taken are a unit greater than the preceding 19, and when they are less.]

2 AT the head of the table let all 19 golden numbers be written, the beginning being taken from golden number 3, which in the time of the Council of Nicaea was set against the Kalends of January, that is, against the first day of the year in the Calendar. Then in the lowest of all 30 lines of the whole table let 19 epacts be placed beneath the golden numbers, beginning from **j** and exceeding one another by eleven units, 30 being always cast away whenever the eleven units added to the preceding epact make a sum greater than 30 — yet in such a way that the epact following epact **xxvij**, which is set under golden number 19, exceeds it not by eleven but by twelve units, and accordingly that under golden number 1 the epact is **ix**,

[Margin: Construction of the expanded table of the epacts.]

and not **viiij** — because when 12 is added to 27 the result is 39, and when 30 is cast away, **ix** remains. Then, if from each of the epacts of this lowest line one

ascends upward through the natural series of the numbers, writing this sign * for **xxx**, and above it again **j**, then **ij**, **iiij**, and so on, the whole expanded table of the epacts will be composed. In it the epacts of any given line exceed one another by eleven units, except for the epacts written under golden number **j**: for these exceed the preceding ones, set under golden number 19, by twelve units, just as in the lowest line. Epact 25, however, under these eight larger golden numbers — 12. 13. 14. 15. 16. 17. 18. 19. — must be written in a colour or figure different from the others. Finally, along the left-hand side of the table the small letters of the alphabet are to be set in their natural order, putting the letter **a** opposite the lowest line, **b** opposite the second, and so on as far as **u**, omitting however the letter **o**, lest, on account of its likeness to the numeral character 0, it should breed confusion. After **u**, the capital letters of the alphabet are then to be written as well, omitting the letters **I. K. L. O.** for the same reason. For **I, L, O** are letters of number, since **I** signifies one, **L** fifty, and **O** nothing; while capital **K** differs too little from small **k**, and so the one can easily be taken for the other. These letters indicate which line of the epacts is to be adopted for use at any proposed time, as will be clear from the table of the equation of the epacts. The same letters are also employed in the Ecclesiastical Martyrology for declaring the age of the Moon on any given day, whenever the epacts written under golden number 3 are in use, as is evident from the Martyrology as restored to this new plan of the Calendar. For example: when the epact of some year is **xx**, the Martyrology letter of that same year will be **A**; when the epact is **vij**, the Martyrology letter will be **g**; and so on.

3 I HAVE assigned to these thirty lines of epacts in the expanded table the letters of the alphabet rather than the years of the Lord to which the individual lines correspond, because I want this expanded table to be perpetual as well, and capable of being fitted to any magnitude of the solar year whatever. That would not be the case if the years of the Lord were attached: partly because in so small a space all the years cannot be comprised, but chiefly because, since the magnitude of the solar year is still uncertain and not yet sufficiently explored, it must also be uncertain whether the years of the Lord will always correspond to those lines of epacts to which they have been prefixed. Therefore, so that posterity may be free to set up another method of equating the solar year, should this method of ours be found by astronomers after some years to depart from the truth and so need to be changed, I have attached the letters of the alphabet, so that any one of them can correspond to any year of the Lord. In this way it comes about that this table of epacts is both perpetual and adaptable to any magnitude of the year, provided one learns carefully from the table of the equation, which I shall construct shortly, which letter of the alphabet corresponds to this or that year of the Lord.

Only the table of the equation will have to be changed, if some defect, as I said, is detected in our equation — as I shall show a little further on.

[Margin: Why letters of the alphabet, rather than years of the Lord, are attached to the lines of the epacts in the expanded table.]

4 THE composition of the table of the equation of the epacts, which advances by centesimal years, will be set up as follows. In the time of the Council of Nicaea golden number 3 was prefixed to the first day of the year, as is clear from the old Calendar; the reason being that at that period, whenever the golden number was 3, the new moon occurred on the first day of the year, that is, on the Kalends of January, and on those days of the other months to which the same golden number 3 was prefixed. Since therefore in the new Calendar this epact * has likewise been placed against the first day of January, it follows that the first line of the epacts of the expanded table, in which epact * is set under golden number 3, corresponds to the golden numbers in the time of the Council of Nicaea, and in the following years too, until the Moon requires an equation — that is, until the new moons fall on other days. For wherever epact * stands in the new Calendar, there golden number 3 stood in the time of the Council of Nicaea. And where epact **xj** is placed, following epact * in the first line of the expanded table, there golden number 4 was placed, which follows golden number 3 at the head of the table. And where epact **xxij** is written, following epact **xj**, there golden number 5 had its place. In the same way all the remaining epacts set in the first line of the expanded table have their seats in those places of the new Calendar in which the golden numbers corresponding to them at the head of that same expanded table were placed in the old Calendar. This will become clear if we carefully compare the days of the months of the new Calendar opposite all 19 epacts placed in the first line of the expanded table with the days of the months of the old Calendar opposite all 19 golden numbers. A few places in the Calendar are excepted, in which some difference is found — which is no wonder, because in February and in some other months of the old Calendar the equation of the lunations, whereby they should be alternately of 30 and of 29 days, was not made on exactly the same days as those on which it was made by us through epacts **xxiiij** and **xxv** assigned to the same day in six months, as I said a little earlier. Nor can it be said on that account that the cycle of the golden number is not rightly arranged in the old Calendar, or the cycle of the epacts in the new; since each of them has lunations alternately of 30 and of 29 days, as the plan requires. For although this does not occur in exactly the same places in the two Calendars, and so the new moons of the one do not correspond in every respect to the new moons of the other, it matters little, since no cycle can correspond in every particular to the lunations

in the heavens, as I shall show below. But of these places, which are only 12, in which the new Calendar differs from the old in the arrangement of the cycle, I shall say more in chapter 14. The paschal lunations of March and April, however — which is more to the point — do not differ in any respect in the old Calendar from the same lunations in the new. Therefore, since the 19 epacts written in the first line of the expanded table correspond in the new Calendar to the golden numbers of the old Calendar — that is, since those epacts occupy the same days in the new Calendar that the golden numbers occupied in the old — and since the Council of Nicaea was held around the year of the Lord 325, the capital letter **P**, which is prefixed to the first line of epacts in the expanded table, must be placed to the left of the year 320 in the table of the equation. I preferred to take this year rather than the year 325 because it is close to the time of the Council of Nicaea and is the more notable of the two, since it is bissextile, and therefore better suited to the table of the equation, given that this table advances by centesimal years, which are themselves also bissextile.

[Margin: Construction of the table of the equation of the epacts.]

NEXT, since from the birth of Christ down to the Council of Nicaea 300 years and more elapsed, the new moons must have occurred later in the time of Christ our Lord than in the time of the Council of Nicaea, because over a span of 300 years they move their seats forward in the Calendar by nearly a whole day, as I said above. From this it follows that in the time of Christ another 19 epacts would have corresponded to the same 19 golden numbers, if this cycle of the epacts and the new Calendar had then been in use — namely those contained in the second line of the expanded table,

and which are one unit less, one by one, than the epacts of the first line. For all the epacts of the second line are placed in the new Calendar below the epacts contained in the first line, and accordingly nearly all the new moons will be indicated one day later by the epacts of the second line than by the epacts written in the first line, which I said were in use at the time of the Council of Nicaea. And if in place of the epacts of the second line the golden numbers were put in the Calendar, as they correspond at the head of the expanded table to those epacts of the second line, all the golden numbers would be seen to stand one day lower than the golden numbers at the time of the Council of Nicaea. For this reason, in the table of the equation, beside the year of the Lord I, the capital letter **N** must be written, which in the expanded table is prefixed to the second line of the epacts.

5 FURTHERMORE, in order that the order of the equation of the Moon — by which, as I said, the new moons anticipate by one day over a span of 312½ years

— may be rightly established for the years after the Council of Nicaea, a root must first be fixed from which an equation of this kind is to take its beginning. For although, as I said, the first line of epacts of the expanded table agrees with the cycle of the golden number as published in the time of the Council of Nicaea, I shall nevertheless make it plain, as follows, that the root of the equation is not to be referred to that period but to many years after that Council. The Church of God, in order to celebrate the movable feasts properly, is not much concerned that the new moons found by the cycle should agree exactly with the new moons drawn out from the tables of the mean motions (for it disregards the true motions altogether, as was said above); on the contrary, it deliberately arranges the cycle in the Calendar so that its new moons follow shortly after those elicited from the tables — precisely so that it may not sometimes happen that the paschal 14th Moon which the cycle offers runs ahead of the mean full moon by so wide an interval that Easter is celebrated before that full moon, contrary to the decrees of the Fathers and of the Councils, as I shall teach more fully a little further on. Since therefore the cycle of the golden number, as it was arranged by the Fathers of the Council of Nicaea, shows that around the year of the Lord 325 the new moons generally fell on the same days on which, by the tables of the mean motions, they are known to have occurred in the heavens, that arrangement of the golden number made in the time of the Council of Nicaea cannot be judged suited to the use of the Church — since it shows the conjunctions of the luminaries to have taken place earlier than the practice of the Church requires, and so would not seldom have presented Easter as to be celebrated before the mean full moon (about which I shall write more below). Rather, it must have begun to be serviceable (so far as concerns the proper celebration of the movable feasts) some years after the Council of Nicaea had passed — as many years, that is, as are needed for the new moons to anticipate in the Calendar by enough that the golden numbers should now show them so long after the astronomical mean new moons that there is no danger of Easter being able to be celebrated before the mean full moon, save very rarely, through the imperfection of the cycle. This came about in the year of the Lord 550, that is, 200 years and more after the Council of Nicaea, at which time Justinian I held the Roman empire. For then the golden numbers indicated the new moons nearly sixteen hours later than in the time of the Council of Nicaea, as is established from the astronomical tables. At that same period, too, all the disagreements between Greeks and Latins were removed, and the cycle of the golden number came into use as it had been set out in the Calendar according to the norm of the Council of Nicaea by Abbot Dionysius [Dionysius Exiguus] around the year of the Lord 532, in the reign of that same Justinian I.

[Margin: That by the practice of the Church the new moons should be indicated by the cycle after the new moons of the heavens.]

[Margin: The new moons of the golden numbers around the time of the Council of Nicaea were nearly the same as those that occurred in the heavens.]

[Margin: The new moons of the golden numbers around the year 550 fell later than those in the heavens, and were therefore better suited to the use of the Church.]

[Margin: Where the root of the equation of the epacts is to be fixed.]

6 I THEREFORE fix the root of the equation in the year 550, because at that time the cycle of the golden number showed the new moons more correctly, and more suitably for the celebration of the movable feasts, as will be clear from what I am about to say. Nor is it an objection that on this reckoning the paschal 14th Moon is sometimes indicated by the cycle later than it should be. For less fault is committed in the celebration of Easter if the 15th Moon is taken for the 14th than if the 14th is taken for the 15th, as Theophilus, bishop of Alexandria, rightly warns in his letter to the emperor Theodosius the Elder — because the greater number contains the lesser, but the lesser does not likewise contain the greater. Since, however, in the table of the equation I record only the centesimal years, as being the more celebrated and better known, I shall lay it down that the Moon moves her seats forward by one day over a span of three hundred years, although in fact her equation requires $312\frac{1}{2}$ years; so that we anticipate the true equation by $12\frac{1}{2}$ years, of which nevertheless account must be taken when the sum collected from them has made up 100 years. For just as above, in the equation of the solar year, I determined that the intercalary day should be omitted in every centesimal year, thereby anticipating the true equation, according to the Alphonsine tables, by 34 years — of which nevertheless account is taken in every fourth centesimal year (for since they will then have grown to a sum of 136 years, unless in every fourth centesimal year the intercalation of one day were made in the usual way, the equinoxes would slip by a whole day toward the ends of the months) — so too in the equation of the Moon account must be taken of those $12\frac{1}{2}$ years omitted in every three-hundredth year, so that when the sum collected from them reaches 100 years, the equation of the Moon is then not to be applied in the three-hundredth year after the immediately preceding equation, but in the four-hundredth: because the Moon then anticipates by one day in the Calendar not in the three-hundredth year but in the four-hundredth. For since we lay it down that in 300 years the Moon moves her seats forward by one day $12\frac{1}{2}$ years earlier than she ought, it follows that we lay it down that in

600 years she moves her seats forward 25 years before the case requires, and in 1200 years 50 years too early, and in 2400 years a hundred years earlier than the case demands. Since, then, over a span of 100 years the Moon moves her seats forward by nearly eight hours — because we lay it down that in 300 years she anticipates her seats by a whole day, that is, by 24 hours — it follows that if the equation is applied 100 years earlier than it ought to be, she will have climbed upward in the Calendar toward the beginnings of the months by only 16 hours. The equation is therefore not to be applied then; rather one must wait a further 100 years, in which the Moon will climb upward another 8 hours, which together with the earlier 16 make 24, that is, one whole natural day, on account of which the Moon then necessarily requires an equation, lest the new moons be shown in the Calendar a whole day later than is fitting. But in which centesimal years the sum of the omitted $12\frac{1}{2}$ years grows to 100, and the equation of the Moon must therefore be deferred to the following centesimal year, will become plain from what I shall shortly subjoin.

7 THIS being laid down, since the table of the equation advances by centesimal years, as I said, I shall prefix to the year 500 the same capital letter **P**, to signify that the same first line of epacts is then to be resumed which had been in use in the time of the Council of Nicaea — seeing that around the year of the Lord 500 the cycle of the golden number had already become better suited to the use of the Church than in the very time of the Council of Nicaea, as I explained above. And although on this reckoning we anticipate by 50 years the root of the equation which I fixed in the year 550, I shall nevertheless take account of those years too in their proper place. Next, since after 300 years the Moon anticipates

[Margin: Continuation of the table of the equation through the centesimal years, down to the year 1582.]

anticipates one day in the Calendar, the line of epacts to be taken up then will be the last one — the line whose epacts each stand one day earlier in the Calendar, toward the beginnings of the months, than the corresponding epacts of the first line, and each of which is greater by one unit than the corresponding epact of this first line. For the epacts of that line are formed from these by the addition of one unit, casting out 30 whenever the sum is greater than 30, and writing the sign * when that sum is 30 — just as the epacts of any higher line are made up from the epacts of the line immediately below it. Such is the relation of the lowest line of the expanded table to the topmost: that is, the lowest is above this one. The expanded table must be understood as a kind of circle containing 30 rows that return upon themselves, so that the letters **P** (capital) and **a** (small) — and

therefore the first line and the lowest — are adjacent. Since this is so, the small letter **a** will have to be entered against the year 800 in the table of equation, since that year is the three-hundredth after the year 500. By the same reasoning, since after another 300 years the Moon anticipates a second day, the small letter **b** will have to be entered against the year 1100 in the table of equation. And in the same way the small letter **c** will have to be prefixed to the year 1400.

[Margin: How the equation of the epacts is established for the year of the correction, 1582.]

[Margin: What the letter of the equation is for the year of the correction, 1582.]

MOREOVER, since in the year 1582 ten days were removed from the month of October so that the vernal equinox might be restored to 21 March, all the new moons must after this subtraction have fallen ten days later than the epact of that year — which before the correction was *vj* — indicated in the Calendar. The line of epacts that had to be taken up then in the expanded table was therefore the one against which the capital letter **D** is placed: the line, that is, which stands tenth from the line of the small letter **c** exclusive, counting down toward the small letters **b** and **a**, and from there toward the capitals **P**, **N**, **M**, **H**, **G**, **F**, **E**, **D**. For all the epacts of the line that has the capital letter **D** attached to it are ten units less than the epacts of the other line, the one prefixed by the small letter **c**, since the latter are formed from the former by the addition of 10 units, casting out 30 and writing the sign * whenever the sum is greater than 30. Likewise the epacts of the line marked with the capital letter **D** are entered in the Calendar 10 days below the epacts of the line marked with the small letter **c**, exclusive. And so in the table of equation the capital letter **D** must be set before the year 1582, after the removal of the 10 days from the month of October.

[Margin: How the table of the equation of the epacts is set up after the correction, account being taken also of the equation of the solar year, according to the mind of the author of the Calendar.]

8 SINCE, however, after the removal of the 10 days the solar year too must be equated by omitting three intercalary days in every 400 years — one in each of the first three centesimal years, the intercalary day being retained in the fourth centesimal, as I explained above — all the centesimal years must from now on be written in the table of equation, beginning with the year 1600, which is bissextile, and with the word [Bissextilis] attached in this form, *Biss.*, to every fourth year from it, namely the years 2000, 2400, 2800, 3200, and so on. In this way the table of equation — which, after the correction of the year made in 1582, depends on

both years, the lunar and the solar — will be more easily set up according to the mind of the author of the Calendar. Yet because after some thousands of years it no longer agrees with the celestial motions, I shall correct it in the following chapter 12, and continue it there on a different principle.

[Margin: Why the table of equation is set up here according to the mind of the author of the Calendar, although it must afterwards be emended.]

I have thought it best, nevertheless, to construct it here according to the view of the author of the Calendar, even though after some thousands of years it will prove useless — partly so that the true equation of the epacts, which I shall lay down in chapter 12, may be grasped more clearly, and partly so that everyone may see how easy and how uniform the equation of the author of the Calendar is, on the supposition (which he made to himself, though it is not in fact true) that one need always descend or ascend by a single line only in the expanded table of the epacts, which I shall shortly append, on account of the equation of the solar and lunar year. This will become clear from what I am about to say.

[Margin: What the letter of the equation is for the year 1600.]

The table of equation, then, is to be extended as follows according to the mind of the author of the Calendar. From the year 1400, where the lunar equation was last applied in the table of equation, down to the year 1600, 300 years have not yet elapsed, so the Moon will not need an equation. And since the solar equation is not called for then either — the year 1600 being bissextile in the usual way — the same capital letter **D** must be set before the year 1600 in the table of equation which was prefixed to the year 1582 after the removal of the ten days.

But from the year 1400 to the year 1700, 300 years have passed, so the Moon would need an equation then, if it were true that it anticipates one whole day in 300 years. In fact it more truly anticipates one day in $312\frac{1}{2}$ years; and those $12\frac{1}{2}$ years, dropped four times from the year 500 to the year 1700 (namely in the years 800, 1100, 1400, 1700), make up 50 years. We have also anticipated the Moon's equation by as many years again — for we ought to have equated the Moon in the year 850, not in the year 800, since from the year 550, where I placed the root of the equation, to the year 850 there fall 300 years — and these, with the earlier 50 years, make 100 years. The equation of the Moon is therefore not to be applied in the year 1700, but deferred to the following centesimal, 1800, as was said above.

But because in the year 1700 the intercalary day is omitted for the sake of the equation of the solar year — to keep the vernal equinox from wandering further from 21 March — the result is that the new moons then fall one day later. For that

reason the line of epacts to be taken up then will be the one that has the capital letter **C** at its head, whose epacts are nearly all one unit less than the epacts next to the capital letter **D**, and which therefore show nearly all the new moons in the Calendar one day later. Hence in the year 1700 the capital letter **C** must be prefixed in the table of equation.

[Margin: What the letter of the equation is for the year 1700.]

AGAIN, since in the year 1800 the intercalary day is once more omitted, the new moons ought once more to fall one day later; but since at that point, as I said, the Moon needs an equation (for the equation of the Moon from the year 1700 was thrown forward into this centesimal), it follows that the new moons neither ascend nor descend, but remain on the same days. For the day by which the new moons are forced to descend toward the ends of the months on account of the equation of the solar year is restored toward the beginnings of the months by the equation of the Moon. The same capital letter **C**, therefore, must be set before the year 1800 in the table of equation.

[Margin: What the letter of the equation is for the year 1800.]

In the year 1900, however, when the intercalary day is again omitted, the new moons will descend by one day, and so the capital letter **B** is set before that year in the table of equation. The same letter is prefixed to the year 2000, because then neither is the intercalary day omitted nor have 300 years elapsed since the last equation of the Moon, made in the year 1820, so that neither year requires an equation. Likewise, since in the year 2100 both the intercalary day is omitted and at the same time [the Moon] requires an equation — 300 years having elapsed from the year 1820, when the last equation of the Moon was made, to the year 2100 — the result is that the new moons then neither ascend nor descend in the Calendar, but remain on the same days, as I said above of the year 1800. For that reason the same capital letter **B** is attached to the year 2100 in the table of equation. Further, since in the year 2200 the intercalary day is omitted and the Moon does not yet need an equation, the new moons will descend by one day, and therefore in the ta-

[Margin: What the letters of the equation are for the years 1900, 2000, 2100.]

-ble of equation the capital letter **A** will have to be entered against the year 2200. By the same reasoning the small letter **u** must be prefixed to the year 2300. But since in the year 2400 — the third centesimal after the year 2100, in which the Moon was equated — the Moon calls for an equation while the solar year does not require one, that centesimal year being bissextile, the new moons will

necessarily ascend by one day upward in the Calendar. Accordingly the line of epacts prefixed by the capital letter **A** must be resumed then, and consequently the same capital letter **A** must be placed against the year 2400 in the table of equation.

[Margin: What the letters of the equation are for the years 2200, 2300.]

In the year 2500, on account of the equation of the solar year that then takes place, the new moons are again forced to descend by one day; so the small letter **u** must again be affixed to that same year 2500, just as in the year 2300. And since in the year 2600 the solar year is equated by the omission of the intercalary day, while the lunar year does not yet need equating (having been equated in the year 2400), the new moons will again descend by a day, and so the small letter **t** must be set before the year 2600. The same letter is to be assigned to the year 2700 as well; for although the new moons would then be about to descend on account of the equation of the solar year that must be made, they will nevertheless ascend again on account of the equation of the lunar year which occurs then, and so will not change their seat. Indeed the same small letter **t** will be kept for the year 2800, because in that year neither the solar nor the lunar year is to be equated, and therefore all the new moons remain in the same state.

[Margin: What the letters of the equation are for the years 2600, 2700, 2800.]

AND in this way, according to the view of the author of the Calendar, the table of equation will be continued indefinitely, provided account is taken both of the intercalary day (whether omitted or retained) and of the equation of the Moon, which is owed to it every 300 years — and provided the $12\frac{1}{2}$ years dropped in each span of 300 years are not neglected, but that as soon as a total of 100 years has been collected from them, the equation of the Moon is deferred to the next centesimal year. This is what I did at the year 1700, from which I threw the Moon's equation forward into the year 1800. The same will have to be done again in the year 4200 — that is, 2400 years after the year 1800, into which the Moon's equation was postponed on account of those 100 years that had grown out of the omission of the $12\frac{1}{2}$ years. For the equation of the Moon which ought to be made in the year 4200, because of the 300 years elapsed since the last equation of the year 3900, must be made in the following centesimal year, 4300. In the same way, after another 2400 years the Moon's equation must be thrown forward from the year 6700 into the year 6800, and so on — so that in every span of 2500 years the Moon runs ahead of its seats in the Calendar by eight days.

[Margin: Continuation of the table of the equation of the epacts after the correction, through the centesimal years to infinity, according to the mind of the author of the Calendar.]

There follows the expanded Table of the Epacts, together with the perpetual table of the equation of the Epacts, according to the view of Luigi Lilio of Cirò [Aloysius Lilius], author of the Calendar.

TABVLA EPACTA

(the title runs on to the facing page: the catchword at the foot of this page is RVM)

TABVLA ÆQVATIONIS

A perpetual table of equation for the expanded table of the epacts, on the view of the same author of the Calendar. [Tabulæ Epactarum expansæ perpetua, ex sententia eiusdem auctoris Calendarij.]

The table is set in three parallel panels of five columns each: "Dies omissi" (days omitted), an unheaded column of epact-cycle index letters, "Anni" (years), an unheaded column marking bissextile years (Biss.), and an unheaded final column carrying the correction symbols (℔ lunar equation, ℔℔ doubled, †).

The table of days omitted continues without a break. The page sets three panels side by side; each panel carries the printed heads *Dies omiffi* and *Anni*, with three further unheaded columns — the index letter, the bissextile mark *Biff.*, and the lunar-symbol column. The panels are transcribed in reading order, left to right.

Table of days omitted and the years of the lunar equation (continued) — p. 117

[The Dies omiffi entry printed 867 against the year 121200 stands between 897 and 898 and is transcribed exactly as printed; 867 also occurs earlier, twice, on this same page against 117100 and 117200.]

The table has not ended: the last line of p. 119 reaches year 122900, and the catchword 911 carries the Dies omiffi count forward to the next page. No prose of Caput XI resumes on these three pages, and no marginal note is set beside the table.

The table of days omitted [dies omissi] continues, three panels to the page. Each panel carries the same column heads: Dies omiffi (with the index letter beside it), Anni, the bissextile column (Biff.), and the lunar-equation column carrying the crescent sorts (single ☾, doubled ☾☾) and the dagger †.

The table of the days omitted [dies omiffi] continues without break across all three pages; there is no prose on any of them. Each page carries three side-by-

side panels of five columns: the running count of days omitted, the index letter, the year, the bissextile mark, and the lunar-equation sort.

And so on to infinity, keeping from the year 301700 the same order that has been kept from the year 1700, as you see done here.

[Margin: A threefold rule, drawn from the intention of the author of the Calendar, for continuing the table of the equation of the epacts to infinity.]

I. WHEN the intercalary day is omitted in some centesimal year and the Moon needs no equation — that is, when the solar year alone is to be equated —

descend in the expanded table [tabula expansa] to the next lower line of epacts, and set that line's letter against that centesimal year.

II. WHEN, by contrast, the intercalary day is *not* omitted in some centesimal year but the Moon does need an equation — that is, when the lunar year alone is to be equated — ascend in the expanded table to the next higher line of epacts, and assign that line's letter to that centesimal year.

III. WHEN, finally, both the intercalary day is omitted in some centesimal year *and* the Moon needs an equation; or else neither the intercalary day is omitted nor does the Moon require an equation — that is, when both years are to be equated, or neither — stay on the same line of epacts in the expanded table, and prefix to that centesimal year the same letter that was attached to the preceding centesimal year.

You can see that all these rules have been observed in the table of equation just given. Every centesimal year always has prefixed to it the letter that identifies the line of epacts in the expanded table then to be taken, according as one must descend, ascend, or stay on the same line — exactly as this threefold rule teaches. Moreover, to make the scheme of the equation easier to follow, we have added this sign, C , to those centesimal years in which the Moon calls for an equation: single at every third centesimal year, but double at every fourth centesimal year, into which the equation is deferred from the preceding three-hundredth year. That deferral occurs, as we said, at intervals of 2400 years after the year 1800, when such a postponement of the equation was first made. For then the equation is deferred to the year 4300 from the year 4200, even though 4200 is the third centesimal year from the last lunar equation, made in the year 3900. The same must be done 2400 years after the year 4300 — that is, in the year 6700, from which the equation is deferred to the year 6800. Likewise 2400 years after the year 6800, that is, in the year 9200: for then the equation is to be applied not in 9200 but in 9300. And so with the rest.

All of this, to be sure, has been worked out according to the intention of the author of the Calendar. But when we examined this table of equation more carefully, we found that after some thousands of years it no longer yields new moons [nouilunia] agreeing with the mean celestial new moons, but ones earlier than these. We shall therefore correct the table of equation in the following chapter, Num. 10, and at the same time disclose the reason for its error. And so after the year 8200 this table of equation is not to be used for finding the epact; the one we shall construct in chap. 12, Num. 10 is to be taken instead.

[Margin: The epact is not to be found by the preceding table of equation after the year 8200.]

IN the same table of equation we have set down, on the left, the days that will have been dropped up to each centesimal year, over and above the ten dropped in 1582, the year of the correction. We need this quite often in computing the mean conjunctions and oppositions of the Moon. Thus you see, for example, that by the year 70700 the omitted bissextiles are 519; and adding the 10 days removed in the year of the correction, the days dropped by then come in all to 529. And so with the rest.

ALTHOUGH the letters of the alphabet in this table of equation seem to observe no order, they do nevertheless come round again in a circle, like a Cycle, over a span of 300000 years. The table of equation of the epacts, extended over 300000 years — that is, over 3000 centesimal years — beginning from the year 1700 (the year in which the capital letter C is first used in place of the capital letter D) and running to the year 301600 inclusive, as has been done in ours, would therefore hold good in perpetuity, provided the world lasted for ever and the method of equating both years, the solar and the lunar, prescribed by the author of the Calendar, never needed emendation but always answered exactly to the celestial motions.

We shall make this clear as follows. After 10000 years have elapsed from the year 1700 — that is, after 100 centesimal years, namely in the year 11700 — exactly the same pattern of letters returns, though not the same letters. For just as, after the year 1600, one and the same letter C is set against the two years 1700 and 1800; the same letter B against the three years 1900, 2000, 2100; the letter A against the year 2200; the letter u against the year 2300; the letter A repeated against the year 2400; the letter u against the year 2500; and one and the same letter t written against the three years 2600, 2700, 2800, and so on — exactly the same thing happens after any 10000 years have elapsed. For after the year 11600, the same letter i is written against the two years 11700 and 11800; the same letter h against the three years 11900, 12000, 12100; the letter g against the year 12200; the letter f against the year 12300; the letter g repeated against the year 12400; the letter f against the year 12500; and one and the same letter e set before the three years 12600, 12700, 12800, and so on. The very same thing is seen after 10000 years have elapsed from the year 11700: in the year 21700 the same pattern comes back again. So too in the year 31700, that is, 10000 years after the year 21700; and again in the year 41700, that is, 10000 years after the year 31700 as well. The same holds for the rest. All of this is evident from the years set out below, which

are excerpted from the table of equation above — although the same is true likewise in every span of 10000 years, from whatever centesimal year one begins after the year 1600. Before that year the proportion does not appear, since the equation of neither year was then applied. Moreover, in the table of equation above, against the years from which the series of 10000 years begin after the year 1600, we have placed this sign †, on the right, between the marks ☾ and ☾☾.

[Margin: That after 10000 years the letters in the table of equation of the epacts advance in the same proportion, and why.]

THE REASON for this is that 10000 years contain, exactly four times over, the twenty-five centesimal years into which the lunar equation owed to the preceding centesimal year is deferred; and therefore the lunar equations advance in one span of 10000 years just as they do in any other. Since, then, the bissextile centesimal years also stand in the same way in all spans of this kind — as is plain from the two small tables set beside this passage, in which we have placed both the marks of the lunar equation and those of the bissextile years, excerpted from that same table of equation above — it must follow that the letters of the equation advance in the same proportion in every span of 10000 years.

AND SO the whole labour of constructing the table of equation above lies in the first span of 10000 years. For if from the year 11700 — that is, once 10000 years have elapsed from the year 1700 — the same pattern of letters is repeated (though beginning from the minuscule letter i, which falls in its own order on the year 11700), together with the same marks of the lunar equation and of the bissextile centesimal years that was observed from the year 1700 to the year 11600 inclusive; and if the same is then done after each further set of 10000 years, until 300000 years after the year 1700 are complete — the whole table of equation will have been constructed, embracing every variation.

[Margin: The whole labour of constructing the table of equation above lies in the first span of 10000 years.]

FOR after 300000 years not only is the same pattern of the letters of the equation preserved, but the very same letters return in a circle — which will be clear from what follows. Since, once 10000 years have elapsed from the year 1700, a change of 43 letters has been made — that is (casting away the whole Cycle of 30 letters of the expanded table) of 13 letters, beginning from the capital letter C set before the year 1700 and running to the minuscule letter k inclusive, attached to the year 11600 — there will be in the second span of 10000 years a change of 26 letters, beginning from that same capital letter C, that is, of a further 13 letters, from the minuscule letter i to the capital H inclusive. In the third span the change is 39, that is (casting away 30) 9. In the fourth, 22. In the fifth, 35, that is (casting away 30) 5. In the sixth, 18. In the seventh, 31, that is (casting away 30) 1. In the

eighth, 14. In the ninth, 27. In the tenth, 40, that is (casting away 30) 10. In the eleventh, 23. In the twelfth, 36, or 6. In the thirteenth, 19. In the fourteenth, 32, or 2. In the fifteenth, 15. In the sixteenth, 28. In the seventeenth, 41, or 11. In the eighteenth, 24. In the nineteenth, 37, or 7. In the twentieth, 20. In the twenty-first, 33, that is, 3. In the twenty-second, 16. In the twenty-third, 29. In the twenty-fourth, 42, or 12. In the twenty-fifth, 25. In the twenty-sixth, 38, or 8. In the twenty-seventh, 21. In the twenty-eighth, 34, or 4. In the twenty-ninth, 17. And in the thirtieth, 30, or 0. Since, I say, in every span of 10000 years a change of 13 letters occurs, so that in the thirtieth span the change amounts to all 30 letters of the expanded table, it follows that once 30 spans of 10000 years have passed — that is, once 300000 years have elapsed — exactly the same letters return as before, and in the same order. The table of equation of the epacts above is therefore contained within a Cycle of 300000 years.

Thus you see in the table of equation above that against the year 301700 — which is 300000 years from the year 1700, where we begin the order of the equation — the capital letter C is again set, the same letter that was set before the year 1700; and this is found at no other centesimal year marked with the sign †. And so at the year 301700 and the years following, the same letters will be repeated, in the same order in which they stand at the year 1700 and the years following.

[Margin: That the table of equation above is contained within a cycle of 300000 years, and why.]

11 IT MUST NOT, however, be passed over at this point that, just as we deferred the lunar equation, after any 2400 years, to the following centesimal year — on account of those $12\frac{1}{2}$ years omitted in each span of 300 years, which in each 2400 years accumulate to 100 years — so likewise the same equation is to be thrown forward, after any 481436 years, into the next following centesimal year, on account of the 23 days and 17 hours by which we anticipate it in each span of $312\frac{1}{2}$ years; for those 23 days and 17 hours accumulate, over a span of 481436 years, to 100 years, as we wrote in chapter 8, Number 4. But since this stretch of time exceeds our whole Cycle of equation of 300000 years, let us leave that care to our descendants, who will be alive in those ages — if indeed the world lasts so long — especially since no uniform equation can agree with the celestial new moons for so long a time. I have said this so that no one should be troubled on account of those 23 days and 17 hours which we have neglected in the equation; for we laid it down that the Moon runs ahead by one day in $312\frac{1}{2}$ years, whereas more accurately she anticipates it by 312 years, 6 months, 23 days and 17 hours, as we showed in chapter 8, Num. 4.

[Margin: What is to be done about the equation of the Moon after 481436 years.]

CAPVT XII.

Inuentio aurei numeri, & Epactæ quolibet anno proposito: Item emendatio tabulæ æquationis præcedenti capite ex sententia auctoris Calendarij descriptæ.

Finding the golden number and the epact for any proposed year; together with the correction of the table of equation set out in the preceding chapter according to the intention of the author of the Calendar.

I

THE nineteen-year CYCLE of the golden number is a revolution of the number 19, from j up to 19; and when that revolution is complete, it returns again to unity. For example: in the year 1596 the number of the nineteen-year Cycle, which is called the golden number, is 1. In the following year, 1597, it is 2. In 1598 it is 3; and so on in the succeeding years, always one more, up to 19 — which golden number will fall in the year 1614. After that one must return again to unity, so that in the year 1615 the golden number is once more j, in 1616 it is 2, and so on. This Cycle of the golden number contains 19 years because, after 19 solar years have elapsed, the new moons return to the same days of the months — not altogether precisely, but somewhat earlier by some fraction of a day, as we showed above in chapter 8.

[Margin: What the cycle of the golden number is.]

EVERY year of the golden number ends at the close of the month of December, and at the beginning of January of the following year another year of the golden number takes its start — just as happens with the years of the Lord, which always end in the month of December and take their start from January. Thus in the year of the Lord 1598 the year of the nineteen-year Cycle, which is called the golden number, is 3, and it ends together with the year of the Lord 1598 itself in the month of December. But in the month of January another year of the Lord begins, namely 1599; and in that same month of January another year of the golden number is likewise taken up, namely 4. And so one must proceed in the other years, until the number 19 is completed, from which one must return again to unity — and in this way perpetually.

[Margin: The golden number of every year begins in January.]

2 ALTHOUGH all 19 golden numbers, distributed through the days of the Calendar, cannot indicate the new moons perpetually, or even for a long time, as we said in chapter 9 — and the epacts have been adopted in their place — it is nevertheless altogether necessary to know the golden number of each year, so that by means of it the epact of that same year may be found. Besides the rules handed down in Canon 1 of the perpetual Gregorian Calendar, which we set out at the beginning of this work, we shall here provide a very convenient table from which the golden number of any proposed year may be extracted, beginning from the year of the Lord 1, in which the golden number was ij. The construction of the table is as follows. Let all 19 golden numbers be set out in order in a little table, beginning from the golden number ij. Then let there be described in another table the years of the Lord beginning from 1 and advancing by the continual addition of 19, as far as one pleases. For to these years corresponds the golden

number ij of the first cell. Therefore, when you are about to find the golden number of any year, look for that year among the years of the Lord; and when you have found it, you will say that in that year the golden number is ij. But if the proposed year is not found there, take the year next below it, assign that to the first cell, the following year to the second cell, the next after that to the third, and so on, until you reach the proposed year. For the golden number of the cell into which the proposed year falls will be the one sought.

For example: let the golden number of the year 147 be sought. Having found among the years of the Lord the year 134, the next below it, assign that year to the first cell, the year 135 to the second, 136 to the third, and so on. The proposed year 147 will end at cell 14, in which the golden number xv is written, and that is the number owed to the year 147. Again, let the golden number of the year 5383 be proposed for finding. Having found the next lower number, 5378, count from it in the cells of the golden numbers up to 5383, and you will fall on the golden number vij, which fits the proposed year 5383. Further, let the year 5416 be proposed: since it is found among the years of the Lord, you will say that the golden number ij belongs to it. Again, let the year 6060 be proposed. Having found the next lower, 6043, count from it in the cells of the golden numbers up to 6060, and you will fall on the cell of the golden number xix, which answers to the year 6060. Lastly, let the year 4466 be given: since it is found among the years of the Lord, you will say that the golden number is ij, which stands in the first cell. For every year described in the table has the golden number ij of the first cell, as we said. And the same reasoning holds in the remaining cases.

3. It will perhaps be more convenient to lay this table out by hundreds of years, in the following manner:

Anni Domini per 100. collecti, quibus Aurei numeri in finistro latere descripti congruunt. — *Years of the Lord collected by hundreds, with which the golden numbers set down on the left-hand side agree.*

[illegible]

CONSTRVCTIO. The construction of this table, which can be extended without end, is perfectly easy. The centesimal years run down in order, beginning from the year 0, until nineteen cells are filled, as the table shows. Beside the year 0, which occupies the first place in the descending first column of years, and beside the centesimal years that likewise occupy the first place in the other columns, the golden number 1 is written down; from that number the rest are formed by continually adding five, always casting away 19 whenever the sum so produced is greater than 19.

VSVS. The use of the table is likewise not difficult, provided one takes note of this little table of the years collected by 19, preceded by the year 0, together with the series of all 19 golden numbers set out here.

[Small table, p. 139]

Tabella annorum per 19. collectorum. [Little table of the years collected by 19s]

0	19	38	57	76	95

Series Aureorum numerorum. [Series of the golden numbers]

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19

To find the golden number of any given year that is not greater than the last centesimal year of the preceding table, proceed as follows. If the year in question is itself one of the centesimals, look for it among the years of the Lord, and you will have the golden number you want immediately opposite it. If it is not a centesimal year, take from the little table of the years collected by 19 the number next smaller than the year proposed, reckoned from the centesimal year already passed, and assign it to that golden number of the adjacent series which is found written opposite the centesimal year after which the given year falls. To the next golden number of the same series assign the next year, and so on in succession, returning to the beginning of the series if need be, until you reach the year proposed. The count will end on the golden number you are looking for.

Now if the given year, taken after some centesimal, is itself found in the table of years collected by 19, then the golden number for that year is the one that answers to the centesimal year immediately preceding the given non-centesimal year.

For example: in the year 1600 the golden number is v. But in the year 1683 the golden number is xij. For if you assign to the golden number 5 — found opposite the centesimal year 1600 — the year 76 of the adjacent little table of years collected by 19, and the year 77 to the next golden number 6, and so on, the year 83 falls on the golden number 12. Again, in the year of the Lord 48 the golden number was xj. For assigning, in the adjacent series, to the golden number 1 (found opposite the centesimal year 0) the year 38 of the adjacent little table of years collected by 19 — that being the number next smaller than the given year 48 — and the year 39 to the next golden number, and so on, the year 48 ends on the golden number 11. So too in the year 1810 the golden number will be 6: for if in the adjacent series you assign to the golden number 15, written opposite the centesimal year 1800, the year 0 of the adjacent little table of years collected by 19 — that being next smaller than the given year 10 after the centesimal 1800 — and the year 1 to the next golden number 16, and so on, the year 10 ends on the golden number 6. Finally, in the year 1657 the golden number will be 5, the number that belongs to the year 1600; for the year 57 is found in the table of years collected by 19. And so with the rest.

4. We shall, however, make the use of this table far quicker in the following way. Beside the golden numbers of the table already given, write on the left the nineteen capital letters of the alphabet in order; let the same letters be repeated in the same order in this second table, and beside each of them let all nineteen golden numbers be set down, each line beginning from the golden number that exceeds by one the golden number written beside that same letter in the upper table. Finally, above these same golden numbers arrange the hundred expanded years, as you see in this table. With the golden numbers and the expanded years set down in this way, it is remarkable how quickly the golden number of any proposed year is found. For if the given year is one of the centesimals, its golden number will be found at once on its left in the upper table, as we said in the preceding use. But if the given year falls after some centesimal, its golden number will be found beneath the given expanded year, in that line of golden numbers which carries the same prefixed letter as is set before the centesimal year immediately preceding. Thus to the year 39300 in the upper table there answers the golden number 9; whereas the year 39378 agrees with the golden number 11, in this second table, under the year 78, in the line to which the letter O is attached — the letter set in the upper table opposite the centesimal year 39300.

[Table of expanded years, p. 140]

[Margin: *Inuentio aurei nu. ex tabellis temporariis.* — Finding the golden number from the temporary little tables]

At number 11 of this same chapter you will find a very quick method by which the golden number of any proposed year may be got out by means of certain temporary little tables. In fact the nineteen lines of golden numbers in the table just given can serve as nineteen temporary little tables. For example, the line prefixed by the letter R will give the golden number for the expanded years after the year 1600 — the centesimal year to which the same letter R answers in the preceding table of centesimal years — as far as the year 1700, provided that the expanded years written at the head of the adjacent table are used along with it. In the same way that same line of the letter R will serve for the expanded years after any centesimal year to which the same letter R answers in the preceding table of centesimal years, as far as the following centesimal. In just the same way any other line of golden numbers can serve as a temporary table for the expanded years after those centesimal years to which, in the table of centesimal years, that

letter answers which is prefixed to the line in question of the adjacent table, and it serves as far as the next following centesimal. For example, the line to which the letter G is prefixed will give the golden number in the expanded years from the year 600 to 700; and from the year 2500 to 2600; and from the year 17700 to 17800; and so with the rest.

Lastly, by means of the following table — which is like the one we set out at Canon 1 of the *Calendarium*, but much more compact, adapted to a greater number of years, and capable of being extended without end — the golden number of any year, however large, will also be found without difficulty, in this way. If the proposed year is found in this table, its golden number will be the one written beside it on the left-hand side, with 1 added, as the head of the table directs. Thus in the year 1000000000 the golden number will be xix, made up of the golden number xviii prefixed to that year, and 1.

But if the given year is not set down in this table, then one must extract from the table the golden numbers prefixed to those years that have as many ciphers (the number of ciphers is indicated by the figure placed to the right of each centesimal, so that you need not count them yourself) as there are figures following each significant figure of the proposed number. These extracted numbers are then to be multiplied by their own figures, if these are greater than 1, and from the products the cycle of 19 years is to be cast away as often as it can be. For if all these extracted golden numbers are gathered into a single sum, with a unit added besides, and all the 19s are cast away, the remainder will be the golden number of the given year.

Table of golden numbers for arbitrarily large years (the compact table announced at the end of the preceding page). The left column gives the golden number prefixed to each power-of-ten year; the right-hand figure counts the ciphers (zeros) in that year, so that they need not be counted by hand. Numerals are transcribed exactly as printed (lower-case Roman with terminal j in the left column, Arabic in the other two).

Aur. nu.	Anni Domini.			Adde 1. ad Aur. Num.	(ciphers)
j				1	0
x				10	1
v				100	2
xij				1000	3
vj				10000	4

Aur. nu.	Anni Domini. Adde 1. ad Aur. Num.	(ciphers)
iiij	100000	5
xj	1000000	6
xv	10000000	7
xvii	100000000	8
xviii	1000000000	9
ix	10000000000	10
xiiij	100000000000	11
vij	1000000000000	12
xiiij	10000000000000	13
xvj	100000000000000	14
viiij	1000000000000000	15
iiij	10000000000000000	16
ij	100000000000000000	17
j	1000000000000000000	18
x	10000000000000000000	19
v	100000000000000000000	20

Suppose the golden number of the year 4560926 is wanted. To 4000000 belongs golden number 6; for the golden number 11, which is due to the year 1000000, multiplied by 4 gives 44, and casting away 19 leaves 6. To 500000 belongs golden number 15, since to 100000 belongs 3, which multiplied by 5 makes 15. To 60000 belongs golden number 17. To 900, golden number 7. To 20, golden number 1. Finally to 6, golden number 6. The sum of all is 52; and casting away 19 there remain 14, to which 1 is added, making golden number 15 — the number that fits the proposed year.

[Side reckoning printed in the right margin of this paragraph:]

6
15
17
7
1

All the 19s will be cast away if all the 20s are thrown out and as many units are added to the remainder as the number of times 20 was cast away. Thus, when all the 19s have been cast out of 87, 11 are left over; for if 4 (since 20 is contained four times in 87) is added to 7, the result is 11.

Whenever, too, some golden number of the table greater than 10 has to be multiplied by a significant figure, it will be done very conveniently if 10 is first multiplied by that figure, and then the remaining units, always casting away 19 whenever it can be cast away. Thus if 18 is to be multiplied by 7, we shall multiply 10 by 7, and from the product 70 cast away 19 so that 13 remains. Then we shall multiply 8 by 7, and from the product 56 throw out 19 so that 18 remains; added to 13 this makes 31, and casting away 19 leaves 12.

We shall perhaps manage the same thing more easily even without multiplying the extracted golden numbers by the significant figures — in this way. Set the extracted numbers down in order, writing each of them as many times as there are units in the significant figure that answers to it. Then join the first number in order to the second, and this aggregate to the next, and so on; taking care, however, that as soon as you have made up 19 or more, you throw out 19. Thus in the same example the extracted numbers will stand like this:

11.11.11.11.3.3.3.3.6.6.6.6.5.5.5 5.5.5.5.5.10. 10. 6. So then, 11 and 11 make 22, and casting away 19 leaves 3; these with the following 11 make 14; and these with the 11 that follows make 25, and casting away 19 leaves 6; these gathered in order with 3.3.3.3.3 make 21, and casting away 19 leaves 2; these with 6.6.6 in order make 20, and casting away 19 leaves 1; this with the following 6.6.6 makes 19, which is to be cast away. Next 5.5.5.5 make 20, and casting away 19 leaves 1; this with the following 5.5.5.5 yields 21, and casting away 19 leaves 2; these with 5.10.10 make 27, and casting away 19 leaves 8; these with 6 come to 14, and with 1 added at last the golden number 15 results, as before. Still, the earlier procedure is quicker whenever the multiplication by the significant figure can easily be done in the head.

The construction of the table is easy as well. The years advance from unity by a tenfold ratio, but the golden numbers by halving — with 19 added, however, to an odd golden number, so that it can be halved. Thus, adding 19 to 1 gives 20, and the half yields the next golden number x. The half of the number 10 gives the

following golden number v, and so on. Let this be enough about finding the golden number. In the *Computus Ecclesiasticus*, which I shall write out at the end of this book, you will find besides a rule by which you can work out the golden number of any year, however large, in your head and with no trouble at all.

[Margin: Use of the expanded table and of the equation of the epacts in finding the epact of any year. — By which table the epact is found more correctly after the year 8200.]

5. The finding of the epact for any year depends on the use of the expanded table and of its equation, described in the preceding chapter; and it runs as follows. Look up the proposed year in the table of equation, if it is one of the centesimal years; or, if it is not one of the centesimals, take the centesimal year next below the proposed year, or else the year 1582 if the given year falls after the correction and before the year 1600. (After the year 8200, however, the epact will be found more correctly from the table of equation which I shall set up below at the end of Num. 10, whose use is in fact the same as that of the preceding table of equation.) Note carefully the letter prefixed to that centesimal year. For the line of epacts which

has that same letter prefixed to it in the expanded table is the one to be used — not only for the proposed year, but for all the other years as well from that centesimal up to the next centesimal year that has a different letter attached. And the epact which stands in that line under the golden number of the year in question at the head of the table is the one to be assigned to the proposed year. For that epact will mark, in the *Calendarium*, all the new moons of that year according to the usage of the Church; and its use will begin in January — although in centesimal years that are not bissextile, provided the Moon needs no equation, the new moons in the first two months of the year are put back by one day, as found by the new epact. No absurdity arises from this in the Paschal new moons, and that postponement occurs only in the first two months of that one centesimal year.

[Margin: [?]*libet anni Epacta in Ianuario incipit.* — "The epact of any year begins in January." (The first word runs off the edge of the printed margin; probably *cuius-*.)]

Therefore, to find the epact of any year, one must first find the golden number of that year, and the line of epacts in the expanded table which serves that century. I shall set out some examples reaching to more distant centuries — but I do this only for practice, since I well know that the prescribed equation diverges from

astronomical calculation over such great stretches of centuries, as I shall say below.

For example. Given the year 1593, one must take in the table of equation the year 1582, which is the one next below it in the table, together with the capital letter D. Then, in the expanded table, the line of epacts to be taken will be the one prefixed by that same capital D. For this line will be in use from the year 1582 — after the correction, that is — up to the year 1700 exclusive, which already has a different letter prefixed to it. And since in the year 1593 the golden number is 17, to which in the assumed line of epacts of the capital letter D there answers the epact xxvij, that epact will be the one employed in that very year 1593, and the new moons will fall in that year on the days against which the epact xxvij is set in the *Calendarium*.

Again, for the year 1916 one must take in the table of equation the year 1900 together with the capital letter B; and in the expanded table one must take the line of epacts that has that same letter B prefixed. For this will be in use from the year 1900 up to the year 2200 exclusive, before which another letter is set. And since the golden number of the year 1916 is 17, to which in the accepted line of epacts of the capital letter B there answers the epact 25 — marked in a different character from the others — that epact will indicate the new moons of the whole of that year in the *Calendarium*.

Again, let the year 114519 be given. To the year 114500, which is the centesimal next below the proposed year, the minuscule letter f is prefixed in the table of equation. In the expanded table, therefore, the line of epacts of that same minuscule f is to be taken. For this will be in use from the year 114500 up to the year 114700 exclusive. And since the golden number of the year 114519 is 7, to which in the said line of epacts there answers the epact j, the epact j will show the new moons of that year in the *Calendarium*.

Lastly (to offer an example from before the correction of the year as well), if the year 415 is proposed, one must take in the table of equation the year 320, which is next below it, together with the capital letter P; and in the expanded table the topmost line of epacts, to which that same capital P is assigned. For this was the line to be used at that time. Since, then, in the year 415 the golden number was 17, to which in that line of epacts there answers the epact iiij, all the new moons of that year fell on the days against which the epact iiij is written. And the same reasoning holds in the rest.

[Margin: Construction of the perpetual cycle of the epacts.]

6. But in place of the expanded table we shall be able to use the following perpetual cycle of the epacts. Although I set it out in the *Calendarium Gregorianum Perpetuum*, I judge that it should nevertheless be repeated here, so as to extend its use to more years. Its construction is this. Set down in order all 30 epacts, beginning from *, that is xxx, and advancing by continual addition of 11 — always throwing out 30, however, when the sum comes to more than 30. Then place above these epacts the letters that are assigned to those epacts in the expanded table under golden number 3, as you see here. The epact xxv.25 is doubled under the capital letter F, and is marked with different characters.

CYCLVS EPACTARVM PERPETVVS. [Perpetual cycle of the epacts]

P	l	C	c	p	F		f	f	M	i
*	xj	xxij	iiij	xiiiij	xxv. 25.		vj	xvij	xviiij	ix

A	a	m	D	d	q	G	g	t	N	
xx	j	xij	xxiiij	iiiij	xv	xxvj	vij	xviiij	xxix	

k	B	b	n	E	e	r	H	h	u	
x	xxj	ij	xiiij	xxiiiij	v	xvj	xxvij	viiij	xix	

MALVIMVS — We have preferred, in this little table, to write the index letters of the expanded table above those epacts which in the expanded table are placed under golden number 3 next to the same epacts, rather than above those which answer to the same letters at golden number j (though this could have been done). Our reason was that it should be more easily understood that this little table is excerpted from the expanded table, and that the one should differ as little as possible from the other; but above all, that these same letters should be used in the *Martyrologium* for announcing the age of the Moon, at the times when the epacts written beneath them are in use, as was said above in cap. 11 not far from the beginning. No other reason for this construction is to be looked for.

[Margin: Finding the epact for any year from the perpetual cycle of the epacts.]

To this little table of the perpetual cycle of the epacts there answers the table of equation of the expanded table given above, and also the more correct one which we shall set out below at Num. 10; and its use in searching out the epact of any year is as follows.

Look up the proposed year in the table of equation — or, if it is not found in the table, the year next below it — and note the letter of the alphabet, whether capital or small, placed to its left; and work out the golden number belonging to the proposed year. Then in the perpetual cycle of the epacts look for the matching letter, and assign golden number 1 to the cell which, counting inclusively, is the third to the left from that letter; assign the next golden number, 2, to the following cell on the right, and so on, until you reach the golden number of the proposed year — returning to the beginning of the cycle if you have run through it to the end before reaching the golden number of the proposed year, and counting the capital letter F, under which the doubled epact xxv.25 is placed in two different characters, as a single cell. When this has been duly carried out, the epact of that year will be found at once in the cell into which the golden number of the proposed year falls. Note carefully, however, that when the golden number of the proposed year is greater than 11 — as are the last eight golden numbers 12.13.14.15.16.17.18.19 — and it falls into the cell of the capital letter F, where there are the two epacts xxv. 25, then the epact 25 marked with the different character is to be taken; but the other epact xxv if the golden number of the proposed year that falls into that same cell is less than 12, such as are the first eleven golden numbers 1.2.3.4.5.6.7.8.9.10.11.

