- Moreover, if one examines the preceding table with any care, he will see very clearly that our cycle of Epacts is rightly distributed and adjusted within the Calendar. For it almost always yields the Paschal 14th moons in such a way that the day following either falls on the mean full moon or follows it by no great interval — which agrees most aptly with the decrees of the Councils and the enactments of the holy Fathers. Thus it comes about that Easter is always celebrated either at the mean full moon or after it, all the way to the year 5000; and we shall find the same holding good in the years beyond, if we care to extend the table to more years. [Margin: The Paschal table above shows that the Epacts correctly indicate the 14th moons.]

A few years are excepted — these fifteen, namely 2133, 2491, 2725, 3083, 3300, 3317, 3344, 3611, 3631, 3675, 3909, 3936, 4047, 4619, 4639 — in which the 14th moons appear to run ahead of the mean oppositions more than is proper, so much so that in these same years the mean opposition falls after sunset on Easter day. But this ought not to seem surprising to anyone, since it springs from the very nature of a cycle, whatever cycle it be, and occurs more often in any other cycle than in this our cycle of Epacts, as I shall show a little below. [Margin: In which years the 14th moons seem to run ahead of the mean oppositions more than is right.]

There are indeed 26 further years — namely 1900, 2106, 2451, 2718, 2738, 3043, 3063, 3310, 3330, 3401, 3459, 3479, 3500, 3635, 3648, 3655, 3726, 3902, 3922, 4051, 4071, 4318, 4643, 4663, 4910, 4995 — in which the mean full moon falls on Easter day itself, after noon but before sunset. Yet this should not be reckoned altogether contrary to the Canon of the Council of Nicaea, since in this matter the full moon must be taken with some latitude, and not as an instant of time in the way the astronomers take it. [Margin: That the mean full moon falling on Easter day before sunset is not contrary to the Canon of the Council of Nicaea.] Only that Easter seems to run counter to the Decree of the Council of Nicaea which has its mean full moon after sunset — as is the Easter in the fifteen years enumerated above. For when the full moon occurs before sunset, it can rightly and with the

best of justice be said that Easter is celebrated at the full moon itself, since it then falls before the end of Easter day, which the Canons do not forbid.

Much less is that Easter altogether illegitimate in which the mean full moon occurs before noon, or even at noon itself, since it is then manifestly celebrated at the full moon itself, seeing that the full moon in that case too falls before the end of Easter day. I would not deny, however, that Easter is more correctly celebrated if the full moon occurs before sunrise on Easter day; but since no cycle can always secure this, that Easter ought not to be judged altogether illegitimate in which the full moon falls after noon but before sunset, and still less that in which the full moon occurs before noon but after sunrise — especially if this happens rarely. There are besides some other years, from the year 1600 to the year 5000, in which the Paschal 14th moons precede the mean oppositions by somewhat more than a whole day; but because the day immediately following is not a Sunday, Easter will not then be celebrated before the full moon, but either at it or after it, so that the Dominical letter very neatly amends and corrects the error that would otherwise be admitted into the celebration of Easter. This was the reason we did not count these years among the former ones.

But you will say: ought not that cycle to be preferred which avoided all these inconveniences? Quite rightly, and I gladly agree with you here; yet that such a cycle can be found is more to be wished than hoped for, since no cycle can be built that does not now and then fall into error, as we showed in chapter 20, Num. 9. The one thing to be most carefully seen to is that the cycle be chosen above the rest which contains the fewest errors — and that this is our cycle we have shown at length above, especially in chapter 19, Num. 7 and 8, where we set out several years in which one and the same Epact number exhibits the 14th moon now before the mean opposition, now after it; so that the Epacts cannot be more fittingly distributed in the Calendar than they are arranged. For if you were to advance them to higher places, or thrust them down to lower ones, you would fall into greater absurdities, as is plainly clear. [Margin: That the same Epact presents the 14th moon now anticipated, now postponed, and now finally consonant with the Canons.]

The very same thing happens in the years enumerated above. Take, for instance, the year 3300, in which the Epact 17 is charged on this ground — that it offers us the 14th moon more than is right before the mean opposition, and so sets Easter to be celebrated before the mean full moon, which then falls after sunset. What of it? Are the Epacts on that account to be rolled down to lower days, so that Epact 17 might show its own 14th moon later? By no means. For since the same Epact

17 — in these years, 3110, 3129, 3167, 3186, 3243, 3338, 3357, 3376, 3395 — shows the Paschal 14th moon most correctly, as the Canons require (as is clear from the table of movable feasts above), while in those years, 3148, 3205, 3224, 3262, 3281, it sets the same after the mean opposition, do you not see that, if this Epact were to migrate from a higher place into a lower one, the 14th moon would here be set back further, but there be forced out of its proper place? The same happens in other years too.

And so it ought not to seem absurd that, within the span of 3418 years — namely from the year 1582 to the year 5000 — in those few years recited above Easter is celebrated somewhat earlier than the Canons prescribe, since this can be avoided in no cycle. To make this plainer, let us examine the cycle of the golden number, which the Fathers approved in the Council of Nicaea. If it be brought level for 300 years after the Council of Nicaea — that is, 300 years after the year 325 — so that the individual golden numbers are advanced upward by one day (so that the lunations then fall one day earlier), you will indeed see how often it errs in anticipating the 14th moon — if that is to be called an error which no cycle can avoid. The following table will show this plainly, in which the 14th moons are marked as if the golden numbers in the ancient Calendar of the Council of Nicaea had risen by one day, exactly as they are arranged in the last of those 30 Calendars described in chapter 15, under the small letter *a*.

Table: the golden-number 14th moons raised by one day, against the mean oppositions (folios 502–503)

Columns as printed: **Anni Domini** | **Aurei Numeri** (golden number) | **Lunæ xiiij. si aurei num. Concilii Nicæni sursum ascendant** (the 14th moon, if the golden numbers of the Council of Nicaea rise upward — day · month) | **Oppositiones mediæ / D. H.** (mean oppositions — day · hour · month). Parsing note: in the last column the first figure is the day of the month (D), the second the hour (H), followed by the month; e.g. "5. 23 Aprilis" = 5 April, hour 23.

Anni Domini	Aurei Numeri	Lunæ xiiij. (raised)	Oppositiones mediæ (D · H)

742	2	24. Martij	25. 11 Martij
743	3	12. Aprilis	13. 9 Aprilis

Anni Domini	Aurei Numeri	Lunæ xiiij. (raised)	Oppositiones mediæ (D · H)
747	7	29. Martij	31. 20 Martij
763	4	1. Aprilis	2. 10 Aprilis
766	7	29. Martij	31. 13 Martij
779	1	4. Aprilis	5. 12 Aprilis

In all these years, then, you see the 14th moons so far anticipate the mean oppositions that, were the day immediately following a Sunday, Easter would fall before the mean opposition — and indeed in the years 647, 709, 728, 747, 766 by more than a whole day. I have passed over those years in which the mean opposition falls on Easter day before sunset, even if it falls after noon, since this ought not to be reckoned to conflict with the Canons. I have set down only those years which have the mean opposition on Easter day after sunset — such as our fifteen years above. Our cycle of Epacts, therefore, cannot justly be faulted without the cycle of the golden number of the Council of Nicaea being condemned along with it (and indeed more justly). [Margin: That the same error in the 14th moons which is found in the cycle of Epacts is detected in the cycle of the golden number when it has been advanced to a higher place.] For although in the aforesaid 39 years the Dominical letter usually amends the error of the 14th moon — because it does not immediately follow the 14th moon — this nonetheless does not wholly excuse the cycle from showing the Paschal 14th moons wrongly by its very nature. In these 8 years, at any rate — 627, 647, 651, 671, 715, 722, 742, 766 — the Dominical letter does not remove this error, but Easter is celebrated in them before the mean full moon, just as in our 15 years above.

If, then, this error of Easters occurs in the cycle of the golden number within the span of 153 years — those reckoned inclusively from the year 627 to the year 779 — why should we take it ill that the same error is committed in 15 years within the span of 3418 years, namely from the year 1583 to the year 5000 inclusive? Surely the difference is no small one, between 8 years and 153, and between 15 years and 3418. For, to make the proportion equal, an error of 15 years would have to be committed in 287 years, if an error of 8 years is detected in 153. [Margin: That the same error which is noted in the Epacts is detected in the same cycle of the golden number at the time of the Council of Nicaea.]

5. But come now: if you are not yet fully satisfied, let us examine a little more closely that same cycle at the very time of the Council of Nicaea — the cycle

which most people (only out of a wish to disparage) prize more highly than our cycle of Epacts. I for my part note more faults in it than in the Epacts, if we consider the nature of the 14th moons, according to which they ought to precede the mean oppositions by not more than one day, lest, should the following day chance to be a Sunday, we be compelled to keep Easter before the mean full moon, as we wrote in chapter 18, Num. 4. Look, then, at the following table.

Caput XXII (conclusion)

[Table of the years around the Council of Nicaea, showing for each year the golden number, the 14th Moon as reckoned by the Council of Nicaea (day and month), and the mean opposition of Sun and Moon (day, hour, and month).]

Anni Domini	Aurei Numeri	Lunæ xiiij. Concilij Nicæni (day · month)	Opposition. med. — D.	Hmon . th tij

In these 28 years within a span of 100 years you can see the 14th Moon anticipating the mean oppositions by a greater interval than is proper — so much so that on the following day, if it happened to be a Sunday, Easter would be celebrated before the mean full moon. For although the Dominical letter usually does not fall immediately after the 14th Moon, and so mends and corrects that error, still such 14th Moons are by their very nature faulty, since they occur nearly two days before the mean oppositions. I have passed over very many other years in which the mean oppositions occur before sunset; for in those cases the day of Easter, if it were kept immediately after the 14th Moon, would in some measure reach the mean full moon — and that seems to be enough. I have recorded only those years in which the mean full moon falls after sunset, as we did in the preceding cases as well.

From all this I think it sufficiently confirmed that in every cycle, whatever it may be, the Paschal 14th Moons are sometimes marked in the Calendar earlier than the mean oppositions than they ought to be; and it is therefore no wonder that the same thing happens in the epact cycle of the new Calendar. Those who harass it so violently, and try to make it hateful to everyone, are labouring in vain — in vain, I say, since no cycle can be free of every fault, as we have often remarked, and since far fewer errors are found in our epact cycle than in the other cycles. This is clear from what we have said, and anyone can easily verify it for himself by examining any other cycle whatever and comparing the 14th Moons of our own cycle with it. I did just this myself not long ago, when I examined the calendrical scheme of a most ingenious mathematician — one he believed to be perfectly accurate, and certainly far superior to this Gregorian one — in which, as the saying goes, he went wholly astray from the heavens. For I found countless absurdities in it, nearly all of which are avoided in our own scheme.

[Margin: *Quare nihil hic dicatur de indictione.* — Why nothing is said here about the indiction.] It would remain now to treat of the Indiction; but since we have said more than enough about it in the new Roman Calendar, which we set out at the beginning of the work, and shall say more in the Ecclesiastical Computus, which will follow this work, nothing seems to need saying about it in this place.

CAPVT XXIII.

That the most holy Passover [Easter] is to be celebrated on one and the same day in all parts of the world.

Some raise doubts about the time of year at which the most holy Easter should be celebrated by those who inhabit the other hemisphere, toward the southern region from the Equator, and have the Antarctic pole visible above their horizon. For since the precept is that we observe the spring season — when the Sun, having crossed the Equator, moves more and more toward our regions and daily draws nearer to us — if those peoples were to keep Easter at the same time as we do, they would surely be celebrating it in the opposite season of the year, namely when the Sun is receding further and further from them, and in the very season of autumn; for among them it is autumn at the time when spring is present for us. Add to this that the Lenten fast is highly inconvenient and burdensome for them, because it falls among them at the end of summer, when the greatest heat still prevails. Nevertheless it must be said, briefly, that all Christians ought to celebrate Easter in the same month and on the same day as the Roman Church celebrates it, according to the decree of the Sacred Council of Nicaea and of the first Council of Arles — in which, as is found in *De consecratione*, Distinction 3, chapter *De observatione*, it is thus laid down: "*We ordain that Easter be observed on one day and at one time throughout the whole world.*" And the same was enacted in the Fourth Council of Carthage, as is found in the same Distinction, in these words: "*The solemnity of Easter is to be celebrated on one day and at one time.*" The same is attested by St Ambrose in Epistle 83, addressed to the bishops appointed throughout Aemilia, where he writes as follows about this same Paschal solemnity — as we also reported above in chapter 1, Num. 4:

"It is a matter of no ordinary wisdom to determine the day of the Paschal celebration. Both divine Scripture instructs us in this, and the learning of our forefathers, who, coming together at the Council of Nicaea — among those Decrees of the Faith that were as true as they were admirable — and treating also of the celebration just mentioned, when the men most skilled in calculation had been gathered, worked out the reckoning of nineteen years and established, as it were, a certain cycle, from which a pattern might be produced for the remaining years. This cycle they called the [Greek: ἐννεαδεκά(?)ῖδα ("nineteen-year period"); the middle cluster of the printed form does not resolve] — following this principle: that we ought not to waver in some empty opinion over a celebration of this kind, but that, once the true reckoning has been ascertained, the resolve of all should so concur

that on one and the same night everywhere the sacrifice for the Lord's Resurrection may be offered."

Nor is it any objection that for them Easter falls in September. For the holy Easter is celebrated in memory of the death and Resurrection of our Lord Jesus Christ, who willed to undergo death in this region of our world — that is, in the northern hemisphere — at the season of our vernal equinox, and to rise again from the dead. This feast, therefore, they all ought to celebrate at the time at which he willed to rise from the dead. But if for the southern peoples the Lenten fast should prove too laborious and burdensome on account of the season of the year, they will be able to obtain from the Supreme Pontiff that he grant them the eating of dairy foods and of other things, as necessity may advise.

2. Nor indeed is this hindered by the diversity of meridians. For since the Sun is carried from its rising to its setting in the space of 24 hours, all will be able within that span to have the Lord's Day in succession — some earlier, others later — on which they may celebrate the day of the holy Easter in honour of the Resurrection of our Lord Jesus Christ; whom, now that I have at last, at some point, been brought forward to the completion of the work I undertook — not with any boasting — I honour and revere, as is right. He it was who furnished me the strength to bear a most heavy burden; he who suffered light to be drawn from his own light, if any light has been brought to a matter so very obscure. Whatever, therefore, right and divine law demands — whatever of strength or of years remains to me — this we consecrate to him, mindful of the benefit received, reckoning it will stand to us in place of a vast reward if our labours, undertaken as they always have been, may likewise turn to his glory and to some benefit for the Christian Commonwealth.

CAPVT XXIIII.

THE CALENDAR OF FRANÇOIS VIÈTE [Franciscus Vieta] IS EXAMINED AND REFUTED.

1. I had already, by God's good help, finished this book, and had resolved to send it to the press very shortly, when — behold — there came into my hands a book on the Calendar by François Viète, a most learned Frenchman, marked with this title: [Margin: *Inscriptio Calendarij Vietæ*. — The title of Viète's Calendar.]

A Report on the truly Gregorian Calendar, addressed to the ecclesiastical doctors, presented to the Supreme Pontiff Clement VIII in the Jubilee Year of Christ 1600.

This book (as appears on its final page) was printed at Paris by Jean Mettayer [Ioannes Mettayer], royal printer. To it, as a kind of appendix, a Perpetual Gregorian Calendar is attached — one that was also issued separately and is wholly anonymous, with no mark of country, or of family (that is, of the author) and of the printer appended to it; made almost after the form and pattern of that Calendar which Gregory XIII saw to be printed and publicly issued in the year 1582. He wrote up in that book many excellent things indeed (as befits a man of great genius), and disputed admirably about the whole scheme of the Calendar. And yet, being human, he did a human thing in himself falling into error: for, having abandoned the arrangement of the epacts set out in the Gregorian Calendar

— and having neglected the beginning of the year, which the Roman Church, treading in the footsteps of Julius Caesar [Iulius Caesar], derives from the month of January — he devised a certain new scheme of the epacts, and distributed them among the days of the month in a new fashion, following no precedent; and he held that the year should truly begin, under his own auspices, from the eighth day of March. His chief reason (as he asserts) was this: to prevent the Lunar months, in a bissextile year, from ever comprising 31 days on account of the intercalary day added to February — a thing which, however, is not absurd, as will be shown shortly. On the contrary, indeed, while he strives to avoid this inconvenience, he imprudently entangles himself in far greater difficulties by following that new placement of his epacts. For, as will become plain in its proper place, that man — acute though he otherwise is — does not see that sometimes even by his own reckoning, and even outside a bissextile year, a Lunar month of 31 days is made up, and that several months are reckoned at only 28 days, or even at 27. How far all these depart from the true reckoning, and how monstrous and disordered [Greek: ἄτακτα (ataxta, "disordered, irregular things")] they are, he will himself testify — he who detests such months as portents.