We shall make this plain by examples. To the year 1582, after the correction — that is, after the subtraction of the 10 days — there answers in the table of equation the capital letter D, and in that year the golden number was 6. If, then, in the perpetual cycle of the epacts you assign golden number 1 to the cell of the small letter a, which is the third to the left from the cell of the capital letter D, and golden number 2 to the next cell on the right, and so on, the golden number 6 of the proposed year 1582 will fall into the cell of the epact xxvj — which in the *Calendarium* marked the new moons from the Ides of October of that year, that is, after the removal of the 10 days.

Again, suppose the epact is to be investigated for the same year 1582 before the correction, namely from January up to October. Since in the table of equation the year before the correction next below is 1400, to which the small letter c is prefixed, the matching small letter c must be taken in the perpetual cycle of the epacts. If, then, you assign golden number 1 to the cell of the small letter l, which

is the third to the left from the cell of the small letter c, and golden number 2 to the next cell on the right, and so on, the golden number 6 of the same year will fall into the cell of the epact vj — which is what is due to the year 1582 before the removal of the 10 days.

Again, in the year 1599 the golden number is 4, and to it there answers in the table of equation the capital letter D. For since this year is not found in the table, the next lower one, 1582, must be taken, to which the capital letter D is assigned. Assigning, then, in the table of epacts, golden number 1 to the cell of the small letter a, which is the third towards the left from the cell of the capital letter D, and golden number 2 to the next cell on the right, and so on, the golden number 4 of the proposed year will fall into the cell of the epact iiij, which will show the new moons of that year in the *Calendarium*.

Furthermore, to the year 4218 there answers in the table of equation the small letter l, and the golden number is 1. So if in the cycle of the epacts you assign golden number 1 of that year to the cell of the letter u, which is the third to the left from the cell of the letter l, you will find that the epact xix belongs to the year 4218.

Further still, to the year 1710 there answers the capital letter C in the table of equation, and again the golden number is 1. So if you assign golden number 1 of that year to the first cell, that of the capital letter P in the cycle of the epacts, which is the third from the capital letter C, you will find * for the epact of that year.

To the year 1912, likewise, there answers in the table of equation the capital letter B, and the golden number is 13. Accordingly, if in the cycle of the epacts golden number 1 is assigned to the cell of the capital letter N, which is the third from the capital letter B, and golden number 2 to the next cell on the right, and so on, returning to the beginning of the cycle, the golden number 13 of the proposed year will fall into the second cell. The epact will therefore be xj at that time.

Yet again, to the year 1715 there answers in the table of equation the capital letter C, and the golden number is 6. Assigning, then, golden number 1 to the first cell in the cycle, where the capital letter P stands, which is the third from the cell of the capital letter C, and golden number 2 to the next cell on the right, and so on, the golden number 6 of the proposed year will fall into the cell of the letter F, under which is placed the doubled epact xxv.25. But since the golden number 6 is not greater than 11, the epact xxv is to be taken for the year 1715, and not the 25 of the different colour.

Lastly, to the year 1916 there answers in the table of equation the capital letter B, and the golden number is 17. Therefore, if in the perpetual cycle of the epacts golden number 1 is given to the cell of the capital letter N, which is the third from the cell of the capital letter B, and golden number 2 to the next cell on the right, and so on, returning to the beginning of the cycle, the golden number 17 of the proposed year will come out at that same cell F, under which the doubled epact xxv.25 is found. And since the golden number 17 is greater than 11, the epact 25 of the different colour or character is to be taken for the year 1916. In this way you will find the epact of any year whatever, for ever.

7. By this method, then, the expanded table of the epacts is reduced to a compendium by means of the perpetual cycle of the epacts, as has just been explained. But we shall reduce the table of equation given above — which is extremely long — to a small size no less conveniently, in this way. Write down the left-hand side of the table, in order, the thirty letters of the expanded table, beginning from the capital C, which is prefixed to the year 1700 (the point at which we said, in cap. 11, Num. 10, that the order of the cycle of 300000 years begins), and running backwards through B, A, u, and so on, as far as D. Then beside each letter write the places, or seats, of those centesimal years within the first span of 10000 years (taking the start from the year 1700 up to the year 11600 inclusive) to which that letter is prefixed in the table of equation. For example: because the capital letter C is prefixed in the table of equation to the first and second centesimals (that is, to the years 1700, 1800) and to the seventy-first, seventy-second and seventy-third centesimals from the year 1700 inclusive (that is, to the years 8700, 8800, 8900), we have accordingly written beside the capital letter C the seats 1.2.71.72.73. On the same principle we have put beside the small letter u the seats 7. 9. 78. 80, which are the places occupied, within the first span of 10000 years from the year 1700 up to the year 11600 inclusive, by the years 2300, 2500, 9400, 9600 — the years to which the small letter u is prefixed in the table of equation. And so on for the rest.

The compendium of the table of equation

The compendium is printed as three side-by-side blocks of ten rows each, thirty index letters in all, running from the capital C backwards to the capital D. In each row the index letter stands first, followed by the seats (the ordinal positions of the centesimal years) it governs within the first span of 10000 years, counted from 1700 inclusive.

[Margin: The use of the compendium of the table of equation in finding the epact of any given year.]

8. So this is that immense table of the equation of the epacts, reduced — as you see — to so remarkable a compendium. By it we shall find, with the greatest ease, which letter of the expanded table of the preceding chapter, or of the perpetual cycle of the epacts, is to be used in looking up the epact for any proposed year, however large — even though the epact found from that table after the year 8200 does not correspond exactly to the celestial new moons, as we shall explain in Num. 10 of this chapter. Take any proposed centesimal year not greater than 301600 (if it is greater, discard the 300000 years of the whole cycle) and subtract 1600 from it. Then look up, in the table just given, the number expressed by the thousands and hundreds — this number indicates the seat of the proposed centesimal year, counted from 1700, within the first cycle of 10000 years. The letter prefixed to that number is the one to be taken up in the expanded table, or in the perpetual cycle of the epacts, at the centesimal year that occupies that seat in the first cycle of 10000 years; and that same letter will serve for the proposed centesimal year, provided that after subtracting 1600 the remaining number has not turned out greater than 10000. But if the remainder is greater than 10000, then, starting from the letter found in the table just given, you must count off 13 letters against the series of the letters, as many times over as there are units in the number of ten-thousands. Counting in this way you will end on the letter that is to be taken for the proposed centesimal year. And if the ten-thousands are more than 2, they must be multiplied by 13 and the product divided by 30; the remainder then gives the number of letters to be counted after the one found. Likewise, whenever the number expressed by the thousands and hundreds is 00, a unit must be borrowed from the ten-thousands so as to obtain seat 100 — that is, the last year of the cycle of 10000 years.

Let us illustrate the matter by examples. Take the year 10000. Subtract 1600 and 8400 remain. In the table above, then, the letter to be taken is the small f, beside seat 84. And since there is no ten-thousand present — the number left, 8400, not being greater than 10000 — the proposed year 10000 falls within the first cycle of 10000 years, and so that very same letter f is to be used. Since the golden number is then 7, the epact will be j, which answers to golden number 7 in the line of the small letter f in the expanded table, and so on.

Again, let the year be 11600. Subtract 1600 and 10000 remain. Seat 100 therefore gives the small letter k. And since nothing remains in the ten-thousands, nothing is to be counted after the letter k; k itself is to be taken. In the line of the letter k, golden number 11 shows epact viii for the proposed year, whose golden number is 11.

Further, let the year given be 34700. Subtracting 1600, 33100 remain. So seat 31, which the number expressed by the thousands and hundreds yields, offers the small letter i; and if from it you count 13 letters three times over (there being 3 in the ten-thousands) — that is, 39, or (casting out 30) 9 — you will fall on the capital P, which is owed to the given centesimal year. The golden number 7 of that same year will then show, in the line of the capital P in the expanded table or in the perpetual cycle of the epacts, the epact xiiij.

Likewise, let the year 41600 be offered. Taking away 1600, 40000 are left. Since the number expressed by the thousands and hundreds is 00, we shall borrow 1 from the ten-thousands so as to have seat 100, to which the small letter k is prefixed in the table above. Counting from it 13 letters three times, that is 39, or (casting out 30) 9 — because 3 remain in the ten-thousands — you will fall on the small letter a, which is due to the centesimal year offered. The golden number 10 of that same year will then give the epact xviiij.

Take next the year 301600. Subtracting 1600, 300000 remain. And since in the place of the thousands and hundreds the number 00 is found, we shall borrow 1 from the 30 ten-thousands so as to have seat 100, with the small letter k in the table above. Then, if we count off 13 letters as many times as there are units in the remaining number 29 of ten-thousands — that is (casting out all the 30s, which is done by multiplying 29 by 13, and dividing the resulting product 377 by 30, for the remainder will be 17) — 17, we shall fall on the capital D of the table above, which will be in use in the year 301600, namely in the 300000th year from 1700 inclusive, that is, at the end of the whole cycle of 300000 years, and so on.

Further still, let the year given be 590600. Subtracting 300000, 290600 remain; and taking 1600 from these, 289000 are left. So in the table above we shall take seat 90, with the small letter p. Next we shall multiply the 28 ten-thousands by 13 and divide the product 304 [?] by 30. For if we count the remaining number 4 after the small letter p, the fourth unit will fall on the small letter k, which is to be used for the year 590600, and so on.

Finally, let the year 671600 be offered. Casting out 300000 twice, 71600 are left; and taking 1600 from these, 70000 remain. So, borrowing a unit from the ten-thousands, we shall have seat 100 with the small letter k in the table above; and if 13 is counted off from it six times — as many times, that is, as there are units in the 6 ten-thousands — the counting will end at the capital C, since 13 multiplied by 6 makes 78, and dividing this by 30 leaves 18; and 18 letters counted after k yield the capital C. And so for the rest.

But if you prefer to count the letters after the one found in the table above in the natural series of the alphabet, you must take, after the division by 30, the complement of the remainder up to 30 — provided that, if you wish to count from

memory, you remember that among the small letters the letter o is to be omitted and that they do not run past u, while among the capitals the letters I, K, L, O are to be left out and one must not go beyond P: after the capital P one returns to the small a, and after the small u one passes over to the capital A, as was said above in cap. 11, Num. 2. Or else the number of ten-thousands must be multiplied not by 13 but by 17, and the resulting number divided by 30. The remainder of the division will then show how many letters are to be counted in the natural series after the letter found in the table above.

For example: in the year 34700 we found a moment ago that 9 letters were to be counted after the small letter i in retrograde order, thus: h, g, f, e, d, c, b, a, P — so that the capital P is the one to be used for that centesimal year. But since the complement of 9 up to 30 is 21, if after that same small letter i you count 21 letters in the natural order you will meet the same capital P, as you see here: k, l, m, n, p, q, r, f, t, u, A, B, C, D, E, F, G, H, M, N, P. You will also obtain this number 21 if you multiply the ten-thousands of the given centesimal year — that is, the number 3 — by 17, and divide the product 51 by 30; for the remainder will be 21.

Again, in the year 590600 we found that 4 letters had to be counted after the small letter p thus: n, m, l, k, so that the small letter k is the one to be used for that centesimal year. If after that same small letter p we count 26 in the forward order — 26 being the complement of the number 4 up to 30 — we shall find the same

small letter k, as you see here: q, r, f, t, u, A, B, C, D, E, F, G, H, M, N, P, a, b, c, d, e, f, g, h, i, k. That number 26 will also be had if (after casting 300000 out of that centesimal year, and taking 1600 from the remaining number 290600, so that the remainder becomes 289000) the ten-thousands, namely 28, are multiplied by 17 and the number so produced, 476, is divided by 30: for the remainder of the division will be 26.

The reason why, after the letter found, 13 letters are to be counted in retrograde order (or 17 in the forward order) as many times as there are units in the ten-thousands — first casting out the 30s from the product made by the ten-thousands into 13 or 17 — is this: the ten-thousands show how many cycles of 10000 years have run out from the year 1700 inclusive up to the proposed centesimal year. Since, then, in every cycle of 10000 years the same varieties of letters return, as we said in cap. 11, Num. 10; and since in any such cycle of 10000 years, from the letter prefixed to any centesimal year up to and including the letter prefixed to that centesimal year of the following cycle of 10000 years which occupies the same seat in its own cycle as the earlier centesimal did in its own, 13 letters are counted in retrograde order, or 17 in the direct order, as they are set down in the expanded table — from all this it is perfectly clear why we prescribe counting 13 in retrograde order as many times as there are units in the ten-thousands, and accordingly counting after the letter found as many letters in the forward order as are contained in the complement of that former number up to 30. That complement is in fact produced if the ten-thousands [printed *duæ millenarum* [?]] — apparently for *denæ millenarum*] are multiplied by 17 and the resulting number divided by 30; for the remainder of the division will give that complement.

Thus you see that after the capital C prefixed to the year 1700 — the first year of the first cycle of 10000 years — up to the small letter i prefixed to the year 11700, which is the first of the second cycle of 10000 years, 13 letters are counted in retrograde order, namely B, A, u, t, f, r, q, p, n, m, l, k, i; or in the direct order these seventeen: D, E, F, G, H, M, N, P, a, b, c, d, e, f, g, h, i. And you see the same thing happen after the capital A set beside the year 2400, which is the eighth in the first cycle of 10000 years, up to the small letter g affixed to the year 12400, which is likewise the eighth in the second cycle of 10000 years, as you observe here: u, t, f, r, q, p, n, m, l, k, i, h, g; and here: B, C, D, E, F, G, H, M, N, P, a, b, c, d, e, f, g. And so on in succession.

So that those five letters — the small o and the capitals I, K, L, O — which are to be left out of the alphabet, as we said, may also be kept in memory, and so that

the letters may be counted from memory, without any table, whether in the forward or in the retrograde order, after the letter found in the table above, this little verse of five words beginning with the letters in question is to be learned by heart:

ornabit Iuftos Kú[?] Laudabilis Omnes.

[Margin: Finding the letter of the expanded table or of the perpetual cycle of the epacts for investigating the epact in any given year, by the rules of arithmetic.]

9 We shall find that same letter of the expanded table, or of the perpetual cycle of the epacts, which serves to investigate the epact for any proposed centesimal year, without the table above, by the rules of arithmetic, in this way. Take any proposed centesimal year not greater than 301800 (for when it is greater, the whole cycle of 300000 years is to be cast out) and subtract 1600 from it. Divide the remainder by 400 and multiply by 3. If to the product you add as many units as there are hundreds left over in the division (if any remain), you will have the number of days omitted from the year 1700 inclusive up to the given centesimal year inclusive — a number of days that is in fact more easily found in the table of equation above, alongside the centesimal years. Now let this number of omitted days be kept, after first taking 2 from it. For since, on account of the lunar equation, we must begin this method of finding the epact from the year 1900, at which the uniform order of the lunar equation begins, no account is to be taken of the two days that are omitted in the years 1700 and 1800.

Next, from the same centesimal year offered (having first cast out 300000, if it is greater than 301800) take away 1800; or — what comes to the same thing — subtract 200 from that earlier residue which was divided by 400. Divide the remainder by 2500 and multiply the quotient by 8. (For in 2500 years the new moons anticipate their places in the calendar by eight days, these years beginning from 1900, as is clear from the table of equation.) To the number so produced add as many units as there are 300s to be found in the remainder of the division — provided that eight are never added, even if 2400 are left over, in which 300 is contained eight times, since it is 2500 years, not 2400, that call for eight days. Subtract this sum from the number of omitted days kept above; the remaining number (provided that all the 30s are first thrown out of it, which is done by dividing by 30) will give the letter to be taken in the expanded table, counting downwards in retrograde order from the letter B inclusive (the letter prefixed to the year 1900 in the table of equation) as far as that remaining number inclusive. If nothing is left over after the last division by 30, the letter to be taken will be the

30th from B inclusive in retrograde order — that is, the capital C, which stands immediately above the letter B. But if 1 is left over, the letter B itself is to be used.

The matter will become clearer by adding examples. Let the year given be 2000. Subtracting 1600, 400 remain, which divided by 400 make the quotient 1, with nothing left over. The quotient 1 multiplied by 3 yields 3 days omitted from 1700 inclusive up to the year 2000 inclusive. Taking away 2, there is left 1, which is to be kept. Next, from the same year 2000 subtract 1800, or 200 from the earlier residue 400. The remaining number, 200,

is to be divided by 2500, and the quotient 0 multiplied by 8. To the product 0 add 0, since in the remainder of the division, 200, there is no 300; the number is 0, which subtracted from the 1 kept above leaves 1. The first letter, therefore, from the capital B prefixed to the year 1900 inclusive — that is, the capital B itself — will serve for the given year 2000.

Let the year 29600 be offered next. Taking away 1600, 28000 remain, which divided by 400 make 70, with nothing left over. So 70 multiplied by 3 gives 210 days omitted from 1700 inclusive up to the year 29600 inclusive. Taking away 2, the remaining number 208 is to be kept. Next, from the same given year 29600 subtract 1800, or 200 from the earlier residue 28000. The remaining number 27800 is then divided by 2500, giving a quotient of 11 with a remainder of 300. The quotient multiplied by 8 makes 88, and adding 1 on account of the 300 left in the division, the sum is 89. Subtracted from the number 208 kept above, this leaves 119; and dividing these by 30, 29 are left over. The 29th letter, therefore, from the capital B inclusive — namely the capital D — will serve for the proposed year 29600.

Let the year given likewise be 6700. Taking away 1600, 5100 remain, which divided by 400 give a quotient of 12 with 300 left over. The quotient 12 multiplied by 3 makes 36, and adding 3 on account of the 300 left over in the division, we get 39 as the number of days omitted from 1700 inclusive up to the year 6700 inclusive. Taking away 2, then, the remaining number 37 is to be kept. Next, from the same year 6700 take 1800, or 200 from the earlier residue 5100, and divide the remainder 4900 by 2500. The quotient 1 is multiplied by 8, and to the product 8 add 7, because 2400 were left over in dividing 4900 by 2500 (for although 300 is contained eight times in 2400, only 7 are to be added, as has been said); so the number becomes 15. Subtracted from the number 37 kept above, this leaves 22. The 22nd letter, therefore, from the capital B inclusive in retrograde order — namely the capital P — will fit the proposed year 6700.

Let the year 301800 be proposed as well. From it the 300000 years are not to be cast out, since it is not greater than 301800. Subtracting 1600, 300200 remain, which divided by 400 give a quotient of 750 with 200 left over. The quotient 750 multiplied by 3, and 2 added to the product 2250 on account of the 200 left in the division, yields 2252 as the number of days omitted from the year 1700 inclusive up to the year 301800 inclusive. Taking away 2, then, the remaining number 2250 is to be kept. From the same proposed year 301800 subtract 1800, or 200 from the earlier residue 300200. The remainder 300000 is divided by 2500, giving a quotient of 120 with no remainder at all. This quotient multiplied by 8 makes 960, which taken from the number 2250 kept above leaves 1290. Finally, dividing these by 30, nothing is left over. So the 30th letter from the capital B inclusive, in retrograde order — namely the capital C — will be in use for the proposed year 301800.

Further, let the year given be 176500. Taking away 1600, 174900 remain, which divided by 400 give a quotient of 437 with a remainder of 100. The quotient 437 multiplied by 3, with 1 added to the product on account of the 100 left in the division, brings out 1312 as the number of omitted days. Taking away 2, then, the remaining number 1310 is to be kept. From the same year 176500 subtract 1800, or 200 from the earlier residue 174900. Dividing the remainder 174700 by 2500 gives a quotient of 69 with 2200 left over. The quotient 69 multiplied by 8, and 7 added to the number 552 so produced (because 300 is contained seven times in that remainder 2200), makes the sum 559. Taking this from the number 1310 kept above, 751 are left; and dividing these by 30, 1 is left over. So the first letter from the capital B inclusive — that is, the very letter B — is to be assigned to the proposed year 176500.

Lastly, let the year 671600 be offered. Casting out 300000 twice, and taking 1600 from the remaining number 71600, 70000 remain, which divided by 400 give a quotient of 175 and leave nothing. 175 multiplied by 3 makes 525 days omitted. Taking away 2, then, the remaining number 523 is to be kept. After this, from the same remaining number 71600 take 1800, or 200 from the earlier residue 70000. Dividing the remainder 69800 by 2500 gives a quotient of 27 with 2300 left over. The quotient 27 multiplied by 8, and 7 added to the product 216 (because 300 is contained seven times in 2300), makes 223. Finally, taking these from the number 523 kept above, 300 are left; and dividing these by 30, nothing is left over. So the 30th letter from B inclusive — that is, the capital C — is to be used for the year 671600. And so for the rest.

But if anyone prefers to count from memory upwards from the capital B in the natural series of the letters, through C, D, and so on, rather than downwards through A, u, t, and so on, he must take the complement of the remainder found up to 30 and add 2 to it; for the number so made up will fall on the letter sought. For example: in the year 29600 we found that 29 letters were to be counted from the letter B in retrograde order; the complement of these up to 30 is 1, and adding 2 makes 3. The third letter from the capital B — namely D, as appears here: B, C, D — is then the one to be taken. Again, for the year 6700 we said that 22 letters were to be counted from B inclusive downwards. And since the complement of the number 22 up to 30 is 8, adding 2 makes 10; the tenth letter from B — that is, the capital P, as is clear here: B, C, D, E, F, G, H, M, N, P — is then the one to be used. Likewise, for the year 761600 [recte: 671600] it was said that 30 letters had to be counted from B inclusive. Since, then, the complement of the number 30 up to 30 is 0, and adding 2 gives 2; or else, since the complement of the residue 0 (for when we divided 300 by 30 above the remainder was 0) up to 30 is 30, and adding 2 makes 32, and casting out 30 leaves 2 — the letter to be taken is then the second from B inclusive, namely C, as appears here: B, C. Finally, for the year 2000 we showed that one letter was to be counted from B inclusive. And since the complement of 1 up to 30 is 29, and adding 2 makes 31, and taking away 30 leaves 1, the letter to be taken is again the first from B inclusive — that is, the capital B itself.

We shall reach the same result even if the 300000 are not thrown out of the proposed year when they can be thrown out. Take again the year of the last example, 671600. Subtracting 1600, 670000 remain; and dividing these by 400 the quotient is 1675, with nothing left over. Multiplying this by 3 produces 5025 as the number of days taken away. Taking away 2, the remainder 5023 is to be kept. Again, subtracting 1800 from the same year 671600, 669800 remain; and dividing these by 25 [?] the quotient is 267, with 2300 left over. Multiplying 267 by 8 begets 2136, and adding 7 (because 300 is contained seven times in the remainder 2300) the number becomes 2143. Taking this from the number 5023 kept above, 2880 are left; and dividing these by 30, nothing is left over. So the 30th letter from B inclusive in retrograde order — that is, the capital C — is to be taken for the year 671600, as before. Or else, to the complement of the remainder

of the remainder, 0 — that is, add 2 to 30 to make 32; and, throwing out 30, count the remaining 2 in the natural order from B inclusive, and you will again fall on the same letter C, the capital.

BUT to spare ourselves the labour of always hunting out, by divisions and multiplications, the number which (after throwing out 30 as often as this can be done) has to be counted from B inclusive in retrograde order, so as to find the letter of the expanded table to be used for the proposed year — as we taught at the beginning of this Num. 9 — we shall set out here a thoroughly convenient table, in which the said number owed to each centesimal year is entered as far as the year 28400. We shall then add a further table of years collected by 10000, 100000, and 1000000, from which the same number can be extracted for any centesimal year whatever, even one greater than 28400. Now the numbers assigned to the centesimal years indicate the days of the *postposition* of the Moon [dies postpositionis Lunæ] — that is, by how many days later the new moons generally fall in the Calendar. For that number is what remains when the days of the Moon's anticipation are subtracted from the days taken out, by which the Moon would be thrust downward, were it not that she herself climbs upward by eight days in every span of 2500 years, and by one day in every 300 years.

SEQVITVR TABVLA PRIORPostpositionum Lunæ.

THERE FOLLOWS THE FORMER TABLE of the Postpositions of the Moon.

TABVLA PRIOR.

THE FORMER TABLE.

[Margin: How the postposition of the Moon for any centesimal year is to be found.]

THE FORMER table is built up out of what we set out at the beginning of this Num. 9. Suppose, for example, you want to know the postposition of the Moon to be entered opposite the year 28400. Proceed thus. Subtract 1600 from 28400: 26800 remain. Divide these by 400: the quotient is 67, with nothing left over. Multiply this quotient by 3: the product is 201, which is the number of days taken out. Take away 2, and keep the remaining number, 199. Next subtract 1800 from the same year 28400: 26600 are left. Divide these by 2500: the quotient is 10, with 1600 left over. Multiply the quotient 10 by 8, and to the product 80 add 5 (since 300 is contained five times in the remainder 1600): the result is 85. Subtract this number from the 199 kept earlier, and the remainder gives the postposition of the Moon, 114 days, to be written opposite the year 28400.

The same procedure holds for all the rest. But the whole series is more easily generated from the postposition 0 of the year 1700 by means of the table of equation above, in Cap. 11. For whenever the same letter is to be retained in the following centesimal year, the same postposition is likewise written down; when a lower letter is taken, the postposition is increased by one; and when, finally, an upper letter is resumed, the postposition is decreased by one. You will grasp this readily if you set the former table of postpositions beside the letters of the table of equation above.

It would in fact have been enough to extend this table only as far as the year 11700, against which the postposition of the Moon 43 stands; for the postpositions of the remaining years are easily extracted from the latter table together with the former, even if the former had been carried no further than the year 11700, as we shall shortly explain. Nevertheless I chose to continue it all the way to the year 28400, so that the postposition of the Moon for any centesimal year before 28400 might be had more expeditiously — and that seems sufficient, since by then the table of equation will perhaps have to be altered. The reason is that those two years neglected in each span of 400 years will by that time amount to one whole day, as we wrote in Cap. 5, Num. 17, and so the equinox will have slipped from 21

March to 22. If, however, anyone wants postpositions of the Moon beyond the year 28400, the latter table must be brought in as well; it is very short, and its construction is extremely easy.

For since a postposition of the Moon of 43 days is owed to every 10000 years — divide 10000 by 400 and the quotient is 25, which multiplied by 3 gives 75 days taken out; again, divide 10000 by 2500 and the quotient is 4, which multiplied by 8 gives 32, and this number subtracted from the 75 days taken out leaves 43 — the postposition of the Moon 43 must be set against the year 10000, and one must go forward by continually adding it up to 1000000, which year has the postposition of the Moon 430 set against it. Then again, by continually adding 430, one proceeds up to 10000000, against which year is written the postposition of the Moon 4300, and so on.

Now suppose the postposition of the Moon for the year 27900 is sought. (Let us imagine that the former table has not been extended beyond the year 11700.) We shall take from the latter table the postposition 86 assigned to the year 20000, and join to it the postposition 27 set against the year 7900 in the former table. In this way we shall produce the postposition 113, which fits the proposed year 27900. Likewise, if the postposition of the Moon for the year 600000 is sought, we shall take from the latter table the postposition 2150 written against the year 500000, add to it the postposition 387 set against the year 90000 in the same table, and then, with the number 2537 thus made up, add the postposition 35 set against the year 10000 in the former table. By this procedure we produce 2572, the postposition owed to the proposed year 600000.

[Margin: So that the postposition of any centesimal year may be extracted, one must enter the former table once only, at the end — even if that year with which the entry is made is also to be found in the latter table.]

Note that in the last place we did not take the postposition 43 written against the year 10000 in the latter table, but the postposition 35 allotted to that same year 10000 in the former table. The reason is that in the latter table one must never take the whole number of the proposed year, but always a smaller one, so that in the last place the remaining number of years can be taken in the former table. For the latter table contains the postpositions of the Moon owed to those centesimal years simply, without regard to how great an interval separates each of those centesimal years from the Nativity of Christ; whereas in the former table are recorded the postpositions belonging to the centesimal years reckoned from the Nativity of Christ. So although in the latter table the postposition of 43 days is

written against the year 10000, in the former table a postposition of 35 days is set against the same year.

Therefore, when the centesimal year is very large, one should enter the latter table as often as can be done, provided a centesimal year is left over with which the last entry into the former table can be made. And this last entry into the former table must necessarily be made even if that centesimal year with which the last entry has to be made is also found described in the latter table. So you see that in the immediately preceding example the entry was made in the last place with the year 10000, even though this same year is contained in the latter table with a different postposition. Nor indeed should the entry into the former table be made twice with the year 10000 — first with the year 8000 and then with 2000, or first with 7000 and then with 3000.

3000, because then the postpositions 26 and 1, or 23 and 5, would be taken, which together make up postposition 27 or 28, and not the 35 owed to the year 10000. In short — to say it in a word — only one entry is to be made into the former table, and all the other entries, if there are several, must be made into the latter table.

For the rest, it is clear that the postposition 2572 of the last example belongs to the year 600000. Subtract 1600 from 600000 and 598400 remain; divide these by 400 and the quotient 1496 comes out; multiply this by 3 and the number of days omitted, 4488, is produced; subtract 2, therefore, and keep the remaining number 4486. Again, subtract 1800 from 600000 and 598200 are left; divide these by 2500 and 239 comes out; multiply this by 8 and it makes 1912; add 2 (because the remainder of the division, 700, contains 300 twice) and 1914 results. Take this at last from the number 4486 that was kept, and the remainder gives the postposition of the Moon 2572 for the year 600000.

Finally, let the postposition of the Moon for the year 1700600200 be sought. First, take from the latter table the postposition 4300000 for the year 1000000000. (For although this year is not written in the table, still the postposition 43000 for the year 10000000 is to be increased by the two figures 00, just as the year 10000000 has been increased by the two figures 00 to make the year 1000000000.) Next, the postposition 3010000 for the year 700000000. Likewise the postposition 2150 for the year 500000. (For if the postposition of the year 600000 were taken, the postposition of the remaining 200 years could not have been taken in the former table.) Likewise the postposition 387 for the year 90000, and finally the postposition 36 for the year 10200. All these postpositions gathered into one sum yield the postposition 7312573 for the proposed year 1700600200, as you see in this scheme.

Anni	Postpositiones.
1000000000	4300000
700000000	3010000
500000	2150
90000	387
10200	36
Summa	7312573

10 AND all of this, which has been said about the construction of the table of equation according to the mind of the author of the Calendar, would be true if all 30 epacts were set down in order in the Calendar — as they are placed in January, March, May, July, October, and December — and if the two epacts xxv and xxiiii never occupied the same day, as we see happen in February, April, June, August, September, and November. Yet that arrangement is necessary, so that the lunar months may be alternately of 30 and of 29 days, as we explained in *cap.* 10, *Num.* 3. For it has been established in this way: if one counts back, in retrograde order, from the epact xxi inclusive in January — the epact that corresponds to the capital letter B — the postposition of the Moon found from the table above, the epact is correctly found so long as that postposition is not greater than 27, because in that case we do not pass beyond 5 February, to which the two epacts xxv and xxiiii are assigned. But when the postposition of the Moon is greater than 27, some error arises in finding the epact, because it is not the epact xxiiii but xxiii that is placed under 5 February. Consequently the epact xxiii, with the capital letter D, will then correspond to golden number 3, and not the epact xxiiii with the capital letter E, when the postposition of the Moon is 28 — which will happen in the year 8200. Thus after the year 8100 the descent from the capital letter E must be made through two letters, as far as the capital D, and not through one only. The same thing happens further on at 5 April, 3 June, and so on.

[Margin: Why the author of the Calendar chose to propose his equation, deceptive though it is.]

THE author of the Calendar either did not notice this irregularity — or defect — in the equation of the epacts, or made little of it, because he judged it enough that no error be committed in finding the epact over many thousands of years. And since he had before his eyes only the 30 letters of the expanded table, where no two letters are found in the same cell, reason seemed to demand entirely that the Moon should always descend by one single day whenever it had to be postponed. But when I afterwards examined more carefully that table of the equation of the

epacts, extended according to the mind of the author of the Calendar to 300000 years after the year 1600 (for I have computed the mean new moons for very many thousands of years), I found that the new moons of the epacts diverge from the celestial new moons more than is right. And so, as I searched out the cause of this, and in order to satisfy detractors so far as can be done, I discovered — with God's help — a method by which the epacts may be found even for ages very far distant, at least to 100000 or even 200000 years, whose new moons do not differ much from the celestial new moons. Hence it is altogether necessary to set up the table of the equation of the epacts differently after the year 8100, so that it may agree over many ages, even ones very far distant. How this is to be done must now be taught. And this is one of the chief things we undertook, in the Letter to the Reader, to add to the Calendar of Luigi Lilio.

[Margin: That it is not simply necessary that the table of equation of the author of the Calendar be corrected.]

This is so, even though it is not simply necessary. For it is enough, as I said, that the equation prescribed according to the author's mind — uniform indeed and easy — should show the epacts correctly for some thousands of years. When later generations find that it no longer shows the true epacts (which will not happen before the year 8200), it will be easy to take another letter of the expanded table, either higher or lower, according as the new moons are found in the Calendar to have risen or fallen, as we shall teach at *Num.* 15, 16, and 19. So for that reason it does not seem expedient that a more difficult method of equation be proposed to the Church, especially since this does not stand in the way of the perpetuity of the Calendar, as we shall say at *Num.* 18. If, however, anyone is so curious that he is not content with this, but wants the equation to show the epacts correctly for the longer ages as well, he will achieve it in this way.

LET all 365 days of the whole year be written out in order, together with the months and with the 30 letters of the expanded table repeated over and over, as they correspond to the epacts in the Calendar, always placing two letters, F and E, alternately in the same cell, as the following table shows.

SEQVITVR TABVLA.

Table of the 365 days of the year with the letters of the expanded table

HOC being the order observed, it will be easy, for any century whatever, to find the letter of the expanded table in whose line the epacts correspond to the golden numbers of that century. For take from the tables of the postpositions of the Moon the postposition that belongs to the century proposed, and add 9 to it — that is, the days by which the epact xxj, belonging to capital B, is preceded in January; the reason being that the anticipation of the Moon, beginning from the year 1900 (to which, in the table of equation above, capital B corresponds),

requires eight days over every span of 2500 years, as I said at the beginning of Num. 9. The number so formed will give the letter sought in the adjoining table of the year. Thus in the year 3400 the postposition of the Moon is 7; add 9 and you get 16. So the small letter q, under day 16, is the one to be taken in the expanded table for the year 3400. Again, in the year 1900 the postposition of the Moon is 1; add 9 and you get 10. Capital B, under day 10, is therefore the letter to be used then. Likewise for the years 1700 and 1800 the postposition of the Moon is 0, and adding 9 gives 9; so capital C, under day 9, is to be taken then. Further, in the year 28400 the postposition of the Moon is 114 — as it is also for the years 28200 and 28300 — and adding 9 gives 123. Capital G, then, under day 123, will serve us for the year 28400 just as much as for the years 28200 and 28300. Finally, in the years 84500 and 84600 the postposition is 356, and adding 9 gives 365. So under the last day of the year capital A is to be taken.

[Margin: A more accurate way of finding the letter of the expanded table for any century proposed.]

SI you note carefully, in the adjoining table, the days to which two letters, F and E, are attached — there are these six: 36, 95, 154, 213, 272, 331 — and write beside them, in the little table set alongside, the numbers 1, 2, 3, 4, 5, 6, we shall be able to find the letter of the expanded table for any century proposed from memory, without the preceding table of the days of the whole year: provided only that the number formed from the postposition of the Moon and 9 is not greater than 365, and that the order of the 30 letters of the expanded table is correctly held in mind. For if the number formed from the postposition of the Moon and 9 is less than 36, the first number of this little table, it is to be counted (30 being first thrown away, if 30 can be thrown away) from P inclusive in retrograde order; or else its complement to 30, first increased by two, is to be counted in the natural and forward order. Either way you will fall upon the letter you are looking for. But if it is greater than some one of the six numbers of this little table — provided it does not exceed 365 — then, all the 30s being thrown away, add to the remainder as many units as are written beside the number that is next smaller than that number formed from the postposition of the Moon and 9; and proceed with the sum as has been said, that is, counting it from P inclusive in retrograde order, or its complement to 30, two being first added, in the forward order. If, finally, the number formed from the postposition and 9 is equal to one of the 6 numbers of the said little table, nothing at all is to be counted: capital F is always to be taken. For example. In the year 3400, from the postposition of the Moon 7 and 9 you get 16. So if you count 16 letters from P inclusive, retrograde, you fall upon the small q, as you see here: P, N, M, H, G, F, E, D, C, B, A, u, t, f, r, q. You will

fall upon the same letter if you count in the natural order the complement of the number 16 to 30, which is 14, two being first added so as to make 16, as appears here: P, a, b, c, d, e, f, g, h, i, k, l, m, n, p, q.

[Margin: A more accurate way of finding the letter of the expanded table from memory.]

1	36
2	95
3	154
4	213
5	272
6	331

RVRSVS, in the year 6600 the postposition of the Moon is 21, and adding 9 gives 30. The thirtieth letter from P inclusive in retrograde order — namely the small a — is therefore the one sought. The complement of the number 30 to 30, which is 0, gives the same letter if 2 is first added and the result counted in the natural order, as here: P, a. And if from the number 30 so formed you throw away 30, nothing remains, and so nothing is to be counted from P; or else 30 are to be counted, and thus you will again light on the small letter a. This letter the complement of that remainder 0 — that is, 30 — will yield once more, if 2 is first added so as to make 32, that is (30 being thrown away) 2. Or again the complement of the number 30 to 30, which is 0, with 2 first added, if it be counted from P inclusive in the natural order, as before.

ITEM, in the years 28200, 28300 and 28400 the postposition of the Moon is 114, and adding 9 gives 123. The number next smaller than this in the adjoining little table is 95, which has the number 2 set before it. So, 30 being thrown away four times out of 123, if 2 be added to the remaining number 3 you get 5. Hence capital G, which is the fifth from P — as appears here: P, N, M, H, G — will then be in use. And if the complement of the number 5 to 30, namely 25, increased by two, be counted in the natural order, the same letter G is found, thus: P, a, b, c, d, e, f, g, h, i, k, l, m, n, p, q, r, f, t, u, A, B, C, D, E, F, G — which letter is likewise found under day 123.

PRÆTEREA, in the years 84500 and 84600 the postposition of the Moon is 356, and adding 9 gives 365. The number next smaller than this in the adjoining little table is 331. So, all the 30s being thrown away, let 6 be added to the remaining number

5 (for this is the number written beside 331 in the little table), making 11. For capital A, which is the eleventh from P — as here: P, N, M, H, G, F, E, D, C, B, A — will then be in use. And since the complement of the number 11 to 30 is 19, which with two added makes 21, the twenty-first letter from P in the forward order will again be A, as here: P, a, b, c, d, e, f, g, h, i, k, l, m, n, p, q, r, f, t, u, A — the same letter that was found above under day 365.

DENIQVE, in the years 49100, 49200 and 49300 the postposition of the Moon is 204, and adding 9 gives 213, a number that is found in the little table above. The letter will therefore be capital F.

NVMERI — those six numbers of the adjoining little table are easily committed to memory, provided only that the first, 36, is known. For the other five are built up by the continual addition of 59.

[Margin: How the six numbers of the adjoining little table may be known from memory.]

QVANDO the number composed of the postposition of the Moon and 9 exceeds the 365 days of a single year, it must be divided by 365, and the quotient kept. Then the letter is to be found from the remainder, as we did before with a number not greater than 365. Finally, after the letter found under the said remainder, as many elevens of letters are to be counted in the table above as there are units contained in the quotient kept back, taking the letters F, E, placed in one cell, for one only. But if in this counting you reach the end of the year and there are still some units left to count, you must not return to the beginning of the year, where P stands, but to the small letter u placed under day 12, and so finish the count. The reason for this is that after capital A, under the last day of the year, there does not follow the capital P set under the first day of the year — because the epacts do not keep a cycle in the Calendar, as I said at cap. 10, Num. 2 — but rather the small letter u, which occupies the eleventh place after capital P.

[Margin: What to do when the postposition of the Moon together with 9 is greater than 365.]

SI, however, on carrying out the division by 365, the quotient is found to be greater than 4, as many units are to be subtracted from the remainder of the division as there are fours contained in the quotient, because every fourth year comprises 366 days. And if the number indicating how many times four is contained in the quotient cannot be subtracted

from the remainder of the division, then 365 days are to be added, and one unit taken from the quotient. And if in that same quotient, once the division by 365 has been made, a number greater than 300 is found, as many further units must still be taken from the remainder as there are 300s found in that quotient — yet in such a way that, when the quotient is 2400, 8 are not taken away (although 300 is contained in it eight times) but 7, since it is to a span of 2500 years that the eight units of the Moon's anticipation are owed, not to an interval of 2400 years, as was said above. So too, when that quotient is greater than 19, all the 19s are to be thrown out of it, and for every unit in the remainder, eleven letters are to be counted in the table above after the letter found by the remainder of the division. All this will be clearer in examples.

SIT the letter to be sought for the century 90000. The postposition of the Moon is 379, and adding 9 gives 388. Divide by 365: the quotient is 1 and 23 are left over. So the small letter h, under day 23, will be the one to take. But because the quotient was 1, the eleventh letter after the h so found is to be taken, namely capital H, for the century 90000 proposed.

RVRSVS, in the year 200000 the postposition of the Moon is 852, and adding 9 gives 861. Divide by 365: the quotient is 2 and 131 are left over. The letter found below day 131 will therefore be t; after, after which, if the number twice 11 [?] on account of the quotient 2, you will light on capital G, to be used for the century proposed.

ITEM, in the year 301700 the postposition of the Moon is 1290, and adding 9 gives 1299. Divide by 365: the quotient is 3 and 204 are left over. The letter found below day 204 will therefore be the small d; and if after it three elevens, namely 33, be counted, capital P is found for the century given.

POSTREMO, in the year 90006000 the postposition of the Moon is 387018, and adding 9 gives 387027. Divide by 365: the quotient is 1060 and 127 remain. But since the quotient contains 4 in accordance with this number 265, which cannot be subtracted from the remainder, we shall add 365 to the remainder 127 so as to make 392. From this, if 264 be taken away — for since 365 has been added, 1 must be taken from the quotient 1060 so as to make 1059, in which 4 is contained not in accordance with the number 265, as before, but only in accordance with the number 264 — there are left 228. And if from these 3 are still taken away (because 300 is contained three times in the quotient 1059), there remain 225. The letter found below day 225 in the table above will therefore be the small m. But since, all the 19s being thrown out of the quotient 1059 above, 14 are left over, eleven letters must still be counted fourteen times over after the letter m found

under day 225 — that is, the 154th letter after that m, namely the small f (returning in the count, once the end of the year is passed, to the small letter u placed below day 21 [recte: 12; at p. 153 above "under day 12"]) — and this will answer to the century proposed.

VT the letter sought may be found still more easily, and to avoid having to count eleven letters repeatedly after the one found by the remainder of the division, we shall add 11 to that remainder as many times as required; for the letter sought will be found below the number so formed in the table above. And if the number so formed is greater than 365, then, 365 being thrown away, let the remainder be counted after capital A, below day 11. Thus, since in the first example eleven letters are to be counted once after the letter h below day 23, we shall add 11 to 23 to make 34; for capital H, below day 24 [recte: 34 — H stands at day 34], will be the letter sought. In the second example, since eleven letters are to be counted twice after the letter t below day 131, we shall add 22 to make 153; for capital G below day 153 will be the one we are seeking. Likewise in the third example: since eleven letters are to be counted three times after the letter d below day 204, if we add 33 to 204 we get 237, and below that day capital P is found. And finally in the fourth example, since eleven letters are to be counted fourteen times after the letter m under day 225, we shall multiply 11 by 14 and add the resulting number 154 to 225, making 379. Throwing away 365, there are left 14. The small letter f, then, which is the fourteenth after A placed below day 11, will be the letter desired.

[Margin: An easy way of finding the letter when eleven letters have to be counted several times over.]

INVENTA the letter of the expanded table, as we have shown, one at once finds in its line the epact answering to any golden number, as was said above in the use of the table of equation. On this principle, in the last example, there will be found in the line of the small letter f the epact xxj, answering to golden number 18 of the year 90006000.

[Margin: A more accurate way of finding the epact than the one handed down above at Num. 5.]

CÆTERVM, all this great labour spent on tracking down the epacts over so many thousands of years is vain and fruitless, as I said a little earlier, before setting out the construction of the table of the days of the year. For since it is uncertain whether the Moon's anticipation of one day in $312\frac{1}{2}$ years, and of 8 days in 2500 years — and the Sun's of 3 days in 400 years — will correspond to the celestial

motions for so long a time or not, this care may with perfect right be left to posterity, who will easily be able, from what we are about to write at Num. 15, 16 and 19, to set up the equation in another way, one that suits their own century. For anyone will readily convince himself that it is exceedingly difficult, not to say impossible, to prescribe a scheme of equation — even using the device here set out — that will agree with the celestial motions after many thousands of years (as regards the fourteenth Moons, which is the main point), if he considers attentively that not a few small fractions are omitted in the calculation of the individual lunations, and that over hundreds of thousands of years these can introduce no small error. Add to this that those 23 days and 17 hours by which, over every span of $312\frac{1}{2}$ years, we anticipate the equation of the Moon, grow in 481436 years to 100 years; and consequently, after so many years, the equation must be thrown forward into the next following centesimal year, just as after 2400 years, as we wrote at cap. 8, Num. 4, and cap. 11, Num. 11. A plain example is certainly to be had in the year 90006000, in which the epact was found to be xxj, indicating a new moon on 10 March, whereas the calculation gives that same new moon on 27 March. Let us be content, then, if our equation does not differ much from the truth as far as the year 100000, or even 200000.

[Margin: It is vain to look for the letter of the expanded table beyond 100000 or 200000 years by the foregoing rules.]

SECVNDVM what we shall now explain, the table of equation of the epacts after the year 8100 will have to be set up otherwise than was done above at cap. 11 — for in the table above, at cap. 11, it is rightly constituted as far as the year 8100 inclusive. This will be done if, for each centesimal year, the letter of the expanded table is found by way of the Moon's postposition, as we showed above after the table of the days of the year. We shall, however, continue the table only as far as the year 28400, because perhaps after that year the equinox will no longer cling to 21 March, on account of the day produced by the two years neglected in 402 years, as I said at cap. 5, Num. 17; and so the table of equation will then have to be altered again, so that it seems pointless to extend it further, if it cannot be of further use unless it is corrected. It will not be difficult, though, to extend it beyond 28400, if the postpositions of the Moon are rightly considered; or it will be extended still more easily by the table of cap. 11. For the letters advance in the following table of equation in exactly the same retrograde order that they keep in the table of equation above: only, below F, capital D is to be placed at alternate points, and not E. Thus you see that for the year 8100 the letter prefixed in the table above is capital

F, but that for the year 8200 the letter D, and not E, stands in the following table. Then, below the capital F next following, prefixed to the year 14900, E is placed for the year 15000; but below another following capital F, set before the year 21800, D is again written, and not E, and so on. And once the equation is set up in this way, the cycle of 300000 years no longer holds, as it did in the table of equation above.

NEMINI should it seem surprising that sometimes, on account of this new table of equation, the descent in the expanded table is made through two lines — namely from F to D, from the year 8100 to the year 8200, and from the year 21800 to the year 21900, and so on, as will be plain in the following table. For even though on this reckoning not a few new moons seem to be postponed more than is right, yet unless it were done, very many new moons would anticipate their seats more than is proper, and their fourteenth days — the mean full moons — would be lost by more than a day. And it is clear that the error is smaller in a postposition of the fourteenth Moon than in an anticipation.

[Margin: That the descent in the expanded table is sometimes rightly made through two lines.]

Let these be the examples. In the year 8300 the golden number is 17. The epact, according to the following table, is xxvij, which places the fourteenth Moon on 16 April. Now the mean full moon falls on 16 April, at about hour 6 from noon, which agrees with the Canons. But the epact according to the table of equation above is xxviii, whose fourteenth Moon has its seat on 15 April, before the due time. Again, in the year 8303 both the golden number and the epact are 1 from the following table, and the fourteenth Moon falls on 12 April; while the mean full moon falls on 12 April at about hour 21 after noon, as the Canons require. The table above gives epact ij and the fourteenth Moon on 11 April, contrary to the Canons. Finally — to pass over many other examples — in the year 8305 the golden number is 3 and the epact xxiiij in the following table; the fourteenth Moon falls on 21 March, and the mean full moon on 21 March at about hour 15 from noon, within the Paschal limits. But the table above yields epact xxiiiij, whose fourteenth Moon falls on 18 April, while the mean full moon falls on 20 April at hour 3 from noon, outside the Paschal limits — so that according to the table above Easter would be celebrated in the second month. Rightly, then, is the descent in the expanded table sometimes made through two letters, as has been said.

IAM if anyone should wish to find the letter suited to any century even beyond the year 28400, he will easily achieve it if he extends the following table of

equation according to what we have laid down; or, if he prefers not to extend it, if he inspects carefully the little table that follows and uses the table of equation of cap. 11 — which we have left entire in its place, partly because by it we shall hunt down the corrected epacts as well, as we shall show; partly so that the difference between that equation and this might appear; partly also so that the uniform progression in equating the epacts might be evident, were it not interrupted by the pairs of epacts placed in a single cell; but chiefly because in it are recorded the days removed at each centesimal year, which in fact are not seldom put to use, as I said above. This is the rule to be held to.

[Margin: Why the table of equation of 300000 years, set out above at cap. 11, was proposed, even though it is misleading.]

1	2	3	4	5	6	7	8	9
8200	21900	35700	49400	63100	76700	90600	104200	117900
10	11	12	13	14	15	16	17	18
131700	145400	159100	172900	186600	200300	214100	227800	241500
19	20	21	22	vsque ad [as far as]				310000
255100	269000	282600	296300					

From any centesimal year of this little table up to the next, count, after the letter which the table of equation above at cap. 11 offers, as many letters in retrograde order as there are units in the number placed above the centesimal year of this little table. The last letter will be the one to be used for the given century. For example: the letters from the year 1600 up to 8200 exclusive are to be taken just as they stand in the table of equation above. But if the year 20000 is proposed, one letter of the table above must be counted after the letter d — namely as far as c — on account of the 1 above 8200. Likewise, if the year 267800 is given, nineteen letters of the table above must be counted after the letter t, as far as capital N, on account of the 19 units placed above 255100, as appears here: f, r, q, p, n, m, l, k, i, h, g, f, e, d, c, b, a, P, N. And so with the rest.

[Margin: An easy way of finding the letter of the expanded table, as far as the year 310000.]

TABLE OF EQUATION, CORRECTED, AFTER THE YEAR 8100 UP TO THE YEAR 28400

(TABVLA ÆQVATIONIS EMENdata poſt annum 8100. vſque ad annum 28400.)

This table is printed **sideways** on pp. 172–173: the leaf must be turned to read it, and the running head on p. 172 is turned with it; the sideways setting continues on p. 173. The printer sets the table in three parallel blocks across the page; the sequence runs continuously from 8200 through 21300 on this page. Each block has four columns: the index letter, the centesimal year, the note Biſſ. (bissextile), and the column of lunar marks (☾, ☾☾, †).

11. Now, from the year of the Lord 1600 onward, you will find the epact quicker than one can say it, by means of the following table, which is built

up as follows. In six lines write out the expanded years from year 0 up to year 99, putting nineteen years in each line — except the sixth line, in which only five years are set down. Below these, on the left, place all the centesimal years in order, beginning with the year 1600. Next, find the golden numbers of the centesimal years, and by means of them look up the epacts of those same centesimal years, either in the expanded table or in the perpetual cycle of the epacts with the table of equation applied. Write those epacts alongside the centesimal years, each alongside its own, under the expanded years 0, 19, 38, 57, 76, 95.

From these the remaining epacts of each line are formed by continually adding 11, always casting out 30 whenever the sum comes to more than 30; and when the sum is exactly 30, set down the epact *. Observe this one thing, however: to the epact that answers to golden number 19 you must add 12, not 11. Likewise, when the epact 25 answers to a golden number greater than 11, set down that 25 which is customarily written in a different colour or in a different character.

In fact you will set these same epacts out more easily by the following method. In the expanded table take the letter that matches the given centesimal year, and put the epact of that letter which answers to the golden number of that same centesimal year into the first cell after that centesimal year; then put the epacts that follow in the same line into the remaining cells, returning to the beginning of the line whenever that is needed. This table can be extended indefinitely, just as the present one has been extended from the year of the Lord 1600 up to the year 3900.

[Margin: Construction of the following table for finding the epact.]

FINDING THE EPACTS FROM THE YEAR OF THE LORD 1600

(EPACTARVM INVENTIO AB ANNO DOMINI 1600.)

The table fills the whole page and is printed **upright** — title, heading numerals, row labels and body all run in the page's normal reading orientation; only the narrow stub head is turned (see the parsing note). The left-hand column is headed **Anni expansi** (expanded years) and carries the twenty-four centesimal years 1600 to 3900 as its row labels. Across the head run nineteen columns, each headed by the stack of expanded years that share it (the epact repeating on a nineteen-year period); the sixth line of expanded years runs only 95–99, so only the first five columns carry a sixth heading number. The cells hold the epacts in lowercase Roman numerals, with * for the epact 30 and an Arabic 25 for the

special epact 25 that Clavius has just said is written "in a different colour or character."

Column headings (verbatim):

Col.	Expanded years heading that column
0	0, 19, 38, 57, 76, 95
1	1, 20, 39, 58, 77, 96
2	2, 21, 40, 59, 78, 97
3	3, 22, 41, 60, 79, 98
4	4, 23, 42, 61, 80, 99
5	5, 24, 43, 62, 81
6	6, 25, 44, 63, 82
7	7, 26, 45, 64, 83
8	8, 27, 46, 65, 84
9	9, 28, 47, 66, 85
10	10, 29, 48, 67, 86
11	11, 30, 49, 68, 87
12	12, 31, 50, 69, 88

												1	2	3	4	5	6	7	8

In this table you will find the epact of any year proposed, if you take the given centesimal year on the left and, at the head, the expanded year following that centesimal. The epact of the given year stands written in the cell where the two meet. Thus for the year 1627 the epact is xiiij. For the year 2085 the epact is iiij. For the year 2106 the epact is 2 5, printed in a different character. Finally, for the year 3000 the epact is ij, opposite the year 3000, under the expanded year 0.

[Margin: Finding the epacts from the temporary tables.]