Now then, before I pursue the rest, I shall set his Calendar itself before your eyes, so that what we have found wrongly arranged in it may be more clearly perceived. Then briefly I shall dispose of the objections he raises against our Calendar. Finally I shall weigh his epacts, so far as concerns the 14th Moons, and shall show that they are for the most part false. But Viète himself I beg and beseech to interpret in a kinder sense this defence, which I have undertaken for the sake of truth. For it is not out of hatred for the man, whose genius I admire; not out of envy of his name, whose writings I hold in respect; not out of any zeal for contention, from which I have always recoiled; not out of desire for glory, whose nature I have long since contemplated in the light of truth — I set little

store by a shadow in the peddling of learning. Rather, it is by duty, by fairness, and by the good faith with which I once took up this cause that I am brought to refute his Calendar and to defend the Gregorian one.

[Margin: *Vietæ comminisci nouam Epactarum collocationem nouumque anni principium*. — Viète contrives a new arrangement of the epacts and a new beginning of the year.]

THERE FOLLOWS

A View of the Gregorian Calendar according to the opinion of Viète.

Caput XXIII (continued)

A View of the Gregorian Calendar according to the opinion of Viète (continued)

The following three leaves (folios 507–509) set out, month by month, Viète's proposed re-arrangement of the calendar. Each month is tabulated in three columns:

- **Dies confecti** — the day of the (civil) month, 1–31.
- **Dies Vietæ** — "Viète's day," a continuous day-count running through the whole reckoning; it does **not** restart at each month but at Viète's own year-beginning (marked *initium* within March).
- **Epactæ Vietæ** — "Viète's epact" for that day, a lunar age running down 29, 28, ... 1, then the epact-30 marker, then 29 again.

The day-of-month ruler (*Dies confecti*) is printed only against the leftmost month of each opening (January, May, September); it governs the other three months of the opening through the continuous *Dies Vietæ* count.

◆ = Viète's epact-30 marker, a solid black lozenge (the counterpart of the Gregorian epact-30 asterisk * and the *Compendium*'s circular ☉). It recurs every 59 days (two lunations) — at *Dies Vietæ* 30, 89, 148, 207, 266, 325 — and is transcribed as printed wherever it appears.

[Resuming prose, foot of folio 509]

Below the double ornament band the discursive text resumes: a paragraph of some thirteen lines of small italic, running to just above the vu 3 signature. It continues Clavius's critique of Viète's epact-placement, testing it against the golden numbers and the Gregorian epacts.

[Margin: *Pag. 6. Num. 12. tab. 2.*]

... vel quod illa non ignorantur: vel qu[?] aliqua Calendarij [?] Ægyptiorum [?] primo tabella Can[?] Canon 2. Calendarij [?] locum. And so this is my specimen of a Calendar which — as I said at the outset — Viète took care to have printed separately from his *Relatio*, following more or less the same plan by which the Gregorian Calendar, published in the year 1582, was received with such wide popular assent and such approval from learned men. In this I should not want anyone to fault me, as though in less than perfectly good faith I had thought that, once the epacts and the days of the months were retained, the Dominical letters, the Kalends, the Nones, and the Ides might be neglected. For since Viète himself does not depart from common usage in these very items, why should I have delayed my pen — hurrying on toward matters of far greater weight and moment — over transcribing them? I have, however, also inserted the days of the whole year, whose beginning Viète draws from the eighth day of March, even though these very days are not found written out in Viète's separately printed Calendar.

2. Now, since Viète so glories in this Calendar of his that he does not hesitate to call it truly Gregorian — and dares, by way of a certain contempt (as it seems), to give the label "common" to what Gregory XIII himself, after long deliberation, approved and labored greatly to have accepted by the whole Christian world — it is necessary that the matter be examined by me a little more closely, and that it be shown that this Calendar of Viète's is as far removed as anything possibly can be from the Gregorian, that is, from the true one. I see indeed how arduous a province I am undertaking, and I already perceive how hard it will be to win Viète's assent, since he seems to himself to have wholly grasped the very mind of Gregory — by whom, however, he was not only not called into counsel over the Calendar, but perhaps never even heard or seen. Yet I, who know that Gregory's genius (if one may put it so) did not pass over into Viète, am confident it will easily come about that anyone may understand this: our common Calendar can be called "common" on this ground alone, that it does not depart from the now-inveterate usage of the whole Church and from the common judgment of mankind; whereas what Viète has proposed stands utterly at odds with the mind of Gregory, with the opinion of right-thinking men, and finally with the most holy decrees of the Fathers and of the Councils.

[Margin: A bold crime of Viète's, in printing the Calendar separately together with Gregory's bull.]

First of all, then, Viète is convicted of having gravely erred in this: that he took care to have that Calendar of his — for to me it will never be the Gregorian — printed separately on his own authority, in exactly the same words in which the Gregorian appeared in 1582 by Pontifical authority (a few things excepted, which he evidently judged foreign to his own design); and moreover that he prefixed Gregory's Bull to lend it authority, so that those who bought that little book, and, deceived by it, should use it thereafter, might seem to have done so in accordance with Gregory's judgment, and thus to have obeyed the authority of the Apostolic See — when in fact, as I shall demonstrate in what follows, nothing is more opposed to the Gregorian Calendar.

[Margin: That there is no necessity for the year to begin from March 8.]

3. But leaving aside this offense — whatever kind of crime it is, and it is certainly no light one — let us come to those faults that seem to touch the matter more nearly. Viète begins — this new Sosigenes (for by this name he ironically [Greek: εἰρωνικῶς, *eirōnikōs*, "ironically" — the middle vowel is at the ink-spread limit, but the sense is secure] styles the correctors of the

Calendar, professing that he himself will deliver the very things Gregory had expected from his own Sosigeneses) — he begins, I say, the year from the eighth day of March. I do not ask at present how many and how absurd are the things that flow from this novel starting-point of the year. What, I ask, was the reason for drawing the beginning of the year, on no precedent, from the eighth day of March? What compelled him to introduce a new and unheard-of custom? I marvel that a man so remarkably learned in mathematics does not see how great a disturbance must necessarily arise from this, since the beginning and end of all the remaining months must then be unknown. He will say that he set the eighth day of March as the beginning of the lunar months; I hear him. But the lunar year cannot always be begun from the eighth day of March — only when its epact is xxix. For if epact j. be assumed, the year will take its beginning from the fifth of April, and so on. In vain, then, is so great a disturbance and confusion of things brought in, when it would be enough — and far more expeditious — to say that the first Paschal month begins on the eighth day of March and the last on the fifth of April, even if the Cycle of Epacts does not begin from the eighth day of March; especially since, as I said, nothing compels it, and from this new arrangement many absurdities follow, which I shall point out a little further on. Meanwhile, most learned Viète, take here a sample of them.

[Margin: That Viète breaks the common rule for investigating the age of the Moon.]

This new arrangement of your epacts does not merely wrench aside, but shatters, that time-honored rule which for so many centuries the common folk have employed in tracking the age of the Moon by the epacts, the Kalends, and the days of the months. "But," you will say, "that rule is not wholly accurate, nor perfect in every respect." I grant it; yet it does not stray far from the reasoning of the Gregorian Calendar, since it errs at most by one day from the age of the Moon as indicated by the epacts, and not seldom agrees with it — which certainly cannot happen if the Cycle begins to be laid out on the eighth day of March, since on that plan Viète's epact disagrees with the Gregorian one every single year. But Viète, you see, relishes nothing common; he thinks that no account of the common practice should be taken in restoring the Calendar. I, however, would not wish to have the multitude angry with me, and I take no notice of those recondite and utterly — one might almost say — paradoxical [Greek: παράδοξα, *paradoxa*] notions that shrink from the common usage, that is, from the most ancient custom of the whole Church. Indeed, this very point can serve as an argument

that our epacts are rightly arranged in the Gregorian Calendar, since they so carefully preserve, in the tracking of the Moon's age, the nature of the epacts as they were in use before the correction.

[Margin: That Viète's epacts are truly not epacts.]

Since this is so, one might not unreasonably conclude that Viète's epacts are in reality not epacts at all, however they may be named — a conclusion to which I for my part would readily subscribe: either because by them the age of the Moon cannot be tracked from memory (a use which we know to be especially valuable), or because by this new arrangement of the epacts their very nature is utterly abolished. For consider: before the Calendar was reformed, the epacts described in the first table of Canon 2 of the Calendar corresponded with the golden numbers — which Viète too admits in his separately published Calendar. Since, then, through the correction ten days were removed from the year, it is necessary that the same golden numbers should be answered by epacts diminished by ten units, so that they may indicate that the New Moons now fall ten days later. And this has been observed to the letter in the Gregorian epacts, as can be seen from the second table of the same Canon 2 of the Calendar. For in the year, say, 1601, with golden number six, the epact xxvj. corresponds, which is ten units less than epact vj. — or xxxvj. —

which before the correction corresponded to the same golden number 6; and this epact xxvj. is written ten days below epact 6 in the Calendar. So too in the year 1602, golden number 7, the epact vij. corresponds, which is likewise ten units less than the epact xvij. that before the correction answered to golden number 7; and this same epact vij. is placed ten days below epact xvij. And the same is seen in all the rest. Why, then, in the year 1601 does Viète thrust upon us epact ij., only four units less than epact vj. and placed only four days below epact vj.? Why in the year 1602 does he propose to us epact xij., likewise only four units less than epact xvij. and set only four days below epact xvij.? Surely, if by such a procedure the nature of the epacts is preserved, I should be glad to be taught by Viète, at whatever price, what it would then mean to alter and pervert that nature.

Furthermore, the attentive reader will gather from this too that Viète's epacts do not know the nature of the epacts. The epacts are the numbers of days that remain over in the month of December after the last lunation of the year, as we handed down in Chapter 9, Num. 14 — and this Viète himself does not deny. This is seen to be observed perpetually and consistently in our Gregorian Calendar, so that from this very fact one may infer that the epacts stand rightly in it, since they so wonderfully agree in every part with the nature of the epacts. But what of

Viète's epacts — does not the opposite follow? Let him himself see, and teach us, if he can, that this is found in his epacts. For I find the contrary, which I show thus. When in his Calendar epact xix. is running, with any golden number less than 10, the last lunation of the year ends on the sixth of March, and one day is left over; and yet in the following year the epact, according to him, is not j. but xxix.

[Margin: That Viète's epacts are not equal to the days that remain over in December after the last lunation.]

Again, whenever epact xviiij. is in use, with whatever golden number then running, the last lunation of the year is closed on the seventh of March, and no day is left over; and yet in the following year epact 0. — or ♦ — is not employed, but xxix. Once more, when epact xx. exists with a golden number less than 19, the last lunation of the year is finished on the fifth of March, and two days remain over. Is the following year's epact therefore ij., as the law of the epacts requires? By no means, but j. Likewise epact xxj. ends the last lunation of the year on the fourth of March, and 3 days remain over; and yet, unless the golden number be 19, epact ij. — not iij. — is assigned to the following year. And the same may be observed in several other epacts. Who, then, would deny that the Gregorian epacts are more rightly arranged than Viète's, since in the former the nature and condition of the epacts is preserved, but not in the latter? And truly it is a most delightful thing (to speak with Viète) not to depart from the ancient reckoning of the epacts; for when that is kept, the days themselves that are left over after the last lunar month instruct us which epact we ought to assume for the following year — a thing which Viète's epacts can in no way provide, as has been shown. Farewell, then, my dear Viète, to that new arrangement of your epacts, which utterly destroys their very nature.

4. It is a great thing to have retained only the name of the epacts while abolishing their nature, as we have just said — a thing utterly foreign to Gregory's mind, which nevertheless (as it seems to him) Viète alone was able to accomplish. But this could be borne with on some ground. What cannot be borne — and what, even by Viète's own judgment, is portent-like and to be banished to the ends of the earth — is this: that from this unwonted arrangement of the epacts, in common years, when any one of these epacts is running — xvij. xvj. xv. xiiij. xiiij. xij. xj. x. ix. viij. vij. v. iij. iij. ij. j. — together with golden number 19, the lunar month beginning in February will have only 28 days.

[Margin: That many lunar months in Viète contain only 28 days.]

So it is, exactly, most learned Viète: this Calendar of yours, "truly Gregorian" and no "common" one, gives us — as it so repeatedly does — lunar months of only 28 days; and had you not yourself called the thing prodigious, I should truly labor to devise a word by which to name it. And I demonstrate it thus. Since you will have the golden number and the epact change on the eighth of March, and 12 must be added to the epact running with golden number 19 in order that the following epact, running with golden number 1, may be formed — as we too taught in Chapter 12, Num. 12 and 13, and as is established from the Cycle of Epacts directed to the golden number by you, on which see below, Num. 13 — it comes about that, when, for example, epact xvij. is running with golden number 19, and the New Moon accordingly falls on the eighth day of March, the epact of the following year is xxix., concurring with golden number 1, and the New Moon falls in March on the eighth day. Now it is established that from the 8th of February inclusive to the 8th of March exclusive only 28 days are counted, in a common year. And the same reckoning holds for the other epacts enumerated above. Do you perceive, then, most ingenious Viète, that in chasing after exotic novelties you attain neither the counsels of the most wise Pontiff nor even your own — since you so often bring in lunar months of 28 days, which nevertheless you execrate, and rightly so, as monsters and portents?

[Margin: That Viète makes several lunar months of only 27 days.]

I was preparing here to inquire, Viète, into some causes that might have led you to set up a new beginning in the Calendar; but that which — for your own sake — I should least have wished suddenly checked my pen. You understand, I suppose, how unfair a judge of the correctors of the Calendar you have shown yourself, in constituting lunar months, so often and against right and law, of only twenty-eight days. But these unwonted prodigies you not only bring forth, as I see, but, like the Giants of old, you assail heaven itself. This new inauguration of the lunar months — who would ever believe it, or wonder enough? — this new beginning of the year of yours, I say, exhibits several lunations of only twenty-seven days (O unheard-of and singular thing!). And lest you suppose this to be flung out too invidiously by us, see whether you approve of the following, which is truer. When epact xvj. is running, so that in your Cycle of Epacts directed to the golden number, golden number 3 answers to epact xix., the New Moon falls on the ninth day of February. If, then, the following year be a centennial one, in which the table of the equation of the epacts offers the superior letter — that is, an epact greater by one unit under golden number 3, namely xxj. — then to golden number j. of that centennial year the epact xxix. will correspond, as is established from that same Cycle of yours directed to the golden number. Now no one can be

ignorant that from the 9th of February inclusive to the 8th of March exclusive, where epact xxix. is placed, 27 days are counted. And the same occurs whenever any of these epacts — xv. xiiij. xiiij. xij. xj. x. ix. viij. vij. vj. v. iiij. iij. ij. j. — concurs with golden number 19 and one must ascend to the superior letter in the table of the equation. Go now, most acute Viète, and vaunt that "truly Gregorian" Calendar of yours; contend that you alone have seen more than all others! How I could wish that you had never, even on this account, turned your mind to the emendation of the Calendar — that I might not be forced, here and now, to expose the most shameful blunders of a man whose genius in mathematical matters I have always admired to this day. For what could be devised more shameful, or more discordant, in a Calendar

than to prescribe for the synodic month only 27 days? I see that this belongs to the nature of any cycle whatsoever: that when one must pass to the superior letter in the table of the equation, one day is taken away from the first lunation of the year. For this too is seen in our own Calendar, since in that case the first lunation of the year comprises only 29 days, which would otherwise be 30, and sometimes (although very rarely — namely four times up to the year 100000, in the years 15200, 38000, 60800, 83600) only 28.

[Margin: On account of the Moon's equation one day is either added to, or subtracted from, the first lunation of the year.]

This cannot happen unless either one day be added to, or one taken from, the first lunation of the year. But that in your Calendar some lunations are constituted of only 28 days — even though no change be made in the table of the equation, whenever, that is, golden number 19 concurs with the epacts enumerated above — this is very justly censured. And from this too it may be gathered that our Gregorian Calendar is by far more perfect and more excellent than yours.

[Margin: For what cause he so often constitutes a lunar month of 28 days, and sometimes of 27.]

And if you ask the cause why in your Calendar a lunation is so often constituted of 28 days — while in ours it is so rare, as we have said — understand that there is none other than that good "beginning" of yours (as you call it) from the eighth of March, and the faulty arrangement of your epacts. For because the Paschal months you make all of 30 days, and those preceding them, begun in February from these epacts — xvij. xvj. xv. xiiij. xiiij. xij. xj. x. ix. viij. vij. vj. — of only 29 days, it comes about that these same months, when golden number 19 is running, comprise only 28 days. This indeed happens in the years 3420. 3439. 3458. 3477.