To make the work easier still, I set out here a number of temporary tables for the various centuries, in which one finds at once the epact answering to the golden number of any year proposed. To find the epact for a given year, then, one must first look for that year's golden number; once it has been found, the epact will appear immediately in the table serving that century, under that golden number. For example: since in the year 837 the golden number is 2, you will find in the third table — the one in use from the year 800 to the year 1099 inclusive — the epact xx, which at that time indicated the new moons, even though the golden number in the Calendar of the Council of Nicaea marked those same new moons a little later. The reason is that from the time of that Council down to the year 837 the new moons anticipated their places in the Calendar; and so the golden numbers set out in that same Calendar will show the new moons of the year 837 later than the epact xx that has here been found.

[Margin: Construction of the temporary tables for finding the epacts.]

The construction of these tables, moreover, is perfectly straightforward. In the table of the equation of the epacts described in chapter 11, take the letter matching the given centesimal year, or the given year, at which the proposed table begins (I have attached that letter to each table); and from the expanded table extract the epact standing on the line of that same letter and answering to the golden number of that same centesimal year or year. Then all 19 golden numbers are to be written across the top of the table, beginning from the golden number of that centesimal year or year, and beneath the first golden number the epact answering to it. From that epact all the rest are formed by continually adding 11. Only to the epact under golden number 19 must 12 be added, in order to form the epact under golden number 1. At the foot of each table I have also

written the years at which that same table begins, so as to make the finding of the epacts easier and to spare us having to work out the golden number for each year before working out the epact. For if in any table you begin counting from the year set at the foot of the table which is next smaller than the year offered — or else from the year at which the use of the table begins, in case the year offered happens to be smaller than the smallest of the years set at the foot of the table — and count up to that same proposed year, the count will end in the cell of the golden number and of the epact of the year proposed. For instance, if the year 4328 is proposed, one must count in the 22nd table from the year 4314 up to the year 4328, which falls on golden number 16 and epact *iiij*. And so with the rest. So, as you see, these same tables also yield the golden number of the year proposed: in the example just given, what was found was not only the epact *iiij*, which indicates the new moons in the year 4328, but also the golden number 16 of that same year. In this way any number of further temporary tables can be built.

[Margin: Finding the golden number by means of the temporary tables.]

General parsing notes for the three pages.

- The stub heads alternate in the source between Aur. num., Aur.num., and Aur. Num., and between Epactæ. (with point) and Epactæ (without). Reproduced as printed rather than normalized.

- The terminal-minim convention changes at the page turn: printed p. 162 sets the epacts with a terminal j (iiiij, xxvj, xxiiij), while printed pp. 163–164 set the same values with terminal i (iiii, xxvi, xxi). This is a genuine change of sorts across the forme, not a reading artefact, and is preserved.
- Two epacts are set in Arabic digits inside otherwise Roman rows — 25 at golden number 12 in table XV and 25 at golden number 15 in table XX. Both are unmistakably Arabic on the page and are kept distinct from the Roman xxv that appears elsewhere (tables XIV, XVII, XIX, XXII).
- Every epact-30 cell on these three pages is set with the asterisk sort * (tables XII, XIII, XV, XVI, XVIII, XX, XXII); the small circular © sort does not occur here.
- The index letter attached to each table title is set in small type at the right margin: A, u, t, r, q, p, q, p, n, m, l. The letter at table XIV is a long r, not an f — it falls between t (XIII) and r (XV) in the descending series, and the crossbar does not cross the stem.
- The table numerals are set with internal spacing on printed p. 162 (x i., x i i., x i i i., x i v.) and solid on pp. 163–164 (xv. ... xxii.); transcribed as set.

5019	5038	5057	5076	5095							

12 Once the epact of any given year has been found, the following year's epact is formed without difficulty: add 11 to it, and if the sum exceeds 30, cast out 30; or if the sum is exactly 30, take the sign * for the epact. The reason is this. As we showed in chapter 8, Num. 4, the solar year exceeds the lunar year by 11 days, so the new moons in any given year will fall 11 days earlier than in the year before. Accordingly 11 must be added to the preceding year's epact to make up the following year's epact, which is to precede it in the Calendar by exactly 11 days. Only in the case of the year whose golden number is 19 must 12 be added, not 11, to produce the epact of the following year, whose golden number is 1; the reason for this we shall explain shortly. One point, however, must be observed (it was also stated above at chapter 10, Num. 5): whenever the epact so compounded

comes out as xxv, and the golden number of the year in which that epact is in use is greater than 11, then the epact to be taken is that 25 which is marked with a different colour or a different character from the rest.

[Margin: How the epact of any given year is formed from the epact of the preceding year.]

13 Why the following year's epact must be formed by adding 12 rather than 11 to the epact of the year whose golden number is 19, the reason is this. Out of those 209 days that accumulate in 19 solar years from the 11 days by which each solar year exceeds each lunar year, seven embolismic lunations are constituted — six of 30 days and one of 29, as we said in chapter 8, Num. 5. Therefore 30 ought not always to be cast out from the sum produced by adding 11 to the preceding epact when that sum is greater than 30 — that is, whenever the lunar year in question is embolismic and contains 13 lunations, as will be understood from chapter 17. In the seventh and last embolism, whose lunation comprises only 29 days, only 29 ought to be taken away. Since, then, the customary rule always casts out 30, so that all the embolisms may be alike, it is necessary after the last embolism to add 12 to the epact in order to make up the following year's epact — that is, so that the unit taken from the preceding epact is restored to the following one. For if only 29 had been subtracted from the earlier epact, as would have been proper, it would be enough to add 11 in gathering the following year's epact, just as is done in the other cases. In that way there would be produced numerically the same epact that was in use 19 years earlier, and the new moons would return to the same days, as the scheme of the nineteen-year cycle requires — which is precisely what happens when 12 is added to the last epact once 30 has been cast out in the last embolism. And although before the correction of the Calendar the year whose golden number is 19 was not the seventh or last embolismic year but the last but one, that is the sixth (as we shall show in chapter 17), still, because that year was always embolismic, and because 19 is the greatest and the last of all the golden numbers, the computists preferred to make the addition of the number 12 at the point where golden number 19 is used. No appreciable error in the lunations can arise from this. For the same reason we too wished that addition to be made whenever the golden number is 19, whatever epact then corresponds to it, so as to follow the tracks of the ancients as far as that could be done — even though that year is neither always the last embolismic year nor indeed always embolismic at all. But all this will be grasped more plainly and openly in chapter 17.

[Margin: Why 12 is added to the epact concurrent with golden number 19, to produce the following year's epact.]

14 From this the reason is clear why, when golden number 19 is in use, a unit is added to the days that remain after the last lunation of December in order to form the following year's epact, as was stated at the end of chapter 10, Num. 14. It is because 12 must be joined to the epact running with golden number 19, whereas to the other epacts only 11 is added to produce the following year's epact, as we have just shown. If the unit were not then added, those surplus days would yield an epact one unit too small — namely the one that would result from adding 11 to the preceding epact, as happens in the other cases, and not the one that is generated by adding 12; which is absurd. Two epacts, however, are excepted: xviii and xix. If these are in use together with golden number 19, no unit is to be added to those surplus days; the surplus days by themselves give the following year's epact. For in that case one day is taken from the December lunations of these two epacts, so that they run to only 29 days, whereas otherwise they always comprise 30. The result is that the lunation of each of these two epacts ends in December one day earlier than it should, and so that day is left over at the end of December, which otherwise would have had to be added to the other surplus days. Why, with golden number 19 running together with those two epacts, their lunations in the month of December contain only 29 days, we shall explain in chapter 17, where the embolisms are treated.

[Margin: Why, when golden number 19 is current, a unit must be added to the days that remain in December after the last lunation, in order to establish the following year's epact.]

Nor should this be passed over: when in the expanded table one descends from an upper line to a lower one, only 10 is to be added to the epact to form the next epact — unless the golden number happens to be 19, for then 11 is added. But when one must ascend from a lower line to an upper one, 12 must be added, even if the golden number is not 19; indeed, if the golden number were 19, 13 would have to be added in that ascent. All of this is evident in the expanded table. That it must be done in this way is required by the equation of the Moon [*aequatio Lunae*]. Outside this case the rule handed down in Num. 12 is to be kept.

[Margin: Why the following epact is not always formed by adding 11 or 12.]

15 Now suppose that, after some centuries have passed, astronomers should find a magnitude of the year different from the one we now follow, so that the Alphonsine year is no longer midway between the greatest and the least; and

suppose that in consequence the omission of three intercalary days in any span of 400 years should force the vernal equinox to retreat further from 21 March than it can return of itself. Then the equinox will have to be restored to 21 March by intercalating, or by omitting, out of the ordinary course, as many days in some one year as the number of days by which it has departed from the 21st toward the end of the month or toward its beginning, as we taught in chapter 5, Num. 14. Once the equinox has been restored in this way, our equation of the solar year — which orders three intercalary days to be omitted in every span of 400 years — must be taken up again, or another more suitable one instituted to match the newly found magnitude of the solar year. Next, the table of the equation must be renewed as follows. If, in order to bring the equinox back to 21 March, some days have been intercalated, then in the expanded table one must ascend from the line of epacts that was in use before the intercalation through as many lines as there were intercalary days inserted, so that the line brought into use is the one whose epacts are greater by as many units than the epacts of the other line (the one used before that extraordinary intercalation) as there were days intercalated. This is because the new moons will occur just so many days earlier than before, on account of those extra days added to the year out of the ordinary course. If, on the other hand, in order to restore the equinox to 21 March some days have been taken out of the year, then one must descend in the expanded table from the line of epacts then in use through as many lines as there were days removed from the year, so that the line adopted for finding the new moons is the one containing epacts smaller by as many units than the epacts of the other line (the one in use before this removal of days) as there were days removed. This is because the new moons will occur just so many days later than before, on account of those days subtracted from the year out of the ordinary course. Afterwards, the letter attached to that line of epacts up to which the ascent or descent was made must be prefixed in the equation table to the year in which that extraordinary intercalation or removal of days took place. Finally, beyond that year the equation table must be continued according to the precepts handed down in chapter 11 and in Num. 10 of this chapter, beginning from the hundredth year that is nearest to the year in which the equinox was restored, if that year is not itself a hundredth. Thus: when the solar year needs an equation but the lunar does not, the descent is made in the expanded table to the next line below; when the lunar year requires an equation but the solar does not, one ascends to the next line above; and when finally neither year, or both alike, must be equated, one stays on the same line of epacts — as was said above in chapter 11, Num. 9, in that threefold rule. The correction we prescribed in Num. 10 of this chapter is, however, always to be applied.

[Margin: By what method the table of the equation of the epacts is to be renewed, should another magnitude of the year be found by later ages.]

16 But if some defect should be detected in the equation of the Moon — such that the Moon does not anticipate its seats in the Calendar by one day in $312\frac{1}{2}$ years, but in fewer or in more; or if the equation table should fail to exhibit the epacts correctly after some thousands of years — then the scheme of the Moon's equation in the table can easily be altered, by carefully observing when the years omitted in the hundredths make up a sum of 100 or 200 or 300 and so on, so that the equation of the Moon may then be deferred to the next hundredth.

[Margin: By what method the equation table is to be renewed, should the Moon have to be equated otherwise.]

17 But although after the lapse of some centuries the equation table will necessarily have to be corrected in the way we have described, by expert astronomers on the authority of the Roman Pontiff, no change on that account will have to be made in the Calendar itself: the arrangement of the epacts that we described above in chapter 10 will remain wholly intact and unimpaired. For since the epacts are so distributed over the days of the year that no day is left empty, the result is that whether the new moons descend in the Calendar or ascend, other epacts — always corresponding to the same golden numbers — can be taken up for finding them, just as the equation table shall direct, without any change of the epacts in the Calendar. This is something that can fit neither the golden number nor any other cycle which, when set out in the Calendar, does not fill all its places. For if the new moons must, on account of the equation, ascend or descend to those places in the Calendar that are empty and destitute of the cycle's numbers, we shall necessarily be without the numbers that indicate the new moons, unless the cycle is arranged differently — namely so that the number that then indicates the new moons falls into those empty places to which the new moons have slipped. On that reckoning 30 Calendars would have to be constructed, as many, that is, as the number of days by which the new moons can ascend and descend; and of those 30 we shall treat in chapter 15. Now someone may say that there is no need for the cycle to be set out differently in the Calendar, and that it is enough for the number nearest to those empty places to be taken for tracking the new moons; for no appreciable error can be committed thereby, since the cycle cannot show the new moons exactly and precisely, in whatever manner it is placed in the Calendar, but must sometimes indicate them earlier or later. But if anyone says this, who does not see that on such a reckoning

the new moons cannot ascend or descend by as many days as the equation table prescribes for them?

[Margin: Not to change the place of the epacts in the Calendar, even if the equation table must be renewed.]

And who does not notice that a different number of the cycle would then indicate the new moons from the one that the usual rule for finding the golden number — or the number of any other cycle — yields, and that consequently, at every point where the seats of the new moons change, fresh canons would have to be composed for finding that number? I pass over the fact that, since two numbers are always nearest to the empty places in the Calendar, one below and one above, we should be perpetually in doubt which of the two ought to be taken for indicating the new moons. How much disturbance this would bring both to ecclesiastical and to civil affairs, everyone sees.

[Margin: Why the golden number, or any other cycle that does not fill all the places of the Calendar, cannot be unchangeable in the Calendar.]

18 It is on account of this stability of the cycle of epacts in the Calendar alone — namely that nothing in it need be altered even if a different magnitude of the year, or a different period of the Moon, should be discovered by later ages, and the equation table should in consequence have to be changed — that we have called this Gregorian Calendar perpetual and everlasting, and never liable to any change. And rightly so, since in it the cycle of epacts fills every place, and, being keyed to the customary golden number, adapts itself to any magnitude of the solar and indeed of the lunar year, provided the equation table is properly constructed, as we have just explained. Nor did it ever enter the mind of any of us who were summoned by the Supreme Pontiff to this task of the Correction — as certain people wrongly impute to us, men who seek every opportunity to attack the Gregorian Calendar with slanders — that we thought the Calendar should be called perpetual because of the restoration of the equinox and the equation of the solar year prescribed in it. For since it has been observed by the more skilled astronomers that the year is now longer, now shorter, and since its magnitude has not yet been established with certainty (as the great variety of astronomical tables bears witness), who would be so shameless and rash as to dare to affirm and accept that the equinox will remain forever in the seat to which it has been recalled, even if the equation of the solar year is set up with every precaution? And that we did not assert this is most amply attested by that little book of the *Compendium* on restoring the Calendar which was sent to the Christian princes, and which we placed at the beginning of this work: in it a twofold method of

equating the solar year was proposed, one from the Alphonsine year, the other from the Copernican. We should certainly never have done that if we had judged our own equation, which was framed according to the opinion of the Alphonsines, to be so certain that it could never be liable to any change. The same thing is attested most plainly by these words, almost the last of that same *Compendium*: *The vernal equinox having thus been restored to the place from which it had fallen, and this cycle of epacts — which can be adapted to any magnitude of the year — having been set alongside the Calendar, and the scheme of intercalation we have described together with the equation of that cycle having been applied, the years and months will hereafter so agree with the courses of the Sun and Moon that no discrepancy or disagreement can thereafter arise; and if at any time it should, by this very same route they can be most excellently restored to their proper state. But if to anyone the Alphonsine calculations should seem too uncertain to be trusted, and he should think it better to adhere to more recent ones, he will assuredly understand that the arrangement and ordering of this ingenious cycle and of the table of epacts devised by Lilius is such that the calculation of Copernicus, or of any other whatever, can be fitted to it without difficulty, provided that a little equation table drawn up from that calculation is substituted for the one we have written in the margin.* See how clearly and openly we profess that our equation of the solar year is not so firm and settled that we believe it can never stand in need of restoration.

[Margin: Why the Gregorian Calendar is called perpetual.]

[Margin: On what ground the cycle of epacts of the new Calendar is said to be adaptable to any magnitude of the year.]

[Margin: The new Calendar is not called perpetual because we suppose that, by our equation, the equinox cannot depart from 21 March.]

[Margin: Why a twofold method of equating the solar year was proposed in the *Compendium* sent to the princes.]

19 And indeed, as far as the equinox is concerned, it can easily be recalled to its former seat, should it ever desert it, by the omission or the intercalation of a few days, by edict of the Supreme Pontiff — as was done in this very correction of the year by the removal of ten days.

[Margin: How easy the restoration of the equinox is, by the omission or intercalation of a few days.]

20 But to arrange in the Calendar a cycle for showing the new moons that could be adapted to every magnitude of the year, and be perpetual in such a way that nothing in its disposition in the Calendar ever had to be altered — this always seemed to the ancient Fathers and to astronomers extremely difficult, not to say impossible. The reason is that, since the Sun requires fewer days than the Moon in order to anticipate its seat in the Calendar by a whole day, it did not seem possible that over a long period one and the same cycle, whatever it might be, once inscribed in the Calendar, should show the new moons. For when one day is taken out of the year for the equation of the Sun, the new moons must descend by a day in the Calendar, if the Moon does not yet need an equation at that time, as we said above. Unless, then, the cycle is at that point arranged differently in the Calendar, it will be in no way possible for the same number of the cycle as before to indicate the new moons. By the same reasoning, when the Moon requires an equation but the Sun does not, the new moons will necessarily ascend by a day in the Calendar. And so neither then will the same number of the cycle as before correctly show the new moons, unless it is moved upward into the places to which the new moons have advanced. And if in such a case and at such a time anyone were to judge that the new moons should be kept on the same days, he would drive the equinox out of its proper seat and force it to slip toward the end of the month. Thus, if a man applies an equation to the solar year, he will inflict no small loss upon the new moons; while if he sets about equating the lunar year, he will necessarily throw the equinox out of its proper seat — so that what is commonly said fits him exactly:

Incidit in Scyllam cupiens vitare Charybdis. (He falls into Scylla in wishing to avoid Charybdis.)

[Margin: Why it always seemed difficult to inscribe in the Calendar a cycle that should be perpetual.]

But if the equinox and the new moons were to move forward by one day toward the beginnings of the months in the Calendar within the same span of time, this whole difficulty would be entirely removed. Since matters stand as they do, it must be reckoned no small achievement of the correction of the Calendar that the discordant motions of the Sun and Moon have been brought to such concord that the equation of the one does not obstruct the equation of the other, whatever that may be. Hence the Calendar may not undeservedly be called perpetual, even though the equinox, over and above the prescribed equation, occasionally needs some other remedy to keep it from straying too far from 21 March. The greatest thanks and praise, therefore, are due to Aloysius Lilius [Luigi Lilio], who devised

so ingenious a cycle of epacts — one which, inscribed in the Calendar, shows the new moons perpetually, and can be adapted so easily to any magnitude of the year, provided the due equation is applied at its proper times.

[Margin: In praise of the new Calendar.]

The equation table can be corrected in the following way, should an error be detected in it after very distantly separated centuries. For a proposed hundredth year, let the paschal new moon be computed — or rather the full moon, since more account is to be taken of the latter than of the former. Then let it be observed which epact in March or April offers a Moon of *xiiii* days that precedes that full moon by no more than one day. For that is the epact to be taken up with the golden number of that hundredth year; and accordingly there must be prefixed to that hundredth year the letter of the expanded table, opposite which the golden

[Margin: How the equation table is to be corrected in very distantly separated centuries.]

the epact taken up corresponds to the given golden number. For example: in the year 109500, whose golden number is 4, the paschal new moon falls on 18 March, at about hour 11 after noon, while the full moon falls on 2 April, at about hour 5 after noon. The Moon of *xiiii* must therefore fall on 2 April — the day that epact *xi*, written against 20 March, exhibits. That epact must accordingly correspond at that time to golden number 4; and this is indeed what happens in the expanded table, on the line prefixed by the letter P, capital. This letter, then, must be prefixed to the year 109500 in the equation table, and you will also find that same letter by what we set out in this chapter 12, Num. 10.

Next, in the nearest following hundredth year that is not bissextile, if the Moon needs no equation, the letter N, capital, is to be taken up; but if the Moon does require an equation, the same letter P is to be retained. The same must also be done when the following hundredth year is bissextile and the Moon is not to be equated. For if the Moon were to be equated, the letter a, small, would have to be taken up, and so on. This is not a difficult matter, provided that threefold rule given in chapter 11, Num. 9, is carefully weighed. In that hundredth year, therefore, the letter h, small — the one the equation table of chapter 11 offers — is not to be used.

CAPVT XIII.

De Calculo Nouiluniorum, & Pleniluniorum mediorū per Epactas veras.

On the calculation of mean new moons and full moons by means of the true epacts.

Since our cycle of epacts will often have to be examined — to see whether it exhibits the legitimate paschal xiiii, whether it is correctly laid out in the Calendar and correctly equated in the expanded table of the preceding chapter, and finally since other men's cycles will repeatedly have to be compared with ours — I think it worth the effort to set out here a simple and easy method by which anyone can investigate the mean new moons and full moons through the true epacts without great labour. This method, although it is not as accurate as the one drawn from the tables of mean motions, is nevertheless found to depart very little from it. It is given in the Prutenic Tables [tabulae Prutenicae], in the Gregorian Tables of Giuseppe Moletti [Giuseppe Moletti], and also in the tables of Giovanni Antonio Magini [Giovanni Antonio Magini], and it is carefully described by Paul of Middelburg [Paulus de Middelburgo] in his *Paulina* — so that we may safely rely on it in this business of Easter. But a far easier and shorter method of calculating the mean new moons and full moons after the correction you will find in chapters 26 and 27, where first the paschal new moon (or full moon) of any hundredth year is sought, and then, more quickly than can be said, the new moons and full moons of all 100 expanded years after that hundredth year are drawn from the one so found.

[Margin: An easier method of computing the new moons and full moons is given in chap. 25 and 26.]

[Margin: What the epacts of years and of months are.]

Besides the epacts explained so far — which arise from the days by which the solar year exceeds the lunar year, both years being reckoned in whole days and the hours and their fractions neglected — astronomers also consider other, more exact epacts, in which the hours too, and the fractions of hours, are taken into account. These are the days, hours, and minutes of hours which remain over, in any given year (or even month), beyond the whole mean lunations, without completing one whole mean lunation. These are what are called the epacts of years and of months.

[Margin: In what way the epacts of years and of months are gathered and reduced to tables.]

2 THEREFORE, if you subtract the lunar year — that is, 354 days, 8 hours, 48 minutes, 38 seconds, 7 thirds, 36 fourths — from the solar year of 365 days, the remainder gives the epacts of one common year: 10 days, 15 hours, 11 minutes,

21 seconds, 52 thirds, 24 fourths. The epacts of a bissextile year will be 11 days, 15 hours, 11 minutes, 21 seconds, 52 thirds, 24 fourths. From this you will easily make up the epacts of two common years, of three, of four, and so on up to 100, by continually adding the epacts of one common year — always casting out a whole lunation, that is, 29 days, 12 hours, 44 minutes, 3 seconds, 10 thirds, 48 fourths, whenever the sum reached is greater — and adding besides 1 day in bissextile years, such as the years 4, 12, 16, 20 and the rest that four measures out; as you see has been done in the following table of 100 expanded years.

BY THE SAME method you will compose, from the continual addition of the epacts of 100 years, the epacts of 200, 300, 400, 500 and of the following hundredth years, always throwing out a whole lunation whenever this can be done. This is seen in the other table, of years collected by 100 up to 7200. You can nevertheless extend it further, as far as you please, by continually adding 25 days, 4 hours, 30 minutes, 33 seconds, 2 thirds, 16 fourths, and always casting out the whole lunation whenever it can be cast out.

AGAIN, if from the 31 days of January you take away a whole lunation of 29 days, 12 hours, 44 minutes, 3 seconds, 10 thirds, 48 fourths, the remainder gives the epacts of January: 1 day, 11 hours, 15 minutes, 56 seconds, 49 thirds, 12 fourths. If to these you add the days of the following months in order, likewise casting out a whole lunation whenever this can be done, and in a bissextile year assigning 29 days to February, you will make up the epacts of all the months, both of the common year and of the bissextile — just as you see has been done in the double table of the twelve months.

FINALLY, if you begin from the half lunar month of 14 days, 18 hours, 22 minutes, 1 second, 35 thirds, 24 fourths, and proceed by continual addition of the same half month, alternately in each of the two little tables, casting nothing out, until you reach the thirteenth conjunction of 383 days, 21 hours, 32 minutes, 41 seconds, 18 thirds, 24 fourths — that is, the quantity of the embolismic lunar year — then all the tables will have been composed by which both the mean new moons and the mean full moons are readily computed, as we shall shortly explain. These two little tables of Revolutions are what astronomers call Tables of the revolutions of the new moons and full moons.

Now if the calculation is not to be extended beyond the year 6000, it will be enough for the table of revolutions to reach the fourth conjunction, of 118 days, 2 hours, 56 minutes, 12 seconds, 43 thirds, 12 fourths, since the sum to be subtracted from these revolutions can then never be greater than the number of this fourth conjunction. But because in practice it can sometimes happen that

some full moon or new moon after the year 6000 has to be sought — and consequently, as we shall say more than once, that one has to enter the table of years collected by 100 — I have chosen to extend that little table as far as the thirteenth conjunction, because then the sum to be subtracted may be greater than the number of the fourth conjunction. I did this the more deliberately so that the magnitudes of all the lunar months, both of the common year and of the embolismic, might be ready to hand. For thus you see that two lunar months comprise 59 days, 1 hour, 28 minutes, 6 seconds; and that twelve months contain 354 days, 8 hours, 48 minutes, 38 seconds, and so on. Indeed in Num. 4 we shall propose much larger revolutions of the new moons, on account of centuries very far distant, where — because of the very many days omitted which must be added to the calculation, as we shall say in Num. 3 — large revolutions have to be subtracted from the sum of the calculation, as will be said in Num. 3.

Table of the epacts of the expanded years (1–100), with the revolutions of the new moons and full moons

Epoche siue radix Christi calculo addenda. [The epoch, or root of Christ, to be added to the calculation.]

D	H	M	S
16	18	12	30

C A P V T X I I I.

(continued)

THESE tables too we have computed ourselves with care — we did not think other men's tables entirely to be trusted, since an error is easily let in when numbers are printed — in days, hours, minutes, seconds, thirds, and fourths. In the tables themselves, however, the thirds and fourths have been set aside, and the reckoning has been carried only as far as seconds; but with this precaution, that whenever in the construction of the tables the thirds in a sum came to more than 30, one second was added to the seconds.

Finally, at the end of all the tables we have placed the epoch of Christ (commonly called the root of Christ), which, on Magini's authority [Giovanni Antonio Magini] and gathered from the Prutenic Tables [*Tabulae Prutenicae*], contains 16 days, 18 hours, 12 minutes, 30 seconds — for it must be added at the end of every calculation.

3 THE USE of these tables for finding the mean new moons and full moons is as follows. [Margin: How new moons and full moons are to be sought from the tables of epacts.] Gather into one sum the epacts of the years collected by 100s that have elapsed; the epacts of the expanded years that have likewise been completed; and finally the epacts of the month preceding the month whose mean new moon or full moon is sought — together with the root of Christ, as is the practice in astronomical tables — always casting out 60, and for each such casting-out adding one unit to the preceding minutes; and likewise casting out 24 from the hours, and for each such casting-out adding one day to the number of days. Then let this sum be cast out of the next larger number of Conjunctions, in its own table, or of Oppositions, in its own table as well, in the tables of revolutions, according as the mean conjunction or the mean opposition is being sought. The remaining number will give the time of the conjunction or opposition sought — provided, however, that after the correction one first adds the days removed on account of the equation of the equinox, up to and including the year proposed. Moreover, in all new moons and full moons found by these tables the hours, with their fractions, are to be counted from noon.

For example. Suppose the new moon of the month of April in the year 1598 is to be investigated; its epact is xxiii. The epacts of the 1500 years are 23 days, 10 hours, 49 minutes, 37 seconds. The epacts of the 97 completed years are 21 days, 19 hours, 40 minutes, 31 seconds. Lastly, the epacts of the completed month of March in a common year are 1 day, 9 hours, 47 minutes, 50 seconds, as the tables above show. All of these, together with the root, 16 d. 18 h. 12 min. 30 sec., make the sum 63 d. 10 h. 30 min. 28 sec. This sum, subtracted from the next larger number of conjunctions — that is, from 88 d. 14 h. 12 min. 10 sec. — leaves 25 d. 3 h. 41 min. 42 sec. If, then, the year had not yet been corrected by the removal of 10 days, the new moon would fall on April 25, 3 h. 41 min. 42 sec. But because in the year 1582 ten days were removed in order to correct the Calendar, 10 days must be added to the new moon found; and once that is done, the same new moon falls on April 35 — that is, on May 5, 3 h. 41 min. 42 sec., as appears in these schemes.

(Stubs as printed: Anni 1500. / 97. / Martius / Radix / Summa in the left panel; Deme and Apr. bracketing the rows of the right panel.)

AND if from this time of 35 days, 3 hours, 41 minutes, 42 seconds of April (that is, from 5 days, 3 hours, 41 minutes, 42 seconds of May, a whole month of April of 30 days having first been added) you subtract the time of one lunation, namely 29 d. 12 h. 44 min. 3 thirds, there will be left the time of the preceding new moon, which will fall in the month of April on day 5, 14 h. 57 min. 39 thirds. And indeed you would have found nearly the same time if for March you had taken the epacts of February, as you see here.

	36	14	57	38

IF, however, to that same time of 5 days of May, 3 hours, 41 minutes, 42 seconds you add the time of one lunation, and from the sum cast out the 31 days of the

month of May, you will find that the following new moon occurs in the month of June on day 3, 16 h. 25 min. 45 thirds.

BUT if from the time of any new moon you subtract half a lunar month (adding first the days of the preceding month, if the subtraction cannot otherwise be made), or if you add the same half-month, you will find the time of the mean full moon preceding or following. Thus from the new moon that occurs in the year 1598 on April 5, 14 h. 57 min. 38 sec., you will find the preceding full moon on March 21, 20 h. 35 min. 36 sec. And in this way the days of the month proposed are always to be taken away, if the sum collected exceeds the days of that month. Likewise the days of the preceding month are always to be added when the subtraction cannot be made.

AGAIN, suppose the mean Paschal full moon is to be found in March or April of the year 2673, whose epact is xix. I say "in March or April" because it is not yet settled in which month the Paschal full moon will fall. With the 2600 years take the epacts 5 d. 5 min. 9 sec.; and with the 72 completed years the epacts 15 d. 18 h. 32 min. 52 sec.; and with February of the current common year elapsed the epacts 29 d. 11 h. 15 min. 57 sec. The sum of these, with the root 16 d. 18 h. 12 min. 30 sec., comes to 67 d. 5 h. 6 min. 28 sec. Subtracted from the next larger number of oppositions, namely from 73 d. 19 h. 50 min. 8 sec., there remain 6 d. 14 h. 43 min. 40 sec. And adding the 18 days

that will have been removed up to that time, the mean opposition will occur in the month of March on day 24, 14 h. 43 min. 40 sec.; and this is the Paschal one, since it follows March 21, the day assigned to the equinox.

IF in place of February you had taken, with March, the epacts of a common year, 1 d. 9 h. min. 47 min. 47 sec. 50 [recte: 1 d. 9 h. 47 min. 50 sec. — the printed line repeats min. 47. by dittography], you would have produced the sum 39 d. 3 h. 38 min. 21 sec. Subtracted from 44 d. 7 h. 6 min. 5 sec. (which is the next larger number of oppositions), this leaves 5 d. 3 h. 27 min. 44 sec.; and with the addition of the 18 days which will then have been removed from the year, the full moon will occur in the month of April on 23 d. 3 h. 27 min. 44 sec. This is not the Paschal one, since it comes after April 19, with which the mean Paschal full moons close. Take away from it, therefore (after first adding the 31 days of the preceding month of March), a whole lunation, and you will find that the Paschal full moon occurs in the month of March on day 24, 14 h. 43 min. 41 sec. — practically as before.

MOREOVER, suppose the mean Paschal full moon is sought in March or April of the bissextile year 1600, whose epact is xv. With the 1500 collected and completed years take the epacts 23 d. 10 h. 49 min. 37 sec.; with the 99 expanded years that have elapsed, the epacts 13 d. 13 h. 19 min. 11 sec.; and with February of the bissextile year elapsed, the epacts 0 d. 22 h. 31 min. 54 sec. All of these, together with the root 16 d. 18 h. 12 min. 30 sec., make up 54 d. 16 h. 53 min. 12 sec. This sum being subtracted from the next larger number of oppositions, that is from 73 d. 19 h. 50 min. 8 sec., and the ten days removed from the year being added to the remainder, the Paschal full moon will occur in the month of March on 29 d. 2 h. 56 min. 56 sec.

LET IT ALSO be proposed to find the new moon in the month of January of the year 1700, whose epact is ix. With the 1600 collected years elapsed, take the epacts 19 d. 2 h. 36 min. 7 sec.; and with the 99 expanded years elapsed, the epacts 13 d. 13 h. 19 min. 11 sec. These, with the root 16 d. 18 h. 12 min. 30 sec. (since no month has elapsed before January), make the sum 49 d. 10 h. 7 min. 48 sec. Subtract this from the next larger number of conjunctions, namely from 59 d. 1 h. 28 min. 6 sec., and add to the remainder the 11 days then removed, and the new moon will be found in January on day 20, 15 h. 20 min. 18 sec.

SUPPOSE, again, someone wants the Paschal full moon in March or April of the year 325, whose epact is * [the asterisk sort = epact 30]. With the 300 completed years let the epacts 16 d. 12 h. 3 min. 33 sec. be taken among the collected years; with the 24 expanded years elapsed, the epacts 24 d. 22 h. 40 min. 20 sec.; and likewise, February being past, the epacts 29 d. 11 h. 15 min. 57 sec. The sum of these, with the root 16 d. 18 h. 12 min. 30 sec., embraces 87 d. 16 h. 12 min. 20 sec. Taken from the next larger number of oppositions, 103 d. 8 h. 34 min. 11 sec., it leaves as the time of the mean full moon in March 15 d. 16 h. 21 min. 51 sec.; and this is not the Paschal one. A whole lunation being therefore added, the Paschal full moon will be found in the month of March on day 45, 5 h. 5 min. 54 sec. — that is, April 14, 5 h. 5 min. 54 sec.

IF for February you had taken the epacts of March in a common year, you would at once have found the full moon of April at 14 d. 5 h. 5 min. 55 sec., practically as before.

LASTLY, suppose the new moon is to be investigated in the month of January of the year iiii, whose golden number is 16 and epact iiii. Since the collected years exceed the year 7200, we shall first take the epacts of 7000 collected years, 20 d. 20 h. 19 min. 25 sec.; then the epacts of the remaining 4100 collected years, 28 d. 15 h. 54 min. 46 sec.; and the epacts of the 10 expanded years elapsed, 19 d. 17 h.

41 min. 29 sec. (No entry is made for the months, since no month preceded January.) The sum of all these with the root, 16 d. 18 h. 12 min. 30 sec., is 86 d. 0 h. 8 min. 10 sec., and we shall subtract it from the next larger number of conjunctions, 88 d. 14 h. 12 min. 10 sec. To the remainder, 2 days 14 h. 4 min. 0 sec., we shall add the 82 days removed. (How the number of days suppressed up to and including a given centesimal year after the year 1600 is to be found, we showed in Chapter 12, at the beginning of Num. 9; and if to it one adds the 10 days removed in the year 1582, the whole number of days subtracted will be made up.) We shall then find that the new moon of January falls on 84 d. 14 h. 4 min. 0 sec. — that is, the 31 days of January and the 28 of February being taken away, on March 25, 14 h. 4 min. 0 sec. [Margin: What is to be done when the new moon or full moon sought falls beyond the month proposed.] But if from 84 d. 14 h. 4 min. 0 sec. we subtract the largest number of conjunctions — not of full moons — that can be subtracted (which must always be done when the new moon or full moon sought falls beyond the month proposed), namely the time of two lunations, that is 59 d. 1 h. 28 min. 6 sec., there will be left the new moon of January sought, 25 d. 12 h. 35 min. 54 sec.

IF for the 10 expanded years we take the epacts of 9 years, namely 9 d. 2 h. 30 min. 7 sec., and likewise the epacts of October in a common year, 8 d. 16 h. 39 min. 28 sec. — so that, once the 82 days then removed from the year are added, the new moon may fall in January — the sum produced will be 84 d. 1 h. 36 min. 16 sec. Subtracting this from the next larger number of conjunctions, namely from 88 d. 14 h. 12 min. 10 sec., we shall find that the new moon of November in the year *iiii*^o [so printed: four minims with a small superior *o*; see anomaly (c)] falls on November 4, 12 h. 35 min. 54 sec.; and with the 82 days subtracted from the year added, on November 86, 12 h. 35 min. 54 sec. — that is, taking away the 61 days that November and December contain, on January 25, 12 h. 35 min. 34 sec. of the following year *iiii*, as before.

4 FOR THE REST, if you ask why all the days removed or omitted are to be added to the calculation, when nevertheless the descent through the table of expanded epacts has not always been made through as many lines — as is plain from the table of the equation — know that the reason is this. [Margin: Why all the days removed on account of the equation of the equinox must be added to the calculation of the lunations.] Astronomical calculation exhibits the lunations as they truly occur in the heavens, on the supposition that no day has been removed from the year, and with no account taken of the equation of the Moon; for the calculation of itself equates the Moon, and the equation of the Moon is employed in the Calendar solely to correct the nineteen-year cycle. Hence, if up to the time

at which the calculation of some lunation is begun a number of days have been removed on account of the equation of the equinox, that lunation will occur so many days later — inasmuch as in the calculation those same days were reckoned in as though they had not been taken away. Necessarily, therefore, all the removed days must be added, so that the lunations may be indicated so many days later and may fall on their proper days.

SINCE, however, when the year proposed is so large that a great many removed days have to be added to the new moon or full moon found — and consequently a great many revolutions of the new moons have also to be subtracted, so that the new moon or full moon of the month proposed may be left over — we have computed the following revolutions, which are multiples of the last entry of the table above, 383 days, 21 hours, 32 minutes, 41 seconds, 20 thirds, 24 fourths, so that from them one may always take the largest that can be subtracted, and need not subtract those set out in the table above repeatedly and not without trouble. We have disregarded the thirds and fourths, adding however 1 second whenever the thirds are more than 30.

REVOLVTIONESNOVILVNIO RVM.

(Revolutions of the new moons.)

5 SOMEONE will perhaps also ask what the reason is that, when the calculation of the lunations is carried out for two years of which one exceeds the other by 19

years, the anticipation of about 1 h. 27 min. 33 sec. is not perceived — the anticipation which we showed in Chapter 8, Num. 4 to be owed to the Moon every 19 years. [Margin: Why in new moons found by computation the anticipation of 1 h. 27 min. 33 sec. is not perceived after 19 years. (*printed aticipatio for anticipatio, and H. I, with a comma*)] To make this more clearly perceived, we have computed the new moons of March for the five years here. In them the said anticipation is in no way to be found. Now this happens because of the common and bissextile years. For in 19 years, over and above 4 bissextiles, there still remain 3 common years; in 38 years, 2 remain; in 57 years, 1 remains; but in 76 years there are contained 4 cycles, and no common year is left over. And since the epacts of common years are 6 hours less than they ought to be, on account of the 6 hours omitted in the Calendar, the result is that the aforesaid anticipation is not preserved. Yet in the two years 1600 and 1676, whose difference is 76 years, the anticipation of about 5 h. 50 min. 11 sec. plainly appears, as the argument requires.

Anni	D	H	M	S
1600	14	8	34	54
1619	15	1	7	21
1638	14	17	39	48
1657	14	10	12	15
1676	14	2	44	40

But if from the new moon of the year 1600 there are taken 18 hours, on account of the 3 common years passed since the bissextile year 1596 (because in the calculation these 18 hours ought to have been taken from the next larger number of conjunctions as well), the new moon of March will fall on day 13, 14 h. 34 min. 54 sec. Indeed, because at the end of the year the first 1 day accrues, we shall say that it falls on day 14, 14 h. 34 min. 54 sec. Likewise, if from the new moon of the year 1619 twelve hours are removed, on account of the two common years elapsed since the bissextile 1616, the new moon of March will fall on day 14, 13 h. 7 min. 21 sec., which occurs earlier than the new moon just named by 1 h. 27 min. 33 sec. Again, if from the new moon of the year 1638 six hours are taken away, because one common year is left over after the bissextile 1636, it will occur in March on day 14, 11 h. 39 min. 48 sec., which likewise differs from the immediately preceding one by 1 h. 27 min. 33 sec. So too, if you subtract the new moon of the year 1657 (from which nothing is to be taken away, since the year 1656 just elapsed is bissextile) from the nearest new moon — that is, from 14 d. 11 h. 39 min. 48 sec. — the remainder will yield the same anticipation of 1 h. 27 min.

33 sec. Furthermore, if from the new moon of the year 1676 you remove 18 hours, on account of the 3 common years elapsed since the bissextile 1672, it will occur in March on day 13, or rather 14 (because at the end of the year one day then first accrues), at 8 h. 44 min. 40 sec.; and this again differs from the preceding by 1 h. 27 min. 35 sec. Finally, if the new moon of the year 1676 is subtracted from the new moon of the year 1600 (for these new moons are to be taken just as they stand, since those two years differ from one another by 76 years, in which are contained exactly 4 nineteen-year cycles and 19 bissextile years), the anticipation of 5 h. 50 min. 14 sec. will appear.

If anyone wishes to compute new moons and full moons for more distant ages, he may use, in place of the table of years collected by 100s, the following table, which extends as far as the year 1000000000.

Table of years collected by powers of ten, with their epacts (continued)

Anni	D	H	M	S
100	25	4	30	33

900000	14	2	44	50
1000000	12	9	38	16
2000000	24	19	16	31
3000000	7	16	10	43
4000000	20	1	48	59
5000000	2	22	43	11
6000000	15	8	21	27
7000000	27	17	59	43
8000000	10	14	53	55

Anni	D	H	M	S
9000000	23	0	32	10
10000000	5	21	26	23
20000000	11	18	52	46
30000000	17	16	19	9
40000000	23	13	45	31
50000000	29	11	11	54
60000000	5	19	54	14
70000000	11	17	20	37
80000000	17	14	47	0
90000000	23	12	13	23
100000000	29	9	39	45
200000000	29	6	35	28
300000000	29	3	31	10
400000000	29	0	26	52
500000000	28	21	22	34
600000000	28	18	18	16
700000000	28	15	13	59
800000000	28	12	9	41
900000000	28	9	5	23
1000000000	28	6	1	5

So if the year 3469000 is proposed, you must enter this table first with 3000000 years, then with 400000, then with 60000 and 8000 elapsed, and finally with 900 and 99 completed, and so on. When, however, the year is no greater than 7200, the earlier table is quicker, since fewer entries have to be made in it.

CAPVT XIII.

On an easier computation of mean new moons and full moons, worked out by means of the mean new moons computed for 76 years.

[Margin: How the table of new moons for the 76 primary years is constructed.]

To make mean new moons and full moons easier to find, we have computed the new moons for 76 years — because exactly 4 cycles and 19 bissextile years are contained in that span — beginning with the year 1501 and running to the year 1576. These 76 years, from 1501 to 1576, we shall call the *primary* years of the table, since all the new moons of this table suit them just as they stand, with nothing added and nothing taken away. In this we have followed Paul of Middelburg [Paulus de Middelburgo], Bishop of Fossombrone, who did the same thing in book 11 of his *Paulina*. In this computation we have for the most part obtained each new moon from the one before it by adding a single whole lunation, although now and then we have also computed the same new moons by the tables of epacts given earlier; for we found either no difference at all between the two calculations, or an odd one. The new moons of January were computed by the tables for every year, while the new moons of the other months were derived from these by continuous addition of a whole lunation. I mention this so that you will not be surprised if, computing new moons for yourself, you occasionally find a difference of one second or two between your new moons and ours — a difference which I have never found to exceed 3 seconds.

[Margin: How the table of ranks is constructed, and of the time which at each rank is to be added to the new moons or subtracted from them.]

In chapter 8, Num. 4 we showed that over 76 years the new moons anticipate their places by 5 h. 50 min. 10 sec. 44 thirds 0 fourths. Accordingly we have drawn up the following table in front of the table of 76 years, by continuous addition of one such anticipation, and on the left we have written the numbers 1, 2, 3, 4, and so on in their natural order, to indicate the ranks [ordines] of each successive set of 76 years. So you see that at rank 10 — that is, after 76 years have run ten times — the anticipation amounts to D. 2, H. 10, Min. 21, sec. 47, thirds 20. This table has been extended as far as rank 130, at which the anticipation in the new moons will have reached 31 days, 14 h., 43 min., 15 sec., 20 thirds. Anyone who wishes may extend it indefinitely by continuing to add 5 h. 50 min. 10 sec. 44 thirds. That, however, is not necessary, and would make the table swell beyond all measure — especially since, for years that call for a rank greater than 130, the new moons are found more easily and more reliably by the epacts, as in chapter 13. In fact it is not worth investigating new moons beyond the year 28400, because at that point the computed new moons will differ from the new moons of the epacts in the Calendar by one whole day, and after the year

30300 by nearly 11 days. The reason is that around the year 28400 the equinox must be restored to the 21st and 22nd, the point to which it will have slipped

because of the two years by which we anticipate the omission of 3 days in 400 years, as we said in chapter 5, Num. 17. But around the year of the Lord 30300 — that is, some 298700 years after the correction, or thereabouts — it will have slipped from the 21st to the 1st of April, because by then nearly 11 days more would have been dropped than the reckoning requires. Furthermore, in all the new moons of the table that follows, the hours together with their fractions are to be counted after midday.

[Margin: How the series of years to the right of the table of new moons runs on.]

The series of years written against the rank-numbers in the table of 76 years is easy as well. For beside any one of those 76 primary years, the first year of the series is made up of that primary year (whose new moons are computed in the table) together with 76; and all the rest are formed from the first by continuous addition of 76. Or, more easily, they may all be written in without this addition, as follows. Beside the first primary year put the year 1577, which is the next above 1576, the last primary year in the table. Then beside the second primary year write 1578, and 1579 beside the third, and so on. In this way the year 1652 will end up written beside the primary year 1576. Begin again, then: set 1653 beside the first primary year, 1654 beside the second, and so on. Or we may certainly do it this way. Once as many years as you please have been written to the right of the primary year 1501, formed by continuous addition of 76, write the same years increased by one beside the second primary year, which is 1502. Then write these again increased by one beside the third primary year, that is, beside the year 1503; and so on in turn.

[Margin: In what manner the series of years to the left of the table of new moons runs on.]

The series of years to the left of the table likewise runs on by continuous subtraction of 76 from the primary years they are set against, until no further subtraction can be made. Or, more easily, we shall write in the same years without this continuous subtraction, as follows. Once nineteen years have been written to the left of the first year, 1501, formed by that continuous subtraction, write the same years increased by one beside the second primary year, that is, beside the year 1502. Then write these again increased by one beside the third, and so on in turn. But when the last number formed beside some primary year turns out to be greater than 76, subtract 76, so that another, smaller year may be formed. For example: since the last year to the left of the primary year 1520 is 76, opposite rank 19, if 1 is added it will make the year 77, which would have to be written beside the year 1521, opposite that same rank 19. So take away 76 years,

and the year 1 remains, to be written opposite rank 20. These years to the left are all smaller than 1501, just as those to the right are all larger. Finally, over the smaller ones is set the title [Adde], and over the larger the title [subtrahe]; the use of these titles will be explained later.

SEQVVNTVR TABVLÆ.

Tabula ordinum, & temporis, quod quolibet ordine addendum est Nouilunijs, vel subtrahendum.

Table of the ranks, and of the time which at each rank is to be added to the new moons or subtracted from them.

Mean new moons of the year 1525. Golden Number 6.

The page carries a single ruled frame holding four independent panels. On the left stands the *Ordines / Anni Domini — Adde* column (20 rows); next to it the *Menses* column with the mean new moon of each month in days, hours, minutes and seconds; and to the right three *Ordines / Anni Subtrahe* panels running from 1 to 130. The row counts of the left-hand and the month panels do not correspond, so they are set out here as separate tables.

Left panel — years to be added

[Sidenote set vertically in the *Anni Domini* column: For these years the addition of time is made that corresponds to the *ordines*.]

Mean new moons of the year 1527 — Golden Number 8

1527 is an embolismic year: it carries thirteen mean lunations. January and March each hold two, and each of those two months is set with a brace tying its pair of lunations to one month initial; February has no entry of its own.

Menses	D	H	M	S

CAPVT XIII.

Nouiluniorum, Pleniluniorumque ex præcedenti tabula supputatio.

(Computation of new moons and full moons from the preceding table.)

2 When some year is given that belongs to the 76 primary years of the preceding table — one, that is, which neither falls before the year 1501 nor after the year 1576 — the mean new moons of all the months will be found in that year exactly as they are set down. If to these you add D.14. Hor.18. Min.22. sec.2., which is the time of half of one mean lunation, you will have the mean full moons of the same months. When, however, the resulting sum exceeds the number of days in the month in question, that full moon will fall in the following month. And if you then subtract a whole lunar month from the full moon so found, or subtract half a lunar month from the new moon found, what remains will be the full moon of the same month preceding that new moon.

For example, in the year 1520, whose Epact is xj., the new moon in October fell on day 11, hour 7, min. 34, sec. 53. If you add 14 days, 18 hours, 22 minutes, ter. 2 [?], you will find the full moon in the same month, on day 26, hour 1, min. 56, sec. 55. But in February of the same year the mean new moon occurred on day 18, hour 1, min. 42, sec. 29. If, then, you add half a lunar month, you will get for the full moon day 32, hour 20, min. 4, sec. 31. And if you take away the month of February — which in that year, being bissextile, contains 29 days — you will find that that full moon fell on day 3, hour 20, min. 4, sec. 31 of March. Now if you take a lunar month, that is, D.29.H.12.M.44.sec.3., away from the full moon so found, that is, from D.32.H.20.M.4.sec.31. of March; or if you subtract half a lunar month from the aforesaid new moon of February, you will find that the full moon occurred in February, on day 3, hour 7, min. 20, sec. 27.

[Margin: *Nouilunij inuentio in quolibet mense propositi anni primarij, vna cum plenilunio.* — Finding the new moon, together with the full moon, in any month of a given primary year.]

3 If, on the other hand, the year given is later than 1576, and indeed earlier than the Gregorian correction, which was made in the year 1582 after 4 October — since all the years after 1576 down to 1582 have the order 1 written against them at the left — you must subtract from every new moon the time of order 1, which is set down in the table before the new moons, namely D.0.H.5.Min.50.sec.11. (For to the 10 seconds one second is to be added, on account of the three times 44

seconds by which they exceed half of Second 1.) What is left is then the new moon sought.

So, if the new moon of March in the year 1582 is sought, whose Epact before the correction is vj.: since this year is found alongside the year 1506, and order 1 is prefixed to it, the time of order 1, namely D.0.Hor.5.Min.50.sec.11., must be subtracted from the new moon of March which in the year 1506 fell on day 23, hour 19, min. 25, sec. 23. In this way the new moon of the year 1582 will be found to occur on day 23, hour 13, min. 35, sec. 12. And if half a lunar month is added, namely D.14. hor.18. min.22. sec.2., the mean full moon of the same month will be found at D.38. hor.7. min.57. sec.14., that is, on 7 April at hour 7, min. 57, sec. 14. If from this you subtract a lunar month of 29 days, hor. 12, min. 44, sec. 3, you will find that the full moon in March occurred before the new moon, at D.8. hor.19. min.13. sec.11. The same result is obtained if half a lunar month is taken from the new moon of March once found.

[Margin: *Nouilunij ac plenilunij inuentio in quolibet mense dati anni post 1576. vsq̃ ad correctionē Gregorianam.* — Finding the new moon and full moon in any month of a given year from 1576 down to the Gregorian correction.]

4 But if the year given falls after the correction, the days suppressed down to that time must be added. (Those suppressed days are set out in the table for the equation of the Epacts, chapter 11, near the centesimal years; and to them the 10 days removed in the year of the correction, 1582, must always be added.) Then the time of that order which is prefixed to the year in question in the neighbouring table of new moons must be subtracted, so that the new moon sought remains.

If the day of the new moon so found falls beyond the month proposed — which is almost always the case when the year given is far from the year of the correction — we shall subtract from the surplus the largest number in the table of revolutions of the new moons given above in chapter 13, and this as many times as it can be done; then a smaller one, until what is left is less than a whole lunar month. For the number remaining will indicate the new moon of the month proposed. In the centesimal years, however, which are common years, one day must be added for those new moons which fall after the place of intercalation, that is, after 24 February.

Thus, if the new moon of the month of November in the year 1582 is sought, whose Epact after the correction is xxvj.: since this year is found alongside the year 1506, and order 1 is prefixed to it, we shall add to the new moon of

November of the year 1506 — that is, to D.15.H.1.Min.17.sec.47. — the 10 days removed from that year, and we shall get D.25.H.1.min.17.sec.47. If from this number we take away the number of the first order, that is, D.0.H.5.Min.50.sec.11., we shall find that the new moon of November falls on D.24.H.19.min.27.sec.36.

[Margin: *Nouilunij, ac plenilunij inuētio post anni correctionem.* — Finding the new moon and full moon after the year of the correction.]

[Margin: *Quādo Nouilunium inuentum cadit vltra mensem propositū, quid agendum.* — What to do when the new moon found falls beyond the month proposed.]

[Margin: *Quid agendum in annis centesimis communibus.* — What to do in common centesimal years.]

Again, let the new moon of the month of April in the year 1598 be investigated, whose Epact is xxiiij. Since this year is found alongside the primary year 1522, in which the new moon of April falls on day 25, H. 9, Min. 31, sec. 55, if the 10 days removed are added, the new moon will fall on Day 35 of April, H. 9, Min. 31, sec. 55. From this, because order 1 is prefixed to the year 1598, if we subtract D.0.H.5.Min 50.Sec.11., we shall find the new moon on Day 35 of April, H.3.Min.41.sec.44., which is a day falling beyond April. So when a lunar month of 29 Days, H.12, Min.44, sec.3 has been taken away, the same new moon will fall in April on Day 5, Hor. 14, min. 57, sec. 41.

Let it also be required to investigate the new moon of the month of January in the year 1700, whose Epact is ix. This year is written next to the primary year 1548, and order 2 is prefixed to it. If, then, to the new moon of January, that is, to D.10.H.3.Min.0.sec.45., the 11 days then removed are added, that new moon will fall at D.21.H.3.M.0.sec.45. And if the time of the second order is taken away, that is, D.0.H 11.Min.40.sec.21., the same new moon will occur at D.20.H.15.M.20.sec.24.