3496. 3515. 3534. 3553. 3572. 3591. 3610. 3629. 3648. 3667. 3686. 3705. 3724. 3743. 3762. 3781. 3800. 3819. 3838. 3857. 3876. 3895. 3914. 3933. 3952. 3971. 3990. 4009. 4028. 4047. 4066. 4085. 4104. 4123. 4142. 4161. 4180. 4199. 4218. 4237. 4256. 4275. 4294. 4313. 4332. 4351. 4370. 4389. 4408. 4427. 4446. 4465. 4484. 4503. 4522. 4541. 4560. 4579. 4598. 4617. 4636. 4655. 4674. 4693. 4712. 4731. 4750. 4769. 4788. 4807. 4826. 4845. 4864. 4883. 4902. 4921. 4940. 4959. 4978. 4997 — that is, in the span of 3400 years, from the year 1600 to the year 5000, four times and eighty times [i.e. eighty-four times]; whereas among us that happens only four times in the span of 98400 years, from the year 1600 up to the year 100000, namely in the years 15200. 30800 [recte: 38000]. 60800. 83600, whose golden number is 1; and in the table expanded from the lower line one ascends to the upper. For on this account, in those 84 years of yours, a lunation is constituted that begins in February and ends in March with 28 days, even though no change be made in the equation of the epacts, but only on account of golden number 19 then running, which in March is for the first time changed among you into 1 — because, while any other golden number is running, that same lunation contains only 29 days. Hence it is clear that if in some centennial year the golden number in January and February is still 19, and one ascends from the lower line to the upper in the epacts (that is, when epacts greater by one unit are to be assumed), that same lunation would then be constituted of only 27 days — which is worse than any prodigy. This can never happen in our Calendar, since our first lunation of the year, ending always in January, is a full one of 30 days, and very rarely a hollow one of 29 days; whereas among you a golden number of 19 sometimes falls out, so that the ascent must be made, as has been said. Do you see, then, into what a labyrinth that new beginning of the year of yours casts you?

5. From these things it is established, unless I am mistaken, that the new inauguration of the lunar year introduced by Viète cannot have very happy outcomes, seeing that in the Calendar it breeds these prodigies, in every way detestable in the Church of God. Let us see what New Moons Viète could have, if he wished to draw the beginning of the year from the eighth day of March. So far as I gather from his own writings, I understand two things especially: the one chiefly, that unless the Cycle begins on the eighth of March, it will come about that the months of the calendar begin from the Kalends of January — the future case being that several lunar months begun in February in bissextile years should be of 31 days, on account of the intercalary day added, which seems prodigious even to Viète himself. And it would indeed be prodigious if 31 days were attributed to the days of one lunar month in the Calendar; but in the common Gregorian Calendar this is never found, since in it the lunar months contain 30 days, or 29

(except in the first month of the year). And on account of the intercalary day one lunation may sometimes comprise 31 days.

[Margin: Why it is not absurd that one lunation should contain 31 days in bissextile years.]

On account of the added intercalary day it is not to be considered absurd that a lunation should sometimes comprise 31 days, since that intercalary day is not noted in the Calendar. If Viète existed among us, he would agree — or, more gravely, on the authority of the ancient Fathers. For what seems absurd to you was not seen [as absurd] by the Fathers of the Council of Nicaea, nor by the Alexandrians, nor by Julius Caesar, among all of whom several months of the golden numbers contained 31 days in bissextile years. Nor do I judge it absurd that this intercalary day should be added to a lunar month, since — as I have said — a bissextile day is a thing added [from outside], and no disturbance arises from it in the Paschal months. Do you wish then to know, Viète, what the absurdity is? I will tell you in a word. You constitute lunar months, as you do, of 28 days in those years in which the Moon is out of the ordinary — indeed, greater than the equal by more than two days, when the equation of the Moon is applied twice extraordinarily, as appeared at Num. 4. And so much the more absurd is this — that a month of some 31 days should be constituted (all the more since you yourself affirm) — than that a lunar month should be distant 29 days, 12 hours, 44 minutes, 3 seconds; a distance of 28 or 27 days rather than 31, especially since, as has often been said, that 31st day is an added one in the bissextile year and comes from outside.

6. Truly, exceedingly absurd are the things I have just reviewed. What if I should demonstrate, Viète, that with the beginning of the Cycle set on the eighth of March, you can nevertheless by no reasoning escape sometimes constituting, in a bissextile year, a lunation of 31 days? You will change your opinion, and draw back the beginning of the year, with us, to the Kalends of January — so I suppose. Come, then, and turn your eyes and mind carefully hither with me.

[Margin: That Viète sometimes makes a lunation of 31 days in a bissextile year.]

In the year, say, 1647 (which is not far off), before the bissextile, your epact is j., placing the Paschal New Moon on the 5th of April, because the golden number of that year is 14 — which, falling in your Cycle of Epacts directed to the golden number, falls upon the sign ♦, or, as you call it, the Aeolic digamma [Greek: Ϝ (*digamma*), the archaic letter used as the numeral 6; printed here as ϜϜ] — and

therefore, by your prescription, epact j. must be assumed. But the New Moon in the following February, of the bissextile year 1648, falls on the 24th of February, over against the same epact j. Since, then, that same Cycle of Epacts of yours, directed to the golden number, indicates that in the following year, by golden number 15, the epact is xj., whose use begins on the 8th day of March, the Paschal New Moon will fall on the 26th of March. And who does not see that in the bissextile year 31 days are counted from the 24th of February inclusive (which then has 29 days) up to the 26th of March inclusive? Nor indeed, to defend yourself, can you say that in our year 1648 you do not intercalate,

on the ground that the February in which the intercalation is made by us belongs to your year 1647 — since you begin your year 1648 from 8 March. This, I say, you cannot maintain. For if you do not intercalate along with us in the February of that same year 1648 — even though it belongs to your preceding year 1647 — the greatest confusion will arise between leap years and common years. A year that with us would not be a leap year would with you be one, and the reverse. And this, I know, you will not concede but will frankly admit: that before your year 1648 — namely at the end of the year 1647 — you intercalate together with us. This is also gathered most plainly from the temporary table of movable feasts in the Calendar published separately, where in our leap years you employ the very same Dominical letters as we do. And when you do this, take care that the very reproach you level against us in your *Criticus* [Ch.] 7 does not fit you most aptly:

"But what are these little microcosms, Physicist — that I should be affected by chance before the event?" [Latin: *Quæ vero microcosmia hæc Physici, me à casu ante casum affici?* — Clavius quotes Viète's own taunt back at him; "microcosmia" as printed.]

For you apply the intercalation before the leap year — which is 1648 — in the preceding year 1647, whereas we apply it within the year 1648 itself, near its beginning, even though with you it is done at the year's end. And what, then, is this confusion and variety of the years? For my part I see no necessity in it, nor do I understand that any usefulness whatever flows from it. On the contrary, I recognize that the equinox is more correctly kept in its place if the day is intercalated at the beginning of the fourth year, as we do, than if it be done at the end of the fourth year, as you wish. [Margin: It is better for the equinox to be kept in its place if the intercalation is made at the beginning of the fourth year rather than at its end.] For the equinox, at the end of the third year, will have slipped toward the end of the month by at most 18 hours; and by the intercalary day added near the beginning of the fourth year it will fall back to the preceding day,

six hours before its former place, so that the equinox, toward the end of the month in that same fourth year, is restored to its seat. But with you, at the end of the fourth year, the equinox will be found rolled back toward the end of the month by a full 24 hours. And who would deny that one strays less by 18 hours than by 24? On this matter read, if you please, what I wrote in chapter 5, sections 18, 19, and 20.

There is no reason, then, for you to praise so highly that intercalation of yours, to be applied at the year's end. It is therefore settled and certain that in your final year, 1647, you set up a lunar month of 31 days. But you will perhaps say that this happens only once in your Calendar — indeed you seem to insist expressly on this, so that pardon for a single error may be granted you. See how mild my temper is: you plead away this fault easily. Granted that by your new way of beginning the year you were allowed to err once with impunity — but were you also permitted to do so a second time and more often, without penalty? If that be allowed, I appeal to you yourself, who call lunar months of 31 days "monstrosities." Come then, if you please, let us see whether you set up 31-day lunar months more than once. And I claim nothing beyond the truth: this always befalls you whenever, before the leap day, a golden number greater than 10 falls in your Cycle upon the letter $\varsigma\varsigma$ [Viète's epact sign, printed as a doubled hook and called by Clavius the "Aeolic digamma" (*Æolicum digamma*); transcribed here as $\varsigma\varsigma$], as appeared a little earlier. In the year 3099, for instance, which with you begins on 8 March, the golden number is 3 under the letter D, and your Epact is xxij, marking the Paschal new moon on 14 March; and at the year's close it marks the year's last new moon on 3 March. In the year 3100 the golden number will be 4 and the Epact iiij, [so that the golden number 3 then answers to it]; the new moon will therefore then fall on 3 April. Now count from 3 March inclusive up to 3 April, and you will find 31 days contained in that lunar month.

ITEM. Whenever the golden number 3 answers to the letter G (capital), the golden number 8 exhibits the Epact xxj. If, then, in the following year, because of the equation of the Moon, one must descend from G to F, the Epact j will answer to the golden number 9, and again that lunation will have 31 days: namely, as many as are counted from 5 March inclusive, where the Epact xxj is, up to 5 April exclusive, where the Epact j is placed.

RVRSVS. Again, when the letter C (capital) is in use — that is, when the Epact xxij answers to the golden number 3 — the Epact xxv will be owed to the golden number 6. If, therefore, in the following year one must descend to the letter B (capital), so that accordingly the Epact xxj answers to the golden number 3, the

golden number 7 will have the Epact v; and the lunation beginning on 1 March and ending on the last of March will comprise 31 days.

IDEM. The same happens when the golden number 18 answers to the Epact xxix, and so the new moon falls on 25 [February][?] [...]. This occurs when the golden number 3 answers to the Epact xiiij under p (small). For if in the following year one must descend to n (small) [...], the golden number 19 will require the Epact ix [...] of February, where the Epact xxix is found. It is plain [that from...] up to 28 March exclusive, where the Epact ix is placed, [31 days are counted].

Very many other examples of this kind could be adduced, which for brevity's sake I omit. From these it is certainly clear that your Calendar presents lunar months of 31 days. But see how far I am from being unfair to you, Viète: only allow yourself to be persuaded that the year's beginning was wrongfully displaced by you from the Kalends of January to 8 March, namely so that you might escape lunar months of 31 days — which, however, as you have seen, [...], so that you can in no way escape that inconvenience of the 31 days when, in the expanded table, the passage is made from one line to a lower one, as I openly and frankly acknowledged at chapter 18, section 8, and again toward the end of section 4.

7. It is too grave to be pardoned in you that, whether in a leap year or a common one, the Epact drawn from xix, concurring in your table with the golden number [...], [places] the year's new moon on 7 March. And because the Epact xix must then be taken in your Cycle as the sign ♦ [Viète's lozenge epact sign], as you wish, [...] in the following [year] the Epact xix is changed into [xx?], [...] and it is assigned to 7 April. Whichever of your [Epacts] I therefore adopt, see what an absurdity follows. For if I take the one prefixed to 7 March, two new moons will fall on two consecutive days, with no day intervening between them: [the one on 7 March, where] the Epact is xix, and the other on the 8th, where the Epact is xxix. But who ever constituted lunations of merely a single day? Who, save one who would abandon the beaten paths to follow new ones? If, on the other hand, I choose the Epact assigned to 7 April, then the lunar month beginning on 7 March and ending on 6 April will comprise 31 days — which is wholly monstrous and unheard of, since the thirty-first day does not come in from outside, as in the Gregorian Calendar in a leap year, but is in fact included within the number of days of the Calendar. Indeed, if this Epact xxix is chosen in April, where, I ask, is the Paschal new moon in that year? For my part I find none, since 7 April occupies the second day after the last Paschal term; and the Epact assigned to 8 March [...] cannot be assumed, lest no intervening day fall between two new

moons. But the most learned Viète, whom this absurdity did not escape, replies very acutely in proposition 27 that in this case both the year's last day, which for him is 7 March, and the first day of the following [year] share in one and the same new moon: so that (he says) from 8 March the reckoning of the Paschal full moon is, as usual, insti-

-tuted. But is this not to shuffle, or (to use your own words) to bring in a contrivance, and not simply to admit the fact as it is? Consider, I beg you, into what your new beginning of the year and your new arrangement of Epacts have driven you. What computist ever assigned two days of distinct new moons to one and the same new moon? Do not the precepts of your art plainly teach that a new moon always occurs where the year's Epact is found? Why, then, at the end of a year whose Epact is xix, should there not be said to be a new moon on 7 March, since the Epact xix is found written there? And why likewise, in the following year, should we not admit a new moon on 8 March, where the Epact xxix of that year is placed? Truly this ἀμφιβολία [Greek: ἀμφιβολία (amphibolia, "ambiguity")] is in no way to be tolerated. And if we grant you, as you wish, that the new moon is then to be set not on 7 March but on the 8th — are not 31 days counted, in a leap year, from 6 February up to 7 March inclusive? Therefore, like it or not, through your arrangement of Epacts you cannot at times avoid a synodic month of 31 days.

IDEM. Exactly the same will happen when the Epact xix answers to the golden number 18 — which occurs when the Epact iiij answers to the golden number 3. For if in the following year one must then descend, so that the Epact iiij answers to the golden number 3, the golden number 19 will have the Epact xxix, in your Cycle set against the golden number. Thus the same wholly absurd result follows.

PRAETEREA. What is still more intolerable: when the Epact xxv answers to the golden number 3, the golden number 8 will have the Epact xx, and the new moon will fall on 6 March. If, then, in the following year one must descend by one line, so that the Epact xxiiij answers to the golden number 3, the golden number 9 of this following year falls on ζς, or the sign ♦. The Epact xxix must therefore then be taken, by your precepts, and the lunar month beginning on 6 March and ending on the 7th of the same month will comprise only two days, since the next month begins on the 8th from the Epact xxix — which no one will deny is absurd. What counsel, then, will you take, my dear Viète, to free yourself from this difficulty? Will you say that, leaving aside the Epact xxix assigned to 8 March, the following one, affixed to 7 April, is to be taken? I think not. For besides that a new moon would then, against your precepts, not occur on 8 March, where the year's

Epact is placed, the lunar month beginning on 6 March and ending on 6 April would contain 32 days — which is worse than a monstrosity — and no new moon in that year would be Paschal. Or will you say that the two last days of the year, and likewise the first of the following one — that is, 6, 7, and 8 March — share in this case one and the same new moon, so that, namely, from 8 March the reckoning of the Paschal full moon is set up as usual? I can scarcely believe it. For not only would you rouse all the computists against you, who will not subscribe to so unusual a thing as it is to ascribe three days to a single new moon (since this is contrary to the laws of lunations), but a lunar month begun on 6 February and completed on 7 March, so that the Paschal new moon began on the 8th, would comprise 31 days in a common year and 32 in a leap year. Whichever way you turn, then, Viète, you see plainly into what straits you are cast on account of that "truly Gregorian" Calendar of yours.

[Margin: Viète sometimes sets up a lunation of only two days, or of 32.]

8. It is a most ancient and celebrated rule, handed down by all computists and indeed observed most accurately in our Gregorian Calendar, that the Epact of any year's successor is produced from a given year's Epact by adding 11 — unless the golden number of the preceding year was 19, for then 12 are added, the reason for which we set out in chapter 12, section 13; and unless one must perhaps pass from one line to a lower or a higher one in the expanded table, since then either only 10 or 12 are added, even though the golden number is not 19; or again 13, when the golden number is 19 and the higher line must be taken, as we wrote in chapter 12, section 14. This rule, kept sacred and inviolate by all down to this day, Viète simply breaks. For whenever the golden number is greater than 10 and, in his Cycle of Epacts set against the golden number, falls on the Epact of the sign $\blacklozenge$, or on the Aeolic digamma $\zeta\zeta$ — so that by his prescription the Epact j must be taken — only 10 are to be added, in order to form, in the Cycle of Epacts, the Epact xj following the Epact $\blacklozenge$ or $\zeta\zeta$, even though in the equation one need not descend to a lower letter. And when the Epact is xix, 12 must necessarily be added (even though the golden number is not 19, and one need not ascend to a higher letter in the equation), so that the Epact j is produced, which he directs to be used in place of the Epact $\blacklozenge$. Again, whenever the golden number is less than 11 and, in that same Cycle of Epacts set against the golden number, falls on the Epact $\blacklozenge$ or $\zeta\zeta$ — so that then, by his prescription, the Epact xxix must be received — 12 must again be added, although no ascent is made to a higher letter, so that the Epact xi, following the Epact of the letter $\zeta\zeta$ or the sign $\blacklozenge$, is produced in the Cycle of Epacts. And when the Epact is xix, only 10 must be added, though no descent is made to a lower letter, so that the Epact xxix is composed, which is to

be used in place of the Epact $\blacklozenge$ or $\varsigma\varsigma$. I pass over the fact that not rarely, when one must descend to a lower letter, only 9 must be added, as appeared at the end of section 7. Nor do I mention that 13 must be added when the golden number is 19 and the higher line must be taken — for this happens in our Cycle too, as we said a little before, since the equation of the Moon then necessarily requires it to be done so. But to what end, my dear Viète, all this great ἀταξία [Greek: ἀταξία (ataxia, "disorder, irregularity")], and moreover this inconsistency and ambiguity? How will the computist know whether 9, or 10, or 11, or indeed 12 are to be added to form the following Epact, unless he perpetually consults your Cycle of Epacts set against the golden number? The precepts of the art surely do not teach this. Is this to keep the decrees of the Fathers of the Council of Nicaea safe and inviolate, as you profess? For my part, throughout all antiquity I observe an incredible constancy in forming the Epacts, which we too have preserved inviolate, as is right, in the new Calendar — save in those cases we mentioned a little earlier, which indeed are perfectly well known and so cannot escape any computist.