In the same year 1700, let the new moon of March be computed. To the new moon of March under the year 1548, alongside which the year 1700 is placed — that is, to D.9.H.4.Min.28.Sec.51. — let the 11 days suppressed be added; and from the sum, D.20.H.4.Min.28.Sec.51., let the time of the second order be taken, namely D.0.H.11.Min.40.Sec.21.; and to the remainder, D.19.H.16.Min.48.Sec.30., let one day be added, because the year 1700 is a common year and the new moon found falls after 24 February. In this way you will find that the new moon of March occurs at D.20.H.16.Min.48.Sec.30.

Likewise, let it be proposed to find the new moon of the month of January in the year 11111, whose Epact is *iiij*. This year

is written next to the primary year 1535, and has the order 126 prefixed to it. To the new moon of January in the table, that is, to D.3.H.16.Min.48.sec.13., let the 82 days removed down to the year 11100 be added, so as to make D.85.H.16.Min.48.sec.13. And if the time of order 126 is taken away, namely D.30.H.15.Min.22.sec.32., there will remain D.55.H.1.Min.25.sec.41. If from this number you again subtract a whole Lunation of 29 Days, H.12, Min.44, sec.3, that new moon will fall on Day 25 of January, H.12, Min.41, sec.38 — which differs by less than 6 minutes from what we computed above in chapter 13 by means of the Epacts.

Furthermore (to give an example set before the year 1501 as well), suppose someone wishes to find the Paschal new moon in March or April of the year 325, whose Epact is * or xxx. This year is found at the left of the primary year 1541, and has the order 16 prefixed to it, to which corresponds the time D.3.H.21.Min.22.sec.52. approximately. Added to the new moon of March, which falls on Day 26, H. 13, Min. 20, sec. 18, this places that new moon on Day 30 of March, H. 10, Min. 43, sec. 10 — which is the Paschal one. And if half a lunar month of 14 Days, H.18, Min.22, sec.2 is added, the Paschal full moon will fall on Day 45 of March, that is, on Day 14 of April, H.5, M.5, Sec.12. This differs from what we computed in chapter 13 by the Epacts by a little more than half of one minute, namely by 42 seconds.

Lastly, let it be proposed to investigate the Paschal new moon in March or April of the year 11456, which is the last in the preceding table of new moons and has the order 130 prefixed to it. The Golden Number of that year is 19, and the Epact *vj.*, which places the Paschal new moon on 25 March and the fourteenth Moon [*xiiij.*] on 7 April. The year proposed is found alongside the last year of the preceding table, 1576, where the new moon of March falls on D.29. Hor.7. min.15. sec.14. If the 84 days removed down to that time are added, the result will be D.113. Hor.7. Min.15. sec.14. Then, when the time of 31 Days, Hor.14, Min.43, sec.15, which corresponds to order 130, has been subtracted, the same new moon will be found to fall on day 81 of March, H.16, Min.31, sec.59. If from this the time of two Lunations is again subtracted, that is, D.59.H.1.Min.28.sec.6., the same new moon will fall on Day 22 of March, H.15, Min.3, sec.53.

Now if it should ever happen that the time of some order cannot be subtracted from the new moon, the days of the preceding month must be added; the new moon will then fall in that preceding month, and if you add a lunar month to it,

the new moon of the month proposed will emerge. Suppose, for instance, that the new moon of March in the year 9151 is sought, as it would be if the year had not been corrected. Since that year is found alongside the primary year 1551 and has the order 100, to which are due D.24.H.7.Min.37.sec.53. — a time which cannot be subtracted from the new moon of March, D.6, H.19, Min.38, sec.48 — we shall add the 28 days of February, since the year is a common one, so as to make D.34.H.19.Min.38.Sec.48. Then, when the time of order 100 has been subtracted, the new moon will fall in February at D.10.H.12.Min.0.Sec.55. And if a lunar month is added, the new moon will fall in March at D.12, Hor. 0, min.44, sec.58 — that is, in February at D.40, Hor.0, Min.44, Sec.58. But if you add the 67 days removed down to the year proposed, that new moon will fall, after the correction, on Day 79 of March, H.0, Min.24 [?], sec.58 — that is, once March and April have been taken away, on Day 18 of May, H.0, Min.24 [?], Sec.58. Or, when D.59.H.1.Min.28.Sec.6. have been subtracted — the time, that is, of two Lunations — on Day 19 of March, H.23, Min.16, Sec.52.

CAPVT XV.

De triginta Calendarijs Aureorum numerorum, respondentibus triginta lineis tabulæ Epactarum expansæ.

(On the thirty Calendars of Golden Numbers, answering to the thirty lines of the expanded table of Epacts.)

1 It is now time to set out those thirty Calendars of Golden Numbers which, in chapter 9, Num. 14, and chapter 12, Num. 18, we said would be necessary if the Golden Number were to be retained in the Calendar — one being brought into use at one period and another at another, as the rise or fall of the Lunations required; just as in the new Gregorian Calendar now one line of Epacts and now another is used in the expanded table to indicate the new moons. Accordingly we have drawn from our Cycle of Epacts thirty nineteen-year Cycles of Golden Numbers, in which the whole reckoning of the Lunar year according to the use of the Church consists — so that they stand in place of the 30 Calendars which we said would have to be drawn up if the new moons were to be sought in the Calendar by Golden Numbers rather than by Epacts. And this, as we see, was the Church's constant practice down to the Gregorian correction.

2 Now this is the method by which the Golden Numbers are extracted from the Epacts, that is, distributed among the 30 Calendars. Take in hand whichever line of the expanded table of Epacts you please, and note the letter of the alphabet prefixed to it, so that it may be known from the table of equation in which

century the Epacts of that line are in use. Then observe carefully the days of the months in the new Gregorian Calendar against which the nineteen Epacts of the line taken from the expanded table are written: these are precisely the days on which the new moons fall in the century in which the Epacts of that line are in use. For if opposite those same days of the months the nineteen Golden Numbers are written which, at the head of the expanded table, correspond to those nineteen Epacts, the Calendar with Golden Numbers will be complete — the one to be used in the same century as the line of Epacts taken; that is, the Golden Numbers concurring with the Epacts in that century will have been extracted from the Cycle of Epacts.

For example: if a Calendar with Golden Numbers is to be made up for the century in which the first line of Epacts, having the capital letter P prefixed to it, is in use, then the Golden Number 3, answering to the Epact *, is to be written opposite the first day of January and the last of January; likewise opposite the first and the last day of March; and also opposite 29 April; 29 May; 27 June; 25 August; 24 September; 23 October; 22 November; and 21 December — these being of course the days on which, in the Gre-

[Margin: *Qua ratione aurei numeri ex Epactis excerpantur, vt in Calendario quouis seculo inscribantur.* — By what method the Golden Numbers are extracted from the Epacts, so that they may be entered in the Calendar for any century.]

gorian Calendar the Epact * is written. In the same way the Golden Number 4, which in that same first line answers to the Epact xj, is to be written against those days of the months on which the Epact xj is seen to be entered — that is, against 20 January; 18 February; 20 March; 18 April; 18 May; 16 June; 16 July; 14 August; 14 September; 12 October; 11 November; and 10 December. And so with the rest.

You will see that this has been observed in the thirty Calendars that follow, if you carefully compare their Golden Numbers with the Epacts set down on the left-hand side against the expanded table of Epacts. For you will find that in each month of the year the Golden Numbers are set down in thirty ways entirely different from one another, since in most cases any given Golden Number occupies now one day and now another, exactly as the equation of the Moon [aequatio Lunae] requires. It is for this purpose that at the head of the months we have placed precisely the same letters of the alphabet that we prefixed to the thirty lines of Epacts in the expanded table: so that it may be known which arrangement of the Golden Numbers — that is, which Calendar of Golden Numbers (for every arrangement of the Golden Numbers constitutes one Calendar) — is to be taken into use at this or that period. On the left-hand side too

the Epacts are set out just as we arranged them in the new Calendar, together with the Dominical Letters, the Kalends, Nones, Ides, and the days of the months.

But here now are the thirty Calendars, with the thirty different arrangements of the Golden Numbers we have spoken of.

Sequuntur triginta Calendaria Aureorum numerorum, triginta lineis tabulæ Epactarum expansæ respondentia. — There follow the thirty Calendars of the Golden Numbers, answering to the thirty lines of the expanded table of Epacts.

Caput XV — The Thirty Golden-Number Calendars (continued)

[The three leaves of this opening continue the set of thirty golden-number calendars begun earlier in Caput XV. Each leaf carries, side by side, the same month in two equivalent presentations: the "Thirty Calendars of the Golden Numbers" (Calendaria form, headed Literæ triginta linearum and running the Roman-calendar reckoning of Kalends/Nones/Ides), and the "Thirty Lines answering to the Expanded Tables of

*Epacts" (Tabulæ form, headed Tabulæ Epactarum expansæ, without the Roman-calendar column). The thirty vertical "lines" are labelled with a fixed 30-letter sequence and split across successive leaves; this opening carries the April lines q p n m l k i and h g f e d c b a, and the opening of the May lines P N M H G F E.]**

APRIL (Calendaria form)

TRIGINTA CALENDARIA AVREORVM NVMERORVM ("Thirty Calendars of the Golden Numbers")

APRILIS ("April")

Golden-number block heading: **Literæ triginta linearum** ("Letters of the thirty lines") over columns **q | p | n | m | l | k | i**, then **AVREI NVMERI**. ("Golden Numbers").

Left-hand framework and Roman-calendar column (fully legible):

These three leaves continue **Caput XV**, the *Thirty Golden-Number Calendars* and their corresponding *Thirty-line Expanded Epact Tables*, for the month of **May (MAIVS)**. The three leaves alternate in kind:

- p. 273 — *Thirty-line Table corresponding to the Expanded Epact Tables* (expanded-epact leaf), golden-number lines **D C B A u t f r**;
- p. 274 — *Thirty Calendars of the Golden Numbers* (Calendaria leaf, with the Roman-calendar column), golden-number lines **q p n m l k i**;
- p. 275 — *Thirty-line Table corresponding to the Expanded Epact Tables* (expanded-epact leaf), golden-number lines **h g f e d c b a**.

Each of the golden-number value columns runs the descending +8-mod-19 staircase of golden numbers, advancing one day per column across the leaf; the doubled epact of day 4 (Roman xxv, marginal Arabic 25) and the day-numbers of the Calendaria leaf serve to fix each column against its days. The expanded-epact leaves carry **j-terminal** sorts; the Calendaria leaf carries **i-terminal** sorts.

Thirty-line Table corresponding to the Expanded Epact Tables

MAIVS (May).

Spanning heads over the grid: *Tabulæ Epactarum expansæ*. ("Expanded Epact Tables.") over the golden-number line letters, and **AVREI NVMERI** ("Golden Numbers") over the value grid.

Golden-number line letters (left → right): **D | C | B | A | u | t | f | r**

The Thirty Golden-Number Calendars (Caput XV) — JUNE

(Chapter carried only by the running header; no Caput/Num. rubric inside the frames.)

The June (IVNIVS) section of the Thirty Golden-Number Calendars runs across four leaves. This opening covers the first three: a Calendaria leaf (columns **P N M H G F E**), a Tabulæ leaf (columns **D C B A u t f r**), and a Calendaria leaf (columns **q p n m l k i**). The fourth June leaf (columns **h g f e d c b a**) begins on the following opening.

All three June leaves share one framework — the same Epact, Dominical-letter, day-of-month, and (on the Calendaria leaves) Roman-calendar columns. The golden-number columns differ: each column is one of the thirty epact-lines. Within every column the golden numbers run the +8-mod-19 cycle down the days; across the leaf, successive columns rotate that cycle by one and shift their day-mask. The columns that carry a golden number on epact 30 (*, i.e. the days-27 line) place it on **both day 1 and day 30** — a 20-entry column; the others hold 19 entries. On this opening the doubling columns are **N, H, G, E** (leaf 1), **D, B, u, t, r** (leaf 2), and **q, n, m, k** (leaf 3): which columns double genuinely differs from leaf to leaf.

Load-bearing typography preserved: leaves 1 and 3 (Calendaria) are set **i-terminal** (viii, xviii, xiii); leaf 2 (Tabulæ) is **j-terminal** (vii, xvii, xiii, j). The doubled epact 25 is printed in two forms — Arabic **25** at the day-2 row (governing golden numbers > 11) and Roman **xxv** at the day-3 row (governing

golden numbers ≤ 11); both are shown in the Epact column below. Epact 30 is the new-Calendar asterisk *.

Entry counts: q 20, p 19, n 20, m 20, l 19, k 20, i 19 — 137 golden-number cells, all committed, 0 [numeral: ?]. Doubling columns q/n/m/k carry their epact-30 golden number on both day 1 and day 30 (q xv, n vii, m xviii, k x).

The Thirty Golden-Number Calendars, expanded across thirty lines to correspond to the Tables of Epacts (Caput XV, continued)

These three leaves continue the *Thirty Golden-Number Calendars (Triginta Calendaria Aureorum Numerorum)* of Caput XV. Each opening alternates two in-frame forms of the same table:

- the **Calendaria** form — headed *TRIGINTA CALENDARIA AVREORVM NVMERORVM* — which carries the Roman-calendar column (*Kalendae / Nonae / Idus*) beside the day-of-month; and
- the **Tabulæ** form — headed *TRIGINTA LINEIS TABVLÆ EPACTARVM EXPANSÆ RESPONDENTIA* ("[the calendars], expanded across thirty lines, corresponding to the Tables of Epacts") — which omits the Roman-calendar column.

The spanning heads read *Literæ triginta linearum / Tabulæ Epactarum expansæ* ("The letters of the thirty lines" / "The Tables of Epacts, expanded") over *AVREI NVMERI* ("Golden Numbers"). The month of each leaf is set as a centred rubric (*IVNIVS, IVLIVS*).

Each golden-number column (headed by one of the thirty line-letters) distributes the golden numbers I–XIX (here j ... xix) over the days of the month, with roughly one blank day in three. Down each column the entries step by eight golden-number units in the cyclic order of the epacts; the columns are phase-shifted from one another by one day, so at any given day some columns are blank. On these leaves the month's last day repeats the first day's row across the whole grid — **every** column that is inked at Dies 1 is inked with the same value at the month's last Dies, and every column blank at Dies 1 is blank there too (see the June parsing notes). There is no single "base" column carrying the doubling.

The doubled epact 25 stands on each leaf in a narrow **printed ruled column** to the left of the epact column — bounded on the left by the frame's outer rule and on the right by the epact column's rule, with short horizontal rules above and below the figure. It is part of the printed table, not a marginal annotation.

IVNIVS (June) — Tabulæ leaf (no Roman-calendar column)

Golden-number line-columns on this leaf: **h g f e d c b a** (j-terminal sorts: viij, xiiij, xviiij, iiiij, xj). The doubled epact 25 is set in the printed twin column (ruled, inside the frame border — see above), in the two-line form: Arabic **25** on the Dies-2 line and small-capital **XXV** on the Dies-3 line, while the main epact column skips 25 (xxviij, xxvj, xxiiiij). Dies 2 and Dies 3 are accordingly **union rows**, carrying adjacent duplicate golden numbers across neighbouring columns. The Dies-30 row repeats the Dies-1 row across all eight columns (h = ij, g = xiiij/xiii, e = v, d = xvij/xvi, b = viij/viii, a = xix; f and c blank at both ends).

IVLIVS (July) — Calendaria leaf (with Roman-calendar column)

Golden-number line-columns on this leaf: **P N M H G F E** (capital line-letters). This Calendaria leaf uses **i-terminal** sorts throughout its golden numbers (viii, xiii, xviii, iiii, xii, xi, ii, iii). Doubled-epact marker **25** in the printed twin column (ruled, inside the frame border) at Dies 2 and at Dies 31. The Dies-31 row repeats the Dies-1 row (P = xix, M = xi, G = iii, F = xiii), with the union-row duplicates noted below.

Caput XV — The Thirty Golden-Number Calendars (continued)

July — Calendaria (Golden Numbers), first of these two July leaves

Frame title (within the ruled border): **TRIGINTA CALENDARIA AVREORVM NVMERORVM** ("Thirty Calendars of the Golden Numbers") / **IVLIVS**.

Spanning heads over the right-hand block: **Literæ triginta linearum** ("Letters of the thirty lines") and **AVREI NVMERI** ("Golden Numbers"). The seven golden-number columns are headed, left to right, q p n m l k i.

The left framework carries the epacts, the Dominical letter (Lit. Diical.), the Roman-calendar day, and the day of the month (Dies Mensis); the golden-number lines fill the right-hand block. This is an i-terminal leaf (vii, xii, iii... set with terminal i). Blank golden cells are left blank as printed.

Caput XV. — The Thirty Golden-Number Calendars (continued): AUGUST

These three leaves continue Caput XV's parallel presentation of the golden numbers for **August (AVGVSTVS)**, alternating between the *Thirty Calendars of the Golden Numbers* (Calendaria, which carry the Roman-calendar column) and the *Thirty Lines of the Tables of Expanded Epacts* (Tabulæ, without the Roman-calendar column). The two forms are the two faces of the same reckoning — the Calendaria expressed by day of the month with its Roman-calendar date, the Tabulæ by the expanded epacts to which those lines correspond. No Caput/Num. rubric is set inside the frames; the chapter is carried only by the running header.

Each leaf tabulates thirty-one days down the page; the golden-number columns are headed by the thirty line-letters, and each column carries the same golden number one day later than the column to its left. On day 1 several adjacent columns show the same value (the doubling at the head of the month), so that row is the fullest on the leaf; the last day of the month, day 31, is **not** a repetition of day 1 — on each of these three leaves it carries only five inked values, in the columns that stand second in each day-1 pair together with the two unpaired columns.

Leaf 1 — TRIGINTA LINEIS TABVLÆ EPACTARVM EXPANSÆ RESPONDENTIA.

Thirty Lines corresponding to the Tables of Expanded Epacts. — AVGVSTVS.

Spanning heads: **Epactæ** | **Lit. Dñical.** | **Dies Menfis** (framework); **tabulæ Epactarum expansæ.** over the golden columns; **AVREI NVMERI** (Golden

Numbers). Golden-number line-letters: **D · C · B · A · u · t · f · r** (Tabulæ leaf, no Roman-calendar column). Golden numerals are set **j-terminal** (xij, iij, vij, viij, xiiij, xviij, xviiij), as is proper to the Tabulæ leaves, with two cells that appear i-terminal (flagged below).

Leaf 2 — TRIGINTA CALENDARIA AVREORVM NVMERORVM

Thirty Calendars of the Golden Numbers. — AVGVSTVS.

Framework columns **Epactæ** | **Lit. Dñical.** | **Dies Menfis**, then the Roman-calendar date column, then the golden-number columns under the spanning head **Literæ triginta linearum** / **AVREI NVMERI**. Golden-number line-letters: **q · p · n · m · l · k · i**. This is a Calendaria leaf, so it carries the Roman-calendar column, and the golden numerals are set **i-terminal** (xii, iii, vii, viii, xiii, xiiii, xvii, xviii), proper to the Calendaria leaves.

The Thirty Calendars of the Golden Numbers — SEPTEMBER (fourth leaf)

[In-frame title:] Corresponding to the Thirty Lines of the Expanded Table of Epacts [*Triginta lineis Tabulæ Epactarum expansæ respondentia.*]

SEPTEMBER.

Spanning heads: *The Expanded Table of Epacts* [Tabulæ Epactarum expanfæ] over the golden-number columns; *Golden Numbers* [AVREI NVMERI].

This is the fourth September leaf (Tabulæ line-letters h g f e d c b a, all minuscule). September has 30 days; the day-1 golden row recurs unchanged at day 30, so five columns double — h, f, d, c, a, carrying xvij, x, ij, xij, v at both day 1 and day 30 — while g, e, and b are blank at both. Numerals are predominantly j-terminal, but the setting is not uniform: the value-28 epact is set with a plain i-terminal, xxviii, and individual golden cells in the foxed lower bands are also i-terminal (see anomaly c). All are transcribed as printed.

The Thirty Calendars of the Golden Numbers — OCTOBER (first leaf)

[In-frame title:] The Thirty Calendars of the Golden Numbers [*Triginta Calendaria Aureorum Numerorum.*]

OCTOBER.

Spanning heads: *The Letters of the Thirty Lines* [Literæ triginta linearum] over the golden-number columns; *Golden Numbers* [AVREI NVMERI].

This is the first October leaf (Calendaria line-letters P N M H G F E), which carries the Roman-calendar column. October has 31 days; the last-day (31) golden row replicates the day-1 row exactly (verified by direct read of both rows), so columns P, N, H, G, and E are doubling columns — carrying v, xvi, viii, xix, xi at both day 1 and day 31 — while M and F are blank at both. Numerals on this Calendaria leaf are set i-terminal in every row read (Calendaria convention).

The Thirty Calendars of the Golden Numbers — OCTOBER (second leaf)

[In-frame title:] Corresponding to the Thirty Lines of the Expanded Table of Epacts [*Triginta lineis Tabulæ Epactarum expansæ respondentia.*]

OCTOBER.

Spanning heads: *The Expanded Table of Epacts* [Tabulæ Epactarum expansæ] over the golden-number columns; *Golden Numbers* [AVREI NVMERI].

This is the second October leaf (Tabulæ line-letters D C B A u t r r), without the Roman-calendar column. October has 31 days; the day-31 golden row replicates the day-1 row exactly (verified by direct read of both rows), so columns C, B, u, t, and r are doubling columns — carrying iij, xiiij, vj, xvij, ix at both day 1 and day 31 — while D, A, and r are blank at both. Numerals are predominantly j-

terminal, but the setting is not uniform: the value-28 epact is set with a plain i-terminal, xxviii, and four golden cells in the grid are likewise i-terminal (see anomaly c). All are transcribed as printed.

The Thirty Golden-Number Calendars (*Caput XV*) — October and November

These three leaves continue the set of thirty golden-number calendars introduced earlier in *Caput XV*. The first two leaves complete **October**: a *Calendaria* leaf carrying the index letters q p n m l k i (with the Roman-calendar reckoning column) and a *Tabulæ* leaf carrying h g f e d c b a (the expanded epact-tables, without the Roman-calendar column). The third leaf begins **November** with a *Calendaria* leaf carrying P N M H G F E.

In each leaf the golden numbers run as a diagonal cascade, each lettered column repeating the sequence of the column to its left one day later. Blank cells are left blank (they are meaningful).

Typographic conventions preserved: the *Calendaria* leaves (October q...i, November P...E) set the golden numbers and epacts with **i-terminal** sorts (e.g. viii, xiii, xviii); the *Tabulæ* leaf (October h...a) sets them predominantly with **j-terminal** sorts (e.g. viij, xiiij, xviiij), though not uniformly — see that leaf's note. The index letters of the two October leaves are lowercase, with visible descenders on q and p; the November leaf's P N M H G F E are capitals, with no descender on the P. The epact-30 line is marked with the asterisk *. On each leaf a marginal Arabic 25 marks the doubled epact; it is printed one line above the Roman xxv on the two leaves where its line-attachment could be fixed.

Leaf 1 — OCTOBER (*Calendaria*), index letters q p n m l k i

In-frame title: **TRIGINTA CALENDARIA AVREORVM NVMERORVM — OCTOBER**. Spanning heads: *Literæ triginta linearum* / **AVREI NVMERI**

Chapter XV (continued). The Thirty Golden-Number Calendars / Thirty-Line Expanded Epact Tables — NOVEMBER (four leaves; this opening carries leaves 2–4).

NOVEMBER — Expanded Epact Tables answering the Thirty Lines (Tabulæ leaf 2)

In-frame title: **TRIGINTA LINEIS TA-BVLÆ EPACTARVM EXPANSÆ RESPONDENTIA.** ("Tables of epacts, expanded to answer the thirty lines.") —

NOVEMBER. Spanning head over the golden columns: *tabulæ Epactarum expansæ*. ("expanded epact tables") and **AVREI NVMERI** ("Golden Numbers").

This is a Tabulæ leaf: no Roman-calendar column. The eight golden columns are headed **D C B A u t f r** (lines 8–15 of the thirty). Most of the golden sorts are j-terminal, but the leaf is not set uniformly. The **day-15 line is set wholly in i-terminal type** (vii, xviii, x, ii, xiii), with the descendered xviiij / ij / xiiij of the day-14 line immediately above it standing as a control. The **day-30 line is mixed**: xi, xiiii and xvii are i-terminal, while iiij in column B and vj in column t on that same line keep their descenders. Isolated i-terminal sorts also stand at day 11 column B (xiii), day 16 column r (xiii), day 17 column r (ii), and day 25 column t (xii). The value-30 epact is the asterisk sort * (day 22). The value-28 epact is set with a plain i-terminal, xxviii, on this leaf that mixes i- and j-terminal sorts row by row; kept exactly as printed.

Two of the thirty lines coincide on this leaf, and the coincidence falls at **days 26 and 27**: there neighbouring golden columns carry duplicate values — xvij in C and B and xij in f and r on day 26; vj in C and B, ix in u and t, and j in f and r on day 27 — so those two rows carry more inked cells than their neighbours.

Column identity was fixed from the header rules by position and uniform column pitch, and each row was then read straight across from its Dies figure. Blank cells are left blank (meaningful).

The epact xxv is omitted from the main epact column, which runs xxvi (day 26) → xxiiii (day 27); the day-25 line carries nothing in this column.]

NOVEMBER — Expanded Epact Tables answering the Thirty Lines (Tabulæ leaf 4)

In-frame title: **TRIGINTA LINEIS TA-BVLÆ EPACTARVM EXPANSÆ**

RESPONDENTIA. — **NOVEMBER.** Spanning head: *tabulæ Epactarum expansæ.* and **AVREI NVMERI.**

A Tabulæ leaf (no Roman-calendar column; the value-28 epact set with a plain i-terminal, xxviii, transcribed as printed). The eight golden columns are headed **h g f e d c b a** (lines 23–30, the last of the thirty). The sorts are predominantly j-terminal but not uniformly so: isolated i-terminal sorts stand at day 4 column g (iiii), day 14 columns e and d (vi, xvii), day 21 column f (viii), day 25 column d (xvi), and day 29 column b (xiii).

Two of the thirty lines coincide on this leaf, at **days 26 and 27**, where neighbouring columns carry duplicate values — xij in f and e and xvj in c and b on day 26; x in h and g, ij in f and e, and v in c and b on day 27. The **day-30 line reproduces the day-1 line exactly**. Column identity was fixed from the header rules by position and uniform column pitch, and each row read straight across from its Dies figure.

Christoph Clavius, *Romani Calendarii Explicatio* (Opera Mathematica, Tomus V)

Caput XV — The Thirty Golden-Number Calendars: DECEMBER (leaves 1–3 of 4)

This opening carries three of December's four calendar leaves (December, the calendar's last month, has 31 days). There is no running prose on these pages —

the whole opening is the tabular apparatus. The month continues onto its fourth leaf (Tabulæ h g f e d c b a), which lies beyond this opening.

The three leaves are:

- **p. 300** — *Triginta Calendaria aureorum numerorum* (Calendaria leaf; carries the Roman-calendar reckoning column), golden-number lines **P N M H G F E**. i-terminal sorts.
- **p. 301** — *Triginta lineis Tabulæ Epactarum expansæ respondentia* (Tabulæ leaf; no Roman-calendar column), golden-number lines **D C B A u t f r**. j-terminal sorts.
- **p. 302** — *Triginta Calendaria aureorum numerorum* (Calendaria leaf), golden-number lines **q p n m l k i**. i-terminal sorts.

Each golden-number column runs the epact cascade — for the Calendaria (i-terminal) leaves the nineteen values xix, viii, xvi, v, xiii, ii, x, xviii, vii, xv, iiii, xii, i, ix, xvii, vi, xiiii, iii, xi; for the Tabulæ (j-terminal) leaf the same values with j-terminal sorts xix, viij, xvj, v, xiiij, ij, x, xviiij, vij, xv, iiij, xij, j, ix, xvij, vj, xiiij, iij, xj — each column entering the cascade at a different day and stepping one day rightward from its left neighbour, with blank days between successive entries. On the two Calendaria leaves the day-31 golden row reproduces the day-1 row exactly (the columns filled at day 1 are the ones filled at day 31). The Tabulæ leaf does the same, with one exception: its day-31 row carries an additional value, xix, in column D, where day 1 leaves that cell blank.

December — fourth and last leaf of the Thirty Golden-Number Calendars

TRIGINTA LINEIS TA-/BVLÆ EPACTARVM EXPANSÆ / RESPONDENTIA.
(Corresponding to the thirty lines of the expanded table of epacts.)

DECEMBER.

Spanning heads: **Tabulæ Epactarum expansæ** *(The expanded table of epacts)* — golden-number columns **h g f e d c b a** — **AVREI NVMERI** *(The golden numbers)*.

This is the fourth (final) December leaf of the Tabulæ series, completing the thirty-calendar table of Caput XV. It is a Tabulæ leaf (no Roman-calendar column); the framework columns are Epactæ | Lit. Dñical. | Dies Menfis, followed by the eight golden-number columns h g f e d c b a. Blank cells are blank.

[Margin: How the new moons are to be investigated by means of the golden numbers of the thirty Calendars.]

3. The use of the preceding thirty Calendars, in which the golden numbers are set out, for investigating the new moons is in every way the same as that of the new Gregorian Calendar, in which the epacts are inscribed. For when you are about to find the new moons by means of the golden numbers of these thirty Calendars, consider which letter of the alphabet — set down in the upper table of the equation of the epacts [aequatio Epactarum] (Caput 11 and 12) — corresponds to the year proposed, whether that year is itself a centennial year, or the centennial

year within which the proposed year falls. For if you use the golden numbers arranged under that same letter in the preceding thirty Calendars, you will find the new moons on exactly the same days on which they are indicated by the epacts, so that there is no difference at all between the epacts and the golden numbers in the investigation of the new moons. Thus you see, for example, that in the Jubilee year 1600 — to which the capital letter D is prefixed in the table of the equation of the epacts — the golden number 5, which is in use that year, found among the thirty Calendars under the capital letter D, indicates the new moons on precisely the same days as the epact of the year does. That is (which comes to the same thing), the golden number 5 and the epact xv are written opposite the same days of the months. And the same reasoning holds for the rest.

Furthermore, in these thirty Calendars of golden numbers drawn from the Cycle of Epacts, we never find two golden numbers falling on the same day of the month — although two epacts sometimes do, as for instance xxv and xxiii, and 25 and xxvi, and 19 and xx, which are set opposite the same day in the Gregorian Calendar. The reason for this we explained above at Caput 10, Num. 5 and 11.

[Margin: The inconvenience of the thirty Calendars.] And although the method of investigating the new moons is the same whether by the epacts or by the golden numbers arranged in the thirty Calendars, and the one agrees with the other in every respect, nevertheless — because the multitude of thirty Calendars is very inconvenient, both because confusion could easily arise from them in various regions (one region using this Calendar and another that one at the same time), and because, in order to construct Paschal tables from them and to announce the age of the Moon correctly in the Martyrology, thirty Paschal tables and thirty Martyrologies would have to be drawn up for the thirty Calendars — it is safer, and more in keeping with the practice of the Church, to use the numbers of the epacts, in the Calendar as well as in the Paschal tables and the Martyrology. For a single line of epacts distributed through the days in the Calendar accomplishes all this most conveniently, as is plainly evident from the new Calendar and from the Martyrology adapted to the Gregorian restoration of the year.

CAPVT XVI.

The lunations of all thirty Cycles of the expanded table of epacts, resolved into their several quantities throughout the whole year, in that same order which they keep in the Calendar through the months of the entire year.

[Margin: An explanation of the thirty tables comprising all the lunations of the thirty Cycles of the expanded table.]

So that everyone may not only understand, but also perceive with their very eyes, how aptly and suitably the epacts in the new Calendar — and the golden numbers excerpted from the epacts in the thirty Calendars — have been placed for indicating the new moons, and how distinctly and in what order the lunations of each Cycle proceed in the Calendar by alternating intervals of 30 and 29 days, as the reckoning requires, I judge it worthwhile to append here another thirty tables of lunations, corresponding in order to the thirty Cycles of epacts of the expanded table, or to the thirty preceding Calendars of golden numbers. In this way the lunations of each Cycle are resolved into their quantities — that is, into days — in the same order that they keep throughout the months of the whole year in the Calendar.

First, then, in these tables all 19 golden numbers are placed on the left, always beginning from the one that corresponds to epact * in each line of the expanded table, or to epact 1 when epact * is not found in the Cycle of a given line. For from one or the other of these epacts every nineteen-year cycle [Cyclus decennovennalis] must begin, as we shall show in the next chapter. Next follow the 19 epacts in the order they observe within each Cycle of the expanded table — yet in such a way that the first is * (or 1, if the Cycle happens not to have epact *), while the others are produced by continually adding 11 to the immediately preceding epact, with the exception of the epact placed opposite golden number 1. For this last is formed from the preceding epact, placed opposite golden number 10, by the addition of 12, as was shown above at Caput 12, Num. 14. Third, the days of January, or of December, are written down on which the first lunations begin. Fourth, the days of December — or of November — on which the twelfth lunations end are noted. Fifth, the days of December are marked on which the thirteenth lunations end, if the year is embolismic. Sixth, the number of days of the whole lunar year is noted. Finally, all the lunations of the year are set out in order, each being reckoned at 30 or 29 days.

But this too must be understood: the first lunation of the year, whose beginning falls in December, does not begin from the epact that indicates the new moons in that year, but from the one that stands higher in these tables — namely, from the epact that was still in use in December of the immediately preceding year, and which is placed opposite that day of December on which the first lunation is said to begin; for the use of the epact of the year in question begins in January, and not before. For example, although in the first table, with epact xiiij current, the first lunation of that year begins on 18 December, it nevertheless does not begin from epact xiiij — since this is not found opposite the 18th in that same month — but from epact iij, which pointed out the new moons in the preceding year, and

which changes in January into epact xiiij. And the same reasoning is to be observed in the rest. But now examine the tables themselves.

Here follow the Lunations of the Thirty Cycles of the expanded table of Epacts.

How many days each lunation contains, both in a common year and in an embolismic one, in the first Cycle of the expanded table — to which the capital letter **P** is prefixed, and to which, among the thirty Calendars of golden numbers, the first Calendar under the same capital letter **P** corresponds.

Table column heads (verbatim): **AVREI NVMERI** (*The golden numbers*) | **EPACTÆ** (*The epacts*) | **Initium primi mensis Lunar***is tam in anno communi, quam in Embolismico* (*Beginning of the first lunar month, both in the common and in the embolismic year*) | **Finis duodecimi mensis Lunar***is tã in anno communi, quam in Embolismico* (*End of the twelfth lunar month, both in the common and in the embolismic year*) | **Finis tertijdecimi mensis Lunar***is in anno Embolismico* (*End of the thirteenth lunar month in the embolismic year*) | **Magnitudo anni Lunar***is tam communis quam Embolismici* (*Length of the lunar year, both common and embolismic*) | **NVMERVS ET ORDO Lunationum totius anni** (*The number and order of the lunations of the whole year*): columns 1–13 = Prima, Secunda, Tertia, Quarta, Quinta, Sexta, Septima, Octaua, Nona, Decima, Vndecima, Duodecima, Tertiadecima Lunatio.

Below, the last six columns (headed 1–13) give the ordered lengths of the lunations. Blank = no thirteenth lunation (common year).

Caput XVI — Lunation tables of the Thirty Cycles (continued)

(Global source pp. 306–308 / printed pp. 306–308. Three full-page lunation tables: the Second Cycle — capital letter N; the Third Cycle — capital letter M; and the Fourth Cycle — capital letter H. Each is a 19-row table of the golden numbers.)

Second Cycle — capital letter N (p. 306)

The number of days that each lunation contains, in the common year as well as in the embolismic year, for the **second Cycle** of the expanded table — the one headed by the capital letter N, to which corresponds the second of the thirty golden-number Calendars, set under the same capital letter N.

Column headings. Golden Numbers [Aurei Numeri] · Epacts [Epactae] · Beginning of the first lunar month, in both the common and the embolismic year [Initium primi mensis Lunar] · End of the twelfth lunar month, in both the common and the embolismic year [Finis duodecimi mensis Lunar] · End of the

thirteenth lunar month, in the embolismic year [Finis tertijdecimi mensis Lunaris in anno Embolismico] · Length of the lunar year, common as well as embolismic [Magnitudo anni Lunaris] · **The number and order of the lunations of the whole year** [Numerus et ordo Lunationum totius anni], columns 1–13 = First through Thirteenth Lunation (Prima ... Tertiadecima Lunatio).

Golden No.	Ep act	1st month begins	End 12th mo.	End 13th mo.	Le ngt h
14	*	1 Ian.	20 Dec.		354
15	xj	21 Dec.	9		354

12	viiij	24	12		354
13	xix	13	1 Dec.	31 Dec.	384

Anomaly (Golden No. 1, the saltus row): the Length column reads **353** (the shortened saltus year), but the twelve printed lunation cells read 30 29 30 29 30 29 30 29 30 29 30 29, which sum to **354**. On the two parallel Cycles overleaf (pp. 307 and 308) the saltus row begins 29 29 ... (summing to 353); here the First Lunation is printed 30 where the saltus pattern requires 29. Transcribed as printed; the discrepancy is flagged, not silently corrected. All cells were read directly from the page, row by row; the surrounding rows are read glyph by glyph, not derived from the ± 30 alternation.

Third Cycle — capital letter M (p. 307)

The number of days that each lunation contains, in the common year as well as in the embolismic year, for the **third Cycle** of the expanded table — the one headed by the capital letter **M**, to which corresponds the third of the thirty golden-number Calendars, set under the same capital letter **M**.

Golden No.	Ep act	1st month begins	End 12th mo.	End 13th mo.	Length

18	xiiij	19	7		354
19	xxi	8	26 No.	26 Dec.	384

Golden No.	Ep act	1st month begins	End 12th mo.	End 13th mo.	Length
	ij				
1	vj	27	14 Dec.		353
2	xvi j	15	3		354
3	xxv ij	4	23 No.	22 Dec.	384
4	ix	23	11 Dec.		354
5	xx	12	30 Dec.	30 Dec.	384

Here the saltus row (Golden No. 1, Length 353) correctly begins 29 Dec., summing to 353.

Anomaly (Golden No. 5, final row): the page sets the End-12th-month and End-13th-month cells identically as 30 Dec. | 30 Dec. — a twelfth month and a thirteenth month ending on the same day, which is impossible. Transcribed as printed; the expected setting on the pattern of the other embolismic rows would be [recte: 30 No.] in the End-12th column, but that conjecture is **not** entered in the table. Read at high magnification in the bottom row of the grid, anchored on that row's epact xx and on the heavy bottom table rule immediately below; the Dec. matches the Dec. of 14 Dec. and 11 Dec. one and two rows above and is plainly distinct from the No. of 26 No. and 23 No. in the same part of the page.

Fourth Cycle — capital letter H (p. 308)

The number of days that each lunation contains, in the common year as well as in the embolismic year, for the **fourth Cycle** of the expanded table — the one headed by the capital letter **H**, to which corresponds the fourth of the thirty golden-number Calendars, set under the same capital letter **H**.

Caput XVI (continued) — Lunationes of the Cycles

The Lunations of the Fifth Cycle (letter G)

How many days each lunation contains — both in a common year and in an embolismic one — in the **fifth Cycle** of the expanded table, the one prefixed by the capital letter **G**, and to which corresponds the fifth of the thirty golden-number Calendars set under the same capital letter **G**.

Column headers, verbatim and translated:

- **AVREI NVMERI** — Golden Numbers
- **EPACTÆ** — Epacts
- **Initium primi mensis Lunaribus tam in anno communi, quam in Embolismico** — Beginning of the first lunar month, in a common year as well as in an embolismic one
- **Finis duodecimi mensis Lunaribus tam in anno communi, quam in Embolismico** — End of the twelfth lunar month, in a common year as well as in an embolismic one
- **Finis tertijdecimi mensis Lunaribus in anno Embolismico** — End of the thirteenth lunar month, in an embolismic year
- **Magnitudo anni Lunaribus tam communis, quam Embolismici** — Length of the lunar year, both common and embolismic
- **NVMERVS ET ORDO Lunationum totius anni** — The number and order of the lunations of the whole year (Prima Lunatio ... Tertiadecima Lunatio = 1st Lunation ... 13th Lunation)

In the date columns, No. = November (Novembris), Dec. = December, Ian. = January; a bare number continues the month named just above it (December unless a No. intervenes). The epact * is the new-Calendar sign for epact 30. The lunation columns 1–13 give each lunation's length (29 or 30 days) in order; the 13th appears only in embolismic (384-day) years. Length 353 marks the saltus year (golden number 1).

The Lunations of the Seventh Cycle (letter E)

How many days each lunation contains — both in a common year and in an embolismic one — in the **seventh Cycle** of the expanded table, the one prefixed by the capital letter **E**, and to which corresponds the seventh of the thirty golden-number Calendars set under the same capital letter **E**. (Column headers as in the fifth-Cycle table above.)

Caput XVI — Lunationes of the Cycles (continued): the 8th, 9th, and 10th Cycles

How many days each lunation contains, both in a common year and in an embolismic year, in the eighth Cycle of the expanded table — the table to which the capital letter D is prefixed, and to which the eighth of the thirty golden-number Calendars under the same capital letter D corresponds.

Column headings of the table (verbatim):

- **Aurei Numeri** — Golden Numbers
- **Epactæ** — Epacts
- **Initium primi mensis Lunaris tam in anno communi, quam in Embolismico** — Beginning of the first lunar month, both in a common and in an embolismic year (**Init.**)
- **Finis duodecimi mensis Lunaris tam in anno communi, quam in Embolismico** — End of the twelfth lunar month, both in a common and in an embolismic year (**End 12th**)
- **Finis tertijdecimi mensis Lunar in anno Embolismico** — End of the thirteenth lunar month in an embolismic year (**End 13th**)
- **Magnitudo anni Lunar tam communis, quam Embolismici** — Length of the lunar year, both common and embolismic (**Length**)
- **Numerus et Ordo Lunationum totius anni** — The number and order of the lunations of the whole year (**1st–13th**), the sub-columns headed *Prima, Secunda, Tertia, Quarta, Quinta, Sexta, Septima, Octaua, Nona, Decima, Vndecima, Duodecima, Tertiadecima Lunatio*.

Dates: bare numbers in the Init. / End 12th / End 13th columns are days of December unless marked **No.** (November) or **Ian.** (January), exactly as the source prints the abbreviation only where the month changes.

How many days each lunation contains, both in a common year and in an embolismic year, in the tenth Cycle of the expanded table — the table to which the capital letter B is prefixed, and to which the tenth of the thirty golden-number Calendars under the same capital letter B corresponds.

On this leaf the Golden-Number column is set beginning from 12 (running 12 → 19, then 1 → 11), because the * epact opens the tenth Cycle at golden 12.

Caput XVI (continued) — The *Lunationes* Tables of the Thirty Cycles

(Continuation of Caput XVI of the Explicatio*: the tables of the lengths of the lunations for each Cycle. This opening carries the 11th, 12th, and 13th Cycles — line-letters A, u, t.)*

Each table has the same column structure:

- **Golden Nos.** (*Aurei Numeri*)
- **Epacts** (*Epactæ*)
- **Init.** — *Initium primi mensis Lunaris tam in anno communi, quam in Embolismico*: the beginning of the first lunar month, in both the common and the embolismic year.
- **End 12th** — *Finis duodecimi mensis Lunaris tam in anno communi, quam in Embolismico*: the end of the twelfth lunar month, in both the common and the embolismic year.
- **End 13th** — *Finis tertijdecimi mensis Lunaris in anno Embolismico*: the end of the thirteenth lunar month, in the embolismic year only.
- **Length** — *Magnitudo anni Lunaris tam communis, quam Embolismici*: the length of the lunar year, whether common or embolismic (354 common / 384 embolismic / 353 or 383 in the saltus year).
- **Number and order of the lunations of the whole year** (*Numerus et ordo Lunationum totius anni*): columns 1–13 = Prima, Secunda, Tertia, Quarta, Quinta, Sexta, Septima, Octaua, Nona, Decima, Vndecima, Duodecima, Tertiadecima Lunatio (each 29 or 30 days; the 13th only in embolismic years).

Eleventh Cycle — litera A (capital)

How many days each lunation contains, in both the common and the embolismic year, in the **eleventh** Cycle of the expanded tables — the Cycle prefixed by the letter **A**, capital, and to which the eleventh of the

thirty Calendars of golden numbers corresponds under that same letter A, capital.

[illegible]

Caput XVI — Lunations of the Fourteenth Cycle (line-letter 𐌒)

How many days each lunation contains, both in the common year and in the embolismic year, in the expanded table of the fourteenth Cycle, to which is prefixed the small letter f, and to which, of the thirty golden-number Calendars, the fourteenth under the same small letter f corresponds.

Column headers (shared by all three tables of this leaf):

- **Golden Numbers** [Aurei Numeri]
- **Epacts** [Epactæ]
- **Beginning of the first lunar month, both in the common and in the embolismic year** [Initium primi mensis Lunararis tam in anno communi, quam in Embolismico]
- **End of the twelfth lunar month, both in the common and in the embolismic year** [Finis duodecimi mensis Lunararis tam in anno communi, quam in Embolismico]
- **End of the thirteenth lunar month in the embolismic year** [Finis tertijdecimi mensis Lunararis in anno Embolismico]
- **Length of the lunar year, both common and embolismic** [Magnitudo anni Lunararis tam communis quam Embolismici]
- **THE NUMBER AND ORDER of the lunations of the whole year** [NVMERVS ET ORDO Lunationum totius anni] — the thirteen columns headed First through Thirteenth Lunation (Prima ... Tertiadecima Lunatio).

In the lunation columns below, No. = November, Dec. = December, Ian. = January. Blank cells in the "End of the thirteenth month" column and in the thirteenth-lunation column are left empty (these apply only to embolismic years).

[illegible]

Lunations of the Fifteenth Cycle (line-letter r)

How many days each lunation contains, both in the common year and in the embolismic year, in the expanded table of the fifteenth Cycle, to which is prefixed the small letter r, and to which, of the thirty golden-number Calendars, the fifteenth under the same small letter r corresponds.

(Column headers as on the preceding table.)

[illegible]

[illegible]

Lunations of the Sixteenth Cycle (line-letter q)

How many days each lunation contains, both in the common year and in the embolismic year, in the expanded table of the sixteenth Cycle, to which is prefixed the small letter q, and to which, of the thirty golden-number Calendars, the sixteenth under the same small letter q corresponds.

(Column headers as on the preceding tables.)

[illegible]

[illegible]

Caput XVI (continued) — The *Lunationes* Tables of the Thirty Cycles

Running heads: p. 321 "CAPVT XVI."; p. 322 "CALEND. GREGOR."; p. 323 "CAPVT XVI."

Each leaf carries one Cycle's expanded lunation table (19 golden-number rows).
The shared column-head block reads:

- **AVREI NVMERI** — Golden Numbers
- **EPACTÆ** — Epacts
- **Initium primi mensis Lunaris tam in anno communi, quam in Embolismico** — Beginning of the first lunar month, in both the common and the embolismic year
- **Finis duodecimi mensis Lunaris tam in anno communi, quam in Embolismico** — End of the twelfth lunar month, in both the common and the embolismic year
- **Finis tertijdecimi mensis Lunaris in anno Embolismico** — End of the thirteenth lunar month, in the embolismic year
- **Magnitudo anni Lunaris tam communis quam Embolismici** — Length of the lunar year, both common and embolismic
- **NVMERVS ET ORDO Lunationum totius anni** — Number and Order of the lunations of the whole year (the thirteen lunation columns: *Prima ... Tertiadecima Lunatio* = 1st ... 13th lunation)

Date abbreviations as printed: Ian. = January, No. = November, Dec. = December.

The Seventeenth Cycle (letter p) — printed folio 321

Caption. How many days each lunation contains, both in the common year and in the embolismic, laid out in the table for the **seventeenth** Cycle — to which the small letter **p** is prefixed, and to which, out of the thirty Calendars of the golden numbers, the seventeenth answers under the same small letter **p**.

Twenty-second Cycle (litera i) — printed folio 326

Caption: How many days each lunation contains, in both the common and the embolismic year, in the twenty-second Cycle of the expanded tables — to which the small letter **i** is prefixed, and to which, out of the thirty Calendars of golden numbers, the twenty-second answers under that same small letter **i**.

(Column heads as above.)

[illegible]

[Printed p. 327 — Twenty-third Cycle, small letter h]

Column headings, verbatim: **AVREI NVMERI** (Golden Numbers) · **EPACTÆ** (Epacts) · *Initium primi mensis Lunaris tam in anno communi, quam in Embolismico* (Beginning of the first lunar month, in both the common and the embolismic year) · *Finis duodecimi mensis Lunaris tam in anno communi, quam in Embolismico* (End of the twelfth lunar month, in both the common and the embolismic year) · *Finis tertijdecimi mensis Lunaris in anno Embolismico* (End of the thirteenth lunar month, in the embolismic year) · *Magnitudo anni Lunaris tam communis quam Embolismici* (Length of the lunar year, both common and embolismic) · **NVMERVS ET ORDO Lunationum totius anni** (The number and order of the lunations of the whole year: First ... Thirteenth Lunation).

Caput XVI — *Lunationes* of the Thirty Cycles (continued)

Twenty-sixth, twenty-seventh, and twenty-eighth Cycles (line-letters e, d, c)

The six framework columns and the thirteen lunation columns are identical in all three tables on these leaves; their headers translate as follows:

- **AVREI NVMERI** — Golden Numbers
- **EPACTÆ** — Epacts

- Month abbreviations as printed: **Ian.** = January, **No.** = November, **Dec.** = December. A bare number in the "End 12th"/"End 13th" columns means December is carried down from the row above.

Caption. How many days each lunation contains — in both the common year and the embolismic year — in the twenty-sixth Cycle of the expanded tables, to which the small letter *e* is prefixed, and to which, out of the thirty Calendars of golden numbers, the twenty-sixth under that same small letter *e* corresponds.

Caput XVI (continued) — *Lunationes* Tables of the Twenty-Ninth and Thirtieth Cycles; Caput XVII begins

How many days each lunation contains — both in a common year and in an embolismic one — in the twenty-ninth Cycle of the expanded table, to which the small letter b is prefixed, and to which, out of the thirty Calendars of golden numbers, the twenty-ninth (under the same small letter b) corresponds.

Column headings (verbatim, left to right): **AVREI NVMERI** (Golden Numbers) | **EPACTÆ** (Epacts) | *Initium primi mensis Lunar is tam in anno communi, quam in Embolismico* (Beginning of the first lunar month, both in a common and in an embolismic year) | *Finis duodecimi mensis Lunar is tam in anno communi, quam in Embolismico* (End of the twelfth lunar month, in a common and in an embolismic year) | *Finis tertijdecimi mensis Lunar is in anno Embolismico* (End of the thirteenth lunar month, in an embolismic year) | *Magnitudo anni Lunar is tam communis, quam Embolismici* (Length of the lunar year, both common and

embolismic) | **NVMERVS ET ORDO Lunationum totius anni** (The number and order of the lunations of the whole year: 1st through 13th lunation).

[illegible]

[illegible]

(Column headings identical to the preceding leaf: Golden Numbers | Epacts | Beginning of the first lunar month | End of the twelfth lunar month | End of the thirteenth lunar month | Length of the lunar year | number and order of the lunations, 1st through 13th.)

2. It is clear from the tables above that every nineteen-year cycle contains seven years of thirteen lunations — the years called embolismic, which I shall discuss in the next chapter. Likewise, a lunar year of twelve lunations

sometimes comprises only 353 days; above, in Chapter 8, Number 1, I called such a year "hollow" [cavum]. An embolismic year, too, occasionally contains only 383 days, which I likewise called hollow. A lunar year, whether common or embolismic, becomes hollow when the transition is made from golden number 19 to golden number 1. For in that case 12 is added to the epact that is in use together with golden number 19, in order to form the following epact, which corresponds to golden number 1 — as I explained above in Chapter 12, Number 14 — so that the first lunation of the year comprises only 29 days, whereas in other years it contains 30. Moreover, an embolismic year becomes hollow when the nineteen-year cycle begins from golden number 1 and epact xix or xviii concurs with golden number 19, as may be seen in tables 8 and 9; or likewise whenever a year whose golden number is 1 is embolismic, because — for the reason just given — the first lunation of that year comprises only 29 days, on account of the addition of 12 to the epact concurring with golden number 19. But I shall write more on this matter in the next chapter, at Numbers 7 and 14. And as for why, in the following thirty tables, the lunations do not always proceed alternately by 30 and 29 days, but several consecutive lunations sometimes occur — now of 30 days, now of 29 — I shall explain this in the next chapter, at Number 15.

[Margin: When the lunar year, whether common or embolismic, becomes hollow — namely, of 353 or 383 days.]

CAPVT XVII. — On the Embolisms, and on what they call the *Saltus* [Leap] of the Moon

Now that I have inscribed all thirty epacts in the Calendar, and have constructed both the expanded table of those same epacts and the table of equation — the latter indeed corrected for many thousands of years, so that in any age it may be known which 19 epacts out of all 30 are to be taken, corresponding to the nineteen golden numbers, for determining the new moons — the proper order seems to require that I also bring forward a few remarks about the embolisms and the *Saltus* of the Moon. For from this it will become still clearer that the epacts have been most correctly placed in the Calendar, and that their Cycle now performs entirely the same office that the Cycle of the golden number, or any other Cycle, once performed. But two things seem to require explanation first. The first is that any lunation is assigned by the computists to the month in which it ends, even if it took its beginning in another month. On this matter there is this little verse:

In quo completur, mensi Lunatio detur. [Let the lunation be given to the month in which it is completed.]

If anyone should ask the reason for this, the following may be offered. While epact * is running, there can be no doubt that the first lunation of the whole year begins on the very Kalends of January, together with the year itself, and must be assigned to that same January, ending on the 30th of January. From this it follows that the second lunation, whose end falls on the last day of February, must be ascribed to February, although it begins on the last day of January. The third, beginning on the Kalends of March and ending on the 30th, must be given to March. Then the fourth to April, whose end falls on the 28th of April, even though it begins on the last day of March. And the fifth to May, which ends on the 28th of May, though it begins on the 29th of April. And so, throughout that whole year, the lunations are to be assigned to the months in which they end, although they begin in others — so that the twelfth lunation, whose end falls on the 20th of December, must be ascribed to December, even though it begins on the 22nd of November. And since a common lunar year contains only 12 lunations, the following lunation — beginning on the 21st of December and ending on the 19th of January — must be called the first of the next year, and therefore assigned to January, the first month of that year; for on the 20th of December the common lunar year of 12 lunar months is already ended. From this it follows that the next lunation, which begins on the 20th day of January, must be assigned to February, in whose 17th day it ends; and therefore the other lunations of the same year, too, must be granted to the months in which they end, even though they take their beginning from others. It is no different in an embolismic lunar year: the last and thirteenth lunation will have its end in December, and the one next following — whether it begins on some day of December or at the beginning of January — must be called the first of the next year. This seems to me to be entirely the reason why all the computists assign the lunations to the months in which they terminate: namely, so that the first lunation of the year — which always has its beginning in December, except when epact * is in use (for that lunation begins on the first day of January) — and its end in January, may be ascribed to the first solar month of the whole year, that is, to January, reason itself so requiring.

[Margin: That the lunation is assigned to the month in which it ends; and why.]

2. In the second place, it must be declared from which epact each cycle of nineteen years takes its beginning — the cycle, that is, in which are contained the 19 epacts of some one line among those 30 set out in the expanded table, corresponding to the nineteen golden numbers. For those

thirty cycles of the expanded table do not begin from the epacts that hold the first place in them and are set under golden number 3, as perhaps someone considering the matter without sufficient attention might suppose. Rather, every nineteen-year cycle of the expanded table takes its beginning always from epact *, and from the first day of January, if * is contained in that cycle; or from epact 1 and from the last day of December, if epact * is not found in the cycle. Now epact * is contained in 19 of the cycles, or lines of the expanded table — namely in the 1st, 2nd, 4th, 5th, 7th, 9th, 10th, 12th, 13th, 15th, 16th, 18th, 20th, 21st, 23rd, 24th, 26th, 27th, and 29th — and therefore each of these cycles takes its beginning from it, under whatever golden number it may be placed. But in the other 11 cycles — namely the 3rd, 6th, 8th, 11th, 14th, 17th, 19th, 22nd, 25th, 28th, and 30th — * is not found; so the beginning of those cycles is then taken from epact 1, under whatever golden number that epact may be found placed. For although in every cycle it might seem free to fix the beginning wherever one pleases, yet since the 19 lunar years are made equal to the same number of solar years — though not in every respect, as was said above in Chapter 8 — it seems fitting that the beginning of the nineteen-year cycle in the epacts be taken there where the Church's custom sets the beginning of the solar year in the Calendar, namely on the Kalends of January, when this can be done; or at any rate near the Kalends. So that, whenever in a nineteen-year cycle epact *, inscribed on the Kalends of January, is in use, the begin-

[Margin: That every cycle of 19 epacts begins either from *, if it is contained in the cycle in question, or from 1, if * is not found in the given cycle.]

[Margin: Which nineteen-year cycles begin from *, and which from epact 1.]

[the begin]ning of the cycle is taken from that epact and not from another, and the new moon that falls on the first day of January is the first in that whole nineteen-year cycle. But it not rarely happens that in the whole span of nineteen years no new moon falls on the Kalends of January, because throughout that whole period epact * is not in use — as is clear from the eleven cycles of the expanded table enumerated above, namely from cycles 3, 6, 8, 11, 14, 17, 19, 22, 25, 28, and 30. In that case the beginning of our cycle cannot be taken from the Kalends of January, nor from epact *, since that epact is not contained in that cycle; rather, the cycle must be begun from the epact nearest to the Kalends of January — either from epact xxix, set against the second day of January, or from the epact that would have to be entered against the last day of December, if the

year began there. In this way the new moon nearest the beginning of the solar year — the one that falls either on the second day of January or on the last day of December — is called the first in that whole cycle. But since a new moon falling on the second day of January is not the first of the whole year but the second (because the preceding lunation, which ends on the Kalends of January itself, is assigned to January and called the first of the whole year, as we wrote a little earlier), we must take the new moon that is then the first of the whole year and is assigned to January, and that is the nearest one — for all the other new moons assigned to January fall, in that cycle, on other days of December, the ones that precede the last day.

Two days, therefore, must be assigned to the beginning of our cycle: the Kalends of January, where epact * is placed, and the day before the Kalends of January [Pridie Cal. Ianuarij], where epact 1 would have to be placed if the solar year began there — just as in other places of the calendar epact 1 is placed immediately above epact *. But since the solar year begins on the first day of January and ends on the last day of December, and the epacts in the calendar cannot preserve the order of the cycle — as we explained in chapter 10, no. 2 — it is not epact 1 (which in the natural order precedes epact * in the calendar) that is set against the last day of December, but epact xx, together with epact 19, marked in a different colour or character. For these two epacts fall, in the natural order, below epact xxj set against the second-to-last day of December, and they are still in use in the month of December, in those years in which the new moons are shown by them — since our epacts change in January, just as the golden numbers do. From this it follows that the beginning of any nineteen-year cycle of our epacts must be taken either from the first day of January and from epact *, when that epact is in use in the nineteen-year cycle, or from the last day of December and from epact 1, when epact * is not found in that cycle.

[Margin: That any nineteen-year cycle begins either from the first day of January or from the last day of December.]

And this is the reason why, in the thirty tables of lunations in the preceding chapter, we began every nineteen-year cycle either from epact * or from epact j, and why the first lunation of the whole cycle, in each table, takes its start either from the Kalends of January or from the last day of December — while all the golden numbers, meanwhile, gave the start to the nineteen-year cycle.

3. Furthermore, so that you may see that those two days must necessarily be appointed for the beginning of each of our nineteen-year cycles, we shall show that the same would have to be done in the golden-number cycle, if it were

written out in the calendar and both equations — that of the solar year and that of the lunar — were preserved. Let us take in hand, then, the old Roman calendar, in which golden number 3 is placed at the first day of January, and from which, right down to our own correction, the beginning of the cycle was always taken — because the equation of the Sun and Moon had never been applied.

[Margin: That the golden-number cycle, before the correction, always began from golden number 3.]

That the beginning of the cycle was always taken from golden number 3 is clearly gathered from this: that from golden number 3 the seven embolismic years were counted, as you will see most plainly from what we shall set out a little below about the embolisms in this same chapter.

Therefore, if on account of the equation of the solar year — the Moon not yet requiring an equation — the several golden numbers must be moved down by one day, golden number 3 will be written against the second day of January, and golden number 14 will be set against the first day, since elsewhere in the calendar it is always placed immediately above golden number 3. So the beginning of the cycle will then be made from golden number 14, and from that same first day of January. But if the golden numbers must be moved down by a further day, golden number 3 will fall on the third day of January and golden number 14 on the second, while the first day will appear empty — because above golden number 14 golden number 6 is placed not immediately, but with an empty day left between, as is clear from chapter 9, no. 5. So the beginning of the cycle cannot then be made from the first day of January, since no golden number is placed there; nor, again, will golden number 14, now assigned to the second day of January, any longer give the beginning, because the lunation beginning on the second day of January, while golden number 14 is running, is the second of that year and not the first, as we taught before. The cycle must therefore then be begun from the golden number that would have to be assigned to the last day of December if the solar year began there — that is, from golden number 6, which in the calendar always stands two days higher than 14. For the lunation then falling on the last day of December is the first of the whole following year; and this is indicated by golden number 5 [?], which shows the new moons in the preceding year and is then assigned to the last day of December — since we suppose it to have descended by two days from the 29th of December, where it is written in the old calendar. And that golden number 5 [?], and not 6, is then to be set against the last day of December — the 6 that in the calendar is always found written above 14 —

the reason is that the golden numbers in the calendar cannot preserve the order of the cycle, as was said in chapter 9, no. 6; and this is plain from the third calendar of golden numbers, whose index letter is M, majuscule.

[Margin: That the nineteen-year cycle of the golden number begins either from the golden number written at the Kalends of January, or from the one that would have to be entered against the last day of December, if the solar year began there.]

Exactly the same would happen if, on account of the equation of the Moon (the solar year then not requiring an equation), the golden numbers in the old calendar had to be moved up by one day. For golden number 11, assigned to the third day of January, would rise to the second day, while golden number 3, placed on the first day, would pass to the last day of December, leaving the first day of January empty. So the cycle could not then begin from the first day of January, since there is no golden number there, nor from the second day of January, for the reason given above, but from the last day of December, from golden number 3, which would then have to be placed there if we began the solar year there. Yet, since we begin the year from the start of January, and the golden numbers in the calendar do not preserve the order of the cycle — as we said in chapter 9, no. 6 — golden number 2 would then be seen placed there, below golden number 13, which would then be assigned to the second-to-last day of December, as is clear from the thirtieth calendar of golden numbers, whose index letter is a, minuscule.

4. You see, then, that the beginning of the cycle of golden numbers is taken from all the golden numbers in turn and successively — now from the first day of January, if some golden number is placed there, now from the last day of December, if the first day of January has no golden number. This happens on account of the equation of the solar and lunar year, since, because of that equation, all the golden numbers can be written in turn on the first day of January and on the last day of December — as plainly appears from the thirty calendars of golden numbers above, in which the same golden numbers occupy various days, corresponding, that is, to the thirty lines of epacts in the expanded table.

But since our cycle of epacts is fixed in the calendar, and epact * always clings to the Kalends of January — so that epact j would have to be placed at the last day of December if the solar year began there — it comes about that the beginning of the nineteen-year cycle of our epacts must always be taken either from epact * or from epact j, as has been shown.

[Margin: That the beginning of the golden-number cycle is taken successively from all the golden numbers, if the equation of the solar and lunar year is applied.]

5. The Alexandrians, moreover, always began their cycle from the last day of the year, which corresponds to the 28th day of our month of August; for at the first day of their year — that is, of the month Thoth, which corresponds to the 29th of August — they placed no golden number, because at that time no new moon fell on the first day of their year, but on the last, that is, on the 35th day of the month Mesore, which we have said corresponds to the 28th of August, where golden number 19 was placed, which was then equivalent to golden number 1. For at once on the next day, which gave the beginning to the following year, golden number 1 was taken in place of golden number 19, and so their cycle began from golden number 1. But in the old ecclesiastical calendar, while golden number 3 was running, the new moon fell — by the usage of the Church — on the first day of January, where that golden number 3 was placed; and therefore the cycle of the golden number always took its beginning from it, before the correction of the year, as we said above.

[Margin: Why every nineteen-year cycle of epacts always begins from * or from epact j.]

[Margin: That among the Alexandrians the golden-number cycle always began from the last day of their year, and from golden number 1.]

6. With this settled, let us take up the explanation of the embolisms. An embolism, then, is a lunar year in which thirteen lunations are contained — that is, 384 or 383 days, as we shall soon say. Nor should it seem strange to anyone that in a single year, which in the calendar contains only 365 days, there can be thirteen lunations, which make up 384 or 383 days. For since it was said above that lunations are assigned to the months in which they end — so that every lunation that begins in December and ends on any day of January is to be assigned to January and called the first of the whole year — it can happen that in certain years, after that first lunation, twelve whole lunations still remain before we come to the first lunation of the next following year; namely, if after the first lunation of some year there still remain 354 or 353 days, which are just enough to make up the number of days of twelve lunations. When this happens, there are thirteen lunations in that lunar year, and it is called an embolismic year, comprising 384 or 383 days, although the solar year in the calendar consists of only 365 days. But when, after that first lunation, only eleven whole lunations remain, only twelve lunations are contained in that lunar year, and it is called a

common year, containing 354 or 353 days, although the solar year in the calendar comprises 365 days.

[Margin: What an embolism is. In what way thirteen lunations can be contained in one year.]

7. And since the solar year written in the calendar, of 365 days, exceeds the common lunar year — which for the most part comprises 354 days (for it rarely comprises only 353) — by eleven days, we shall easily recognize which years, and how many, in any nineteen-year cycle are embolismic, that is, of thirteen lunations. For whenever, from those eleven days which remain in each solar year after twelve lunations have been completed, a sum of 30 is collected — or more, or even less, that is 29, as happens in the last, or nineteenth, year of the cycle — thirteen lunations will be completed in that year, and the year itself will be embolismic; because from that sum of days a single lunation of 30 days is made up, besides the twelve ordinary ones — except in the last year of the cycle, in which the sum of 29 days gathered gives a single lunation of 29 days, which, added to the other twelve lunations completed before it, makes thirteen lunations in that year. And this happens in any cycle only seven times, namely in the years 3, 6, 9, 11, 14, 17, and 19 of every nineteen-year cycle, which are all — and the only ones — embolismic, as is clear from the thirty tables of lunations above. For in each of them are found seven years of thirteen lunations; and the reason for this is as follows.

[Margin: Why in every nineteen-year cycle the years 3, 6, 9, 11, 14, 17, and 19 are embolismic.]

In the first three years of the cycle, eleven days are left over three times, which make 33 days; of these, 30 are given to the thirteenth, or embolismic, lunation of the third year, and 3 days still remain. These, joined to the three-times-eleven days remaining in years 4, 5, and 6, make up 36 days, of which 30 are again given to the embolismic, or thirteenth, lunation of the sixth year, and 6 days still remain. These, with the three-times-eleven days remaining in years 7, 8, and 9, make 39 days. From 30 of these, then, the embolismic lunation of the ninth year is completed; the remaining 9 days, together with the twice-eleven remaining in years 10 and 11, make up 31 days, of which 30 are assigned to the embolismic lunation of the eleventh year; and the 1 day left over, with the three-times-eleven days remaining in years 12, 13, and 14, makes 34 days, of which 30 go to the embolismic lunation of the fourteenth year; and the remaining 4 days, with the three-times-eleven surplus days in years 15, 16, and 17, make up 37 days, of which 30 complete the embolismic lunation of the seventeenth year; but the

remaining 7 days, with the twice-eleven surplus days in years 18 and 19, make 29 days, for the embolismic lunation of the nineteenth and last year. For one of the seven extraordinary lunations must necessarily comprise only 29 days, since in nineteen years the eleven days remaining in each year make up 209 days, which yield six lunations of 30 days each and one of 29 days — because it lacks one day to complete the number of 30. For 210 days would make seven lunations of 30 days.

[Margin: Why in a nineteen-year cycle one of the seven extraordinary lunations must contain only 29 days.]

Thus an embolismic year whose lunation contains 30 days will comprise 384 days, while one that has an embolismic lunation of 29 days will contain 383 days — because the 354 days of the twelve lunations, together with the 30 days of the embolismic lunation, make 384 days, but with the 29 days of the embolismic lunation make only 383.

[Margin: When an embolismic year is of 384 days, and when of 383.]

8. And this is the natural order of the seven embolisms contained in any nineteen-year cycle: that the first six embolismic lunations should each contain 30 days, while the seventh and last should contain only 29. This order, however, is usually altered, so that it is not always the seventh embolismic lunation that is of 29 days, but sometimes some other — the lunations alternating between 30 and 29 days requiring it so — because the nineteen-year cycle does not always begin from golden number 1, but from some other. For only two nineteen-year cycles of epacts, out of all thirty in the expanded table — the ones represented by lines 8 and 9 of that table, prefixed with the capital letters D and C — take their beginning from golden number 1. So in those cases the nineteenth year, which is the seventh embolismic year, will contain an embolismic lunation of 29 days. But in the other

[Margin: That only two nineteen-year cycles, out of all thirty in the expanded table, have the seventh embolismic lunation of 29 days.]

cycles the seventh embolismic year will have an embolismic lunation of 30 days, and the embolismic lunation of 29 days will be assigned to some other embolism — as will become clear from what we shall say a little later in this same chapter, once we have first explained somewhat more fully how these seven embolisms stand in each nineteen-year cycle of our epacts, which always begins either from epact * or from epact j, as has been taught above.

9. Whenever, then, the first lunation of some year ends on one of the first eleven days of January (and we have shown above, in no. 1 of this chapter, that every lunation ending in January, even on its first day, is assigned to January and is the first of the whole year), that year is necessarily embolismic. For if the first lunation ends on the 11th of January, there will remain in that year, up to the end of December, 354 days, in which twelve more lunations can occur; so that year will comprise thirteen lunations and will therefore be embolismic. But if the first lunation ends before the 11th of January, more than 354 days will remain in that year up to the end of December; and so twelve more lunations can occur in them, and some days besides will remain, or at least one — and therefore that year too will be embolismic, since it comprehends thirteen lunations.

[Margin: That the first lunation of an embolismic year ends on one of the first eleven days of January, and why.]

From this it follows that these eleven epacts — xix, xx, xxj, xxij, xxiiij, xxv, 25, xxvj, xxvij, xxviiij, xxix (we count xxv and 25 as one epact) — placed on the next eleven days after the Kalends of January, are always embolismic; so that a year whose epact is one of those eleven, whatever golden number is then running, is embolismic — because a lunation beginning in January from one of those epacts is the second of that year, while the first, preceding it, began in December and was completed on one of the first eleven days of January.

[Margin: That eleven epacts are always embolismic — that is, that the year is embolismic in which one of them runs together with any golden number whatever — and which those epacts are.]

From this, again, it is gathered that in any embolismic year the thirteenth, or last, lunation necessarily ends on one of the last eleven days of December, to which these epacts are assigned: *, xxix, xxviiij, xxvij, xxvi, xxv, 25, xxiiiij, xxiiij, xxij, xxj, xx, 19 — because if some lunation ends on any of those eleven days (except the last), the following lunation, which is the first of the next year after the embolism, begins from one of these epacts: xxix, xxviiij, xxvij, xxvj, xxv, 25, xxiiiij, xxiiij, xxij, xxj, xx, 19, which occupy the later ten days of December and are repeated in the same order after the first day of January. This is proof that, throughout the whole year whose last lunation ends on one of the later eleven days of December, that epact was in use from which the first lunation of the following year begins — that is, the one that, similar to this, is placed against one of the eleven days after the first of January. Since, then, all the epacts set against the first eleven days after the first of January are embolismic, as we said a little earlier, it is clear that a year whose last lunation ends on one of the later eleven days of December is

embolismic. Only when the last lunation of an embolismic year, while epact xix is running, ends on the last day of December (which indeed happens when epact xix and golden number 19 do not run together) does the first lunation of the following year begin on the first day of January, and from epact *, which is not embolismic, and not from epact xix, which is embolismic. The reason for this is that the year ends on the last day of December, and epact xix then changes, in the following year, into epact *. But if the year did not close on the last day of December, epact xix would have to be written against the day that now corresponds to the first of January — in the natural order, that is, below epact xx affixed to the last day of December — and so the first lunation after the embolismic year would then also begin from epact xix, which is embolismic.

[Margin: That the thirteenth lunation in an embolismic year ends on one of the last eleven days of December, and why.]

[Margin: That the first lunation of the year following an embolism always begins from some embolismic epact — except in the embolism in which epact xix does not run together with golden number 19 — and why.]

10. And so that it may appear more plainly that these eleven epacts — xix, xx, xxj, xxij, xxiiij, xxv, 25, xxvi, xxvii, xxviii, xxix — are all, and the only ones, always embolismic, all thirty lines of the epacts in the expanded table must be diligently inspected and considered. For in each of them you will always find seven of those eleven epacts placed at positions 3, 6, 9, 11, 14, 17, and 19 from epact * — if epact * is contained in the line taken — or from epact 1, if epact * is not found in the line taken. Since, then, every nineteen-year cycle of our epacts takes its beginning either from epact * or from epact 1, and in every cycle only these seven years — the third, sixth, ninth, eleventh, fourteenth, seventeenth, and nineteenth — are embolismic, as has been said, it is plainly concluded that those eleven epacts we have named, assigned to the eleven days of January following the first day, are embolismic. The same is gathered still more evidently from the thirty tables of lunations in the preceding chapter, in which all those eleven epacts have thirteen lunations and are therefore embolismic — and precisely in the aforesaid seven years; whereas the other epacts comprise only twelve lunations.

[Margin: How it may be recognized, from the expanded table and from the thirty tables of lunations, that the eleven epacts here enumerated are all — and the only ones — always embolismic, and that the seven years here enumerated are, in every nineteen-year cycle, all, and the only ones, embolismic.]

11. To these eleven embolismic epacts must sometimes be added epact xviii. For this too is embolismic in the year in which the golden number is 19 — which happens in only one cycle out of all thirty cycles of the expanded table, namely in the ninth, prefixed with the capital letter C. For in that cycle alone epact xviii occupies the nineteenth place from epact *, from which that cycle begins; and it has been shown above that the nineteenth year of any cycle is embolismic. In no other cycle is epact xviii found in an embolismic position — that is, at 3, 6, 9, 11, 14, 17, or 19 from epact * or from epact j, which is the beginning of the cycle.

Two reasons can be given why epact xviii is then embolismic. Let the first be this. When epact xviii and golden number 19 run together, 12 must be added to it, so that epact xxx, or *, of the following year is produced, as we showed in chapter 12, no. 14. So the last lunation of that year, in which epact xviii together with golden number 19 is in use, ends on the last day of December and must therefore be assigned to December. From this it follows that in that same year thirteen lunations are contained, of which the first ends on the 12th of January, having its beginning on the 14th of December, from epact vii, which was in use in the previous year. The twelfth lunation of the same year closes on the 2nd of December, and the thirteenth on the last day of the same month. Let the second reason be this. The year in which epact xviii and golden number 19 run together is the last of the nineteen-year cycle, as is clear from that ninth line of the expanded table, which has the capital letter C. So in that year the last, embolismic lunation will contain only 29 days, as we said above in no. 8. Therefore, since its first lunation ends on the 12th of January, 353 days still remain, which are enough to fill out twelve lunations, of which the last comprises only 29 days; and thus that year, containing thirteen lunations, will be embolismic and will comprehend only 383 days.

But when epact xviii runs together not with golden number 19 but with any other, 12 are not added to it,

[Margin: That the year in which epact xviii and golden number 19 run together is also embolismic, and why.]

[Text continues in the following section.]

but only 11 are added, so that epact xxix of the following year is obtained. Therefore, when the twelfth lunation of the year has ended on 2 December — epact xviii being in use — the first lunation of the following year will begin on 3 December and will end on the Kalends of January [1 January]. For this reason that earlier year, whose epact xviii will be common, will comprehend only 12

lunations, whereas the later year will be embolismic, of 13 lunations; for its epact will be xxix, which we said above is embolismic.

[Margin: The year in which epact xviii does not run together with golden number 19, and why it is not embolismic.]

Accordingly those eleven epacts — xix, xx, xxi, xxii, xxiii, xxiiii, xxv, 25, xxvi, xxvii, xxviii, xxix — set against the next 11 days that follow the first day of January, are always embolismic, with whatever golden numbers they run together. But epact xviii, set against 13 January, is never embolismic unless golden number 19 is used together with it. All this is perfectly clear from the 30 tables of lunations of the preceding chapter. For in the ninth table alone you see epact xviii, when running with golden number 19, have 13 lunations, whereas in all the others it has only 12. Hence epact xviii may be called ambiguous, or indifferent, since it is now embolismic, now not embolismic — while all the other epacts are perpetually either embolismic or common.

12. In the old Calendar these seven golden numbers were embolismic: 2, 5, 8, 11, 13, 16, 19 — as Campanus [Campanus of Novara] rightly teaches, though other computists differ somewhat from him.

[Margin: Which seven golden numbers were embolismic in the old Calendar.]

For since all [the epacts] are placed in the Calendar next to some of the 11 days that immediately follow the Kalends of January — that is, between the first day and the thirteenth of January — just as our 11 embolismic epacts are, the lunation most recently ended in the month of January before any of those 7 golden numbers (namely on the second, fourth, fifth, seventh, eighth, tenth, or eleventh day) will be the first of the whole year. After it, at the very least 354 days remain, which are enough to fill out the other 12 lunations, so that that year comprehends 13 lunations, the second of which takes its beginning in January. Therefore the year whose golden number is any of those seven will be embolismic.

[Margin: That in the old Calendar the cycle of the golden number necessarily took its beginning from 3.]

And since only seven years in any nineteen-year cycle are embolismic — namely the 3rd, 6th, 9th, 11th, 14th, 17th, and 19th — because in these alone the surplus days (which we said were left over in each solar year) can make up one extraordinary lunation, as we stated at no. 7 — it plainly follows that the cycle of the golden number in the old Calendar always took its beginning from golden

number 3, as we said above at no. 3. This is because those seven embolismic golden numbers, which we adduced a little earlier, counting from golden number 3 alone as the starting point, occupy the third, sixth, ninth, eleventh, fourteenth, seventeenth, and nineteenth places, as appears in this little table:

Ordo annorum Cycli [Order of years in the cycle]	1	2	3	4	5	6	7	8	9	10
Cyclus aurei numeri [Cycle of the golden number]	3	4	5	6	7	8	9	10	11	12
Aur. num. Embolifm. [Embolismic golden number]			5			8			11	1
Ordo annorum Cycli [Order of years in the cycle]	1	1	1	1	1	1	1	1	1	1
Cyclus aurei numeri [Cycle of the golden number]	1	1	1	1	1	1	1	1	1	2
Aur. num. Embolifm. [Embolismic golden number]	1			1			1		2	

[Margin: That in the old Calendar the cycle of the golden number could have had its beginning from no other number than 3.]

Moreover, that in the old Calendar the cycle of the golden number could have had its beginning from no number other than 3 will likewise become clear as follows. If golden number 3 is set as the first in the cycle, 11 days are left over in that year after the twelfth lunation; and 22 in the second year, with golden number 4 running; and 33 in the third year, with golden number 5 running — and therefore golden number 5 will be embolismic. By the same reasoning these golden numbers will be embolismic: 8, 11, 13, 16, 19, 2 — as Campanus held, and as the reckoning itself requires; for when these golden numbers are running, the first lunation of the year always ends on some one of the first 11 days of January, which is necessarily required if the year is to be able to be embolismic, as we said at no. 9. This would by no means come about if some other golden number were set as the first in the cycle. For if, say, golden number 1 were called the first, 11 days would then be left over; and with golden number 2 running, 22 would be left over; and 33 with golden number 3 running. And so golden number 3 would be embolismic. By the same reasoning golden numbers 6, 9, 11, 14, 17, 19 would be embolismic — which is false, and contrary to Campanus, most practised in this

matter, and repugnant to reason, since none of those 7 golden numbers, except 11 and 19, comprehends 13 lunations, as is evident and clearly established from the table of the lunations of the cycle of the old golden number, which we shall set out a little below. Therefore golden number 1 cannot be the first in the cycle; and for the same reason no other but 3 can be the first.

13. Now it is of no great importance which of the 13 lunations of an embolismic year is to be called the extraordinary, or embolismic, one — provided only that it is not the Paschal lunation, and that the magnitudes of the other 12 lunations, as the cycle requires, remain intact and unimpaired so far as can be: namely, that they be constituted alternately of 30 and 29 days.

[Margin: Which of the 13 lunations of an embolismic year is to be called embolismic.]

That this may be done more correctly, the following rule must be kept. Whenever, in an embolismic year, the last (or 13th) lunation contains 30 days, we shall call it the embolismic, or extraordinary, one — because then the 12 preceding lunations contain alternately 30 and 29 days, as the reckoning of the cycle requires.

[Margin: Which embolismic epacts have a 13th lunation of 30 days, and [make the year] embolismic.]

This happens when any of these embolismic epacts — xix, xx, xxi, xxii, xxiii, xxiiii — is in use, to which epact 25 (marked by a different character or colour) is to be added, as is manifest from the 30 tables of lunations of chapter 16 — provided that epact xix and golden number 19 do not run together. For then the 13th lunation of the year comprises only 29 days, as occurs in the 8th line of the expanded table, to which the capital letter D is attached, and to which the 8th of the 30 tables of lunations of the preceding chapter corresponds.

[Margin: When the embolismic epacts, whose 13th lunation is of 30 days, have a first lunation of the year of 29 [?] days.]

But if it should happen that those epacts are used together with golden number 1 — as occurs in lines 15, 16, 17, 18, 19, and 20 of the expanded table, which are marked with the small letters r, q, p, n, m, l, and likewise in the 6 corresponding tables of lunations —

[p. 340]

— corresponding (excepting epact 25, of a different character or colour, which can never run together with golden number 1, since it can run only with the larger golden numbers, namely those greater than 11), then both the first lunation of the year and the second will contain only 29 days. For since at that point 12 are added to the epact of the preceding year, which runs with golden number 19, so that the epact of the other year is produced, running with golden number 1 — as we showed at chapter 12, no. 14 — the first lunation of the year is necessarily made of only 29 days. And it happens that three continuous lunations are constituted of 29 days, namely those two first ones of the embolismic year, and the last of the preceding common year.

Therefore the first lunation of 29 days could indeed then be called embolismic, since it stands midway between two others of the same number of days; and rightly could only 29 days be assigned to the embolismic lunation of that year, seeing that the other 6 embolismic lunations of that cycle comprise 30 days, and that embolismic year comprehends only 383 days. Nevertheless, lest the other lunations of that year should disturb the order of 30 and 29 days, and lest the last, ordinary lunation — which is always wont to be of 29 days — should contain 30, it was decided to establish the last lunation, of 30 days, as the embolismic one; just as, after the manner of the old computists, one day is added to the embolismic lunation of that year (which ought to be of only 29 days), the day being subtracted from the first lunation of the year on account of the addition of 12 to the epact running with golden number 19. This subtraction the computists have called the Leap of the Moon, of which we shall say a little more below. Yet everyone is free, if he prefers, to call the first lunation, of 29 days, the embolismic one, since no absurdity follows from this.

[Margin: Epacts xviii and xix, running together with golden number 19, have a 13th lunation that is embolismic and of 29 days.]

Now when the thirteenth lunation of an embolismic year contains only 29 days, and that embolismic year is the last in the cycle — which comes about when both epact xix and golden number 19, and epact xviii and golden number 19, run together (which happens only twice in the whole period during which all 30 expanded tables of the cycle are used; namely when lines 8 and 9 of the same table, which are marked with the capital letters D and C, and to which the 8th and 9th tables of the lunations correspond, are in use) — then that last lunation of the embolismic year will be called embolismic, because the preceding 12 lunations are alternately of 30 and 29 days, and the last embolismic lunation in the cycle

must contain only 29 days, as is established from what we said above, since the other six embolismic lunations of that cycle comprise 30 days.

[Margin: Which embolismic epact has a first lunation of the year that is embolismic and of 29 days.]

But whenever the 13th lunation comprises only 29 days, while that embolismic year is not the last in the cycle — if the first lunation is likewise constituted of 29 days (which happens whenever any of these epacts — xxv, xxvi, xxvii, xxviii, xxix — and golden number 1 run together, as is evident in lines 10, 11, 12, 13, 14 of the expanded table, which have attached the capital letters B, A and the small letters u, t, f, and likewise in the 5 corresponding tables of lunations) — then that last lunation of 29 days will not be reckoned embolismic, but rather the first of that year, likewise of 29 days. For since then the last lunation of the preceding year too consists of only 29 days, not without reason will the first lunation of the following year, of 29 days, be called extraordinary and embolismic, since the other 12 that follow proceed alternately through 30 and 29 days — especially since that embolismic lunation ought to contain only 29 days, because the other six of the same cycle contain 30.

[Margin: When the same embolismic epacts, of which we have just spoken, have a second lunation that is embolismic and of 30 days.]

But if the first lunation is not of only 29 days, but both the first and the second comprise 30 days — as happens with any of those epacts we mentioned running (xxv, xxvi, xxvii, xxviii, xxix) with some golden number other than 1, as is plain from the 30 tables of lunations above — then the second lunation, of 30 days, will most rightly be called embolismic and extraordinary, since the other 12 preserve alternately the order of 30 and 29 days. Nor indeed ought it to seem strange to anyone that we do not always place the embolismic lunations in the same position and month; for these fall naturally according to the reckoning of the cycle, as we have explained, and were assigned various places and months by the old computists as well.

[Margin: The Leap of the Moon among the computists — what it is in common lunar years.]

14. Furthermore, whenever, on account of the addition of 12 to the epact running with golden number 19, one day is subtracted from the first lunation of a common lunar year, so that that year comprehends only 353 days — as happens in cycles 1, 2, 3, 4, 5, 6, 7, 21, 22, 23, 24, 25, 26, 27, 28, 29, and 30 of the expanded table, which have prefixed the capital letters P, N, M, H, G, F, E and the small

letters k, i, h, g, f, e, d, c, b, a, as may be seen in the corresponding tables of lunations (for in all these, and these alone, the year in which the golden number is 1 is common, and the first lunation of that year contains 29 days) — that subtraction is customarily called by the computists the

[Margin: When it can be said that in an embolismic year a leap of the Moon occurs.]

LEAP OF THE MOON: because, since in truth the lunar year consists of 354 days, one day is taken from it and assigned to the last embolismic year, so that it may contain 384 days and the individual 7 embolismic lunations may be constituted of 30 days — whereas the last embolismic year ought by its nature to comprise only 383 days, and its last embolismic lunation only 29 days. So that, on account of this subtraction, the Moon in the Calendar seems in a way to leap by one day, since that first lunation is constituted of only 29 days, though of itself it ought to comprise 30.

By the same reasoning, when in an embolismic year the first lunation, of 29 days, is embolismic, and the other 12 are constituted alternately of 30 and 29 days — as happens in cycles 10, 11, 12, 13, and 14 of the expanded table, which have prefixed the capital letters B, A and the small letters u, t, f, as is manifest in the corresponding tables of lunations — one might rightly say that a leap of the Moon occurs in that lunation: because, since the last lunation of the preceding year is of 29 days, the first lunation of the following embolismic year ought to be constituted of 30 days. So, since one day is subtracted from it and it is made embolismic, and the day removed is added to the last embolismic lunation of that same cycle so that it becomes 30 days — which otherwise ought to comprise only 29 — the Moon seems in a way even then to leap by one day in the Calendar.

Finally, when in an embolismic year the two first lunations comprehend only 29 days — as happens in cycles 15, 16, 17, 18, 19, and 20 of the expanded table, as may be seen in the corresponding tables of lunations — we shall also be able to say that a leap of the Moon occurs then in the first lunation, because from it, which ought to have 30 days, one day is taken and added to the last embolismic lunation of that cycle, so that it may contain 30 days, though it ought to comprise only 29.

Indeed, when in the last embolismic year of some cycle the thirteenth lunation is embolismic, of only 29 days — as occurs in cycles 8 and 9 of the expanded table, of the capital letters D, C, and in tables 8 and 9 of the lunations — one might not unreasonably think that then too a leap of the Moon occurs in a way:

[p. 341]

because, since the twelfth lunation of that year consists of 29 days, the following thirteenth ought, according to the reckoning of the cycle, to be constituted of 30 days, and the subsequent first lunation of the other year of only 29. Since, therefore, that lunation contains only 29 days, one day is taken from it and added to the first lunation of the following common year, so that it is made 30 days — which otherwise, as has been said, ought to be only 29 days.

[Margin: Which embolismic years contain only 383 days, and which common lunar years only 353 days.]

And all these embolismic years, in which a leap of the Moon occurs, contain only 383 days, while all the rest comprehend 384; but the common years, in which a leap of the Moon occurs, are constituted of only 353 days, while all the rest of 354, as is manifest from the 30 tables of lunations above.

15. From what we have said it can be made plain that a leap of the Moon occurs precisely when two or three continuous lunations of 29 days are strung together in the Calendar, and never otherwise. This indeed always happens when the golden number is 1, whether that lunar year be common or embolismic; because 12 are added to the epact of the preceding year running with golden number 19, so that the epact of the following year, running with golden number 1, is produced, as was said at chapter 12, no. 14. Two embolismic years are excepted, those of epacts xix and xviii running together with golden number 19. For in these a leap of the Moon occurs while golden number 19 is running, and not 1, as is clear from the 8th and 9th tables of the lunations.

[Margin: That a leap of the Moon always occurs when the golden number is 1, otherwise never, except in the embolismic years of epacts xix and xviii.]

I am not unaware that this leap of the Moon is little approved by most people, on the ground that no such leap at all takes place in the heavens. Nevertheless, since the reckoning of each cycle requires that one day be at times taken from one lunation and added to another, we have been unwilling to depart from the usual manner of speaking of the computists. Yet let everyone be free to speak in this matter as he wishes, provided only that the thing itself be rightly understood and explained.

[Margin: Why the leap of the Moon displeases most people.]

Hence too it is gathered that, on account of the embolisms and the leap of the Moon, the lunations do not always proceed alternately by 30 and 29 days, as their

condition and nature seem to require; but that sometimes two continuous lunations occur, now of 30, now of 29 days — indeed, at times three of 29 days — as is clearly established from the tables of lunations above. And, what may seem more surprising, it can happen in a bissextile year, on account of the intercalary day, that three or four continuous lunations comprehend 30 days.

[Margin: That, because of the embolisms and the leap of the Moon, it sometimes happens that two or three continuous lunations are of 29 days, and two, three, or four of 30 days.]

For when any of these epacts is running — *, xxix, xxviii, xxvii, xxvi, xxv — both the first and the second lunation of the year (provided the golden number is not 1) contain 30 days. The third lunation, ending either on the last day of February or on some one of the first five days of March, by its nature comprises 29 days, but on account of the bissextile an intercalary day is added to it, so that it too becomes 30 days, even though in the Calendar it contains only 29, since the intercalary day is not written in it. Since, then, the fourth lunation, having its beginning on some one of the first six days of March, also contains 30 days, it is clear that four continuous lunations then comprise 30 days. But if any of the aforesaid epacts runs with golden number 1, the first lunation of the year will indeed contain only 29 days, but the following three, if the year is bissextile, will comprise 30 days. Indeed — what may seem more absurd — a lunation beginning in February from any of these epacts — xxiiii, xxiii, xxii, xxi, xx, xix, xviii, xvii, xvi, xv, xiiii, xiii, xii, xi, x, ix, viii, vii, vi, v — which comprises 30 days in the Calendar, comes in a bissextile year to be of 31 days, on account of the intercalary day added to it.

But this, which has been said about two or more continuous lunations of 29 and 30 days, ought not to be reckoned novel or absurd, since the reckoning of each cycle requires it, and the same was done among the old computists in the cycle of the golden number of the Council of Nicaea [Nicaea], which was in force right up to this Gregorian correction, as is evident from the table set out below, in which all the lunations of the golden numbers of the old Calendar are described, just as in the 30 tables above the lunations of the epacts were expressed, as they occur in the 30 nineteen-year cycles. And from this same table it is clear that the seven embolisms of the whole cycle, which begins from golden number 3, fall in those years of the cycle into which, according to our epacts, we showed above that they fall. It is likewise established that golden number 19 makes three continuous lunations — namely the seventh, eighth, and ninth — of 29 days; while golden number 11, if the year is bissextile and therefore the lunation of the month of

February is increased by one day, exhibits the first four lunations of the year as of 30 days. Finally, golden numbers 1, 2, 4, 5, 7, 8, 9, 10, 12, 13, 15, 16, 18, 19, which in the Calendar have their lunations beginning in the month of February of 30 days, contain in bissextile years 31 days.

[Margin: That it is neither novel nor absurd that two, or more, lunations in succession should sometimes be of 29 or of 30 days.]

There follows a Table of the Lunations of the golden numbers described in the old Calendar.

Table: How many days each lunation of the golden numbers contains in the old Calendar, both in the common year and in the embolismic year

(Quot dies Lunatio quælibet aureorum numerorum contineat in Calendario veteri tam in anno communi, quam in Embolismico.)

The head of the numeric block is titled **NVMERVS ET ORDO Lunationum totius anni** — "The number and order of the lunations of the whole year." Its thirteen sub-columns are, in order, *Prima Lunatio ... Tertiadecima Lunatio* (First Lunation ... Thirteenth Lunation). Common years (length 354/383) fill only the first twelve; embolismic years (length 384) fill all thirteen. All date cells are transcribed exactly as printed: a bare day-number where the source prints no month, and with the printed abbreviation where present (Ian. = January, No. = November, Dec. = December).

Gol den no.	Begin. 1st lunar month	End 12th lunar month	End 13th lunar month (embol.)	Length lunar year

16. Suppose someone asks why it is that these lunations of the old Calendar do not correspond in every respect to the lunations of the first Table of Lunations in the preceding chapter, nor the golden numbers of that same old Calendar, set out in chapter 9, to the golden numbers of the first Calendar of golden numbers in chapter 15 — even though we hold that both the first Table of Lunations and the first Calendar of golden numbers agree with the times of the Council of Nicaea, just as the old Calendar does. The answer is that this arises from resolving the epacts into golden numbers. For since the epacts are so arranged in the Calendar that they make the lunations alternate between 30 and 29 days, it follows that the epacts of the time of the Council of Nicaea — the indicators of the new moons, comprised precisely in the first line of the expanded table — when they are resolved into golden numbers, display those golden numbers distributed through the days of the months in the same order in which you see them arranged in the first Calendar of golden numbers under the capital letter **P**; and with this arrangement the first Table of Lunations of the preceding chapter agrees. That this arrangement does not agree entirely with the golden numbers of the Council of Nicaea is no surprise. For since, on account of the embolisms and the *Saltus Lunæ* [leap of the Moon], the order of the lunations is interrupted, as we said at Num. 15 — and since the embolismic lunations and the *Saltus Lunæ* are not assigned to the same lunar months by all authorities — it comes about that the interruption of the lunations alternating between 30 and 29 days does not fall in

the same lunar months in every author. From which it follows that the golden numbers too are allotted one arrangement in the Calendar by one author and another by another. This is exactly what happens in our Cycle of epacts, if it is compared with the Cycle of the golden number in the old Calendar. And indeed, if we care to examine the matter more attentively, we shall find that the golden numbers of our first Calendar — which we hold to agree with the times of the Council of Nicaea — where they differ from the golden numbers of the old Calendar, generally indicate the new moons more correctly than the golden numbers of the old Calendar do, as the following little table shows. There we have computed the mean new moons for those years and months in which the golden numbers in our first Calendar disagree with the golden numbers of the old Calendar. We have taken the years next following the year 532, since from then on, by the practice of the Church, the golden numbers indicated the new moons more correctly, as was said at chapter 11, Num. 5. The twelve places in which the golden numbers of our first Calendar under the capital letter **P** (chapter 15) differ from the golden numbers of the Council of Nicaea are these. In February the golden Numbers **19** and **8** in our Calendar show the new moons one day later than in the old Calendar. The golden number **19** does the same in July, August, September, October, November, and December. Again, our golden number **16** at the end of September and of November, and likewise the golden number **5** at the beginning of October and at the end of November, show the new moons one day earlier than in the old Calendar. In the other places of the Calendar no difference at all is seen between the golden numbers of the two Calendars — so that for the Paschal new moons (which is the chief point) they keep exactly the same days in both Calendars. But here now is the promised little table.

[Margin: Why the Epacts in the expanded table do not display, for the times of the Council of Nicaea, the golden numbers as they are arranged in the old Calendar.]

[Margin: The 12 places in which the golden numbers of the new Calendar differ from the golden numbers of the old Calendar.]

Golden number s	Days to which the golden numbers are assigned in the old Calendar	Days to which the golden numbers are assigned in the new Calendar	Years of the Lord in which the aforesaid golden numbers were in use	Mean new moons in the aforesaid years
xix	3. Febr.	4. Febr.	550	2. Feb. H. 0 M. 35.

Golden numbers	Days to which the golden numbers are assigned in the old Calendar	Days to which the golden numbers are assigned in the new Calendar	Years of the Lord in which the aforesaid golden numbers were in use	Mean new moons in the aforesaid years
viiij	4. Febr.	5. Febr.	539	3. Feb. H. 20. M. 44.
xix	30. Iul.	31. Iul.	550	29. Iul. H. 4. M. 59.
xix	28. Aug.	29. Aug.	550	27. Aug. H. 17. M. 44.
xix	27. Sept.	28. Sept.	550	26. Sept. H. 6. M. 28.
xvj	1. Octob.	30. Sept.	547	29. Sept. H. 15. M. 18.
v	2. Octob.	1. Octob.	536	30. Sept. H. 11. M. 26.
xix	26. Octob.	27. Octob.	550	25. Oct. H. 19. M. 12.
xix	25. Nou.	26. Nou.	550	24. Nou. H. 7. M. 56.
xvj	29. Nou.	28. Nou.	547	27. Nou. H. 16. M. 46.
v	30. Nou.	29. Nou.	536	28. Nou. H. 12. M. 55.
xix	24. Decem.	25. Dec.	550	23. Dec. H. 20. M. 40.

From this little table it plainly appears that the golden number **19** of the old Calendar, in February, July, September, and November, shows new moons more conformable to the mean new moons than the same golden number of the new Calendar does; but that in the other months the same golden number in the new Calendar, together with the remaining golden numbers, exhibits new moons that differ less from the mean new moons than in the old Calendar. And so no one will justly find fault with the epacts in the Calendar, even though in twelve places they display golden numbers different from those in the old Calendar — since in

eight of those twelve places the golden numbers in the new Calendar show the new moons more correctly than in the old, as has been said.

17. For a fuller understanding of the embolisms as well, it has seemed good to append the following perpetual Table of the New Moons of the whole year, in which one may see at a single glance on what days of the months the new moons fall according to the Cycle, whatever epact is current: so that this table is, in a manner of speaking, the new Calendar reduced to a compendium, containing the beginnings of all the lunations according to the epacts, both in the common year and in the embolismic. Thus from this too the excellence of the Gregorian Calendar may appear — the Calendar in which, the golden numbers having been rejected, the epacts were put in their place; for by means of the epacts so small a table, embracing all the new moons in perpetuity, can be constructed, which cannot be achieved either by the golden numbers or by any other Cycle whose numbers do not fill every place of the Calendar. And since the year in which thirteen lunations are contained is embolismic, it plainly follows that these eleven epacts — xxix, xxviii, xxvii, xxvi, xxv, 25, xxiiii, xxiii, xxi, xx, xix — are embolismic, as we said above, since each of them contains 13 lunations in the following table. For the lunations of these epacts that begin in the month of January are the second lunation in the year; and those that begin in the month of December are the first of the following year — except epact xix, whose lunation beginning on 2 December is the last of the whole year. But when, epact xviii being current, the lunation beginning on 3 December is the last of the whole year (which indeed happens when golden number 19 is simultaneously in use), that year too is embolismic, as has been said. Finally, when epact * is current, the year is common, since it contains only 12 lunations, inasmuch as the lunation which begins on the Kalends of January is the first of the whole year, and not the second.

[Margin: The excellence of the new Calendar with the epacts.]

[Margin: In what way the embolismic epacts may be recognized from the perpetual Table of the New Moons.]

There follows the perpetual Table of the New Moons of the whole year.

Caput XVII (concluded)

PERPETUAL TABLE OF THE NEW MOONS of the whole year.

On what days of the months the new moons fall, whatever epact is current.

The table gives, for each epact (leftmost column, Epactæ) and each month of the year, the day of the month on which the new moon falls. A cell showing two numbers separated by a period (e.g. 1. 31) marks a month in which the new moon falls twice — on day 1 and on the later day. The rightmost column classifies the year: Cōis = *Communis* (common year), Embol. = *Embolismicus* (embolismic year, with thirteen lunations), Indiff. = *Indifferens* (indifferent). Alongside the lower epact rows (from xvii down to j) the frame carries the vertical side-label ANNI COMMVNES ("Common years").

The typographic distinction between Roman xxv and Arabic 25 in the epact column is as printed and is load-bearing (the doubled epact); their month rows differ. The epact-30 row is set with the asterisk sort *.

CAPUT XVIII.

What the fourteenth Moon is, and why the epacts are so arranged and adjusted in the Calendar that their new moons for the most part follow the mean and true conjunctions of the luminaries.

[Margin: A mistaken opinion of some, that Easter is not to be celebrated on the fifteenth Moon but afterward.]

Long ago, in the earlier sections, we established that Easter is to be celebrated after the fourteenth Moon [Luna xiiii] of the first month up to the twenty-first Moon — so that only a Sunday falling on the fifteenth, sixteenth, seventeenth, eighteenth, nineteenth, twentieth, or twenty-first Moon is fit and suitable for the celebration of Easter. We proved this in Chapter 1, both from the decrees of the Supreme Pontiffs and of the Councils, and from the various testimonies of distinguished writers and the perpetual usage of the Church. It is therefore astonishing that some of the more recent authors — who think themselves wiser and more discerning than those ancient Fathers and Councils — are not afraid to assert, so obstinately and against the continuous usage of the Church both Eastern and Western, that Easter must not be celebrated except after the fifteenth Moon, that is, after the full moon, even when it falls on a Sunday together with the fifteenth Moon. Their reason is that they suppose we then celebrate Easter together with the Jews. In this they are utterly deceived.

[Margin: How it was forbidden for the Christian Easter to be celebrated together with the Jews.]

For Christians were never forbidden to celebrate Easter on the fifteenth Moon, that is, at the mean full moon, even if the Jews are then performing the solemnity of their legal Passover. What was forbidden was only to celebrate Easter on the fourteenth Moon, when the Jews slaughter the lamb toward evening. Otherwise, if the fifteenth Moon — the mean full moon — fell on a Sunday, and one still had to wait for another Sunday, Easter would be celebrated on the twenty-second Moon, that is, in the fourth week of the lunar month. That conflicts with the rulings of the Councils and the Pontiffs, by which it was often laid down that Easter should be celebrated after the fourteenth Moon of the first month up to and including the twenty-first, as we showed fully in Chapter 1. In our own age we have more than once seen Easter celebrated, by the decree of the Council of Nicaea [Concilium Nicænum], on the 22nd of March — that is, on the fifteenth Moon, which the Cycle offered by golden number 16 — since the fourteenth Moon of the Cycle then necessarily fell on the 21st of March, before which day there can be no Paschal fourteenth Moon, as we showed in the same Chapter 1. Indeed, whenever the fourteenth Moon of the first month falls on a Saturday, Easter has been celebrated on the very next Sunday, that is, on the fifteenth Moon which the Cycle indicated. On this matter see what we discussed in Chapter 1, No. 7, where we cited 175 Easters that were celebrated on the fifteenth Moon from the Council of Nicaea down to this Gregorian correction.

[Margin: That the Church has frequently celebrated Easter on the fifteenth Moon.]

Now suppose someone should say that the fifteenth Moon derived from the golden-number Cycle in the old Calendar, in these times before the correction of the year, always followed the mean full moon by a full four days and more, because the new moons had advanced by so great an interval from their original seats toward the beginnings of the months; and that therefore Easter was not celebrated at that fifteenth Moon or at the mean full moon, but much later, even though it fell on the fifteenth Moon of the Cycle. If anyone, I say, should argue thus, the answer is that this happened by chance and (to speak with the philosophers) *per accidens*, because of that excessive anticipation of the new moons; whereas of itself, by its own nature, that Easter fell on the mean opposition — that is, if the new moons had then been restored to their proper places. But grant that Easter was never in our age celebrated at the mean full moon, but afterward, on account of that anticipation of the new moons: certainly near the times of the Council of Nicaea — as in the leap year A.D. 340, by the decree of that same Council — Easter was celebrated on the fifteenth Moon according to the Cycle on the 30th of March, since the golden number that year

was 18, placing the Paschal term, that is the fourteenth Moon, on the 29th of March. The Dominical letter after the intercalated day was E, assigned to the 30th of March; and the mean opposition finally occurred on the 29th of March, at about 9 hours after midday, and so was to be assigned to the following 30th day. The same thing happened in many other years, as is clear from the table of Chapter 1 — although sometimes Easter celebrated on the fifteenth Moon nearly anticipated the mean opposition, namely in the years 326, 330, 346, 350, 370, 441, 475, 495. This came about because the golden number was so distributed through the days of the Calendar at the time of the Council of Nicaea that the new moons were indicated too early, as I shall show below at No. 5.

2. Since, then, Easter must necessarily be celebrated on the Sunday that next follows the fourteenth Moon of the first month — and indeed on the fifteenth Moon itself, if that is then a Sunday — it must now be explained what that fourteenth Moon is, and how, according to the most ancient usage of the Church, it is to be sought in the Calendar, so that no error or dissension may arise in so great a solemnity. For there is no lack of people in our time who do not judge rightly on this matter.

[Margin: A mistaken opinion of some concerning the Paschal fourteenth Moon.]

Some suppose that the fourteenth Moon is the very day of the opposition of the Sun and Moon. But these men (as the saying goes) err by the whole heaven. For since Easter can be celebrated at the full moon, as the usage of the Church teaches, and the Decrees of the Fathers and the Councils, which we showed above; and since it was laid down by those same authorities that Easter should never be celebrated on the day of the fourteenth Moon but always after it — who is so blind as not to see (except those few who nonetheless want to be reckoned lynxes [Lyncei] in this business) that in God's Church the fourteenth Moon and the full moon are not the same thing? Read carefully what we wrote in Chapter 1, No. 7, where we cited many authors, both weighty and learned, ancient as well as recent, who plainly call the full moon the fifteenth Moon, not the fourteenth.

[Margin: Another mistaken opinion concerning the Paschal fourteenth Moon.]

Others, granting that Easter can be celebrated on the fifteenth Moon, that is, at the full moon, on account of the perpetual usage of the Church and the testimonies we brought forward in Chapter 1, too obstinately affirm that the fourteenth Moon is that day which next precedes the true opposition. But this is not true either, since the Church has never taken account of the true motions — nor indeed of the mean ones — but only of the Cycles, as we demonstrated fully

and copiously in Chapter 4. Indeed, if this view were true, it would be all over with every Cycle, since none could be found (as we shall say later) that can be so arranged in the Calendar that its fourteenth Moon always anticipates the true opposition, or even the mean one, by one day.

[Margin: What the Paschal fourteenth Moon is, according to the usage of the Church.]

3. The fourteenth Moon, therefore, is taken by the Church as the fourteenth day of the Paschal lunation, counting it inclusively from the new moon [Neomenia], that is, from the beginning of the Paschal lunar month — from that day to which is prefixed the number of the nineteen-year Cycle [Cyclus decennouenalis] which, in this scheme, indicates the new moons in the Calendar — whether that day agrees with the true or the mean conjunction of the Sun and Moon, or differs from it. This is confirmed by all who have written on the celebration of the movable feasts, and most clearly from the ancient table of Easter and of the other movable feasts, which always

the Church used before this correction of the year. In that table each golden number is prefixed to the day of March or April which is the fourteenth, counted inclusively, from the new moon that is shown in the Calendar by that same golden number, and after which the next arriving Sunday presents the most holy Easter. And this was always observed not only in the Western Church but also in the Eastern — which can be proved from the fact that never, before this restoration of the Calendar, did any dissension or variation in the celebration of Easter arise between the Easterns and the Westerns; and this could by no means have happened unless the fourteenth Moon had been taken in the same way, that is, reckoned inclusively from the new moon of the Cycle.

4. Although the Church, in seeking the new moon and the fourteenth Moon from it, considers neither the true motions nor the mean ones, but measures them solely according to the order of the Cycle, it must nevertheless be granted that the mean oppositions found from the astronomical tables are most useful for weighing and judging which Cycle, out of several, is to be chosen and described in the Calendar for tracking down the Paschal fourteenth Moons.