9. I ask you besides, most learned Viète, what these six days of the year have done wrong — namely 26 January, 6 April, 4 June, 2 August, 30 September, and 28 November — that all new moons flee from them as from unlucky days; for in all eternity no new moon can fall on them by your reckoning, on account of the Epact of the letter $\varsigma\varsigma$, or the sign $\blacklozenge$, set against those days, in place of which you direct that either the Epact xxix written below that sign, or the Epact j noted above the same sign, is always to be taken. Is not this to be judged a rash assertion, in no way to be believed? For how can it be that a new moon may fall on every other day, but on those six none at all?

SED. But if I may also venture a guess at the cause of this, it seems to be that, since you shrank from a pairing of two Epacts assigned to the same day in six months, you were forced to strike out one of the 30 Epacts in six months, so that the lunations might be constituted alternately of 30 and 29 days. And you willed this [expunged] one to be $\varsigma\varsigma$, or $\blacklozenge$. Hence, if it were to mark a new moon whenever the golden number in the Cycle of Epacts set against the golden number fell upon it, the Paschal new moon would then occur on 6 April, outside the Paschal terms; and in the six months where it is not found, no new moon would be had — both of which are absurd. Since, therefore, it is also absurd to deprive certain days of new moons, we ought not to shrink from a pairing of two Epacts assigned to the same day: for by that device all absurdities are avoided, as can plainly be seen from our Calendar, especially if its Epacts are resolved into golden numbers, which we did in chapter 15 in the thirty Calendars.

10. A second reason seems to have moved Viète to assign the year's beginning to 8 March: namely that, this beginning laid down and the arrangement of Epacts established upon it, all the Paschal lunar months are full — that is, of 30 days. But what has this to do with the correct celebration of Easter? Would Easter be dislodged from its place if even one of those months, or indeed all of them, were hollow — that is, of 29 days? Certainly the Fathers of the Council of Nicaea did not think so, for they made all the Paschal months hollow, that is, of only 29 days; and this same thing we too accomplished most carefully in the new Calendar, with two months excepted, those of the Epacts xxiiij and 25, as was explained in chapter 10, section 9. [Margin: It is not necessary that the Paschal months be full; indeed it is contrary to the Fathers of the Council of Nicaea.] Moreover, lest seven lunations should be made of 30 days, we rejected the equation applied by the Epacts [sigil: ?] [the epact-30 sort of the 1577 *Compendium*; on the page it prints as a small solid, blotted rounded oval with a short flick at the left — **not** a circle enclosing a dot. No character is committed: the sort is too heavily blotted in this copy to identify] and xxix at the end of March in the Calendar transmitted to the Christian princes in the year 1577, and chose this other one, established in the new Calendar by the Epacts xxv and xxiiij on 5 April. With what face, then, can you say in proposition 29 that it has hitherto been the custom, not only among the Hebrews but among all other computists, to constitute the first month — that is, with you, the Paschal month — as full? Look to it. Or, at the time when the Council of Nicaea was convened — at the time, I say, when so great a harvest of the most upright and learned men flourished — was there no single method of computation? Or is Dionysius the Abbot, surnamed Exiguus [Dionysius Exiguus], easily the foremost computist of his age, to be held wholly contemptible — he who, in the year 532, to remove the seeds of discord between Greeks and Latins over the celebration of Easter, inscribed the Cycle of the Alexandrians, that is, of only 29 days, constituting those same Paschal months hollow? Or has the authority of those most weighty Fathers no weight with you? There is no reason, then, my dear Viète, to boast so greatly that you have made all the Paschal months full — unless perhaps it seems glorious to you to rescind the most wise decrees of the Council of Nicaea on this matter, which nevertheless the whole posterity of mankind has always deemed it most shameful not to venerate with the utmost zeal.

SED. But you did not foresee, I believe, that these full Paschal months would cast you into that labyrinth of so many lunations of 28 days, of which above, at the end of section 4, we conjectured [you would fall into]; otherwise you would doubtless have entered upon the beaten path of hollow Paschal months, together with the computists.

SCIO. I know indeed that all computists constituted the first lunar month, which always ends in January, as full; but at the same time I also know that they made all the Paschal months hollow. Our Calendar, then, agrees better with the doctrine of the computists than yours.

11. Let these things be noted in passing against the Viètan Calendar. For we shall point out several more absurdities a little further on, when we examine the Paschal fourteenth Moons alone, in which we shall show that he has committed notable errors — provided, however, that we first briefly reply to his [?] [a Greek word set in small italic: only the initial κ, a second letter (ε or ρ), an ι and an unresolved cluster can be made out, and the final vowel carries an inked grave; no reading is committed], with which he quite severely passes judgment on our Calendar. In the first place, then, he accuses the Gregorian Calendar of constituting the lunar months, beginning from 6 February up to the day of intercalation (if the year is a leap year), as of 30 days. But that this is not absurd we showed in section 5. Yet it is foreign to correct computation to constitute many months of only 28 days, and now and then a month of 31 days — all of which, described in your Calendar even where the equation-letter need not be changed, we showed Viète to do, in section 4. In our Calendar, however, no lunation described in the Calendar contains 31 days, but only 28 — if you except the first lunar month of the year, when, because there is a passage from a higher line to a lower and from a lower to a higher, the added intercalary day sometimes brings it about that a 30-day lunation contains 31 days, which nevertheless are not all noted in the Calendar; so that we may truly say that no month of the Moon in our Calendar is assigned 31 days, or 28, unless the equation of the Moon must be applied, as has been said.

DEINDE. Next he says that in the new Calendar there is a certain new moon of the year which, once given, does not yield the Paschal new moon, on account of the two Epacts 19 and xx assigned to the last day of December; and Viète seems to act in good faith. For although these two Epacts, 19 and xx, are assigned to the last day of December, yet both are not used in the same year, but only one; and which one that is, the precepts of the art teach most clearly, as is manifest from the expanded table and its equation. Indeed, at the end of December in the Calendar we taught most plainly when the Epact 19, placed beside the Epact xx, will be of use. And so, when the Epact 19 is to mark a new moon on the year's last day, there is no doubt that the Epact xix has thereby shown, in that year, the Paschal new moon on 12 March; whereas when the Epact xx marks a new moon on the last day of December, it is likewise manifest that the same Epact xx has already marked the Paschal new moon on 11 March in that same year. Where,

then, is that ἀμφιβολία [Greek: ἀμφιβολία (amphibolia, "ambiguity")] which Viète so greatly reproaches us with?

TERTIO. Thirdly, he argues to the same effect when he says that there are certain Paschal new moons which, once given, do not thereby yield the other new moons of the year. He brings forward two examples. The first is this. "Let there be given," he says, "a Paschal new moon on 4 April, and the year's golden number 12, or greater. The other new moons of the year are sought. The fourth of April exhibits a double Epact, 25 and xxvi. The former argues a new moon on 4 May, the latter on 3 May. But why I should choose this rather than that, the precepts of the art do not teach." The second example is this. "Let there be given again," he says, "a Paschal new moon on 5 April, and the golden number 11, or less. The other new moons of the year are sought. The fifth of April exhibits a double Epact, xxiiij and xxv. The former argues a new moon on 5 May, the latter on the 4th. But why I should choose that rather than this, the precepts of the art do not teach." Good God! Who would believe that Viète, a serious and learned man, could take delight in such trifles? Did we not show, more clearly than daylight, in chapter 10, that two Epacts

that two Epacts ascribed to the same day cannot both be in use within the same nineteen-year cycle? And did we not also, in that very place, instruct the reader of the Calendar in chapter 12 which of the two he ought to take together with the golden number of the year? Why then does he clamour that the principles of the art do not teach this?