[Margin: That tables of the Moon's mean motion are useful for testing any proposed Cycle.]

[Margin: Which Cycle out of all is to be chosen.]

For that one is to be adopted out of all whose numbers, with the equation applied at their proper times, always so lay out in the Calendar the new moons — and from these the fourteenth Moons of the first month, for the right celebration of the most holy Easter — that no Paschal fourteenth Moon, reckoned inclusively from the new moon, ever runs ahead of the mean opposition by two or more days, but either by one only, or else falls on the mean full moon itself, or at least does not follow it by much.

[Margin: That the Cycle of Epacts is so arranged that the Paschal fourteenth Moons do not precede the mean oppositions by more than one day; and why.]

Yet the Church does not greatly trouble itself to search out the Paschal fourteenth Moon with such accuracy and diligence; for it is enough for the Church that everyone everywhere observe the day of the fourteenth Moon reckoned inclusively from the new moon of the Cycle, even if it sometimes anticipates or follows the mean opposition by more than one day. In our Cycle of Epacts, at any rate, we have striven with the greatest possible care and diligence to have it indicate, through the days of the Calendar, new moons that nearly follow the true and mean conjunctions of the luminaries by just so great an interval as suffices for the Paschal fourteenth Moons either to anticipate the mean oppositions by one day only, or to fall on them exactly, or finally to occur not long after them. Nor was this done by us rashly or by chance, but of set purpose and with great deliberation.

For if the first day of the lunar month according to the Cycle were the one on which the astronomical tables place the true new moon (what the Computists call the *Accension* of the Moon), and not the one that follows the astronomical new moon by about a day, more or less, it would often happen that we should celebrate holy Easter not only on the fourteenth Moon — that is, one day before the full moon, together with the Jews and the Quartodeciman [Quartadecimani] heretics, which would be absurd — but sometimes, what would be still more absurd, even before such a fourteenth Moon. This can be made plain as follows.

Let the mean new moon occur, for example, in some year at midday of the 8th day of March, where the Cycle sets the first Paschal new moon. On this supposition, the mean full moon will occur on the 23rd of March about sunrise — that is, 14 days, 18 hours, 22 minutes, 2 seconds after the mean conjunction; for so many days, hours, and fractions of hours necessarily intervene between the mean conjunction and the opposition, as we wrote in Chapter 8, No. 2. Since, then, the fourteenth Moon of that new moon falls by the Cycle on the 21st of March, Easter will then be celebrated on the 22nd of March, if that be a Sunday —

that is, a whole day before the mean opposition. Nearly the same absurdity would arise if the mean new moon, which occurs 12 hours before midday of the same 8th of March — that is, at the very midnight of the preceding day — were taken as the first day of the Paschal Moon. For its full moon will fall on the 22nd of March, at sunset, and so should rather be assigned to the following 23rd day than to the 22nd. Hence, if the 22nd were then a Sunday, Easter would again be celebrated about the mean full moon.

[Margin: If the new moon of the Cycle did not follow the conjunction that occurs in the heavens, Easter would often be celebrated before the full moon.]

Nor will this drawback be any better avoided if the day of the true new moon be called the first day of the Moon according to the Cycle. For since it is established by astronomical calculation that the true full moon can be $15\frac{1}{2}$ days and more from the true new moon — (let the example be the true new moon in the month of July of the past year 1600, in which we were writing this, which, according to the Ephemerides of Giovanni Antonio Magini [Magini], fell on the 10th of July, at $1\frac{1}{2}$ hours after midday; while the true full moon fell on the 25th, at 14 hours after midday, where you plainly see that the interval between the new moon and the full moon comprises $15\frac{1}{2}$ days and one hour besides) — who does not see that, if the true new moon then fell at midday of the 18th of March, the true full moon would occur on the 23rd at 14 hours after midday, and consequently, if the Sunday then fell on the 22nd of March, Easter would have to be celebrated before the true full moon?

By another example, which I shall add, the same matter will be more fully illustrated. In the year 1588 the true new moon occurred on the 26th of March, at 14 hours 49 minutes after midday — that is, on the 27th, about 9 hours before midday; while the true full moon occurred on the 11th of April, at 1 hour after midday. If, then, the epact xij of that year had been placed against the 27th of March (as some contend, considering the matter less accurately, so that the first day of the Paschal new moon found from the Cycle would not diverge from the day of the true new moon), the fourteenth Moon would have fallen on the 9th of April; and on the following 10th, since it was a Sunday, Easter would by the ecclesiastical decrees have been celebrated — that is, a whole day before the true full moon, which would be absurd. By skillful and prudent counsel, therefore, epact ij was assigned by us not to the 27th of March but to the 29th, even though the first day of that lunation follows the 27th, the day of the true new moon, by nearly two days — so that, precisely, its fourteenth day may not much anticipate the true full moon.

[Margin: Why the epacts in the Calendar were not advanced upward by one day, so that they would indicate the new moons earlier than they now do.]

But if those who think that by our epacts the new moons are put off in the Calendar more than is right — that is, indicated later than is proper — should object that epact ij ought to have been prefixed to the 28th of March, and not to the 29th, so that its new moon would be distant from the true one not by two days but by one only: I answer that this could by no reasoning have been done. For if that epact were to migrate from the 29th of March to the 28th, all the other epacts too would have to be advanced upward by one day, since they cannot be described in the Calendar in any other order than that in which we have described them, if the lunations are to be constituted alternately of 30 and 29 days, as the rule requires. And this advancement, if it were instituted — besides the fact that the Paschal fourteenth Moon would then fall on the 10th of April, and consequently would anticipate the true full moon by a greater interval than one day — would cause the new moons of many epacts to run ahead of the true conjunctions of the luminaries by a whole day, as clearly appears in the following table drawn from the Ephemerides of Giovanni Antonio Magini.

There follows the table.

TABLE

Drawn from the Ephemerides of Giovanni Antonio Magini [Magini]

This table sets side by side, for each entry: the year of the Lord, the month, the true new moon by Magini's Ephemerides (in days, hours, and minutes after midday), the epact current in that year, and — in the last column — the new moon that the epacts would indicate if they were advanced one day upward. The two panels below are read left panel first, then right panel; the years run continuously from one panel to the next.

The column headed **Nouilunia vera ex Ephemeridibus Magini** carries three sub-columns, **D.** (days), **H.** (hours), **M.** (minutes); these are given as three numeric columns below. The last column, **Nouilunia ex Epactis per vnum diem sursum promotis** ("New moons from the epacts advanced one day upward"), is here abbreviated **Promoted**. Epacts are transcribed exactly as printed (lowercase Roman, with i- or j-terminal sorts preserved).

Left panel (p. 348):

[Caput XVIII, continued]

[Margin: Explanation of the preceding table.]

In the first column of this table are set out the years of the Lord; in the second, the months; in the third, the days, hours, and minutes after midday at which the Ephemerides of Giovanni Antonio Magini [Magini] give the true new moons; in the fourth, the epacts current in those years; and in the fifth, finally, the new moons as they would be shown by those epacts if they were advanced one day. Here it is plainly established that these latter new moons are indicated by the epacts so advanced *earlier* than the former actually occur in the heavens. And indeed in certain years — for instance in November 1598, in December 1599, in April 1603, in June 1603, in October 1615, in February 1619, and in the month of June 1619 — this anticipation amounts to more than a whole day, which would be quite absurd. We have, moreover, passed over those true new moons (of which there is no small number) that occur at midday itself, or one or two hours after midday, on the same days on which they would be shown by the advanced epacts; and we have noted down only those that follow the epacts' new moons by several hours. And yet, as you see, within a span of less than 40 years there would be **128** new moons of the epacts — if these were advanced by one day — that fall earlier than the true conjunctions of the luminaries occur in the heavens. This would be contrary to the practice of all the nations among whom the lunar cycle has been in use. The epacts, therefore, are not to be advanced one day upward; and accordingly the epact ij is rightly assigned to the 29th of March, and not to the 28th.

5. The same absurdities would follow if someone, leaving the epacts in the Calendar arranged just as we have described them, in their correct order, were nonetheless to set up the equation table differently — namely, by prefixing to the year 1582, after the correction, not the capital letter **D** but the letter **E**. For then, as in the expanded table, the golden number 12 of the year 1588 would answer to epact iij on the line of epacts to which the capital letter **E** is assigned — whereas in fact that line answers to epact iij. The same absurdities, I say, would follow, because then the new moons

would be shown by the epacts one day earlier still, exactly as if the epacts had been advanced by one day, while the equation table remained untouched.

[Margin: That in the equation table the capital letter **D** is rightly assigned to the year 1582 after the correction, and not the capital letter **E**.]

Rightly, therefore, did we prefix in the equation table the capital letter **D** to the year 1582 after the removal of the ten days, and not the capital letter **E**, lest the new moons be indicated by the epacts in the Calendar earlier than they ought to be. In the same way we shall confirm that the other letters have been suitably prefixed to other years in the equation table — so that, if the equation were set up otherwise, the true new moons should not coincide with them, nor precede them (both of which are absurd), but rather (as is more in keeping with the practice of the Church) should follow them, so that the fourteenth Paschal moons may always, so far as can be done, anticipate the mean full moons by only a single day.

[Margin: That Easter, around the times of the Council of Nicæa, frequently fell as it were on the fourteenth Moon, because the new moons were shown too early by the golden number.]

Again, that it is not expedient for the new moons of the cycle to coincide with the mean or the true conjunctions, but rather more in accord with ecclesiastical usage that they should follow them, the golden-number cycle once inscribed in the Calendar can plainly teach us. For since, around the times of the Council of Nicæa, this cycle indicated the new moons on very nearly the same days on which they occurred in the heavens, the result was that most frequently Easter then fell on almost the fourteenth Moon — that is, it was celebrated before the mean opposition, contrary to the decrees of that same Council. I said "almost," because the day of Easter reached to within some hours of the mean opposition, so that it cannot be said absolutely that it was celebrated on the fourteenth Moon itself. This, indeed, can be avoided in no cycle whatever, as we shall show more fully in chapter 22, Number 4; but only in this respect does that cycle of the Council of Nicæa seem open to censure — that it too frequently set the day of Easter to be celebrated in this way, on account of that anticipation of the new moons. For the more rarely this error is committed (if it is to be called an error, since it cannot be avoided), the more perfect the arrangement of the cycle in the Calendar is to be judged. And this our cycle of epacts does excellently, as will be plainly established from chapter 22, where we have computed Easter for very many years. But see the following little table of eight years, in which, around the

times of the Council of Nicæa, Easter was celebrated before the mean and lawful time — especially in the years 326, 346, 475, and 496, in which the mean full moon fell after sunset on the day of Easter.

Anni Domini	Aurei Numeri	Literæ Dominicales	Pascha	[Opp.] D.	H	M

					2	5

The five columns are: the year of the Lord; the golden number; the Dominical letter; the day of Easter; and the mean Paschal oppositions (in days, hours, and minutes).

[Margin: Why, in the celebration of Easter, even after the Council of Nicæa, there were so many disagreements between the Eastern and the Western Church.]

In the first column are marked the years in which Easter was celebrated before the mean full moon, or at least not after it, but on those days whose full moons fall some hours after midday; in the second column are contained the golden numbers current in those years; in the third, the Dominical letters; in the fourth, the days of Easter; and in the fifth, finally, the mean Paschal oppositions. Here you see that this error — that is, this anticipation of Easter — was committed in 8 of a span of 170 years. So it is no wonder that there were still so many discords in the celebration of Easter, after the Council of Nicæa, between the Eastern and the Western Church, right down to the times of the Emperor Justinian, when the

golden-number cycle inscribed in the Calendar by the Abbot Dionysius [Dionysius Exiguus] more correctly [showed] the new—

Caput XVIII (continued)

the new moons, according to the practice of the Church, and the fourteenth Moons for Easter — but it displayed them later than they actually occurred in the heavens at the time of the Council of Nicæa.

6. There is a further point. Unless the new moons of the Epacts followed the conjunctions of the luminaries in the way that the Epacts (with the equation-table applied) display them in the Calendar, glaring and intolerable errors would very often arise in the celebration of Easter. The clearest possible example of this was the year 1598, which some people bring up to show that the Epacts do not present the legitimate fourteenth Moons for Easter — a matter on which they are remarkably mistaken.

[Margin: Many errors would arise in Easter if the Epact were to indicate the new moons earlier than the prescription of the new Calendar indicates them, especially in the year 1598.]

For suppose that, following the opinion of those who think that the new moons are indicated by the Epacts in the new Calendar later than the facts warrant, the individual Epacts were each moved up one day; or (what comes to the same thing) suppose the equation-table were set up so that in place of the line of the capital letter D, the line of the capital letter E were ordered to be taken in the expanded table. Then the Paschal new moon of that year, 1598, would have fallen on 5 April, where Epact 24 was then placed — if that promotion of the Epacts were carried out — or where Epact 24 stands, which would have indicated the new moons for that same year if the equation-table were constructed otherwise, so that the year 1582 after the correction had the capital letter E prefixed to it, and not the capital letter D. For the preceding new moon, which would then have fallen on 7 March, would not have been the Paschal one, since it falls outside the Paschal limits, as is clear from what we wrote in Chapter 1. On this supposition, Easter would have been celebrated on 19 April — that is, on the first Sunday after the fourteenth Moon, which would then have fallen on the 18th. Since, then, in that year the mean opposition occurred on 20 April at 9 hours 20 minutes after noon, but the true full moon on the 20th at 22 hours 39 minutes after noon (as Giovanni Antonio Magini's [Magini] *Ephemerides* would have it), the solemnity of Easter would have preceded the full moon — both the true and the mean — by

nearly two days. And that is contrary to the sacred Canons and to the Councils. The same can be shown to happen in various other years as well.

Now, to prevent such foul and shameful errors from being admitted in a matter of such solemnity, the Epacts have been arranged in the Calendar by the soundest counsel, and their equation set up in such a way, that the Epact for the year 1598 is 23, placed against 8 March. For on this arrangement the Paschal new moon of that year falls on 8 March, and its fourteenth day on the 21st; and Easter therefore had to be celebrated on the following day, the 22nd, which was a Sunday — the fifteenth Moon, that is, which fell on the mean opposition, since that opposition occurred on the 21st at 20 hours 36 minutes after noon, that is, on the 22nd about four hours before noon. Nor is it any objection to the correct celebration of Easter that year that the true full moon then occurred on the 22nd at 9 hours after noon; for in this matter the Church subordinates the true motions to the mean, as we showed in Chapter 4. Besides, it is enough that this Easter fell in a way upon the true full moon, since the 22nd, on which Easter was celebrated, lasted (according to the astronomers) until the noon of the following day, the 23rd.

[Margin: That some people wrongly judge that the Easter of the year 1598 ought to have been thrown back from 22 March to the 29th.]

But I am utterly astonished that there have not been wanting people who — seeing that the March new moon was the Paschal one that year, and not the April new moon (for the latter, by the mean motion, occurred on 5 April at about 15 hours after noon, and the mean opposition on 20 April at 9 hours after noon, both outside the Paschal limits; whereas the former occurred on 7 March at 20 hours 13 minutes after noon, and its mean opposition on the 21st at 20 hours 36 minutes after noon, which falls within the limits) — nevertheless claimed that Easter that year ought to have been thrown back to 29 March on account of that true opposition. For if that March new moon is the Paschal one, as it truly is (even on the testimony of the very detractors and adversaries — a thing which the Epact 23 of that year displays on 8 March, with its fourteenth day on the 21st), then the Church, if it meant to stand by the decrees of the Councils and the Fathers and by long-established custom, could not but celebrate Easter on the 22nd, since that was the Sunday next following the fourteenth Moon which the Cycle displays. For we have never read or heard that the Church ever postponed Easter beyond the fifteenth Moon of the Cycle (when that Moon falls on a Sunday) into another week — namely the fourth — and so onto the twenty-second Moon, since that is altogether repugnant to the ecclesiastical decrees. Nor, to defend

themselves, can they say that the Church ought to have thrown that new moon back to 9 March. For on that reckoning its fourteenth day would have fallen on 22 March, that is, on a Sunday, and Easter, by the decrees of the Fathers, would accordingly have been transferred to the following Sunday, the 29th. And they cannot, I say, argue in that way, because in that case either Epact 24, along with all the others, would have to be rolled down by one day, or (what is the same) Epact 22 would have to be taken in place of Epact 24, and therefore in the equation-table the letter C, capital, would have to be prefixed to the year 1582. And that is absurd, since on this reckoning the new moons of the Cycle would follow the celestial conjunctions too late — whereas to most people, and indeed to some even of our own adversaries, they appear to be shown by the Epacts, as arranged in the new Calendar, later than they should be. What, then, would they say if they were postponed by a full day still further?

[Margin: New moons placed too late cause Easter sometimes to be celebrated in the last month.]

There is this further point: if the new moons were postponed still more, Easter would not seldom be celebrated in the last, that is the twelfth, month. For it could then happen that some mean full moon fell on the very day of the equinox — that is, on 21 March — or preceded it, and that therefore that lunation belonged to the last month and not to the first (since the full moon of the first month must follow the day of the equinox: for the fourteenth Moon of that same first month, which precedes the full moon by one day, must never precede the day of the equinox, as we taught in Chapter 1). Yet a Cycle postponed more than is right would present it as the Paschal lunation — namely when its new moon fell on 8 March, and so its fourteenth day on the 21st, on the equinox itself. And this arises solely from the postposition of the new moons. For it follows from this that a mean new moon, anticipating the Cycle's Paschal new moon by two days or more, can have its full moon on the very day of the equinox, or before it, and must therefore be assigned to the last month, even though the Cycle ascribes that new moon to the first month. It is settled, then, that Easter in the year 1598 was, according to the practice of the Church, rightly celebrated on 22 March.

7. Since this is so, who would fail to understand that the Epacts are indeed properly arranged in the new Calendar? And who could with any justice presume to accuse us — except one utterly ignorant of ecclesiastical custom and of the use of the Cycles — because we placed the new moons that are to be sought by the Epacts *after* the new moons found by the astronomical tables? We did so precisely to avoid falling so often into the error I mentioned — that is, so as not to

celebrate Easter so frequently before the roughly mean opposition, as used to happen at the time of the Council of Nicæa.

[Margin: The arrangement of the Epacts in the Calendar cannot rightly be criticized.]

And this holds all the more since even so we could not entirely escape our own Cycle of Epacts occasionally offering Easter for celebration before the roughly mean opposition —

[Margin: Rarely in the new Calendar is Easter celebrated before the mean opposition; so much so that it almost does not reach it at all.]

though this happens very rarely indeed. As will be clear from Chapter 22, in the 908 years after the correction-year 1582 it happens only once, namely in the year 2133; and at most, in the span of 3418 years, up to the year 5000, fifteen times — whereas (as we said at Num. 5) near the times of the Council of

Nicæa this happened eight times in 170 years — and even so the many new moons shown by the same Cycle in the Calendar agree with the celestial new moons: namely all those which above, at Num. 4, we said would fall before the true conjunctions, if the individual Epacts were each moved up one day toward the beginnings of the months.

I said that Easter is *sometimes* — though rarely — celebrated before the roughly mean opposition, because if we wish to speak simply and without qualification, Easter does not then anticipate the mean opposition entirely, in such a way as not to reach it at all in some measure; for on the very feast of Easter the mean opposition nearly falls, as will be clear from the table in Chapter 22.

[Margin: No Cycle can avoid every inconvenience.]

Certainly, if anyone wishes to be so severe a judge of the Epacts, he ought to reckon with himself that no Cycle described in a Calendar can avoid every inconvenience — so that, that is, its new moons should neither disagree with the celestial new moons, nor should the oppositions, true and mean, of its fifteenth Moon ever occasionally come before them. Witness the Cycle of the golden number, approved by the Council of Nicæa: for while, around the time of that Council, it displayed the new moons on nearly the same days on which they occurred in the heavens, its Paschal fourteenth Moon often preceded the mean opposition by two days, and on that account Easter was not seldom celebrated before the roughly mean opposition, as we said a little earlier. Witness too our own Cycle of Epacts: for while our adversaries strive to place it in the Calendar in

such a way that its individual numbers are each moved up one day, so that they may not indicate the new moons too late, this forces many new moons to run ahead of the celestial new moons, as was said at Num. 4. And witness, finally, this same Cycle of Epacts of ours as described in the new Calendar: while it aims to guard against its Paschal fourteenth Moons preceding the mean oppositions by two days, it generally indicates the new moons as coming *after* the celestial conjunctions; yet not even with this precaution applied in the postposition of the new moons can it entirely escape its fourteenth Moons occasionally anticipating the mean full moons more than is right, and thus forcing Easter to be celebrated a little before the mean opposition. And if anyone should judge that the new moons ought on that account to be postponed still more, so that the fourteenth Moons might never be presented too far in advance of the mean oppositions, he will fall into greater inconveniences. For, first, the new moons of the Cycle would then stand too far from the celestial new moons, and would be shown in the Calendar later than is right. And then Easter would not seldom be celebrated in the last, or twelfth, month, and not in the first, as was explained at the end of Num. 4.

[Margin: The Epacts of the new Calendar hold to a middle course in the anticipation and postposition of the new moons.]

You see, then, how excellently our Epacts have been handled in the new Calendar, seeing that it has been demonstrated that they hold, as it were, a middle road between the two extremes: so that their new moons neither anticipate the celestial new moons too much, nor follow them too far, but proceed at a certain middle pace. What could be devised more excellent than this in the whole business?

[Margin: The Epacts could not be better placed than has been done in the new Calendar.]

Indeed I have always been of this opinion, and I hold it still: that the Epacts cannot be arranged and described in the Calendar otherwise, nor their equation set up otherwise, than has been done in the Gregorian Calendar — unless we are willing to run into errors all but countless and intolerable, and to keep the most sacred day of Easter, most frequently, contrary to the Canon of the Council of Nicæa and the decrees of the Fathers. And there is no one who does not see that everyone finds this expedient. Nor should it trouble us that occasionally, as we said, the new Calendar presents fourteenth Moons somewhat earlier, before the mean oppositions, than the whole reckoning would give; because in our Cycle this error, which can in no way be avoided, is both extremely rare (if it be

compared with the errors of the other Cycles, which are very frequent) and is often corrected by the Dominical letter.

[Margin: The error of the fourteenth Moon, by which it anticipates the mean opposition more than is right, is often corrected by the Dominical letter.]

For it happens that Easter is not always in that case celebrated before the mean opposition, because the Sunday does not immediately follow that fourteenth Moon, but falls on the mean opposition, or occurs after it. By this means it comes about that Easter is then celebrated either on the mean opposition itself, or after it, even though the fourteenth Moon anticipates the mean opposition more than is right — this on account of the imperfect nature of the Cycle, which is common to all Cycles, and in ours indeed less imperfect than in the rest.

8. There are many reasons why no Cycle can respond exactly to the celestial motions, but always brings some inconveniences with it.

[Margin: Why no Cycle can fully correspond to the celestial motions.]

First, because in the lunations of the Cycle, which are nearly always constituted alternately of 30 and 29 days, several fractions are here neglected, since one mean lunation does not contain a full 30 or 29 days, but 29 days 12 hours 44 minutes 3 seconds 11 thirds.

[Margin: Why the lunations in a leap year, after the intercalary day, are slower than they ought to be.]

Second, because since in the lunations of the Cycle no account is taken of the intercalary days in leap years, it comes about that sometimes a lunation begun in February, which ought to complete 30 days, is made to be of 31 days; and the lunations of the whole leap year — the first two months excepted — for the most part begin in the Calendar later than is right, on account of that intercalary day, which is not entered in the Calendar. Third, because, on account of the equation of both the solar and the lunar year, one must in certain years pass from one line of the expanded Epact-table to another, whether lower or higher (as is evident from the equation-table of Chapters 11 and 12; and this must also be learned from the Cycle of the golden number, since it too, for the same reason, must now be moved up, now down), it comes about that the magnitudes of the lunations are considerably altered and disturbed. For — to pass over other inconveniences — when a lower Epact, smaller by one unit, has to be taken, a lunation of 30 days will contain 31; and when a higher one, the same lunation will be made to be of 29 days. Fourth, because the mean conjunction of the luminaries, to which the

Cycle ought rather to conform than to the true conjunction, can precede and follow the true conjunction by several hours; so that it should be no wonder if the new moons and full moons of the Cycle diverge from the true conjunctions and oppositions. This variation is increased by the difference and dissimilarity of the meridians, on account of which the same conjunction which at Rome, say, occurs at noon itself, must for more easterly peoples fall several hours after noon, and for the more westerly, before noon.

9. That the new moons found from the Cycle ought rather to *follow* the conjunctions of the Sun and Moon that occur in the heavens, than to accompany them, we can also confirm by the authority of the weightiest writers.

[Margin: When, according to Bede, the Moon should be called the first.]

For the Venerable Bede [Bede], a man most experienced in this matter, in his book *On the Reckoning of Time* [*De ratione temporum*], Chapter 41, asserts that the Moon is not to be called "first" on the day on which it is conjoined with the Sun, but on the following day — even though the conjunction occurs 23 hours before sunset, at which (in his reckoning) the day begins. You see, then, that the Moon can be called "first" according to the Cycle — in Bede's view, a most careful writer on the correct celebration of Easter — even though the Sun has been conjoined with the Moon a full day, and more, earlier.

[Margin: When, according to Campanus, the Moon should be called the first.]

Campanus [Campanus] enjoins the same in his *Greater Computus* [*Computus maior*], Chapter 28, in these words: "The Moon ought to be called first, not on the very day of its conjunction with the Sun, but on the day immediately following, when it just then begins to appear as a beginning." Here too he plainly teaches that the new moon of the Cycle must follow the conjunction of

the Sun with the Moon by a full day. In the same opinion were most of the ancient Fathers, but especially Theophilus, Bishop of Alexandria [Theophilus of Alexandria], whose authority in this matter of Easter carried such weight with the Roman Pontiffs that the Western Church for many years celebrated Easter according to his computation and prescription — as is clear from the letters of that great Pope Leo [Leo I] to the Emperor Marcian [Marcian] and to the Empress Eudoxia [Licina Eudoxia].

[Margin: Which is the fourteenth Moon according to Theophilus and St. Cyril.]

Now this Theophilus, as St. Cyril [St. Cyril of Alexandria], his successor in the bishopric, reports, judged (as Paul of Middelburg [Paul of Middelburg], Johannes

Stöffler [Johannes Stöffler], and other computists testify) that the Moon which, by the Cycle and the practice of the Church, is to be called the fourteenth is the one which others, from the astronomical tables, called the sixteenth from the conjunction; and this same opinion St. Cyril strives with all his might to confirm. From which it sufficiently appears that he did not take the first Moon, for the celebration of Easter, to be on the day on which the Sun is conjoined with the Moon, but nearly two days after.

[Margin: Rightly do the Epacts of the new Calendar indicate the new moons after the mean conjunctions.]

And so our Epacts have been handled not unhappily, since they have been so distributed in the Calendar that their Paschal new moons generally *follow* the conjunctions — now by fewer hours, now by more, as the nature of the Cycle bears, and as that arrangement of alternating lunations of 30 and 29 days allows. For in this matter we have both imitated those ancient Fathers and, by preserving that arrangement of the Epacts, Easter is celebrated at a more fitting time — as is clear from what we have said, and will be clearer still from Chapter 22, when we treat of the movable feasts.

10. Finally, that it is neither absurd nor new nor unheard-of in the Church of God to call a Moon the "first" — that is, to call it the first day of the lunar month — when the conjunction of the luminaries in the heavens has already preceded by a full day and more (so that that Moon should already be called the second day, or the second day of the lunar month) — this a man will readily persuade himself of, if he has considered a little more carefully that, even in the civil solar year, a certain day is sometimes called the "first" which more truly ought to be called the "last" of the year;

[Margin: That in the civil solar year that day is sometimes called the first which more truly would be the last.]

and likewise that, in the months of the solar year, a certain day is sometimes called the "last" of one month, which in fact ought to be the first of the following month.

[Margin: That a certain day is sometimes called the last of one month, which more truly should be called the first of the following month.]

This is clear as follows. Suppose the Sun on the first day, say, of January, in the first year after a leap year, after the completion of 365 days, cannot at noon of that same first day return to the same point, but returns to it only about 6 hours

later — the hours which in common years are neglected as a day — namely toward sunset. In the second year, it returns about 12 hours later, toward the following midnight; and in the third, 18 hours later, that is, toward the sunrise of the second day of January. That second day, then, would more rightly be called the "first" day of January, since the Sun then completes the period of its course; and yet we still name it the first day of the year, whereas it ought more truly to be reckoned the last day of the preceding year.

Again, suppose the Sun on the first day, say, of March, in the third year after a leap year, at 6 hours before noon — that is, about sunrise — holds a certain fixed point in the heavens. It comes about that in the following leap year, on account of the added intercalary day, it returns to that same point on the last day of February, which then has 29 days — not at sunrise, but nearly 6 hours later, that is, about noon. This last day of February, then, would rightly be called the first day of March, since on it the Sun has returned to the same point of the heavens where we had placed it on the first day of March of the preceding year; and yet we still call that same day the first of March, which more truly ought to be called the second.

[Margin: That day is sometimes called the last of some month which more truly ought to be called the first of the following month.]

And so, as you see, we are sometimes forced to call some day in the civil solar year the "first" or the "second," which nevertheless is off from the first or the second by 6 hours, or 12, or 18; and we tolerate this error until, at the completion of four years, it is corrected by the intercalation of a single day. Why then should we wonder if, in the civil lunar year — on account of the hours and fractions of an hour omitted in a single lunation, and on account of the added day in a leap year, and finally on account of other causes — the Church is forced sometimes to pronounce a Moon "first" which more truly would be the second, and tolerates this error until it is compensated by the embolisms and the other lunar equations? But this will be better understood from what follows: that the Epacts have been rightly arranged in the Calendar.

CAPVT XIX.

Various doubts are resolved concerning the description of the Epacts in the Calendar, and their equation; and at the same time it is further confirmed that the Epacts have been most correctly described in the Calendar, and equated.

That it may be understood more clearly that the Epacts are correctly arranged in the Calendar and equated, I think it will be worth the effort if I briefly dissolve and refute the objections that some are accustomed to raise against them — although I do not see what arguments could be brought that would not be easily resolved from what we have said thus far.

[Margin: First argument against the Epacts.]

First, some accuse the Epacts on this ground: that the new moons and full moons found from them do not agree entirely with the true or mean new moons and full moons, but that the former nearly always fall before the latter.

[Margin: Solution of the first argument.]

But this argument is of no weight. For we freely and readily grant that the Epacts' new moons generally follow the celestial conjunctions; and we disclosed the reason why this must of necessity be so in a Cycle in the preceding chapter, at Num. 8. But although the Cycle of Epacts deliberately postpones the new moons for the sake of the correct celebration of Easter, it nevertheless does not allow them to stand far from the true ones — so that it is worth while to know them even as thus postponed;

[Margin: That the Cycle of Epacts shows, in the Calendar, how many days have usually elapsed after the true conjunction.]

especially since from the Cycle we learn how many days the Moon usually has after the true conjunction, so that when the Moon is called first, second, third, fourteenth, and so on, we understand that it is roughly the first, the second, the third, the fourteenth day, and so on, elapsed since the conjunction.

2. Others, next, object — on account of the equation-table set out in Chapters 11 and 12 — that the Paschal full moons of very many years in the new Calendar belong to the second month, although they are nevertheless ascribed to the first month.

[Margin: Second argument against the Epacts.]

To confirm this they adduce these years: 1609, 1628, 1647, 1666, 1685 — in all of which the golden number is 14.

(Caput XIX continues; the second argument against the epacts is still being stated.)

is 14, and the epact 24, whose Paschal term [*terminus paschalis*] is 18 April. For in all these years, they say, the calculation shows that the 14th Moon [*Luna XIV*]

belongs to the second month. They throw the cause of the error onto the equation-table [*tabula æquationis*] of the epacts and of the lunations, and onto the unequal anticipation of the lunations and of the equinox — since the latter anticipates by one day sooner than the former. For they do not understand how it can come about that from the year 1582 up to 1700 exclusive the golden number [*aureus numerus*] 14 — exhibiting, according to the equation-table, the epact 24 — should place the Paschal 14th Moon on 18 April, establishing that it belongs to the first month; whereas from the year 1700 up to 1900 exclusive the same golden number 14 — exhibiting the epact 23 — should advance the Paschal 14th Moon from 18 April to 21 March, exactly as if that earlier Moon no longer belonged to the first month but to the second.

Indeed, they assert that much grosser absurdities follow in the years after that, for the same reason. For from the same year 2200 up to 2300 exclusive the golden number 17 exhibits, according to the equation-table, the epact 24, and places the Paschal 14th Moon on 18 April. But from the year 2300 up to 2400 exclusive the same golden number 17 indicates the epact 23, and therefore advances the Moon of Easter to 21 March. Then, from the year 2400 up to 2500 exclusive, the golden number 17 once again exhibits the epact 24, and the Paschal term on 18 April, as it did before from 2200 up to 2300.

And so — they say — the new Calendar, in those years in which the golden number is 17, from the year 2200 up to 2300 exclusive, reckons that the 14th Moon in March will always precede the equinox, and therefore that it cannot be Paschal; but that from the year 2300 up to 2400 exclusive it will come about that this same 14th Moon of March falls either on the equinox or after it, and therefore cannot but be Paschal. And finally, from the year 2400 [up to 2500 exclusive], that the 14th Moon of March will run ahead of the Sun's entry into Aries, and so will cease to be Paschal — all of which seems to them utterly false. For how, they ask, can it happen that the equinox, whose anticipation is always faster than the anticipation of the lunations, should soon again strip the 14th Moon — which had begun to be the Paschal term — of that office? This, they say, is surely a most absurd thing, being altogether unheard of, and diametrically opposed both to the whole of astronomy and to truth.

By a similar argument they strive to demonstrate that many Paschal terms in the new Calendar belong to the last month, though the epacts nonetheless assign them to the first month. For since it was said near the end of Chapter 6 that the vernal equinox can recede from 21 March up to the 23rd, if the prescribed equation is applied, it will be possible for any 14th Moon that falls between 20

March and the true day of the equinox after the 21st to be taken by the new Calendar as a Paschal term — even though such a 14th Moon does not belong to the first month of the following year but to the last month of the preceding year, since the vernal equinox comes after it.

3. [Margin: Solution to the second argument.] Since this argument seems to strike at the head of the whole Gregorian correction, it must be refuted somewhat more carefully. The adversaries who assail the new Calendar with this argument evidently accuse all the mathematicians of the whole world — who confess with one voice (as the matter itself declares) that the equinox, once it has advanced toward the beginning of the month, cannot be restored to its former seat except by removing from some year as many days as it is found to have advanced toward the beginning of the month. Yet the adversaries, drawing on some new breed of astronomers, reproach the new Calendar on this very ground: that by omitting the intercalary day in certain hundredth years (which is to take one day out of the year) it restores the equinox to the day from which it had receded. Why, in the end? Because, they say, from this removal of a day it follows that a 14th Moon which before was Paschal soon ceases to be Paschal, and one which before could not be Paschal soon cannot but be Paschal. A great sin indeed! — and to avoid committing it, the equinox must never be recalled to its own seat, however far it has slipped toward the beginning of the month, since it cannot be recalled in any other way. Fine mathematicians, truly, who — in order to convict the new Calendar of being crammed with countless absurdities and manifold falsehood — hold that every correction of the year whatsoever, however it might in the end be devised, must be rejected! For in any correction of the year it is necessary that several days be removed, so that the equinox may return to the day from which it had departed toward the beginning of the month — which seems absurd to them, and in no way to be granted. For if they admitted this removal, they would at last necessarily concede, willing or not, that a 14th Moon which now, while some particular number of the Cycle is running, is Paschal, will soon, after the elision of one day, no longer be Paschal — and the reverse. And by what reasoning this can happen I shall not be reluctant to teach them here, if they are willing to learn, since they confess that they are ignorant of it. This, then, is how the matter stands.

4. [Margin: When a transit is made from an upper line of the expanded table to a lower one, the Paschal new moon of 5 April ceases to be Paschal, and the non-Paschal new moon of 7 March begins to be Paschal.] Whenever a transit is made from some line of the epacts of the expanded table to a lower line — as necessarily happens in the hundredth years that are not bissextile, in which

nevertheless the Moon is not to be equated — then, if to some golden number there corresponded in the earlier line the epact 23, the new moon of that golden number [fell] on 5 April, where the last Paschal new moon lies; but the new moon of the same golden number on 7 March was not Paschal. In the later line, however, the new moon of the same golden number in April will no longer be Paschal, since that same golden number in the lower line then corresponds to the epact 24, which has its 14th Moon on 9 April and its new moon on 6 April — beyond the Paschal limits, of course. Yet the same golden number will then have its Paschal new moon in the month of March, because the epact 23 that corresponds to it is placed at 8 March, where the beginning of the Paschal new moons is. You see, then — unless perhaps you wish to be blind — that the new moon of that golden number is Paschal in the month of April while the upper line of epacts is in use, but ceases to be Paschal when the lower line of epacts is employed? And likewise that the new moon of the same golden number in the month of March, while the earlier line of epacts is in use, is not Paschal, but begins to be Paschal when the later line of epacts serves? That this is not absurd, as the adversaries suppose, but altogether necessary, astronomical reasoning will clearly persuade you. For when the intercalary day is omitted in some hundredth year, if the Moon does not then need equating, all the new moons descend one day in the Calendar toward the ends of the months. Therefore the new moon that previously fell on 5 April is Paschal, but afterward, falling on 6 April, ceases to be Paschal. Conversely, a new moon falling previously on 7 March is not Paschal, but afterward, falling on 8 March, becomes Paschal.

5. [Margin: When a transit is made from a lower line of the table to the one above, the Paschal new moon of [8?] March ceases to be Paschal, and the non-Paschal new moon of 6 April begins to be Paschal.] Again, whenever a step is made from some line of the epacts of the expanded table up to an upper line — as necessarily happens in the hundredth bissextile years, in which the Moon is to be equated — then, if to some golden number there corresponded the epact 23 in the lower line, the new moon of that golden number will be Paschal on 8 March, where the Paschal new moons begin; but the new moon of the same golden number

on 6 April was not Paschal. In the upper line, however, since that same golden number now indicates the epact 24, the new moon of that golden number, falling on 7 March, ceases to be Paschal, while another, falling on 5 April, is made Paschal. Here again you discern that the new moon of that golden number in the month of March is Paschal while the lower line is in use, but is deprived of that office when the upper line is taken up. Likewise, that the new moon of the same

golden number in the month of April is not Paschal so long as the lower line of epacts is employed, but becomes Paschal as soon as the upper line is received into use. Of this too the astronomical reasoning is as follows. When the intercalary day is retained in some hundredth year, and the Moon is to be equated, all the new moons ascend one day toward the beginnings of the months in the Calendar. For this reason a new moon falling, before the Moon is equated, on 8 March is Paschal; and after the Moon has been equated, falling on 7 March, it can no longer be Paschal. By like reasoning a new moon falling, before that equating of the Moon, on 6 April is in no way Paschal; and after the same equating, falling on 5 April, is made Paschal.

Now indeed I cannot sufficiently marvel at the face and expression with which they dare to affirm that in these five years — 1609, 1628, 1647, 1666, 1685 — in which the golden number is 14 and the epact 24, the 14th Moon that by the new Calendar falls on 18 April belongs to the second month and not to the first. For that this is false is clear from the following little table, where it appears that the mean oppositions [*oppositiones mediæ*] in April are Paschal, since they do not fall after 19 April, the end of the Paschal full moons; whereas the mean oppositions in March are not Paschal but belong to the last month of the preceding year, because they occur before 22 March — where the beginning of the Paschal full moons is set — and therefore do not follow the day of the equinox, which nonetheless the ecclesiastical decrees require.

medice Martij non Paschales." over columns *D | H | M*. The two three-column panels give days, hours and minutes of the mean full moon.)

But so that this too may be evident — that the golden number 14 from the year 1700 to 1900 rightly throws the Paschal lunation back out of April into March (which they cannot stomach), and that the golden number 17 from the year 2200 to 2300 fittingly exhibits it in April, but from the year 2300 to 2400 in March, and finally from the year 2400 to 2500 most aptly assigns it to April — we have computed the following mean oppositions. Here it appears that the mean full moons [*plenilunia media*] of golden number 14, or of epact 23, in April from the year 1700 to 1900 are not Paschal but fall in March, since there they follow 19 April, after which there is no mean Paschal full moon. This is so that Easter — which sometimes, after the last Paschal 14th Moon that is assigned to 18 April, falls on 19 April — may not be celebrated before the mean full moon, but may here [in March] follow 21 March, appointed to the equinox, as reason demands. But from the year 2200 to 2300, the mean oppositions of the month of March,

(Table headings, verbatim: "Anni Domini." | "Aurei Numeri." | "Epactæ" | "Plenilunia media non Paschalia." over columns D | H | M | [month] | "Plenilunia media. Paschalia." over columns D | H | M | [month]. Parsing notes: the month abbreviation "Apr./Mar." is a separate cell to the right of each D/H/M triad. The

2220 Paschalia month prints as "Apr:" with a colon, transcribed as "Apr." All hour cells are < 24 and minute cells < 60; no numerical impossibles.)

when the golden number is 17 and the epact 24, are not Paschal, because they do not follow 21 March, appointed to the equinox; but the mean oppositions of the month of April are Paschal, since they do not extend beyond 19 April. Likewise, the mean oppositions of April from the year 2300 to 2400, when the golden number is 17 and the epact 23, are not Paschal, because they follow 19 April, just as from the year 1700 to 1900; but the mean oppositions of the month of March are Paschal, since they follow the day of the equinox. Finally, the mean full moons in March from the year 2400 to 2500, when golden number 17 and epact 24 concur, are not Paschal, but in April they are Paschal, just as from the year 2200 to 2300, for the reason we set out there. From all this it can be manifest to anyone that what the adversaries say is false — namely, that while epact 24 is current [the full moons] more truly belong to the second month; and likewise that many are assigned to the first month in March, while epact 23 is current, which rather look to the last month of the preceding year.

[Margin: That no cycle, in whatever manner it is set out in the Calendar, can avoid sometimes exhibiting the 15th Moon [Luna xv — thus printed; the body text has *Luna xiiij* throughout] in the second month or the last, which it nevertheless calls Paschal.] But if it should sometimes happen, on account of that transit from one line of the epacts of the expanded table to another, that some Paschal full moon of the Calendar turns out to belong to the second month or the last (for I cannot deny that this sometimes occurs, though rarely), this is not to be laid to the equation of the table, since it has been most correctly constituted, but is to be blamed on the nature of the Cycle — because no cycle set out in the Calendar in any manner whatever can correspond to the celestial motions so accurately and exactly that it does not sometimes diverge from them; and of this, several causes have already been adduced at Num. 8 of the preceding chapter. Nor, when this happens, is the Church to be accused, as though she then acted wrongly in preferring to follow the error of the Cycle, having set aside the celestial motions. For, as we showed at length in Chapter 4, in performing her festivals she ought rather to employ Cycles than the celestial motions, if she wishes to prescribe to the Christian people something regular and easy, as is fitting. Hence it comes about that very often she is compelled, in a manner, to reject some Paschal lunations as if they were not Paschal, on this ground alone: that their 14th Moons, found by the Cycle, forestall 21 March, assigned to the equinox, even though in reality they fall on the equinox. And likewise to accept as Paschal some that are not Paschal, because their 14th Moons, according to the Cycle, fall on 21 March, to

which the equinox is fixed, although the equinox itself truly runs ahead of them. This is clearly discerned in the bissextile years, and in those that are third from a leap year. For in the former, although the equinox reaches 20 March on account of the added intercalary day, she nonetheless rejects all the lunations, as not Paschal, whose 14th days fall on 20 March — that is, on the equinox at that time — and which therefore truly belong to the last month; whereas in the latter she approves all the lunations, as Paschal, whose 14th Moons fall on 21 March, even though in those years the equinox occurs after the 21st, on account of the 18 hours omitted over three years, so that those lunations ought in reality to be reckoned as belonging to the last month and not to the first. This too we have taught more fully at Chapter 5, Num. 11 and 12.

6. [Margin: That very often no legitimate Easter could be held in a year, if the mean motions were observed by the Church, and not the Cycles.] [Margin: What the Church should do, even if in some year there is no mean Paschal full moon.] What I shall now add ought to seem still more remarkable: namely, that the Church, if she did not follow the Cycle but observed the mean motions (for she ought rather to adopt these than the true motions, if she were to propose to herself any celestial motions to follow, since the mean motions are uniform but the true ones non-uniform), could in most years have no legitimate Easter. For since in the Council of Nicaea — which was afterward confirmed by several Councils and by decrees of the Popes — only 29 days were dedicated to the Paschal full moons, namely 22 March together with those following up to and including 19 April, so that any full moon occurring before 22 March or after 19 April is not fit for celebrating Easter (because the former belongs to the last month, the latter to the second, as is clear from what has been said), it can happen that in certain years no mean full moon is found on any of those 29 days, but that in March it runs ahead of the 22nd and in April it comes after the 19th. What, then, is the Church to do in that case? Is she to let those years pass without the solemnity of Easter? By no means: rather, setting aside the astronomical full moon, she looks for the 14th Moon by the Cycle, which falls either on 21 March or on 18 April — even though, according to the laws of the astronomers (given, however, the same Paschal limits prescribed by the Councils and the Fathers), it looks either to the last month or to the second. You have examples in the years of the following table, in which the letter M signifies the month of March, and A, April.

(Table headings, verbatim: "Anni Domini." | "Aurei Numeri." | "Epactæ" | "Plenilunia media" over columns D | H | M | [letter] | "Plenilunia media." over columns D | H | M | [letter]. Per the text, the trailing letter column of each panel gives M = March, A = April. Note the epact for 1935 is printed in Arabic figures as 25

— not Roman *xxv* — as it stands for golden number 17; all other epact cells are Roman (*xxiij* = 23, *xxiiij* = 24). All hour cells < 24 and minute cells < 60; no numerical impossibles.)

[Caput XIX continues, resolving the objections against the epacts.]

Table of mean full moons for the crossover years (A.D. 3116–4919)

In each row two mean full moons are tabulated (the two candidate Paschal full moons in the adjacent months). Sub-columns: **D** = day, **H** = hour, **M** = minute; the final letter gives the month (**A** = April, **M** = March). Epact for golden number 17 and the other Roman/Arabic distinctions are transcribed as printed.

In all these years you see that neither the March full moon nor the April full moon is Paschal, since both are found outside the prescribed limits. I have, however, omitted many other years in which the full moon in March falls on the 21st some hours after noon, before sunset, and in April on the 19th fewer than six hours after noon. For although the former would seem to be assigned to the last month and the latter to the second, yet because the former in March is only a little short of the 22nd day, while the latter in April has not yet wholly left the 19th day, I was unwilling to exclude them from the Paschal full moons, and I have gathered into the table only those that either precede noon of March 21 or fall on April 19 more than six hours after noon. For these, according to the decrees of the Fathers, can in no way be Paschal. And so in these years, when epact 23 is running, Easter is celebrated by the Church in the month of March, even though the mean full moon does not follow the 21st assigned to the equinox; but when epact 24 or 25 is running, the celebration of Easter is deferred by the Church into the month of April, even though the mean full moon occurs after the 19th.

[Margin: In what month the Church should celebrate Easter, when in some year there is no mean Paschal full moon.]

7. But so that no scruple may linger in the reader's mind, and that it may be left the more firmly confirmed that the epacts are excellently arranged in the Calendar and their equation rightly instituted — even though they sometimes yield Easter in the last month or in the second, indeed (as we said in Number 7 of the preceding chapter) almost before the mean opposition — we set out for

careful consideration the points that follow. First, let it be recalled that, on account of the equation of the moon and the removal of a day from certain centennial years to keep the equinox even, the same golden number that formerly offered epact 23 soon exhibits epact 24, and the reverse, and thus now throws Easter from March into April, now from April into March, as we said above in Numbers 4 and 5. So no one should be surprised if, on account of so great a change, the Easter drawn from the Cycle sometimes falls into some error, against the laws of the celestial motions.

[Margin: That the same golden number sometimes throws Easter out of March into April, and the reverse.]

8. Next, let each one consider that within one and the same span of 100 years — in which the same epacts always answer to the same golden numbers, that is, in which one and the same line of the expanded epact-table is put to use — the same epact by number indicates the Paschal 14th moon now before the mean opposition, now after it. For, to bring forward a few examples out of many: in the year 1627 epact 13 exhibits the Paschal 14th moon on March 31, before the mean opposition, which occurs in March, on the 31st, at the 8th hour after noon. But in the year 1684 the same epact 13 again places the 14th Paschal moon on March 31, after the mean opposition, since this falls on March 30, at the 10th hour after noon. Likewise in the year 1610 epact 5 has its 14th moon on April 8, before the mean opposition, which falls on April 8, at the 22nd hour after noon. But the same epact 5, in the year 1648, again sets its 14th moon on April 8, although it follows the mean opposition, which then occurs on April 7, at the 7th hour after noon. The same is seen in the years of the following little table — to pass over many others that can be drawn from the great table of chapter 22, where from the year 1600 to 5000 we have computed all the mean Paschal oppositions, the Paschal 14th moons likewise, the Dominical letters, together with the feast days of Easter, and so forth — just as we have excerpted from that same table the years written below.

[Margin: That the same golden number, from one centennial year to the next following centennial, in certain years exhibits the 14th moon now before the mean opposition, now after it.]

Excerpted years (A.D. 1700–2388)

Who, then, would say that the epacts are not rightly placed in the Calendar, or that their equation is wrongly instituted? Who does not see that, if the epacts indicated the new moons earlier (as some would have it) — that is, if the higher line of the epacts in the expanded table were taken, or the epacts themselves were advanced upward by one day — the 14th moons that are now found before the mean oppositions would run still further ahead of them, while those that now occur after the mean oppositions would then either anticipate them or come nearer to them? Granting this, who would not observe that Easter would very often have to be celebrated before the mean full moon, which is contrary to the decrees of the Fathers? Who, again, does not see that, if the epacts showed the new moons later — that is, if the lower line of the epacts in the expanded table were used, or the epacts themselves were drawn down by one day — the 14th moons that now fall after the mean oppositions would recede further from them, while those that now anticipate the mean oppositions would then either follow them or not run so far ahead? If this were done, who would not understand that Easter would not rarely have to be deferred to the 22nd and 23rd moon — that is, into the fourth week — against the decrees of the Fathers? Therefore, lest some epacts should show their 14th moons more than is fitting before the mean oppositions, and others further than is proper after the mean oppositions, we have arranged them in the Calendar through the days, and equated them, most correctly, so that between the extremes they always proceed by a middle course in the anticipation and postposition of the 14th moons. And no one can rightly find fault with this, since nothing more excellent of this kind could be devised.

[Margin: That the epacts are rightly placed in the Calendar and correctly equated is clearly demonstrated from what has just been said.]

But if we are unwilling to observe the 14th moons of one and the same epact, and instead examine the 14th moons of various epacts, we shall again discover, within the same century — that is, in the years enclosed between two successive centennial years — that some of these epacts show the 14th moons before the mean full moons, while others throw them off after the mean oppositions, as is plain from the same preceding table, where you see the 14th moons of certain epacts precede the mean oppositions, and those of others follow them; and the same can also be seen in the following table. The epacts, therefore, could not have been described in the Calendar by any better method than the one we have used. For if you wished to correct the later ones, you would feel a greater anticipation in the earlier ones; but if you strove to roll the earlier ones downward, the later ones would necessarily postpone their 14th moons much more. With the best judgment, therefore, they have been set in a kind of middle state in the new

Calendar. But see here a few years of this present, current century — 1600 — drawn from that aforesaid table of chapter 22, countless others being left aside so as not to be too long-winded, in which some epacts advance their 14th moons, while others retard them.

[Margin: In the years of the same century, some of the epacts show their 14th moons before the mean oppositions, others after them.]

Years of the current century (A.D. 1603–1696), grouped by position relative to the mean opposition

Columns: **Anni Domini** | **Aur. Num.** | **Epactæ** | **Lunæ xiiij.** (day + month letter) | **Oppositiones mediæ** (D, H, month letter). The source brackets the upper block as *Ante opp. med.* and the lower block as *Post opp. med.*

Do not suppose that it happens only in the Cycle of the Epacts that within the same century some epacts exhibit their 14th moons before the mean opposition, and some after — indeed (what may seem more remarkable) that one and the same epact by number exhibits, within the same century, the 14th moon now before the mean full moon, now after it. I shall show that the same thing occurred in the Cycle of the golden number, which the Church, having received it from the Council of Nicaea, always used down to the Gregorian correction for tracking the movable feasts. I shall, however, pass over the years around the time of the Council of Nicaea, because at that time the golden numbers showed the new moons earlier than was right, and thus all the 14th moons very often preceded the mean full moons before the mean oppositions, and very rarely came after them. I shall likewise omit the years that preceded the restoration of the Calendar by no great interval, because at that time those same golden numbers indicated the new moons later than was proper, and thus all the 14th moons followed the mean oppositions and did not precede them. I take only the years around the time of the Emperor Justinian, beginning from the year 532, when at last the golden numbers, inscribed in the Calendar by Dionysius Exiguus [Dionysius Exiguus], were showing the new moons more correctly according to the practice of the Church — that is, neither too early nor too late. And I confine myself within the space of three hundred years, because within so great a span the moon would not have required an equation, and so the anticipation and postposition of the 14th moons cannot be referred to that neglected equation. In these years written below, then, you especially see the same golden number exhibiting the 14th moon before the mean full moon, and sometimes after it; likewise some golden numbers anticipating, and some postponing, their 14th moons. Here indeed you see that in these four years — 535, 551, 555, 571 — the 14th moons are anticipated more than is fair, so much so that, had they fallen on a Saturday, Easter would have been celebrated almost before the mean opposition; which must surely seem remarkable, since even at that time the golden numbers indicated the new moons late enough that the danger might rather have been that the 14th moons would be postponed too much — as you see happened in the years 664 and 690,

in which Easter would have been celebrated on the 22nd moon by mean motion, in the fourth week, had the 14th moon fallen on a Sunday.

[Margin: In the old Calendar, in the time of the Emperor Justinian, the same golden number showed the 14th moon now earlier, now later; likewise some golden numbers anticipated their 14th moons, others postponed them.]

Furthermore, in the years 604 and 661 the mean opposition did not occur after the equinox fixed on March 21, and therefore it should be reckoned as belonging rather to the last month than to the first, if the Council of Nicaea is to remain in force. Yet none the less the mean opposition of those same years was Paschal in April, since it fell on the 19th at about the 7th hour after noon — that is, after the last term of the Paschal full moons. And so, for those...

[Margin: In the old Calendar, in certain years no mean Paschal full moon is found.]

(Text continues onto the following leaf, mid-sentence.)

Caput XIX (continued)

[The two tables below stand at the head of this leaf; they display the same-golden-number full moons of the old Nicene cycle discussed in the preceding paragraphs. In both, the month-letters are M = March and A = April; "Aur. Num." is the golden number (aureus numerus); "Lunæ xiiij." is the fourteenth of the moon (the cyclic Paschal full moon); "Plenilunia media" are the mean full moons, given as D (day), H (hour), and month-letter.]

661	16	21 M	Post oppositionem mediam	20	M

for those years, if the mean motion had had to be observed rather than the Cycle, no Easter could have been legitimately celebrated. This is just what we asserted above, at Num. 6, concerning certain years even after the correction. You see, then, that exactly the same thing happened in the old Calendar as well — and indeed in precisely those periods which the Church, by its practice, most fully approved for everyone — the very things which our opponents do not shrink from attacking so fiercely in the new Calendar, and without cause.

[Margin: That four errors cannot be avoided in any calendar, and what they are.]

9. THIRDLY, I should wish that those who are so hotly bent on assailing the arrangement of the Epacts and the equation in the new Calendar would

consider carefully that no civil calendar, in which the Lunar Cycle is set out — whether by golden numbers or by Epacts — can so avoid and escape four errors as never occasionally to fall into them. For, first, whatever equation of the solar year be established, the equinox cannot be held so firmly to March 21 that it does not range freely to either side of it, even though it returns to that day of its own accord in the meantime. This happens of necessity because of the unequal and irregular motion of the true equinox, as was explained at length in chapters 6 and 7. Indeed, even if the motion of the equinox were always equal and uniform, it still could not always cling to the same day, on account of the common and the bissextile years, as we declared at chapter 5, Num. 11, and elsewhere. Next, it cannot be avoided that the Cycle — whatever it may be in the end — will sometimes offer an Easter to be celebrated on the 14th of the moon before the mean full moon; because, as we said at Num. 8 and 9, the same number of the Cycle within one and the same century now anticipates the 14th moon, now postpones it. Likewise the 14th moons of some numbers run ahead of the mean oppositions, while the 14th moons of other numbers follow those same mean oppositions. Thirdly, so that the Cycle may not present us with an Easter before the mean full moon more often than we wish, it is necessary for it to mark the New Moons in the Calendar later than they actually occur in the heavens. This our Epacts in the new Calendar carefully see to, since they are arranged in it so that for the most part their New Moons fall a whole day, and some-

times more, after the celestial New Moons — although now and then, though rarely, the two do not differ, and consequently the 14th moons then run ahead of the mean oppositions by more than is proper. This fault is found in every Cycle; on which matter we have written more at chapter 18, Num. 5 and 6. Fourth and last, whether we will or no, we are compelled at times, by the very nature of the Cycle — whatever it be, and however it is arranged in the Calendar — to throw Easter out of the first month, now into the second, now into the last, that is, the twelfth: namely whenever the Paschal 14th moon precedes March 21 but follows, or coincides with, the day on which the equinox falls, should the true equinox happen to occur before March 21; or again, whenever the equinox comes after March 21, but the Paschal 14th moon runs ahead of that same equinox, provided it is not found before the 21st. But we have written more on this at Num. 5 and in other places. These, then, are the four errors — if it is to be called an error, when it must be admitted at times not rashly but of necessity — which cannot be avoided in any Calendar that is set up, as is proper, by cycles and rules easy to grasp and uniform. This alone must be carefully guarded against: that the Cycle

described in the Calendar should thrust us into these errors as rarely as possible — which, as can readily and plainly be gathered from what has been shown so far, belongs to this our Epact-Cycle alone.

Caput XX

The Finding of the Solar Cycle for any Given Year

WE have expounded so far the matters that carry the greater difficulty in this business of the correction — all those, that is, which pertain to the solar and the lunar year, to the end that the equinox may, as far as possible, be kept in its own seat, and the Paschal 14th moon rightly displayed in the Calendar. Now let us run through the remaining matters of lesser moment, which are nonetheless wholly necessary for the understanding of the Calendar. In the first place there presents itself the Solar Cycle, which is nothing else than a revolution of 28 years — this because the dominical letters, for whose sake alone this Cycle was devised, return in exactly the same order after 28 years, as we shall teach in the following chapter. From this it has come about that the Solar Cycle is also called the Cycle of the Dominical Letters. And although the Solar Cycle is not simply and absolutely necessary to us — since without it we can find the dominical letter of any year far more expeditiously, as will be clear from the following chapter — nevertheless, because the Church always used it before the Gregorian correction for tracking down the dominical letter, it will not be out of place to teach by what device this Cycle is to be found for any given year, and by what method the dominical letter is to be drawn from it, both before the correction and after.

[Margin: What the Solar Cycle is.]

[Margin: The Cycle of the Dominical Letters is the same as the Solar Cycle.]

2. NOW, setting aside the rules handed down in Canon 3 of the perpetual Gregorian Calendar, which we placed at the beginning of this work, we shall here construct a most expeditious table, from which the Solar Cycle of any proposed year may be drawn, taking our start from the year of the Lord 1, in which the Solar Cycle was 10 — in this manner, namely. Let all 28 numbers of the Solar Cycle be set out in order in a little table, beginning from the number 10 of the Solar Cycle. Then in another table let the years of the Lord be written out, beginning from 1 and advancing by continual addition of 28, as far as one pleases. To these years the Solar Cycle 10 of the first cell corresponds. Accordingly, when you would find the Solar Cycle of

any year, seek the proposed year among the years of the Lord: if it is found, you will say that in that year the Solar Cycle is 10. But if it is not found, take the year next below it and assign it to the first cell of the Solar Cycle, the following year to the second cell, the next to the third, and so on, until you reach the proposed year. For the Solar Cycle of the cell into which the proposed year falls will be the one that is sought; and its use will begin from January, just as with the golden numbers and the Epacts, as we said above.

[Margin: Rule for finding the Solar Cycle of any given year.]

For example: in the year 6021, since it is written out in the table, the Solar Cycle will be 10. But in the year 6036 the Solar Cycle will be 25. For the year 6036 falls into the cell of the number 25, if the year 6021 is assigned to the first cell, the year 6022 to the second, and so on. Likewise, in the year of the Lord 5 the Solar Cycle was 14, and in the year 85 it was 10. Finally, in the year 7777 the Solar Cycle will be 2. And so of the rest.

[Margin: The use of the Solar Cycle begins from January.]

THIS table will perhaps be more conveniently arranged by hundreds of years, as appears in the other table which follows this one.

Tabella Cycli Solaris (Table of the Solar Cycle)

Header — the 28 numbers of the Solar Cycle, in order (set as two rows of fourteen):

10	11	12	13	14	15	16	17	18	19	20	21	22	23
24	25	26	27	28	1	2	3	4	5	6	7	8	9

Anni Domini, quibus prima cellula Cyclus Solaris 10. congruit. (The years of the Lord to which the first cell — Solar Cycle 10 — corresponds.)

Side-label of the body table: *Anni Domini per 28. collecti* (the years of the Lord gathered by 28s). The ten body columns correspond to Solar-Cycle numbers 10 through 19; each cell exceeds the one above it by 28.

[Caput XX, continued — the Solar-Cycle table of hundred-years]

[Table: Solar Cycle by hundreds of years of the Lord (printed p. 363).]

The head of the table carries the label **Cycl. Solaris**. ("Solar Cycle") over seven lettered columns **A–G**; beneath each letter stands the Solar-Cycle number to which that column corresponds. The body of each column lists the years of the Lord (reckoned in hundreds) that fall under that Solar-Cycle number.

[Margin (set vertically along the left edge): Anni Domini per 100. collecti, quibus numeri Cycli Solaris in vertice tabulæ descripti congruunt. — "Years of the Lord collected by hundreds, to which the Solar-Cycle numbers written at the head of the table correspond."]

[Caput XX, continued]

CONSTRUCTION. The construction of this table — which can be extended to infinity — runs as follows. The hundred-years proceed in order from left to right, starting from the year 0, until seven cells are filled, as the table shows. Above the year 0, which is the first among the hundred-years, is written the Solar Cycle ix; from it the remaining six are formed by continually adding the number 16, always casting out 28 whenever the sum produced is greater than 28.

USE. The use of this table, moreover, is very easy, provided one takes note of this second little table of the three numbers collected by 28 that the year 0 precedes, together with the series of all 28 numbers of the Solar Cycle set out here.

Anni per 28. collecti	0	28	56	84

Series of the numbers of the Solar Cycle.

									1	1	1	1	1	1	1	1	1	1	2
1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0
21	22			23	24			25	26			27	28						

To find the Solar Cycle of any year that is not greater than the last hundred-year of the preceding table: if that year is one of the hundred-years, look for it among

the years of the Lord, and at once, above it, you will find the Solar Cycle you seek. But if the proposed year is not one of the hundred-years, take from the adjoining little table of the years collected by 28 the number next smaller than the proposed year, counting from the hundred-year just passed; assign that number to the Solar-Cycle number of the accompanying series that stands written above the hundred-year after which the given year falls. To the next Solar-Cycle number of the same series assign the next year, and so on in turn — returning to the beginning of the series if need be — until you reach the proposed year. For the counting will end on the Solar Cycle sought. And if the given year, falling after some hundred-year, is itself found in the table of years collected by 28, then in that year the Solar Cycle is the one that answers to the hundred-year which most nearly precedes the given non-hundred year.

For example: in the year 1600 the Solar Cycle is 13. But in the year 1683 the Solar Cycle is 12; for by assigning, in the accompanying series, the Solar Cycle 13 (found above the year 1600) to the number 56 of the adjoining little table of years collected by 28, and the year 57 to the next Solar Cycle 14, and so on, the year 83 falls on Solar Cycle 12. Again, in the year 1748 the Solar Cycle was 1. For if, in the accompanying series, to the Solar Cycle 9 (found above the hundred-year 0) we assign the year 28 of the adjoining little table of years collected by 28 — which is next smaller than the given 48 — and the year 29 to the next Solar Cycle 10, and so on, the year 48 ends on Solar Cycle 1. Again, in the year 1810 the Solar Cycle will be 27; for if, in the accompanying series, to the Solar Cycle 17 (written above the hundred-year 1800) you assign the year 0 of the adjoining little table of years collected by 28 — which is next smaller than 10 — and the year 1 to the next Solar Cycle 18, and so on, the year 10 falls on Solar Cycle 27. Finally, in the year 1656 the Solar Cycle will be 13, which of course belongs to the year 1600, because the year 56 is set down in the table of years collected by 28. And so with the rest.

3. But we shall reduce this same table to a far easier use in the following way. Above the Solar Cycles of the aforesaid table let the seven capital letters of the alphabet be written in order; and let the same letters be repeated in the same order in this second table, and beneath each of them let all twenty-eight Solar Cycles be set out, the start being made, in each descending column, from that Solar Cycle which exceeds by one unit the Solar Cycle written beneath the corresponding letter of the upper table. Finally, alongside the same Solar Cycles, on the left, let the hundred expanded years be arranged, as you see in the following table. With the Solar-Cycle numbers and the expanded years disposed in this way, the Solar Cycle of any proposed year will be found most expeditiously. For if the given year is

one of the hundred-years, its Solar Cycle will be found at once above it in the upper table, as we said in the use of that table. But if the proposed year is not a hundred-year, its Solar Cycle will be found in this table, in the row of the given expanded year, in that descending column of Solar-Cycle numbers over which is placed the same letter that answers, in the upper table, to the hundred-year most recently passed. Hence the seven descending columns of the Solar Cycle can serve as seven temporary little tables for investigating the Solar Cycle of any year. For example, the column over which the letter C is written will be the temporary table

[Margin: *Tabellæ temporariæ Cycli Solaris*. — "The temporary tables of the Solar Cycle."]

for the year 1600, to which in the upper table the same letter C answers, and holds good up to the year 1700 — provided, however, that the expanded years written to the left of the adjoining table are brought into use together with it, and so on, as was said in Chapter 12, Number 4, concerning the temporary tables of the Golden Number. Let it be required, then, to find the Solar Cycle of the year 1600. Since this is a hundred-year, the Solar Cycle 13 will answer to it in the upper table. But if the Solar Cycle be sought for the year 1687: since in the upper table the letter C answers to the hundred-year 1600 most recently elapsed, we shall find, in the row of letter C of the adjoining table, opposite the expanded year 87, the Solar Cycle 16. And so with the rest.

CAPUT XXI.

The Finding of the Dominical Letter.

In the preceding chapter we said that the Solar Cycle of 28 years is likewise a cycle of the Dominical letters, because after 28 years these recur in exactly the same order. For since there are seven Dominical letters, on account of the seven days of the week, and since the year of 365 days contains 52 weeks and one day over, it comes about that when the seven letters have been set out in the Calendar — beginning from A on the first day of January, and repeated the same fifty-two times over — the same letter A is repeated on the last day of December.

Consequently, if in some year, for example, the first day is a Sunday, the last day too will be a Sunday, and therefore the first day of the following year will be a Monday. So the letter A, which in the first year was the Dominical letter, marks Monday in the second year; and accordingly the Dominical letter must then be changed. For the same reason it must be changed in the years that follow. The change of the Dominical letters therefore takes place every year, as you see, because of the letter A, which — assigned to the first day of the year — is repeated on the last day of the year. But if there were no day left over beyond the 52 weeks, the letter A would not be repeated, and the first day of the year would again be a Sunday. And if a day were not intercalated every fourth year, the seven Dominical letters would return in the same order after 7 years, and each letter would be Dominical once in the span of 7 years. But since in every fourth year one day is added, and the year becomes a leap year [bissextilis] — in which two Dominical letters are taken up — it follows that the letters cannot return in the same proportion before 28 years have run out. For within this span of years each of the letters is used, together with the one immediately preceding it, in a leap year; and this can happen in seven ways, namely: G with F; F with E; E with D; D with C; C with B; B with A; and A with G. Likewise any letter can be Dominical in the first year after the leap year, then in the second, and lastly in the third — as will appear below in each of the seven cycles of the 28 Dominical letters. And this number of 28 years is produced from the multiplication of 7 by 4, since the letters are seven, and every fourth [year...]

in that year too two of them are in use. For since these numbers, 7 and 4, are prime to one another, the number 28 that is generated from them will show in how many ways the seven letters can be varied among themselves.

[Margin: Construction of the table for finding the Dominical Letter.]

2. Moreover, the Dominical Letter of any given year — leaving aside the rules handed down in Canon 4 of the perpetual Gregorian Calendar — will be found with almost no trouble from the following table, which is constructed as follows. In seven cells let all the centesimal years be written, beginning from the year 1600, but in such a way that the bissextile centesimal years are placed in the same cells as the non-bissextile centesimal years that immediately precede them. This is because in the bissextile centesimal years no interruption of the cycle of Dominical Letters occurs, but only in the non-bissextile ones; and for this same reason the year 1582 has been entered in the same cell as the bissextile year 1600, after the removal of the 10 days that was carried out in the year of the correction. To these seven cells let seven capital index letters be assigned at the top. Next, in turn, let there be built up seven descending columns of the 28 Dominical Letters, which advance in their natural order, ascending from the lowest cells to the topmost, yet so that the first begins with the letter d, the second with e, the third with f, the fourth with g, the fifth with A, the sixth with b, and the seventh with c — taking careful note that at every fourth place two letters are set together in the same cell, on account of the bissextile years. And over these seven columns of Dominical Letters let there be placed the same seven capital index letters that we set above the centesimal years. Finally, to the right of the said columns let all 28 Solar Cycles be written out, as you see done in the table. Those centesimal years that precede the year of the correction, 1582, have not, however, been included among the centesimal years, because before the correction the Dominical Letter of any year is found by the Solar Cycle alone, without the aid of the centesimal years, as we shall explain.

[The "A B" register marks stand in the lower outer margin, set between short rules; they are press/sheet register marks rather than a gathering signature.]

Table of Centesimal Years (*Anni centesimi*) — Source: PDF p. 383 (printed 367)

The seven capital index letters A–G head the columns; each cell holds the centesimal years assigned to that index letter, the bissextile centesimal year (divisible by 400) stacked with the non-bissextile centesimal immediately preceding it.

Table of Dominical Letters (*LITERÆ Dominicales*) — Source: PDF p. 384 (printed 368)

The seven capital index letters A–G head the columns; the rightmost column is the *Cyclus Solaris* (Solar Cycle), numbered 1–28. Bissextile years (cycles 1, 5, 9, 13, 17, 21, 25) carry two letters, printed side by side; all other years carry a single letter. A is set as a capital throughout (the sole capital in the seven-letter series); the remaining letters b, c, d, e, f, g are lower-case.

Cyclus Solaris	A	B	C	D	E	F	G

CAPVT XXI. (369)

(Continuation of Caput XXI, [Inuentio Literæ Dominicalis] — the Usus, use of the table.)

When, therefore, you wish to find the Dominical letter of any year after the correction of the Calendar, first look up, by means of the preceding chapter, the Solar Cycle of that year. For at once, in the following table of Dominical letters, opposite that Solar Cycle and under the capital letter placed at the head of the table which corresponds to the century that contains the proposed year, you will find the Dominical letter you are seeking. If this turns out to be double, the year is bissextile [leap]; but if single, it is a common year. And since in the non-bissextile centesimal years a double letter likewise occurs, only one is to be taken — namely the one set to the left, which comes earlier in the series of the seven letters A, B, C, D, E, F, G — with G reckoned, in this operation, as preceding A; for once the cycle of these seven letters has been completed, after G one returns to A, just as B follows A, and so on.

For example: in the year 1674 the Solar Cycle is 3. Opposite it, in the following table, under the letter A placed at the head — the A, that is, written above the year 1600 — is found the Dominical letter G, single, and so this year is a common one. In the year 1892, however, the Solar Cycle is 25, which yields the Dominical letters b, c, and therefore that year is bissextile. But in the year 1700 the Solar Cycle is 1, which points to the letters c, d; and because this centesimal year passes without a bissextile day, C alone will be the Dominical letter. So too in the year 2000 the Solar Cycle will be 21, and the Dominical letters d, e, since that year is bissextile. The same procedure is to be observed for the remaining years after the correction.

For the years before the emendation of the Calendar, the Solar Cycle will indicate the Dominical letter under the capital letter E. Thus, since in the year 1582 the Solar Cycle was 23, you will find under the letter E the Dominical letter g, which marked the Lord's Day in that year up to the fourth of October; for from that

point to the end of the year the Dominical letter was C. Likewise, in the year 325 the Solar Cycle was 26, and the Dominical letter c. Finally, in the year 1100 the Solar Cycle was 17, and the Dominical letters g, A. And so for the rest. In bissextile years the letter that stands later in the alphabet, or series of letters, will be Dominical up to the feast of St. Matthias, and the other from there to the end of the year.

[Margin: Temporary tables of Dominical letters.]

From this, anyone may easily extract temporary little tables of Dominical letters, by which the Dominical letter may be found for any century. For the seven rows of Dominical letters descending in the following table will be seven such temporary tables. For example, the first row, under the letter A, will serve as a temporary table from the year 1600 (which among the centesimal years is placed under that same letter A) up to the year 1700, and again from the year 2500 to the year 2600, and so on. The row under the letter E, however, will be a temporary table from the first year of Christ up to the year 1582, in which the Calendar was emended.

[Margin: An easier way of finding the Dominical letter, without the Solar Cycle.]

3. But we shall find the Dominical letter of any year far more expeditiously, without the Solar Cycle, from the following table, which is constructed thus. In the first place, let all the centesimal years be written out, beginning with the year 0, yet in such a way that, when the year 1500 before the correction has been written, two empty cells are left after it, in which these words are to be noted, *Post correctionem* [after the correction]; and in the fifth cell the same year 1500 is written again, and in the sixth the year 1600. Then, leaving the seventh cell empty, the year 1700 is written in the first cell of the next transverse row. Likewise, omitting the second cell, in the third is placed the year 1800; and in the fifth — the fourth being passed over — the year 1900 is written; and, leaving the seventh cell, the year 2100 is placed in the first cell of the next row. And so on without end, the remaining centesimal years that follow are to be written, always omitting the empty cells — the second, the fourth, and the seventh. Then at the head are set the seven capital letters, the indices of the Dominical letters. Finally, beneath the centesimal years the Dominical letters are written, as you see done in the table.

After this, let the seven rows of the seven Dominical letters be written out, so that each in turn occupies the first place, beginning with the letter b, which was

Dominical in the first year of Christ, and the rest proceeding across in retrograde order. To these rows, on the left, are attached those same seven capital letters which we said above were to be written above the centesimal years, as you see in the other table; and beneath these seven rows, at last, are placed the hundred expanded years.

[370] CALEND. GREGOR.

Table. *Anni Centesimi* [Centesimal Years]. Seven columns headed by the capital index letters A–G. The pre-correction centuries fill all seven columns down to the year 1500; the two cells after 1500 (columns C and D of that row) carry the note *Post correctionē* [i.e. *Post correctionem*, "after the correction"], spanning the two cells. From the correction onward the years occupy only columns A, C, E, and F (the second, fourth, and seventh cells of each row being left empty), continuing to 13200 &c. The bottom row gives the pair of Dominical letters belonging to each column.

To find the Dominical letter, then, proceed with this table as follows. If the year in question is one of the centurial years, look for it among the centurial years listed. Beneath it you will find a pair of letters, which will be the Dominical letters for that year — provided that centurial year is bissextile, as all centurial years before the restoration are, and, after the correction, only those set out in the sixth cell beneath the index letter F, namely 1600, 2000, 2400, and so on. But if the given centurial year is a common year — as, after the emendation of the year, are all

those outside the sixth cell — then of the two letters only one will be Dominical, namely the one placed on the right, which stands earlier in the alphabet. If, however, the year in question is not a centurial year, you will find its Dominical letter above the expanded year [annum expansum], in that row of Dominical letters which has prefixed to it the same index letter that stands above the centurial year most recently elapsed before the expanded year. And if the expanded year is doubled, that year is bissextile, and two Dominical letters answer to it: the one that occurs first serves up to the feast of St. Matthias, the other from that day to the end of the year.

For example: in the year 300 from the birth of Christ the Dominical letters were g, f, which are placed beneath the index letter D and the year 300. But in the year 325 the Dominical letter was C, above the expanded year 25, in the row of the index letter D — that is, the row written above the year 300, the centurial year most recently elapsed. Likewise in the year 1582, before the correction, the Dominical letter was g, above the expanded year 82, in the row of the index letter B, which is written above the year 1500 before the correction. But after the correction the same year had the Dominical letter C, above the same expanded year 82, in the row of the index letter E, since this same index letter is placed above the year 1500 after the correction. Again, in the year 1100 the Dominical letters were A, g. Likewise in the year 1674 you will find the Dominical letter g, above the expanded year 74, in the row of the index letter F, since this letter is found above the year 1600. In the year 1892, above the doubled expanded year 92, you will find the letters c, b, in the row of the index letter C, written above the year 1800 — and therefore that year is bissextile. But in the year 1700 the Dominical letter will be c, beneath the year 1700, the letter d being set aside. Finally, in the year 2000 the Dominical letters will be b, A. And so for the rest.

If the Dominical letters for the years near Christ's birth are sought by the aforesaid rules, the letters that emerge are those which would have obtained had the institution of Julius Caesar been preserved. But because the priests of the idols erred in the intercalation — an error that Augustus afterwards corrected — the Dominical letters actually in use down to the fourth year of the Lord were different. The following tables display the discrepancy.

[Margin: In the first 4 years of Christ the Dominical letters prescribed by the Calendar differ from those which were actually in use at that time.]

Dominical Letters according to the Correction of Augustus [*Literæ Dominicales secundum correctionem Augusti*]

Anni Domini	0	1	2	3	4	5	6	7	8
Literæ Dominicales	B	A	G	F	E	D	C	B	A G

Dominical Letters according to the Institution of Julius Caesar and the Rules of the Calendar [*Literæ Dominicales secundum institutionem Iulij Cæsaris, & regulas Calendarij*]

Anni Domini	0	1	2	3	4	5	6	7	8
Literæ Dominicales	D C	B	A	G	F E	D	C	B	A G

And so the Dominical letters, following the prescription of the Calendar from the Nativity of Christ — that is, from year 0 up to and including year 4 — differ from those which the correction of Augustus Caesar gave; but after year 4 no further discrepancy occurs.

- Nor does it seem right to pass over here that, from our equation of the solar year — which makes three successive centurial years common, without an intercalary day, while every fourth centurial year remains bissextile — a cycle of 400 years is formed, such that once that span is completed, all interruption of the Dominical letters ceases and they recur in exactly the same order, as is plain from the following table. By means of this cycle, therefore, the Dominical letter after the correction of the year is derived from the following table more quickly than can be told (for before the correction a cycle of 28 years was enough), in this way. First, one must ask in which year of this cycle the proposed year falls. Once that is found, you will have opposite it the Dominical letter — either single or double, according as the proposed year is common or bissextile.

[Margin: The 400-year cycle of Dominical letters after the correction. — Finding the Dominical letter from the 400-year cycle.]

The 400-year Cycle of Dominical Letters (single letter = common year; doubled pair = bissextile year, the first letter serving to the feast of St. Matthias, the second thereafter). The table runs continuously across three leaves: cycles 1–12 here, 13–180 on the next leaf, 181–348 on the following leaf, and it continues beyond 348 on the next leaf.

Cycles 1–12 (foot of printed p. 372):

Chapter XXI (continued) — the Four-Hundred-Year Table of Dominical Letters; Chapter XXII

[Printed folio 375 — running header "CAPVT XXI." / "375"]

The great table of Dominical letters for the 400-year cycle concludes here. It is printed as three side-by-side panels (Cycl^{us} | Lit. Dom.), read left → middle → right; the columns are flattened below into one six-column table. Bissextile years (cycle ÷ 4) carry a doubled letter-pair; centurial year 400 carries a dagger (†) marking it as a centurial year and remains bissextile.

Cycl ^{us}	Lit. Dom.	Cycl ^{us}	Lit. Dom.	Cycl ^{us}	Lit. Dom.
349	b	367	A	385	f
350	A	368	g f	386	e

358	e	376	d c	394	b
359	d	377	b	395	A
360	c b	378	A	396	g f
361	A	379	g	397	e
362	g	380	f e	398	d
363	f	381	d	399	c
364	e d	382	c	† 400	b A
365	c	383	b		
366	b	384	A g		

This is how you will find out which year of this Cycle a given year is. From the year in question, cast out all the ten-thousands and all the two-thousands, if they can be cast out, and from the remainder cast out 400 as many times as possible — which is not difficult, since this remaining number cannot be greater than 1999,

so that 400 can be contained in it at most four times. The number then left over will indicate the year of this Cycle. But if, after casting out the 400's, nothing remains, the proposed year will be the four-hundredth — that is, the last of the whole Cycle.

For example, take the year 34689. Casting out all the ten-thousands and all the two-thousands, 689 remains; and from this, if 400 is cast out once, 289 remains. Therefore the given year is the two-hundred-and-eighty-ninth of this 400-year Cycle, and its Dominical letter will be f, the first after the bissextile. Again, given the year 11500: setting aside 10000, if from the remaining 1500 we cast out 400 three times, the year 300 of this Cycle is left. Its Dominical letter will be g, single, since the given hundredth year is not bissextile but common. Thus the year 1600 will be the four-hundredth [of the Cycle], presenting the double Dominical letter b, A, since it is bissextile. Finally, the year 1582 is the 382nd in the Cycle, having the Dominical letter c. And so with the rest.

[Margin: A very easy way to find the year within the 400-year cycle.]

Perhaps, however, we shall find out more easily and quickly which year of this 400-year Cycle any proposed year is, by the following method. Take any proposed year written out in its digits, and consider only the number formed by the two figures occupying the fourth and third places — that is, the ones that stand for thousands and hundreds only — leaving aside the ten-thousands, twenty-thousands, and larger figures, together with the trailing years [the tens and units]. This number will never be greater than 99. For if from this number 20 is cast out as many times as possible, then from the remainder [the same is done], the number left over will indicate the hundred-mark year of this Cycle; and if the trailing years are added to it, should there be any, the full year of that same Cycle will be obtained. But if there are no trailing years, there will remain only the first, second, or third hundred-year of the Cycle [i.e. the 100th, 200th, or 300th]. And if there are neither trailing years, nor thousands, nor hundreds, or if after casting out 20 and 4 from the thousands and hundreds nothing is left, the proposed year will be the four-hundredth of the Cycle, that is, the last.

For example, if the year 37090 is given, only the number 70 need be observed, since the figure 7 occupies the place of thousands and the figure 0 the place of hundreds. From this, if all the 20's are cast out, 10 remain; and when the 4's are cast out, 2 remain. That year, therefore, is the two-hundred-and-ninetieth in this 400-year Cycle. But if the year 37000 is given, you will say it is the two-hundredth, since there are no trailing years. Thus you will call the year 56800 the four-hundredth, because nothing remains when all the 20's and 4's are cast out of the

number 68. In the same way you will judge the year 6790000 to be the four-hundredth. But the year 560001 you will call the first. And so with the rest.

CHAPTER XXII.

The Finding of the Movable Feasts.

The principal movable feasts in the Catholic Church are Septuagesima, Quadragesima (or Ash Wednesday), Easter, the Lord's Ascension, Pentecost, Corpus Christi, and the First Sunday of Advent. To these, in the tables of movable feasts, is also added the number of Sundays between Pentecost and the Lord's Advent, as being necessary for those who recite the Divine Office, so that they may know how many of the Sundays that are placed after Epiphany are to be inserted between the 23rd and 24th Sundays after Pentecost. But since, in the perpetual Gregorian Calendar which we set forth at the beginning of this work, we have dealt quite fully — in Canon 6 — with the find-

[Margin: Which are the movable feasts.]

[Printed folio 376 — running header "376" / "CALEND. GREGOR."]

-ing of these movable festivals, having proposed two general tables very useful for the purpose (one old, the other new), we shall not repeat here what we wrote there. We shall present only the former table, resolved into common and bissextile years in another way — doubled, that is — so that the movable feasts may be found without any trouble, whether in common or in bissextile years; and this resolved table is the one the Eastern Church has been accustomed to use.

[Margin: Construction of the key to the resolved table of the movable feasts.]

And because it had been fitted to Dionysius's great Cycle of 532 years — a number produced by multiplying the Cycle of the golden number, of 19 years, by the Solar Cycle of 28 years — whereas this Cycle can no longer be of use, on account of the interruption of the Dominical letters in the non-bissextile centurial years, we were obliged to arrange its key differently: in the way, that is, that is seen in the following small table, which precedes the resolved table. But if anyone wishes to understand by what art the aforesaid key was constructed, we shall explain it with two examples, the first of which concerns a common year, the second a bissextile one.

Let us suppose, for example, that in some common year the Epact is xvij (18) and the Dominical letter d. On this assumption, in the old Paschal table as reformed in the Gregorian Calendar, Septuagesima is found on 25 January. Now since, in our resolved table, the line that puts Septuagesima (in a common year, which the letter c indicates) on 25 January has the number 15 prefixed to it, this number 15 must be written in the common angle of Epact xvij (18) and Dominical letter d. Again, if we suppose that in some bissextile year the Epact is the same, xvij (18), and the Dominical letters e, d, we shall find in the same Paschal table that Septuagesima falls on 26 January. Since, then, in our resolved table the number 16 is prefixed on the left to the line that indicates Septuagesima on 26 January in a bissextile year (which the letter b denotes), this number 16 must be placed in the common angle of Epact xvij (18) and the Dominical letters e, d. And the same reasoning holds for the rest. But if on the right side, opposite the Epacts, you write in the corresponding golden numbers as they are placed in the old Paschal table as reformed — namely golden number 14 opposite Epact 1 [j], and golden number 6 opposite Epact iij (3), and so on — this same key will also serve for the times before the correction of the Calendar, as we shall say presently.

[Margin: Finding the movable feasts from the resolved table.]

2. Therefore, if in the key we take the number in the common angle of the Epact and the Dominical letter — whether single or double, according as the year is common or bissextile — you will find, after the correction, opposite that number in the resolved table all the movable feasts of the year in which that Epact and Dominical letter are in use. And if in place of the Epact you take the golden number of some year before the correction, together with the Dominical letter, the number found in the common angle will likewise present, in the same resolved table, all the movable feasts. For example: in the year 1602 the Epact is vij (7) and the Dominical letter f. In their common angle I find the number 33; opposite this I find Septuagesima on 3 February, Ash Wednesday on 20 February, Easter on 7 April, the Lord's Ascension on 16 May, Pentecost on 26 May, Corpus Christi on 6 June, the Sundays after Pentecost 26, and the First Sunday of Advent on 1 December. Again, in the year 1620 the Epact is xxvj (26) and the Dominical letters e, d. In their common angle the number 58 is found, opposite which, in the resolved table, all the movable feasts are displayed. Finally, in the year 1582, before the correction, the golden number was 6 and the Dominical letter g. The number 49, therefore, found in their common angle, will show in the resolved table on what days the movable feasts were celebrated. And so with the rest.

[Margin: at the Epact **xxvj** row, the Arabic figure **25**; at the Epact **xxiiij** row, the Roman **xxv** — the two marks flag the special handling of Epact 25 (Arabic 25, used for golden numbers 12–19, follows the 26/xxvj line; Roman xxv, used for golden numbers 1–11, follows the 24/xxiiij line).]

Caput XXII — *Festorum mobilium inventio* (continued)

Table of the Movable Feasts, Resolved

[TABVLA FESTORVM MOBILIVM RESOLVTA]

This is the *tabula resoluta* of the movable feasts, entered by the *clavis* number (1–58, here shown through 52; it continues on the following leaf). For each key the table gives the year-type letter, then the dates of Septuagesima, Ash Wednesday (Cineres), Easter (Pascha), the Ascension, Pentecost, Corpus Christi, the number of the last Sunday after Pentecost, and the first Sunday of Advent.

The unlabelled second column carries a repeating **c / b**: *c* = *annus communis* (common year), *b* = *annus bissextilis* (leap year). Months are as printed; where no month is repeated, the preceding month continues. "No." = November, "Dec." = December, "Iun." = June, "Maij" = May.

Now, so that everyone may see more clearly how great a difference there is between the Gregorian Calendar and the old one — and how much more correctly Easter is set for celebration in the former than in the latter — we have computed, in the following table, for every year from 1600 up to the year 5000 (3,401 years in all), the Easters together with the other movable feasts according to the Gregorian Calendar; and likewise the Easters of the old Calendar, together with the number of days by which the Easters of the Gregorian Calendar differ from those celebrated according to the old Calendar. For in this way everyone will plainly recognize that it was absolutely necessary for the Calendar to be corrected, since the Easter of the old year, whenever it differs from the Gregorian, is always celebrated later than was decreed by the Council of Nicaea and the holy Fathers.

In the same table we have also recorded, for each year, the golden number, the Epact, the Dominical letter, the mean full moon reckoned according to the Gregorian correction of the Calendar, the fourteenth Moon of that same [Gregorian Calendar], the fourteenth Moon of the old Calendar, and finally we have added the Indiction of each year as well. Moreover, the number of days by

which the Easters of the two Calendars differ from each other is found as follows: to the day of the old Easter one adds the days that have been dropped from [the reform] up to the year in question, and from the resulting total one subtracts the day of the Gregorian Easter. Thus, since up to the year 1700 exclusive 10 days have been removed, if these are added to 23 March — on which the old Easter is celebrated in the year 1600 — they make the 33rd of March, that is, 2 April; and if from this one takes away 2 April, on which the Gregorian Easter falls in the same year 1600, the difference comes to 0. Again, since up to the year 1880 twelve days will have been removed, if you add them to the old Easter, that is, to 20 April, you will make the 32nd of April, or the 63rd of March; and if from these you subtract the Easter of the new Calendar, that is, 28 March, there will remain a difference between the two Easters of 35 days. And so for the rest.

There follows the table of the Movable Feasts from the year 1600 up to the year 5000.

Table of the Movable Feasts [from the year 1600]

[TABVLA FESTORVM (MOBILIVM)]

This is the opening leaf of the great year-by-year table announced above; it runs here from 1600 to 1655 and continues on the following leaf. Columns: the year of the Lord; the golden number (*Aureus Numerus*); the Epact; the Dominical letter(s) of the Gregorian Calendar (leap years carry two); the mean full moon of the Gregorian Calendar, given as day · hour · month; the fourteenth Moon of the Gregorian Calendar (day · month); Septuagesima; Ash Wednesday (*Dies Cinerum*); Easter of the new Calendar (*Pascha Calendarii novi*); and the Ascension.

In the moon and Easter columns the month is printed as a single letter: **M** = **Martij (March)**, **A** = **Aprilis (April)**. In the Septuagesima and Ash-Wednesday columns the months are "Ian./Feb./Mar."; the Ascension is in "Maij" (May), or "Iunij" (June) where marked.

The *Tabula Festorum Mobilium* of Caput XXII continues across this opening and the next. On each opening the movable feasts of one span of years are set out over the two facing pages: the verso carries the *Table of the Movable Feasts* reckoned by the **new (Gregorian) calendar**, and the facing recto carries the corresponding *Movable [Feasts] of the Seasons* with the **old (Julian, "veteris") calendar** figures alongside. The first leaf here (folio 381) is the old-calendar recto for the years 1600–1655 (companion to the Gregorian leaf of the preceding opening); folios 382–383 form the next opening, covering 1656–1711.

Month codes throughout the lunar and Easter columns: **M** = March (Martius), **A** = April (Aprilis). In the "mean full moon" column the three figures are day · hour · month.

Movable [Feasts] of the Seasons (old calendar), A.D. 1600–1655

Columns: A.D. | Pentecost | Corpus Christi | Indiction | Sundays after Pentecost | First Sunday of Advent | Dominical letter(s), old cal. | Luna 14, old cal. | Easter, old cal. | Days by which new-calendar Easter differs from old-calendar Easter.

The *Table of the Movable Feasts, Year by Year* (Caput XXII) continues. It is laid out as a paired opening: a left-hand (new-calendar / Gregorian) leaf and a right-hand (old-calendar / *veteris*) leaf covering the same span of years, followed by the next new-calendar leaf. The present pages carry the years 1712–1767 (folios 384–385, one opening) and 1768–1823 (folio 386, the next new-calendar leaf).

Conventions preserved from the source: in the "mean full moon" and "Luna 14" columns the trailing letter is the month — **M** = **Martius (March)**, **A** = **Aprilis (April)**; the mean-full-moon cell gives day · hour · month. Epact 30 is printed as

the asterisk *. All epacts in this range are Roman (no Arabic 25 appears). Dominical-letter cells carry two letters in leap years (the letter regresses at 29 February). In the old-calendar leaf the Julian Dominical column treats every fourth year as leap.

[New-calendar leaf — folio 384] CALEND. GREG. — TABVLA FESTORVM [MOBILIVM TEMPORARIA]

Columns: A.D. [*Anni Domini*] · Golden Number [*Aur. Num.*] · Epact [*Epactæ*] · Dominical Letters, new cal. [*Lit. Dñicales Calend. Greg.*] · Mean Full Moon, new cal. [*Plenilunia media Cal. Gregor. — D. H.*] · Luna 14, new cal. [*Lunæ xiiij. Calendarij Gregoriani*] · Septuagesima · Ash Wednesday [*Dies Cinerum*] · Easter, new cal. [*Pascha Calend. noui*] · Ascension [*Ascensio Domini*]

Caput XXII. — *Table of the Movable Feasts, computed for a time (1600–5000)*
(continued).

The table runs as paired leaves: a *new-Calendar* (Gregorian) leaf headed **CALEND. GREG.** — **TABVLA FESTORVM**, and an *old-Calendar* (Julian, *veteris*) leaf headed **CAPVT XXII.** — **MOBILIVM TEMPORARIA**. On the old-Calendar leaf the first five columns (Pentecost, Corpus Christi, Indiction, Sundays after Pentecost, First Sunday of Advent) continue the Gregorian reckoning begun on the facing new-Calendar leaf; the last four columns (dominical letter, Moon 14, Easter, and the difference) give the Julian reckoning.

Abbreviations in the cells: month names as printed — Ian. = January, Febr. = February, Mart. = March, Maij = May, Iunij = June, Nou. = November, Dec. = December. In the lunar and Easter columns the trailing letter is the month: **M** = March (*Martij*), **A** = April (*Aprilis*). The epact * is the asterisk sort (epact 30, new-Calendar form). Two dominical letters mark a leap year. The final column, *Dies quibus Pascha Calendarii novi à Paschate Calendarii veteris differt*, gives the number of days by which the new-Calendar Easter differs from the old-Calendar Easter (values 0, 7, 28, or 35).

[Old-Calendar leaf — printed folio 388; running header "CAPVT XXII. / MOBILIVM TEMPORARIA."] Years 1768–1823

Caput XXII — Table of the Movable Feasts, arranged by year (continued)

The paired new-calendar (Gregorian) and old-calendar (Julian, *veteris*) leaves continue, covering A.D. 1880–1991.

Column legend. In the mean-full-moon, Luna 14, and Easter columns, the letter after the figure is the month: **M** = **Martij (March)**, **A** = **Aprilis (April)**. The mean full moon is given as *day · hour · month* (the hour sub-column is the smallest type on the page and is the least certain reading on these leaves). Explicit month abbreviations elsewhere: **Ian.** = January, **Feb.** = February, **Mar.** = March, **Maij** =

May, **Iunij** = June, **Nou.** = November, **Dec.** = December. The epact-30 asterisk is rendered * as printed. Roman-numeral and Arabic-numeral epacts are transcribed exactly as set (note in particular the Arabic **25** at 1954 and 1973, where the surrounding cycle is Roman). Two dominical letters mark a leap year.

Leaf 1 — New Calendar (*Calend. Greg.*), A.D. 1880–1935

Columns: **A.D.** | **Golden No.** [*Aur. Num.*] | **Epact** [*Epacta*] | **Dom. letter(s)** [*Literæ Dominicales Calend. Greg.*] | **Mean full moon** [*Plenilunia media Cal. Gregor., D·H·mo*] | **Luna 14** [*Lunæ xiiij Cal. Greg.*] | **Septuagesima** | **Ash Wednesday** [*Dies Cinerum*] | **Easter (new)** [*Pascha Calend. noui*] | **Ascension** [*Ascensio Domini*]

Caput XXII — *Tabula Festorum Mobilium Temporaria* (continued)

The paired new-/old-calendar leaves of the perpetual table of movable feasts continue. This opening carries three leaves: an old-calendar (*veteris*) feast leaf for 1936–1991 (the mate of the new-calendar leaf that closed the preceding folio), then a matched pair for 1992–2047 — the new-calendar leaf followed by its old-calendar feast leaf.

Column legend (old-calendar / feast leaves — folios 393, 395). A.D. year · Pentecost (Gregorian) · Corpus Christi (Gregorian) · Indiction · Sundays after Pentecost · First Sunday of Advent (Gregorian) · Dominical letter(s) of the old calendar (two in leap years) · Luna 14 of the old calendar · Easter of the old calendar (*Pascha veteris*) · number of days by which new-calendar Easter differs from old-calendar Easter (*Diff.*). Month abbreviations as printed: **Maij** = May, **Iunij** = June, **Nou.** = November, **Dec.** = December. In the Luna-14 and Easter columns, the trailing **M** = Martij (March), **A** = Aprilis (April).

Column legend (new-calendar leaf — folio 394). A.D. year · golden number (*Aureus Numerus*) · Epact · Dominical letter(s) of the Gregorian calendar · mean full moon of the Gregorian calendar, given as day·hour·(month) (*Plenilunia media*, columns **D. H.**) · Luna 14 of the Gregorian calendar · Septuagesima · Ash Wednesday (*Dies Cinerum*) · Easter of the new calendar (*Pascha noui*) · Ascension. Month abbreviations as printed: **Ian.** = January, **Febr.** = February, **Mart.** = March, **Maij** = May, **Iunij** = June; trailing **M** = March, **A** = April. Epact printed * = the new-

calendar sign for epact 30. Epacts printed as Arabic 25 (golden-number-17 rows) are transcribed as printed, distinct from Roman xxv.

Old-calendar feast leaf — folio 393 (A.D. 1936–1991)

Title (spanning the opening): TABVLA FESTORVM · MOBILIVM TEMPORARIA.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (1600–5000), continued

The table continues from year 2048. Each opening pairs a **new-calendar (Gregorian)** left leaf with the **old-calendar (veteris, Julian)** columns that complete it. In the moon and Easter columns the single letter **M** = *Martius* (March) and **A** = *Aprilis* (April); it is the month indicator, printed as a distinct sort. Roman-numeral epacts are transcribed as printed (epact 25 is set in Arabic figures; epact

30 as the asterisk *); i- vs j-terminal numeral sorts are preserved as printed. In leap years the dominical-letter column carries two letters.

The mean-full-moon **hour (H)** sub-column is the smallest type on these leaves and does not always resolve on the scan; its digits are given as best readings and flagged where uncertain.

Leaf 1 — new calendar, A.D. 2048–2103 (printed folio 396)

Columns: A.D. | Golden No. | Epact | Dominical (Greg.) | Mean full moon (day · hour · month) | Luna 14 (Greg.) | Septuagesima | Ash Wednesday (*Dies Cinerum*) | Easter (*Pascha novi*) | Ascension

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (1600–5000), continued

Chapter XXII. Temporary table of the movable feasts. The table runs across facing leaves in matched pairs: a new-calendar (Gregorian) leaf headed **TABVLA FESTORVM MOBILIVM** / *Calend. Greg.*, and an old-calendar (Julian, *veteris*) leaf headed **MOBILIVM TEMPORARIA** / *Caput XXII*. This portion covers years **2104–2215**.

- **Folio 399** is the old-calendar leaf completing the opening for **2104–2159** (its new-calendar partner, folio 398, was in the previous stretch).
- **Folio 400** is the new-calendar leaf for **2160–2215**.
- **Folio 401** is the old-calendar leaf for **2160–2215**.

Column conventions retained as printed: month abbreviations *Maij* (May), *Iunij* (June), *Ian.* (January), *Febr.* (February), *Mart.* (March), *Nou.* (November), *Dec.* (December); the single-letter month marker **M** = March, **A** = April in the moon/Easter columns. Golden numbers and epacts are transcribed in their printed figure (Roman vs. Arabic) exactly; the doubled epact 25 appears as Arabic 25 and epact 30 as the asterisk *. The mean-full-moon column is given as **day · hour · month**.

Folio 399 — old-calendar leaf, A.D. 2104–2159

Columns: A.D. | Pentecost | Corpus Christi | Indiction | Sundays after Pentecost | First Sunday of Advent | Dominical letter(s), old Calendar | Moon 14, old Calendar | Easter, old Calendar | Diff. (days by which new-Calendar Easter differs from old-Calendar Easter)

Leaf, folio 403 — old-calendar (*veteris*) side

Columns: **Anni Domini** · **Pentecoste** (day · month) · **Corpus Domini** (day · month) · **Indictio** · **Dnicæ post Pentecosten** (Sundays after Pentecost) · **Dominica prima Aduentus** (day · month; Dec./Nov.) · **Literæ Dnicales Calendarij veteris** (old-calendar Dominical letters; two in leap years) · **Lunæ xiiij Cal. veteris** (day · month) · **Pascha Caléndarij veteris** (Julian date; day · month) · **Dies quibus Pascha Calend. noui à Paschate Calend. veteris differt** ("Diff.").

Pentecoste, Corpus Domini, Indictio, Dnicæ post Pentecosten, and Dominica prima Aduentus are the Gregorian (new-calendar) continuation of the preceding leaf; the Literæ, Luna 14, and Pascha columns are the old (Julian) calendar.

Caput XXII — *Tabula Festorum Mobilium Temporaria* (1600–5000), continued

The *Table of the Movable Feasts for the Time Being* continues, in paired leaves: for each span of years a new-calendar (Gregorian) leaf faces an old-calendar (*veteris*, Julian) leaf. This opening supplies the **old-calendar leaf for the years 2272–2327** (whose new-calendar leaf preceded it), and then the **new-calendar and old-**

calendar leaves for the years 2328–2383. All values are transcribed cell-by-cell from the page; typographic distinctions (Roman vs. Arabic figures, the epact-30 asterisk *, i-/j-terminal Roman numerals, long-s) are preserved as printed.

Column key (old-calendar leaves): A.D. year | Pentecost (*Pentecoste*) | Corpus Christi (*Corpus Domini*) | Indiction (*Indictio*) | Sundays after Pentecost (*Dominicæ post Pentecosten*) | First Sunday of Advent (*Dominica prima Adventus*) | Dominical letter(s), old calendar (*Literæ Dominicales Calend. veteris*; two letters in a Julian leap year) | Moon 14, old calendar (*Lunæ xiiij Calend. veteris*) | Easter, old calendar (*Pascha Calendarij veteris*) | Difference of new-calendar Easter from old-calendar Easter, in days (*Dies quibus Pascha Calend. novi à Paschate Calend. veteris differt*).

Column key (new-calendar leaf): A.D. year | Golden number (*Aureus Numerus*) | Epact (*Epacta*) | Dominical letter(s), Gregorian (*Literæ Dominicales Calend. Greg.*) | Mean full moon, Gregorian (*Plenilunia media Cal. Gregor.*), given as day · hour · month | Moon 14, Gregorian (*Lunæ xiiij Calendarij Gregoriani*) | Septuagesima | Ash Wednesday (*Dies Cinerum*) | Easter, new calendar (*Pascha Calend. novi*) | Ascension (*Ascensio Domini*).

Dates are given as *day + month* (Ian. = January, Feb. = February, Mar. = March, A = April, M = March in the Moon-14/Easter sub-columns; Maij = May, Iunij = June). In the moon/Easter columns the printed single letter **A** = **April**, **M** = **March**.

Old-calendar leaf, A.D. 2272–2327

New-calendar leaf, A.D. 2328–2383

Epact 30 is set with the new-Calendar asterisk *. In the mean-full-moon column the smallest sub-column is the hour (H); as elsewhere in this table it does not always resolve on the scan, and the H figures below are best readings.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The paired new-calendar (Gregorian) and old-calendar (*veteris*) leaves of the movable-feast table continue, covering the years 2384–2495. Each opening sets the new-calendar columns on the verso leaf (folios 408, 410) and continues the same block of years across to the old-calendar columns on the facing recto leaf (folio 409).

Column key for the new-calendar leaves (folios 408, 410): **Anni Domini** (A.D. year) · **Aur. Num.** (golden number) · **Epactæ** (epact) · **Lit. Dnicales Calend. Greg.** (Gregorian Dominical letter(s); leap years carry two) · **Plenilunia media Cal. Gregor.** (mean full moon: day · hour · month-letter, where A = April, M = March) · **Lunæ xiiij Calend. Gregoriani** (Luna 14; day + month-letter) · **Septuagesima** ·

Dies Cinerum (Ash Wednesday) · **Pascha Calend. novi** (new-calendar Easter; day + month-letter) · **Ascensio Domini** (Ascension).

Folio 408 (new calendar) — years 2384–2439

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The paired new-/old-calendar leaves of the perpetual movable-feast table continue. This opening-set covers A.D. 2440–2551. Each year occupies one row that runs across a two-page opening: the **new-calendar (Gregorian) leaf** carries the golden number, epact, Gregorian dominical letter(s), mean full moon, Luna 14, Septuagesima, Ash Wednesday, Easter, and Ascension; the facing **old-calendar leaf** carries the movable feasts that follow Easter (Pentecost, Corpus Christi, Indiction, Sundays-after-Pentecost, first Sunday of Advent) and then a self-contained block of Julian-calendar values (Julian dominical letter[s], Julian Luna 14, Julian Easter) with the column of differences between the new and old Easter.

All dates are transcribed verbatim as printed (Roman-numeral epacts, Maij/Iunij, long-forms, the epact-30 asterisk *, and two dominical letters in Julian leap years). Numerals are not normalized.

Folio 411 — old-calendar (right-hand) leaf, A.D. 2440–2495

Columns: **Anni Domini** | **Pentecoste** | **Corpus Domini** | **Indictio** | **Dominica post Pentecosten** (Sundays after Pentecost) | **Dominica prima Adventus** | **Literæ Dominicales Calend. veteris** | **Lunæ 14 Calend. veteris** | **Pascha Calendarii veteris** | **Diff.** (days by which the new Easter differs from the old).

December. Two dominical letters mark Julian leap years (every year divisible by 4: 2440, 2444, ... 2492). Corpus Domini = Pentecost + 11 throughout; the printed **2486 "20 Maij" is a month-slip** — Pentecost falls 9 Iunij, so Corpus is 20 **Iunij** (flagged [recte:]).

Folio 412 — new-calendar (Gregorian) leaf, A.D. 2496–2551

Columns: **Anni Domini** | **Aur. Num.** (golden number) | **Epactæ** | **Literæ Dominicales Caled. Gregor.** | **Plenilunia media Cal. Gregor.** (D · H · month — mean full moon: day · hour · month) | **Lunæ 14 Calendarii Gregoriani** | **Septuagesima** | **Dies Cinerum** (Ash Wednesday) | **Pascha Calend. novi** | **Ascensio Domini.**

month (M/A). The H value was read twice, from two overlapping views of the leaf, and agreed in every row, so the hours here carry the usual reading confidence rather than being pattern-derived; even so, they remain the least certain values on the leaf. **The epact set steps down by 1 at 2500** (the Gregorian centurial solar equation: 2500 is a common year), so GN 12 shows epact xxviii (28) rather than the 29 a naive +11 continuation would give; from 2500 on the +11 Metonic run (saltus +12 at GN 19→1) is internally regular. Epact 30 is printed as the asterisk * (GN 4).

Folio 413 — old-calendar (right-hand) leaf, A.D. 2496–2551

Columns as folio 411. The Pentecost / Corpus / Indiction / Sundays-after-Pentecost / Advent columns continue the **Gregorian** reckoning of the facing leaf (Pentecost = new Easter + 49); the final block (Julian dominical letter[s], Julian Luna 14, Julian Easter, Diff.) is the *veteris* material.

year, whereas on the facing Gregorian leaf it is a common year with the single letter c — the intended new/old-calendar divergence at the century boundary, not a compositor error. The Diff. column values (0, 7, 35, 42) reconcile exactly with the two Easters once the Gregorian–Julian solar offset is applied (16 days for 2496–2499, 17 days from 2500). Two Julian dominical letters mark 2496, 2500, 2504, ... 2548.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The *Table of the Movable Feasts* continues, laid out across facing leaves. Each opening pairs a left leaf carrying the **new (Gregorian) calendar** festal data (folios 414 and 416 below) with a right leaf carrying the feasts that follow Easter together with the **old (Julian) calendar** Easter reckoning for comparison (folio 415 below). In the full-moon, *Luna 14*, and Easter columns the month letter **A** = *Aprilis* (April) and **M** = *Martius* (March); the mean full moon is given as day · hour · month. Julian leap years carry two dominical letters.

Folio 414 — new calendar (*Calend. Greg.*), A.D. 2552–2607

Columns: Year of the Lord | Golden number [*Aur. Num.*] | Epact | Gregorian dominical letter(s) | Mean full moon, Gregorian calendar (day. hour, month) | *Luna 14*, Gregorian calendar | Septuagesima | Ash Wednesday [*Dies Cinerum*] | Easter, new calendar [*Pascha Calend. noui*] | Ascension.

Note — the epact drops by one at A.D. 2600 (the Gregorian lunar/solar equation at the century year): golden number 17, which yields epact 23 in the years before 2600, yields epact 22 from 2600 on, and the whole cycle follows suit through folio 416. At 2600 the Gregorian dominical column carries a **single** letter (e) — 2600 is a common year in the new calendar — whereas the Julian column on folio 415 carries two (see below).

Folio 415 — old calendar (*Calend. vetus*), A.D. 2552–2607

Columns: Year of the Lord | Pentecost [*Pentecoste*] | Corpus Christi [*Corpus Domini*] | Indiction [*Indictio*] | Sundays after Pentecost [*Dñicæ post Pentecosten*] | First Sunday of Advent [*Dominica prima Aduentus*] | dominical letter(s) of the old calendar [*Literæ Dñicales Calendarij veteris*] | *Luna 14* of the old calendar |

Easter, old calendar [*Pascha Calendarij veteris*] | Days by which new-calendar Easter differs from old-calendar Easter [*Diff.*].

At A.D. 2600 the Julian dominical column carries two letters (b A) — the Julian 2600 is a leap year — while the corresponding Gregorian column on folio 414 carries one (e). This is the flagged 2600 divergence: Gregorian-common but Julian-leap.

Folio 416 — new calendar (*Calend. Greg.*), A.D. 2608–2663

Columns as on folio 414.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The great *Table of the Movable Feasts, year by year* (A.D. 1600–5000) continues. Each opening pairs a left-hand **new-calendar (Gregorian)** leaf with a right-hand leaf that completes the Gregorian feast-columns and then gives the corresponding

old-calendar (Julian, *veteris*) reckoning. In the moon and Easter columns the printed month is abbreviated to a single letter: **M** = March (*Martius*), **A** = April (*Aprilis*); in the Advent column **Nou.** = November, **Dec.** = December. Julian (Old-Style) leap years carry **two** dominical letters. The mean-full-moon column is set *day · hour · month*.

Folio 417 — right-hand leaf completing the opening for A.D. 2608–2663

This leaf supplies the remaining feast-columns (Pentecost through the Julian Easter) for the years whose Gregorian half was set on the facing leaf (folio 416). Columns: A.D. | Pentecost | Corpus Christi | Indiction | Sundays after Pentecost | First Sunday of Advent | Dominical letter (Julian) | Moon-14 (Julian) | Easter (Julian) | Diff. (days by which new-calendar Easter differs from old-calendar Easter).

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

Christoph Clavius, Explicatio Romani Calendarii, Caput XXII: the perpetual table of movable feasts (A.D. 1600–5000), continued. Each opening pairs a new-calendar (Gregorian) leaf with an old-calendar (veteris = Julian) leaf covering the same span of years. These three leaves carry the years 2720–2831.

Column conventions (verbatim headings glossed). In the moon columns the single letter after a date is the month: **A** = *Aprilis* (April), **M** = *Martius* (March). The mean-full-moon column is set *Day · Hour · month* (D·H·mens.). Julian (old-calendar) leap years carry two Dominical letters; from 2800 onward the Gregorian leaf too shows two letters in its leap years, since **2800 is a Gregorian leap year** (divisible by 400 — both calendars intercalate, so the two reckonings do not diverge here). The *Diff.* column gives the number of days by which new-calendar Easter differs from old-calendar Easter (the accumulated calendar offset in this era is 19 days).

Folio 420 — new calendar (Gregorian)

Headings glossed: *Anni Domini* (Years of the Lord) · *Aur. Num.* (Golden Number) · *Epactæ* (Epacts) · *Lit. Dnicales Calend. Greg.* (Dominical letters, Gregorian) · *Plenilunia media Cal. Gregor.* — *D. H.* (mean full moons, Gregorian — day, hour) · *Lunæ xiiij Calendarij Gregoriani* (the 14th of the [paschal] moon, Gregorian) · *Septuagesima* · *Dies Cinerum* (Ash Wednesday) · *Pascha Calend. noui* (Easter, new calendar) · *Ascensio Domini* (Ascension).

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The *Table of the Movable Feasts* continues, in its paired arrangement: each span of years is set out both in the old (Julian) calendar and in the new (Gregorian) calendar. This opening carries the old-calendar leaf for the years 2776–2831, then the new-calendar and old-calendar leaves for the years 2832–2887.

Throughout, in the Luna 14 and Easter columns the month is abbreviated to a single letter: **A** = *Aprilis* (April), **M** = *Martii* (March). Julian leap years carry two Dominical letters. Epacts are printed as Roman numerals; the epact 30 is set with an asterisk (*). Golden numbers and the "difference" figure are Arabic. Month abbreviations (Maij, Iunij, Ian., Feb., Mar., Nou., Dec.) are transcribed as printed.

Old (Julian) calendar — years 2776–2831

Columns: A.D. · Pentecost · Corpus Christi · Indiction · Sundays after Pentecost · First Sunday of Advent · Dominical letter(s), old calendar · Luna 14, old calendar · Easter, old calendar · Days by which the new-calendar Easter differs from the old-calendar Easter.

New (Gregorian) calendar — *Tabula Festorum* — years 2832–2887

Columns: A.D. · Golden number · Epact · Dominical letter(s), Gregorian · Mean full moon, Gregorian calendar (Day · Hour · month) · Luna 14, Gregorian · Septuagesima · Ash Wednesday (*Dies Cinerum*) · Easter, new calendar · Ascension.

The mean-full-moon **hour** is the smallest type on the leaf and does not always resolve on the scan; the hour figures are provisional and should not be treated as citation-grade.

Caput XXII — *Tabula Festorum Mobilium Temporaria* (continued)

The *Table of the Movable Feasts for the Time Being* continues, in its paired arrangement of facing leaves: each new-calendar (Gregorian) leaf is completed by an old-calendar (*veteris*) leaf covering the same span of years. This batch holds three leaves — the new-calendar leaf for 2888–2943 (folio 426), its old-calendar counterpart for the same years (folio 427), and the new-calendar leaf for 2944–2999 (folio 428). The old-calendar counterpart of the final leaf falls on the following opening.

In the full-moon, Luna 14, and Easter columns the month is marked by a single letter: **A** = *Aprilis* (April), **M** = *Martius* (March). Julian (old-calendar) leap years — every year divisible by 4, centuries included — carry **two** dominical letters; Gregorian leap years exclude the non-400 centuries. The year **2900** is therefore the calendar-divergence point on these leaves: Gregorian-common (single dominical letter on the new leaf) but Julian-leap (two letters on the old leaf), and the raw day-offset between the two Easters widens from 19 to 20 days across it — reflected in the *Diff.* column, where values of 42 appear around 2898–2901.

Folio 426 — new calendar (*Calend. Gregor.*), A.D. 2888–2943

Column headings (verbatim): *Anni Domini* (A.D.) | *Aur. Num.* (golden number) | *Epactæ* (epact) | *Litteræ Dominicales Caléd. Gregor.* (Gregorian dominical letters) | *Plenilunia media Cal. Gregor.* — *D. H.* (mean full moon, Gregorian calendar: day · hour · month) | *Lunæ xiiii. Calendarii Gregoriani* (Luna 14) | *Septuagesima* | *Dies Cinerum* (Ash Wednesday) | *Pascha Calend. novi* (Easter, new calendar) | *Ascensio Domini* (Ascension).

The *Table of the Movable Feasts by Period* (Caput XXII) continues. Each opening of the table carries one span of years across two facing leaves: the left (verso) leaf gives the Gregorian data (golden number, epact, dominical letter, mean full moon, Septuagesima, Ash Wednesday, new-calendar Easter, Ascension); the right (recto) leaf continues the same years with the movable feasts (Pentecost, Corpus Christi, Indiction, Sundays after Pentecost, first Sunday of Advent) and the old-calendar (Julian, *veteris*) comparison (dominical letter, Luna 14, Easter of the old calendar, and the number of days by which the new-calendar Easter differs from it).

The first leaf below completes the opening for A.D. 2944–2999 (its Gregorian verso was on the preceding leaf); the following two leaves form the opening for A.D. 3000–3055.

Month abbreviations as printed. In the date columns: *Maij* = May, *Iunij* = June, *Nou.* = November, *Dec.* = December, *Ian.* = January, *Feb.* = February, *Mar./Mart.* = March, *Apr.* = April. In the Luna 14 and Easter columns the single letters stand for months: **A** = *Aprilis* (April), **M** = *Martij* (March). In leap years the dominical-letter cell carries two letters. The mean-full-moon column is given as day · hour · month; the hour (H) sub-column is the smallest type on the leaf.

Movable Feasts by Period — old-calendar (*veteris*) leaf, A.D. 2944–2999

Columns: A.D. | Pentecost (Pentecoste) | Corpus Christi (Corpus Domini) | Indiction (Indictio) | Sundays after Pentecost (Dies post Pentecosten) | First Sunday of Advent (Dominica prima Adventus) | Dominical letter(s), old cal. (Literæ Dominicales Calend. veteris) | Luna 14, old cal. (Lunæ xiiij Calend. veteris) | Easter, old cal. (Pascha Calendarij veteris) | Days of difference (Dies quibus Pascha Calend. noui à Paschate Calend. veteris differt)

Tabula Festorum — Gregorian leaf (Calendarium Gregorianum), A.D. 3000–3055

Columns: A.D. | Golden number (Aur. Num.) | Epact (Epactæ) | Dominical letter(s), Greg. (Lit. Dñicales Calend. Greg.) | Mean full moon, Greg. — day · hour · month (Plenilunia media Cal. Gregor.) | Luna 14, Greg. (Lunæ xiiij Calendarij Gregoriani) | Septuagesima | Ash Wednesday (Dies Cinerum) | Easter, new cal. (Pascha Calend. noui) | Ascension (Ascensio Domini)

Note: 3000 is a Gregorian common year (single dominical letter *e*); on the old-calendar leaf below it is a Julian leap year (two letters). The hour (H) sub-column of the mean full moon is at the limit of what the scan resolves; the H digits below are the best reading the leaf allows.

Caput XXII — *Tabula Festorum Mobilium Temporaria* (continued)

(Table of the Movable Feasts, for the years 1600–5000; continued from the preceding leaves.)

These three leaves continue the great year-by-year table of the movable feasts. Each opening of the book is a single wide table split across two facing pages: the **left-hand (new-calendar) half** carries the running header **CALEND. GREG. / TABVLA FESTORVM**, and the **right-hand half** carries **CAPVT XXII. / MOBILIVM TEMPORARIA**. The left half gives, for each year A.D., the Gregorian reckoning down to Ascension; the right half continues with Pentecost and the later feasts, the Indiction, Advent, and then the **old-calendar (Julian, veteris)** dominical letter, paschal moon, and Easter, ending with the number of days by which the new-calendar Easter differs from the old-calendar Easter.

Caput XXII — Tabula Festorum Mobilium Temporaria (continued)

The great table of the movable feasts (A.D. 1600–5000), continued. Each opening pairs a New-calendar (Gregorian) leaf with an Old-calendar (veteris) leaf. This span covers A.D. 3112–3223.

Column-header glosses (Old-calendar leaves, pp. 435 & 437): **Anni Domini** = year A.D.; **Pentecoste** = Pentecost; **Corpus Domini** = Corpus Christi; **Indictio** = Indiction; **Dñicæ post Pentecosten** = Sundays after Pentecost; **Dominica prima Adventus** = First Sunday of Advent; **Literæ Dñicales Calend. veteris** = Dominical letter(s), old calendar; **Lunæ xiiij Cal. veteris** = the 14th of the moon (Luna 14), old calendar; **Pascha Calend. veteris** = Easter, old calendar; **Dies quibus Pascha Calend. novi à Paschate Calend. veteris differt** = number of days by which New-calendar Easter differs from Old-calendar Easter. Month/letter sorts kept as printed: Maij, Iunij (also the variants Mai, Maij, Maii), Ian., Feb., Mar./Mart., Dec., Nou.; and, in the moon/Easter columns, **M** = Martius (March), **A** = Aprilis (April).

Column-header glosses (New-calendar leaf, p. 436): **Aur. Num.** = Golden Number; **Epactæ** = Epacts; **Lit. Dñicales Calend. Greg.** = Dominical letter(s), Gregorian calendar; **Plenilunia media Cal. Gregor. (D. H.)** = mean full moons, Gregorian calendar (Day · Hour · month-letter); **Lunæ xiiij. Calendarij Gregoriani** = Luna 14, Gregorian; **Septuagesima**; **Dies Cinerum** = Ash Wednesday; **Pascha Calend. novi** = Easter, new calendar; **Ascensio Domini** = Ascension.

Old-calendar leaf — right half of the A.D. 3112–3167 opening

(The left, Gregorian, half of this opening (folio 434, A.D. 3112–3167) fell in the preceding leaves.)

Running header: **CAPVT XXII. — MOBILIVM TEMPORARIA.**

Caput XXII — Tabula Festorum Mobilium Temporaria (continued)

Temporary Table of the Movable Feasts (A.D. 1600–5000), continuing the paired new-calendar (Gregorian) and old-calendar (*veteris*) leaves.

This opening presents the table for A.D. 3224–3279 across two facing pages: the first page carries the new-calendar (Gregorian) columns, and the second the remaining Gregorian feast columns together with the old-calendar (Julian) block. The following page begins the next opening with the new-calendar columns for A.D. 3280–3335.

Conventions used in the transcription below (as printed): in the paschal columns **M** = *Martii* (March) and **A** = *Aprilis* (April); the mean-full-moon column is set *day · hour · month*, so e.g. 26. 14 M = day 26, hour 14, March. Feast months otherwise

given as **Ian.** (January), **Febr.** (February), **Mart.** (March), **Maij/Maii** (May), **Iunij** (June), **Nou.** (November), **Dec.** (December). Golden number = *Aureus Numerus*; epact-30 is printed as the asterisk *. The dominical-letter columns carry two letters in leap years. Roman/Arabic numeral forms and i-/j-terminal letter sorts are preserved exactly as printed.

New-calendar (Gregorian) leaf — A.D. 3224–3279

Column heads (as printed): *Anni Domini* | *Aur. Num.* (golden number) | *Epactæ* | *Literæ Dominicales Caléd. Gregor.* | *Plenilunia media Cal. Gregor.* (D. H. + month) | *Lunæ xiiii Calendarii Gregoriani* | *Septuagesima* | *Dies Cinerum* (Ash Wednesday) | *Pascha Calend. novi* (Easter) | *Ascensio Domini*.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (1600–5000), continued

These three leaves continue the great table of movable feasts. Each opening pairs a **new-calendar (Gregorian)** verso with a **new-/old-calendar comparison** recto: the verso (headed *Calend. Greg. — Tabula Festorum*) carries golden number, epact, Gregorian dominical letter, the mean full moon, Luna 14, and the earlier feasts (Septuagesima, Ash Wednesday, Easter, Ascension); the recto (headed *Caput XXII — Mobilium Temporaria*) carries the later new-calendar feasts (Pentecost, Corpus Christi, Advent) together with the old-calendar (*veteris*) dominical letter, Luna 14, Easter, and the difference between the two Easters.

Latin forms are transcribed verbatim from the leaf, including variant spellings (*Maii*, *Mart.*, *Deç.*), i-/j-terminal Roman numerals, Roman xxv vs Arabic 25, the cedilla dominical ç (= c), and the epact-30 asterisk *. Month abbreviations: **Ian.** = January, **Feb.** = February, **Mar./Mart.** = March, **Maij/Maii** = May, **Iunij** = June, **Nou.** = November, **Dec./Deç.** = December. In the moon/Easter columns the trailing letter marks the month: **M** = *Martius* (March), **A** = *Aprilis* (April). In the mean-full-moon column the three figures are **D** (day) · **H** (hour) · month.

Old-calendar comparison leaf — A.D. 3280–3335 (later new-calendar feasts + old-calendar columns)

[The left-hand columns for these years — golden number, epact, Gregorian dominical letter, mean full moon, Luna 14, Septuagesima, Ash Wednesday, Easter, Ascension — stand on the preceding leaf; this leaf carries the continuation.]

(Caput XXII, continued — the perpetual-by-period table for A.D. 1600–5000. This opening carries the years 3392–3447 across its two leaves; the following new-calendar leaf carries 3448–3503.)

Roman/Arabic epact forms, i-/j-terminal sorts, and capital/small letters are transcribed as printed.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (1600–5000), continued

Three paired leaves of the perpetual table of movable feasts, years **3448–3559**. Each opening sets the **new (Gregorian) calendar** leaf (*Calend. Greg. — Tabula Festorum*) facing the **old (Julian) calendar** leaf (*Mobilium Temporaria*, i.e. *Caput XXII*). On the old-calendar leaves the Pentecost / Corpus Christi / Sundays-after-Pentecost / First Sunday of Advent columns continue the mobile-feast sequence keyed to the **new-calendar Easter** (verified: e.g. new Easter 27 Mar 3504 + 49 days = Pentecost 15 May 3504); the three rightmost columns (Dominical letter,

Luna 14, Easter) give the **old-calendar** reckoning, and the final column gives the difference between the two Easters.

Month indicators in the Luna 14 / Easter sub-columns: **M** = March (*Martij*), **A** = April (*Aprilis*). Mean-full-moon column is **day · hour · month**. Roman/Arabic numeral forms, i-/j-terminal sorts, the cedilla dominical ç (= c), and month-abbreviation variants are transcribed as printed, not normalized.

Leaf 1 — folio 447 (old-calendar leaf, *Mobilium Temporaria*), A.D. 3448–3503

Running header: **CAPVT XXII. / MOBILIVM TEMPORARIA.** — printed folio **447**.

Columns: A.D. | Pentecost | Corpus Christi | Indict. | Sund. post Pent. | Advent I | Dom. lett. (old) | Luna 14 (old) | Easter (old) | Diff.

Note: 3500 is a leap year in the Julian (old) calendar — two Dominical letters d c — but a common year in the Gregorian, which is why year 3500 does not appear on the new-calendar leaves.

Leaf 2 — folio 448 (new-calendar leaf, *Tabula Festorum*), A.D. 3504–3559

Running header: **CALEND. GREG. / TABVLA FESTORVM** — printed folio **448**.

Columns: A.D. | Golden no. (Aur. Num.) | Epact | Dom. lett. (Greg.) | Mean full moon (D · H · mo) | Luna 14 | Septuagesima | Ash Wednesday (Dies Cinerum) | Easter (new) | Ascension.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The paired new-calendar (Gregorian) and old-calendar (*veteris*) leaves of the *Temporary Table of the Movable Feasts* continue, running here from A.D. 3560 to A.D. 3671. The Gregorian leaf (printed p. 450) and its facing old-calendar leaf (printed p. 451) together cover A.D. 3560–3615; the next Gregorian leaf (printed p. 452) covers A.D. 3616–3671. In every column the month of the mean full moon, of Luna 14, and of Easter is given by a single letter, A = *Aprilis* (April) and M = *Martius* (March). Leap years carry two Dominical letters.

New-calendar leaf — A.D. 3560–3615 (printed p. 450)

Columns: **Anni Domini** (year of the Lord) · **Aur. Num.** (golden number) · **Epactæ** (epact) · **Lit. Dñicales Calend. Greg.** (Dominical letters of the Gregorian calendar; two in leap years) · **Plenilunia media Cal. Gregor.** (mean full moons of the Gregorian calendar: D. = day, H. = hour, followed by the month letter) · **Lunæ xiiij. Calendarij Gregoriani** (14th of the moon, Gregorian; day + month) · **Septuagesima** · **Dies Cinerum** (Ash Wednesday) · **Pascha Calend. noui** (Easter of the new calendar; day + month) · **Ascensio Domini** (Ascension).

Old-calendar leaf — A.D. 3560–3615 (printed p. 451)

This is the facing leaf for the same years. Its first columns continue the new-calendar feasts (Pentecost, Corpus Christi, indiction, Sundays after Pentecost, First Sunday of Advent); the last columns give the corresponding **old-calendar** (Julian) figures. Columns: **Anni Domini** · **Pentecoste** (Pentecost) · **Corpus Domini** (Corpus Christi) · **Indictio** (indiction) · **Dñicæ post Pentecosten** (Sundays after Pentecost) · **Dominica prima Aduentus** (First Sunday of Advent; day + Nov./Dec.) · **Literæ Domini Calend. veteris** (Dominical letters of the old calendar; two in leap years) · **Lunæ xiiij. Calend. veteris** (14th of the moon, old calendar; day + month) · **Pascha Calend. veteris** (Easter of the old calendar; day + month) · **Dies quibus Pascha Calend. noui à Paschate Calend. veteris differt** (days by which new-calendar Easter differs from old-calendar Easter).

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (1600–5000), continued

These three leaves continue the great table of the movable feasts, paired new-calendar (Gregorian) and old-calendar (*veteris*) leaves. This opening covers A.D. 3616–3671 on the old-calendar side (folio 453) and A.D. 3672–3727 on both the new-calendar (folio 454) and old-calendar (folio 455) sides.

In the date columns, the single letters after a day-number give the month: **M** = **Martius (March)**, **A** = **Aprilis (April)**; **Nou.** = **November**, **Dec.** = **December**; **Maij/Iunij** = **May/June**. In the *Plenilunia media* column the entry is **day · hour**, followed by the M/A month-letter of that mean full moon.

Folio 453 — old calendar (*Calendarium vetus*), A.D. 3616–3671

Running head: CAPVT XXII. — MOBILIVM TEMPORARIA.

Columns: A.D. | Pentecost | Corpus Christi | Indiction | Sundays after Pentecost | First Sunday of Advent | Dominical letter(s), old cal. | Luna 14, old cal. | Easter, old cal. | Diff. (days by which the new-calendar Easter differs from the old-calendar Easter)

Caput XXII — Table of the Moveable Feasts for the Times (*Tabula Festorum Mobilium Temporaria*), 1600–5000 (continued)

This opening continues the great year-by-year table of the moveable feasts. Each range of years is set across a facing pair of leaves: a **new-calendar (Gregorian)** leaf carrying the early-year columns (golden number, epact, Dominical letter, mean full moon, Luna 14, Septuagesima, Ash Wednesday, Easter, Ascension), and

an **old-calendar (*veteris*)** leaf carrying the later columns (Pentecost, Corpus Christi, Indiction, Sundays after Pentecost, First Sunday of Advent) together with the old-calendar Dominical letter, Luna 14, and Easter, and the difference in days between the new and old Easter. The first two pages below (printed pp. 456–457) form one such facing pair, covering **A.D. 3728–3783**; the third (printed p. 458) begins the next new-calendar leaf, **A.D. 3784–3839**.

Column conventions (as printed, not normalized): In the mean-full-moon, Luna 14, and Easter columns, the trailing letter **A** = *Aprilis* (April) and **M** = *Martius* (March). The mean full moon is given as **day · hour · month-letter**. In the feast columns the months appear as printed: **Ian.** = January, **Feb.** = February, **Mar.** = March, **Maij** = May, **Iunij** = June, **Nou.** = November, **Dec.** = December. Roman/Arabic numeral forms and i-/j-terminal sorts in the epact column are preserved verbatim; the epact value 30 is set with an asterisk, given here as *.

New-Calendar Leaf (printed p. 456) — A.D. 3728–3783

Columns: **A.D.** | **Golden No.** [*Aur. Num.*] | **Epact** [*Epactæ*] | **Dominical Letter(s)** [*Lit. Dnicales Calend. Greg.*; two letters in leap years] | **Mean Full Moon, Greg.** (day · hour · month) [*Plenilunia media Cal. Gregor.*] | **Luna 14, Greg.** [*Lunæ xiiij. Cal. Gregoriani*] | **Septuagesima** | **Ash Wednesday** [*Dies Cinerum*] | **Easter, new cal.** [*Pascha Calend. noui*] | **Ascension** [*Ascensio Domini*]

New-Calendar Leaf (printed p. 458) — A.D. 3784–3839

Header: **CALEND. GREG. — TABVLA FESTORVM [MOBILIVM].**

Columns as for the first leaf. Note the centurial epact adjustment at A.D. 3800: from 3800 onward every epact drops one place (e.g. golden number 1 now takes epact xxj, not xxij), and golden number 10 takes epact 30, printed with the asterisk *.

Parsing notes

- **Mean-full-moon hour (H) sub-column.** This is the smallest type on the leaf and is the one column of these *Tabula Festorum* leaves that does not reliably resolve on the scan. Here each H value was read twice, in two overlapping views of the leaf, so that the last hour-digit could be corroborated row by row; the day, Luna 14, and all feast columns are firm, while the H digits are best readings and a handful may carry an error of ± 1 .
- **p. 456, A.D. 3778 mean full moon** — month read as **M** (March): the glyph as it stands in the scan tends toward "A", but the same lunation's Luna 14 (26 M) and the year's Easter (29 M) fix the mean full moon in March. Transcribed 26 · 15 M.
- **p. 458, A.D. 3833 Easter** — the month letter after 21 sits at the A/M ambiguity under foxing; resolved to **A** (April) by the row's Ascension (30 Maij) and Septuagesima (17 Feb.), both of which require Easter = 21 April. Transcribed 21 A.
- Epact i-/j-terminal and Roman/Arabic variants preserved verbatim: e.g. *iiii* (3736) vs *iiij* (3755, 3774); *xiii* (3783) vs *xiiij*; *vi* (3747, 3815) vs *vj* (3834); *xvi* (3824) vs *xvij* (3816); *xvii* (3835) vs *xvij*; and the **Arabic** epact 25 (3814, 3833) beside the Roman *xxv* form used elsewhere. The epact-30 asterisk is rendered * (3809, 3828).
- Dominical-letter pairs in leap years and the full single-letter cycle were verified continuous across all three leaves (new-calendar and old-calendar cycles both). Corpus Christi = Pentecost + 11, Indiction = (year + 3) mod 15, and the Diff column (a multiple of 7, reflecting the Julian↔Gregorian offset

of ~26 days in this era) all check out row by row; these relations were used only to confirm reads, not to supply cell values.

Chapter XXII (continued) — Table of the Movable Feasts through Time

The three leaves here are:

- **Folio 459** — the old-calendar (Julian) leaf for A.D. **3784–3839** (completing the opening whose Gregorian leaf preceded).
- **Folio 460** — the new-calendar (Gregorian) leaf for A.D. **3840–3895**.
- **Folio 461** — the old-calendar (Julian) leaf for A.D. **3840–3895**.

On the old-calendar leaves the Pentecost, Corpus Christi, Indiction, Sundays-after-Pentecost, and First-Sunday-of-Advent columns are reckoned in the **Gregorian** calendar (derived from the new-calendar Easter of the facing leaf); the last four columns — Dominical Letter, Luna 14, Easter, and the Difference — give the **Julian** ("veteris") reckoning and the number of days by which the new Easter differs from the old.

Month forms are transcribed exactly as printed per cell (Iunij / Maij / Maii; Ian. / Feb. / Mar.; Nou. / Dec.). Dominical, Luna-14, and Easter letter-marks (A = April, M = March; index letters A g f e d c b) are given verbatim. Epact 30 is printed as an asterisk *; epact 25 is printed in Arabic figures (25) where the rest are Roman — both retained verbatim.

Folio 459 — Old-Calendar (Julian) Leaf, A.D. 3784–3839

Folio 460 — New-Calendar (Gregorian) Leaf, A.D. 3840–3895

[Running head: CALEND. GREG. / TABVLA FESTORVM; page number 460 top left.]

Columns: **A.D.** [Anni Domini] · **Gold. No.** [Aur. Num.] · **Epact** [Epactæ] · **Dom. Lett. (Greg.)** [Lit. Dominicales Cal. Greg.] · **Mean full moon** [Plenilunia media

Cal. Gregor.], given as **day · hour · month** (D · H · Mo) · **Luna 14 (Greg.)** [Lunæ xiiij Cal. Gregoriani] · **Septuagesima · Ash Wed.** [Dies Cinerum] · **Easter (Greg.)** [Pascha Cal. novi] · **Ascension** [Ascensio Domini]

The hour (H) sub-column of the mean-full-moon is the smallest type on the leaf and does not always resolve on the scan; these hour figures are provisional and should not be treated as citation-grade. Uncertain H digits are marked [?].

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The perpetual table of the movable feasts (A.D. 1600–5000), continued. This span covers A.D. 3896–4007. The first opening (printed pp. 462–463) presents one

continuous row-block across both leaves: the left leaf gives the new-calendar (Gregorian) columns, the right leaf the Sundays-after-Pentecost / first-Sunday-of-Advent block and the old-calendar (Julian, "veteris") columns. The following left leaf (printed p. 464) resumes the new-calendar columns for A.D. 3952–4007; its facing old-calendar leaf falls on the next page.

Month letters in the astronomical columns: **M** = March (Martius), **A** = April (Aprilis). Feast-date months are transcribed verbatim as printed per cell (Ian. / Feb. / Febr. / Mar. / Mart. / Maij / Maii / Iunij / Iunii / Nou. / Dec.). The golden-number 15 epact is set in Arabic 25 (column-scoped Arabic), all other epacts in Roman; the epact-30 sort is the asterisk *. Roman/Arabic and i-/j-terminal sorts are preserved as printed.

[printed p. 462] CALEND. GREG. — TABVLA FESTORVM MOBILIVM (new-calendar leaf, A.D. 3896–3951)

Columns: A.D. year | Aur. Num. (golden number) | Epactæ (epact) | Lit. Dominicales Cal. Greg. (Gregorian dominical letter[s]; two in leap years) | Plenilunia media Cal. Gregor. — mean full moon: D (day), H (hour), mo. (month letter) | Lunæ xiiij Cal. Gregoriani (14th day of the moon) | Septuagesima | Dies Cinerum (Ash Wednesday) | Pascha Calend. novi (Easter, new calendar) | Ascensio Domini (Ascension).

[printed p. 464] CALEND. GREG. — TABVLA FESTORVM
MOBILIVM (new-calendar leaf, A.D. 3952–4007)

Same columns as printed p. 462. The facing old-calendar leaf for these years falls on the next page. On this leaf the feast months are predominantly set Febr. / Mart. (vs Febr. / Mar. on p. 462); transcribed per cell as printed.

CAPUT XXII — Table of the Movable Feasts, arranged by year (*Tabula Festorum Mobilium Temporaria*), 1600–5000 (continued)

*These three leaves continue the great year-by-year table of the movable feasts. Each period of the calendar is set as a facing pair: a **Gregorian (new-calendar)** leaf and an **old-calendar (veteris)** leaf covering the same span of years. This batch holds the old-calendar leaf for A.D. 3952–4007 (folio 465), then the Gregorian and old-calendar pair for A.D. 4008–4063 (folios 466–467).*

*Column conventions, preserved verbatim from the print: month abbreviations are given exactly as set per cell (Maij/Maii, Iunij/Iunii, Nou., Dec., Ian., Febr./Feb., Mart./Mar.); the single letters in the Moon-14 / Easter / mean-full-moon columns are the month of the event — A = Aprilis (April), M = Martius (March). Epacts keep their printed Roman/Arabic form and i-/j-terminal sorts (xxj, xxvii, xiiii vs xiiij, vj vs vi); the epact-30 asterisk is rendered *. In leap years the Dominical-letter column carries two letters (January–February letter, then March–December letter).*

Folio 465 — old-calendar leaf (MOBILIVM TEMPORARIA), A.D. 3952–4007

Running head: CAPVT XXII. / MOBILIVM TEMPORARIA. The first three feast columns (Pentecost, Corpus Christi, first Sunday of Advent, with the Indiction and Sundays-after-Pentecost) are the Gregorian movable-feast dates; the last four columns give the old-calendar (Julian) Dominical letters, Paschal full moon, Easter, and the number of days by which the new-calendar Easter differs from the old.

Folio 467 — old-calendar leaf (MOBILIVM TEMPORARIA), A.D. 4008–4063

Running head: CAPVT XXII. / MOBILIVM TEMPORARIA.; folio 467. Same column plan as folio 465: the first feast columns are the Gregorian dates, the last four the old-calendar (Julian) values.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

The great table of the movable feasts for the years 1600–5000 continues. Each opening pairs a new-calendar (Gregorian) leaf with the old-calendar (veteris) continuation. Here the new-calendar leaf for A.D. 4064–4119 (folio 468) faces its Caput XXII continuation (folio 469), followed by the next new-calendar leaf for A.D. 4120–4175 (folio 470).

Column key (new-calendar leaves, folios 468 and 470): **A.D.** = year of the Lord · **GN** = golden number (*Aureus Numerus*) · **Epact** (*Epactæ*) · **Dom.** = Dominical letter(s) of the Gregorian calendar (two in leap years) · **FM d./h./mo.** = mean full moon of the Gregorian calendar — day, hour, month letter (M = *Martius*, A = *Aprilis*) · **L.14** = the moon's 14th day (*Luna xiv*) of the Gregorian calendar, with its month letter · **Septuag.** = Septuagesima · **Dies Cin.** = Ash Wednesday (*Dies Cinerum*) · **Pascha** = Easter of the new calendar, with month letter · **Ascensio** = Ascension of the Lord.

Folio 468 — *Tabula Festorum* (new calendar), A.D. 4064–4119

Caput XXII — Table of the Movable Feasts (continued)

Tabula Festorum Mobilium Temporaria (1600–5000), continued. The table is set as facing leaves: a **new-calendar (Gregorian)** leaf headed *Tabula Festorum / Calend. Greg.*, paired with an **old-calendar (Julian, "veteris")** leaf headed *Mobilium Temporaria*. This opening carries the old-calendar leaf completing the years **4120–4175** (its Gregorian partner was on the preceding leaf), then the full Gregorian + Julian pair for the years **4176–4231**.

Reading conventions in the moon and feast columns: the month-letter **A** = *Aprilis* (April), **M** = *Martius* (March). In the mean-full-moon column the three sub-values are **day · hour · month** (the hour is the smallest type on the page). Golden

number, epact, and month spellings are transcribed exactly as printed (Roman vs. Arabic numerals, i-/j-terminal sorts, Feb./Febr., Iunij/Iunii, the epact-30 asterisk *); values are read cell-by-cell off the leaf.

Old-calendar leaf (*Mobilium Temporaria*), A.D. 4120–4175 — folio 471

Columns: A.D. | Pentecost [*Pentecoste*] | Corpus Christi [*Corpus Domini*] | Indiction | Sundays after Pentecost [*Düicæ post Pentecosten*] | First Sunday of Advent [*Dominica prima Aduentus*] | Dominical letter(s), old cal. | Luna 14, old cal. | Easter, old cal. [*Pascha*] | Difference [days by which new-cal. Easter differs from old-cal. Easter]

Caput XXII — *Tabula Festorum Mobilium Temporaria* (continued)

Table of the Movable Feasts for the successive periods (1600–5000), continued. Each opening pairs a Gregorian ("new-calendar") leaf with its old-calendar ("veteris") continuation. The three leaves of this batch cover A.D. 4232–4287 (Gregorian leaf + old-calendar continuation) and A.D. 4288–4343 (Gregorian leaf; its old-calendar continuation falls on the following leaf).

Column key (Gregorian leaves): A.D. year | Golden Number (*Aureus Numerus*) | Epact (*Epactæ*) | Gregorian Dominical letter(s) (*Literæ Dominicales Calend. Gregor.*; two in leap years) | Mean full moon (*Plenilunia media Calend. Gregor.*), given as **day · hour · month** where **M** = March (*Martii*), **A** = April (*Aprilis*) | Luna XIV (*Lunæ xiiii Calendarii Gregoriani*), day · month | Septuagesima | Ash Wednesday (*Dies Cinerum*) | Easter of the new calendar (*Pascha Calend. novi*) | Ascension (*Ascensio Domini*).

Month abbreviations, numeral forms, and terminal i-/j- sorts are transcribed per cell as printed (not normalized). The mean-full-moon **hour** sub-column is the

smallest type on the page and is read at the limit of what the scan resolves; those figures are provisional.

Tabula Festorum Mobilium — Gregorian-calendar leaf (A.D. 4232–4287)

Caput XXII continues with the *Tabula Festorum Mobilium Temporaria* (the perpetual table of movable feasts, A.D. 1600–5000), set as paired leaves: a Gregorian (new-calendar) leaf facing an old-calendar (*veteris*) comparison leaf. This span covers A.D. 4288–4399.

The three leaves here are:

1. the old-calendar comparison leaf for **A.D. 4288–4343**, which completes the opening whose facing new-calendar leaf was on the previous folio (folio 477);
2. the new-calendar (Gregorian) leaf for **A.D. 4344–4399** (page 478);
3. the old-calendar comparison leaf for **A.D. 4344–4399** (folio 479).

Conventions preserved verbatim throughout: month tokens as printed (Ian. = January, Febr./Feb. = February, Mart./Mar. = March, Maij/Maii = May, Iunij/Iuni/Iunii = June, Nou. = November, Dec. = December); the letters A = *Aprilis* (April) and M = *Martius* (March) in the Luna-14, Easter, and mean-full-moon columns; the epact asterisk as ASCII *; Roman-numeral epacts with their terminal i-/j-sorts; and the leap-year Jan/Feb dominical letter printed as ç (a cedilla form of c) where it occurs. The **Diff.** column is "the number of days by which Easter of the new Calendar differs from Easter of the old Calendar" (*Dies quibus Pascha Calendarii novi à Paschate Calendarii veteris differt*); its values are all multiples of 7.

Old-calendar comparison leaf — A.D. 4288–4343

The mean full moon, Luna 14, and Easter here are reckoned in the old (Julian) Calendar; Pentecost, Corpus Christi, the Sundays after Pentecost, and the First Sunday of Advent follow from the *new*-calendar Easter of the facing leaf.

Old-calendar comparison leaf — A.D. 4344–4399

Same layout as the first leaf above (old-calendar mean Luna 14 and Easter; the Pentecost/Corpus/Advent columns follow from the new-calendar Easter of the facing leaf). This leaf is heavily foxed through its middle band; readings were recovered against the column cross-checks and the 19-year Metonic recurrence of the Luna-14 column.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued, A.D. 4400–4511)

The great table of the movable feasts continues, set across facing leaves: each opening carries a **new-calendar (Gregorian)** leaf on the verso and the matching **old-calendar (veteris)** leaf on the recto, both covering the same block of years. This span covers the block **4400–4455** (Gregorian leaf p. 480; old-calendar leaf p. 481) and the beginning of the next block **4456–4511** (Gregorian leaf p. 482; its old-calendar recto falls on the following leaf).

Month abbreviations as printed: **M** = *Martij* (March), **A** = *Aprilis* (April) in the moon and Easter columns; **Ian./Feb./Mar.** = January/February/March; **Nou./Dec.** = November/December; **Maij/Iunij** = May/June. The mean-full-moon column is set *day · hour · month* (D. H. + M/A). Roman/Arabic figures, i-/j-terminal sorts, the epact-30 asterisk (*), and month-spelling variants are transcribed verbatim per cell.

Leaf 1 — CALEND. GREG. / TABVLA FESTORVM (p. 480), A.D. 4400–4455 (Gregorian)

Columns: A.D. | Golden № (*Aur. Num.*) | Epact (*Epactæ*) | Dominical letter, Greg. (*Lit. Dñicales Calend. Greg.*) | Mean full moon, Greg. (*Plenilunia media Cal. Gregor.*, D. H. mo) | Luna 14, Greg. (*Lunæ xiiij. Calendarij Gregoriani*) | Septuagesima | Ash Wednesday (*Dies Cinerum*) | Easter, new cal. (*Pascha Calend. noui*) | Ascension (*Ascensio Domini*)

Leaf 3 — CALEND. GREG. / TABVLA FESTORVM (p. 482), A.D. 4456–4511 (Gregorian)

Columns as Leaf 1. Note the **solar-equation epact decrement at the 4500 century boundary** (4500 is a common century year): from A.D. 4500 onward

each golden number's epact and its Luna 14 stand one place lower than before (e.g. golden № 18: epact xxvi before 4500, printed 25 — in Arabic figures — at 4501; golden № 1: xix at 4484, xviiij at 4503). This is a calendrical feature of the table, not a compositor slip.

Caput XXII — *Tabula Festorum Mobilium Temporaria* (continued)

Table of the Movable Feasts by period, 1600–5000. Each opening pairs a New-Calendar (Gregorian) leaf (Tabula Festorum, verso) with an Old-Calendar leaf (Mobilium Temporaria, recto). This batch covers A.D. 4456–4567.

Reading conventions for the tables below (all values transcribed cell-by-cell from the leaf, not derived): in the day-plus-letter columns (Luna XIV, Easter) the trailing letter is the month — **A = Aprilis (April)**, **M = Martius (March)** — printed exactly as on the leaf. The mean-full-moon column is given as **Day. Hour Month**. Month abbreviations are transcribed as printed per cell (Feb./Febr., Mar./Mart., Iunij/Iunii); Roman-vs-Arabic epacts and i-/j-terminal sorts are preserved verbatim. * is the epact-30 asterisk. [?] marks an uncertain small-type read. [recte: ...] is used only for the two year-column compositor slips, where the correct year is itself legible on the facing leaf; printed values contradicted by their own feast intervals are transcribed as printed and listed among the editorial anomalies below.

Mobilium Temporaria — Old Calendar (A.D. 4456–4511)

Column headers as printed: **Anni Domini** (A.D.) · **Pentecoste** (Pentecost) · **Corpus Domini** (Corpus Christi) · **Indictio** (Indiction) · **Dñicae post Pentecosten** (Sundays after Pentecost) · **Dominica prima Aduentus** (First Sunday of Advent) · **Litterae Dñicales Calendarij veteris** (Dominical Letters, Old Calendar) · **Lunae xiiij. Calendarij veteris** (Luna XIV, Old Calendar) · **Pascha Calédarij veteris** (Easter, Old Calendar) · **Dies quibus Pascha Calend. noui à Paschate Calend. veteris differt** (Days by which New-Calendar Easter differs from Old-Calendar Easter).

Caput XXII — Tabula Festorum Mobilium Temporaria (continued)

Table of the movable feasts for the successive years, 1600–5000, in paired leaves: the new (Gregorian) calendar on the left-hand page, the corresponding old (Julian) calendar and the civil reckoning on the right-hand page. These openings carry the years A.D. 4568–4679.

Legend. In the mean-full-moon, Luna-14, and Easter columns the trailing letter gives the month: **M** = **Martius (March)**, **A** = **Aprilis (April)**. Month abbreviations elsewhere are transcribed as printed (*Ian.*, *Feb.*, *Febr.*, *Mar.*, *Mart.*, *Nou.*, *Dec.*). The mean full moon is given as **day · hour · month**. The epact * is the new-Calendar

sign for epact 30. Roman-vs-Arabic epact figures (e.g. xxv vs 25) and i-/j-terminal sorts are preserved exactly as set.

New-calendar columns (Gregorian) — A.D. 4568–4623

Old-calendar and civil columns — A.D. 4568–4623

Last column heading in full: **Dies quibus Pascha Calend. noui à Paschate Calend. veteris differt** — "The number of days by which the Easter of the new Calendar differs from the Easter of the old Calendar." (Both Easters are Sundays, so the figure is always a multiple of 7.)

CAPUT XXII — Table of the Movable Feasts,
arranged by period (continued)

Tabula Festorum Mobilium Temporaria, A.D. 1600–5000. The table is set across facing leaves: each **new-calendar (Gregorian) leaf** (running head *CALEND. GREG.* — *TABVLA FESTORVM*) is paired with an **old-calendar leaf** (*veteris*; running head *CAPVT XXII — MOBILIVM TEMPORARIA*). This opening carries the old-calendar leaf for A.D. 4624–4679 (folio 489), then the paired new- and old-calendar leaves for A.D. 4680–4735 (folios 490–491).

All calendar cells are transcribed verbatim as printed. Latin month abbreviations (*Maij* / *Iunij* / *Nou.* / *Dec.* / *Ian.* / *Febr.* / *Mart.*) and the single-letter Easter/Luna markers (**A** = April, **M** = March) are kept exactly as in the source, including spelling variants (*Maii*, *Iunii*, *Deç.*, *Feb.*, *Mar.*) and the i-/j-terminal and Roman/Arabic distinctions. [recte: ...] marks a legibly corrupt cell whose correct reading is recoverable; [?] marks a genuinely uncertain glyph.

Old-calendar leaf — A.D. 4624–4679 (folio 489)

Running head: **CAPVT XXII / MOBILIVM TEMPORARIA**. Columns as printed:
Anni Domini · Pentecoste · Corpus Domini · Indictio · Dominicæ post Pentecosten ·
Dominica prima Aduentus · Literæ Dominicales Calendarij veteris · Lunæ xiiij.
Calendarij veteris · Pascha Calendarij veteris · Dies quibus Pascha Calendarij noui à
Paschate Calendarij veteris differt.

New-calendar (Gregorian) leaf — A.D. 4680–4735 (folio 490)

Running head: **CALEND. GREG. / TABVLA FESTORVM**. Columns as printed: *Anni Domini · Aureus Numerus · Epactæ · Literæ Dominicales Calendarij Gregoriani · Plenilunia media Calendarij Gregoriani (D. · H. · month) · Lunæ xiiij. Calendarii Gregoriani · Septuagesima · Dies Cinerum · Pascha Calendarij noui · Ascensio Domini*.

In the "Mean full moon" group, **D** = day, **H** = hour, **mo** = the month marker (A = April, M = March). As noted throughout these leaves, the small-type **H (hour) sub-column** sits at the limit of what the scan resolves; its figures are reading-grade, not citation-grade.

CAPUT XXII — Tabula Festorum Mobilium Temporaria (continued)

*The great table of the movable feasts, year by year, from 1600 to 5000, continues.
Each opening pairs a new-calendar (Gregorian) leaf with the facing old-calendar*

Month abbreviations are transcribed exactly as printed and are **not** normalized (Mai/Maij/Maii, Iunij/Iunii, Feb./Febr., Mar./Mart., Nou., Dec., Ian.). In the lunar columns M = *Martius* (March) and A = *Aprilis* (April). Two dominical letters mark a bissextile (leap) year. Note that 4900 is a common year on the Gregorian leaf (single dominical letter) but a leap year on the Julian leaf (two letters), a genuine veteris/novi divergence.

Columns: **A.D.** | **Pentecost** (*Pentecoste*, new cal.) | **Corpus Christi** (*Corpus Domini*, new cal.) | **Indiction** (*Indictio*) | **Sundays after Pentecost** (*Dominicæ post Pentecosten*, new cal.) | **First Sunday of Advent** (*Dominica prima Adventus*, new cal.) | **Dominical letter(s), old cal.** (*Literæ Dominicales Cal. veteris*) | **Luna 14, old cal.** (*Lunæ xiiij Cal. veteris*) | **Easter, old cal.** (*Pascha Calendarij veteris*) | **Diff.** (*Dies quibus Pascha Cal. novi à Paschate Cal. veteris differt* — days by which new-calendar Easter differs from old-calendar Easter).

[New-calendar (Gregorian) leaf — A.D. 4848–4903]

Running head: CALEND. GREGOR. / TABULA FESTORUM

Columns: **A.D.** | **Golden Number** (*Aureus Numerus*) | **Epact** (*Epactæ*) | **Dominical letter(s)**, **Greg.** (*Literæ Dominicales Cal. Greg.*) | **Mean full moon**, **Greg.** (*Plenilunia media Cal. Gregor.*), given as **Day · Hour · Month** (D · H · M/A) | **Luna 14**, **Greg.** (*Lunæ xiiij Cal. Gregoriani*) | **Septuagesima** | **Ash Wednesday** (*Dies Cinerum*) | **Easter, new cal.** (*Pascha Cal. novi*) | **Ascension** (*Ascensio Domini*).

The mean-full-moon **Hour (H)** sub-column is the smallest type on the leaf and does not always resolve on the scan (see parsing notes); its values are best-effort reads.

Parsing notes

- **Mean-full-moon Hour (H) sub-column (Gregorian leaf, p. 496).** This is the smallest type on the leaf and does not always resolve on this foxed paper; the H values are best-effort reads and are **not citation-grade**. The full-moon **Day**, the **Month (M/A)** marker, **Luna 14**, **Easter**, and every feast-date column read reliably. H for **4862** is ambiguous between 10 and 19 (the leaf seen whole suggests 19, but two closer, overlapping views both show a rounded second digit ≈ 10) — transcribed 10[?]. The hour figures in this column should be treated as provisional throughout.
- **Full-moon Month marker (M/A), Gregorian leaf.** Two markers were read against the Luna-14 month and the 19-year Metonic recurrence and corrected to the value the recurrence + same-lunation constraint require: **4855** = A (Luna 14 = 6 A; Metonic partner 4874 = 5 A), **4880** = M (Day 30, Luna 14 = 31 M; Metonic partner 4861 = 30 M). All other M/A markers agreed with their direct read.
- **Old-calendar Luna 14 cross-check.** The Julian Luna-14 column recurs exactly on a 19-year Metonic period; spot-checks confirmed (4848→4867 = 2

A; 4849→4868 = 22 M; 4857→4876 = 24 M), validating the old-calendar Easter block.

- **Movable-feast cross-check.** On the old-calendar leaves, Pentecost = new-cal Easter + 49 and Corpus Christi = new-cal Easter + 60; verified against the Gregorian Easter column (e.g. 4848: Easter 29 Mar → Pentecost 17 May, Corpus 28 May; 4870: Easter 23 Mar → Pentecost 11 May). This confirms that the first feast block on the old-calendar leaves is reckoned on the new calendar.
- **Epact terminal sorts (i/j).** The small Roman epact numerals read cleanly and j-terminal (house style) in the upper, unfoxed bands (xviiij, xxix, xxiij, xvij, xxviiij, xij, vij, iiiij, xiiij, xxiiij); on the heavily foxed lower rows the terminal hook is often lost to foxing. Epacts are given in the house j-terminal form throughout rather than committing possibly-false i-terminal wrong-sorts; the epact terminal sort on the foxed lower rows is **not citation-grade**, and confirming a genuine wrong-sort there would require a cleaner image of the leaf. No wrong-sort was securely legible on these three leaves.
- **1600-form long-s / hooked dominical.** The cedilla/hooked dominical ç (= c) appears at leap years 4800 and 4856 (both leaves); transcribed ç.
- **Epact 30 asterisk / circle.** No epact-30 cell occurs on these three leaves (the golden-number cycle here runs 4...19,1,2, none landing on epact 30/*).

Source anomalies (transcribed as printed)

- **p. 497 (old-cal leaf), A.D. 4856, Corpus Christi:** printed Inuij — a turned-letter (u/n metathesis) compositor error for Iunij. Both the printed and correct forms are legible; transcribed Inuij [recte: Iunij]. Self-correcting (single cell; the surrounding column reads Iunij).
- **Month-spelling variants (as printed, not normalized):** Mai (p. 495, 4796), Maii (p. 495, 4840; p. 497, 4897), Iunii (p. 497, 4866, 4895). These are house spelling variants, not errors.
- **4900 leap-year divergence (not an error):** single dominical letter c on the Gregorian leaf (4900 common in the new calendar) vs. two letters d c on the Julian leaf (4900 leap in the old calendar). Correct and expected.

Caput XXII — *Tabula Festorum Mobilium* *Temporaria* (continued)

Three leaves of the perpetual table of the movable feasts (A.D. 1600–5000), continuing the run of paired leaves: two Gregorian ("new-calendar") leaves (folios 498 and 500) and, between them, the facing "old-calendar" (*veteris*) continuation leaf (folio 499). Folia 498 and 499 form one opening and share the year-range 4904–4959; folio 500 begins the next opening (4960–5000), whose facing old-calendar leaf falls in the following batch.

Month tokens are transcribed exactly as printed and are **not** normalized. In the mean-full-moon and Luna-14 columns the single letter is the month: A = *Aprilis* (April), M = *Martius* (March). In the feast columns Feb. / Ian. / Mar. and Maij / Maii / Iunij / Iunii stand as set. The mean-full-moon column is given as *day · hour · month*.

Folio 498 — Gregorian ("new-calendar") leaf, A.D. 4904–4959

Columns: A.D. | Golden n^o (*Aur. Num.*) | Epact (*Epactæ*) | Dominical letter(s) (*Lit. Dnicales Calend. Gregg.*; two letters in leap years) | Mean full moon (*Plenilunia media Cal. Gregor.*, day · hour · month) | Luna XIV (*Lunæ xiiij Cal. Gregoriani*) | Septuagesima | Ash Wednesday (*Dies Cinerum*) | Easter (*Pascha Calend. noui*) | Ascension (*Ascensio Domini*).

Caput XXII — Table of Movable Feasts (concluded); on the accuracy of the Epact cycle

Tabula Festorum Mobilium Temporaria — old-calendar leaf,
A.D. 4960–5000 (folio 501)

This is the facing old-calendar (*veteris*) leaf that completes the double spread; the Gregorian half stood on the preceding verso. The table closes at A.D. 5000 (a Julian leap year, hence a two-letter Dominical). Columns as printed:

- **Anni Domini** — year of the Lord
- **Pentecoste** — Pentecost (day · month)
- **Corpus Domini** — Corpus Christi (day · month)
- **Indictio** — Indiction
- **Dnicæ post Pentecosten** — Sundays after Pentecost
- **Dominica prima Adventus** — First Sunday of Advent (day · month)
- **Literæ Dominicales Calendarii veteris** — Dominical letters, old Calendar (two in leap years)

- **Lunæ xiiij. Calendarii veteris** — 14th (Paschal) moon, old Calendar (day · M = *Martij* / A = *Aprilis*)
- **Pascha Calendarii veteris** — Easter, old Calendar (day · M/A)
- **Dies quibus Pascha Calend. novi à Paschate Calend. veteris differt** — days by which new-Calendar Easter differs from old-Calendar Easter (Diff.)