QVARTO. He attacks the cycle of our Paschal new moons more or less as follows. "When the Cycle of the Paschal new moons is set out directly according to the standard of the golden number," he says, "those new moons do not advance by an equal and uniform progression." He proves it thus. Let the golden number be j , and let the Paschal new moon fall on March 22 — which will happen in the year 6802. Then, when the golden number is 8, that is, in the year 6809, the Paschal new moon will fall on April 4, according to the Cycle of Epacts set out directly against the standard of the golden number. Again, let the golden number of the year be j , and the Paschal new moon March 24 — which will occur in the year 7011. Then, when the golden number is 8, namely in the year 7018, the Paschal new moon will fall on April 5, from the same Cycle. Therefore, over an equal interval — 209 years (for that is the count both from 6802 to 7011 and from 6809 to 7018) — the new moon belonging to golden number j is advanced forward by two days, whereas the one belonging to golden number 8 is advanced, by an unfair dispensation, by only a single day.

He then adds another example of much the same kind. Let the golden number be j and the Paschal new moon March 8, which will happen in the year 3610. Then, when the golden number is 15, namely in the year 3624, the new moon falls on April 3. Again, let the golden number be j and the Paschal new moon March 10, in the year 3914. Then, when the golden number is 15, which will happen in the year 3928, the Paschal new moon will fall on April 4. Therefore, over an equal interval of years — 304 (as many as are counted both from 3610 to 3914 and from 3624 to 3928) — the new moon that belongs to golden number j is advanced by two days, but the one belonging to golden number 15 is advanced, by an unfair dispensation, by only a single day.

But look here, Viète: what unfairness is committed in this dispensation? What law, what decree ever forbade that, on account of the alternating lunations of 30 and 29 days, some Epact — such as $xxiii$, set at April 5 — should be shifted from its own place (that is, up from April 6) to April 5? Or that Epact 25, prefixed to April 4, should be shifted from April 5 to April 4? For what harm does this bring to the correct celebration of Easter? Did not the very same thing happen in the golden-number Cycle of the Council of Nicaea? For in it, when the golden number was j , the Paschal new moon fell on March 23; but after 13 years, when the golden number was 14, the same fell on March 30. Again, when the golden number was 9, the Paschal new moon stood on March 25; but after 13 years, when the golden number was 3, the same new moon fell on March 31. Did the Fathers of Nicaea, then, act unfairly in so arranging the golden-number Cycle that from golden number j to golden number 9 the new moon was advanced by two days, but from golden number 14 to golden number 3 by one day only — even though golden number 14 stands as far from j as golden number 3 does from 9? That this is indeed so is plain from the ancient Ecclesiastical Calendar which we set out in chapter 9. Nor will you ever prove this unfair, since on account of the alternating lunations of 30 and 29 days it cannot be avoided.

But perhaps you altogether escape this "unfair" dispensation (if you insist on calling it so) in your own Calendar? What if I convict you of being guilty of the very same crime — if crime it must be called, since it happens of necessity? Let the golden number be j and the Paschal new moon March 24, which occurs when your Epact is $xiii$. Then, when the golden number is 8, the new moon will fall on March 8, where Epact $xxix$ is placed, which you then take for the sign $\blacklozenge$. Again, let the golden number be j and the Paschal new moon March 26, when your Epact is xj . Then, when the golden number is 8, the new moon falls on March 9, where the Epact is $[xij]$. All of which is derived from your own Cycle set directly against the golden number. Do you not see that, over an equal interval of years — 513

(for in the year 7011 the golden number is j and your Epact xiiij, but in the year 7018 the golden number is 8 and the Epact xxix; then in the year 7524 the golden number is again j and the Epact xj, while in the year 7531 the golden number is 8 and the Epact xxviii) — the new moon that belonged to golden number j is advanced by two days, from the 24th to the 26th, whereas the one that fell to golden number 8 is advanced by one day only, from the 8th to the 9th? Once more, let the golden number be j and the Paschal new moon March 24, according to Epact xiiij. Then, when the golden number is 8, and hence your Epact is xxix, out of your Cycle the new moon falls on March 8. Again, let the golden number be j and the Paschal new moon March 25, near Epact xij. Then, when the golden number is 8, the new moon falls on March 8, according to Epact xxix, which then concurs with golden number 8, out of your cycle. Therefore the new moon of golden number j is advanced by one day, but the new moon of golden number 8 remained fixed on March 8. I could bring forward countless examples of this kind, but there is no point in dwelling on a trifling matter. For the lunar months of 30 and 29 days compel this unequal progression to happen — as occurs in our Calendar in six months, on account of Epacts 25 and xxiiij, which are shifted up by one day; and the same is seen in your Calendar, on account of the sign ♦, which forces one to take now Epact j, now xxix, in its place. Wrongly, then, do you condemn the Gregorian Calendar for this unequal progression, since it is found in your Calendar too, and no cycle can escape it.

QVINTO. Viète censures us on the ground that in the Gregorian Calendar we employ Epact xxv with a golden number not greater than 11, but Epact 25, depicted in another colour, with a golden number greater than 11; and that on account of the former we have bound Epact xxiiij to the same day, while the latter we have associated with Epact xxvj. For he would prefer the former to occur with a golden number not greater than 10, and the latter with a golden number greater than 10. Behold a crime that the most learned gentleman Viète can atone for by no expiation! As though we too had not done this on account of the alternating lunations of 30 and 29 days, as we set out fully in chapter 10. And see into what labyrinths he throws himself, when we take Epact 25, ascribed to April 4, with a golden number greater than 11, but he takes Epact j, affixed to April 5; and again, when we use Epact xxv, placed at April 5, with a golden number not greater than 11, while he uses Epact ij, set before April 4 — as we shall point out a little later. The Table of Movable Feasts in chapter 22, computed up to the year 5000, plainly demonstrates that Epact 25 is rightly associated with Epact xxvj, and Epact xxv with Epact xxiiij. And that we distinguish the first 11 golden numbers, which are not greater than 11, from the latter 8, which are greater than 11, we do in agreement with the ancient computists, who divided the

nineteen-year cycle not into a decad and an ennead [ten and nine], as Viète does, but into an endecad and an ogdoad [eleven and eight] — and that with great deliberation and reason. For among all nations the nineteen-year cycle of the golden number has been so arranged in the Calendar that each following [Epact] is formed from the preceding by the addition of

the number eight, and each preceding from the following by the addition of eleven, as we taught in chapter 9, number 7 — a scheme which can in no way accord with an ennead and a decad.

SEXTO. The Epacts seem to Viète to be wrongly ordered in the Gregorian Calendar, which he tries to show as follows. In the year 1500, before the correction, when the golden number was 3, Epact *iiij* was current, indicating in the Gregorian Calendar a Paschal new moon on March 28. After the correction, however, once the 10 days had been removed, March 28 falls on April 7 (I am surprised that he himself says April 6, since 10 added to 28 makes March 38, that is, April 7, not 6); and Epact *iiij* passes into *xxiiij*, which indicates a new moon on April 6, not April 7. He then goes on: "If the Epacts are said to be well ordered, the Paschal new moons will not be consistent with themselves. For since in the year 1500 the new moon, after the correction, has slipped from March 28 to April 7, where Epact *xxij* stands, the Paschal new moon ought then to have fallen on March 9, where the same Epact *xxij* is placed — which is false, since Epact *iiij* has then been changed into *xxiiij*, which puts the Paschal new moon back to March 8, not March 9."

Here Viète behaves maliciously. For he takes March together with April, where — on account of the alternating months of 30 days — Epact *xxiiij*, together with the others below it, has left its own seat and migrated into the higher one; so that it is no wonder the aforesaid variation appears in the new moons, a variation which nevertheless does no harm to the solemnity of Easter. But if we take April together with May, where the two Epacts *xxv* and *xxiiij* are not associated together, that diversity has no place, but everything agrees among itself most beautifully. For, to keep to the same example: in the year 1500, before the correction, with golden number 3, Epact *iiij* was used, whose new moon falls on April 26. Then, after the correction, on account of the removal of the 10 days, April 26 becomes the 36th, that is, May 6, and Epact *iiij* is changed into *xxiiij*; and you see that Epact *xxiiij* is prefixed to May 6. The same may also be observed either in March alone, or in March and April together, provided the 10 days removed do not compel us to descend below Epacts *xxv* and *xxiiij*. For in the same year 1500, before the correction, Epact *vj* answered to golden number 6,

putting the new moon back to March 25. Then, since through the 10 days removed March 25 becomes the 35th, that is, April 4, and Epact *vj* is changed into *xxvj*, you perceive that this is set at April 4.

Viète's other example, too, does not bear on the matter, on account of those two Epacts *xxv* and *xxiiij* tied to the same day. For unless Epacts *xxij* and *xxiiij*, together with *xxiiij*, had risen up by one day in April, Epact *xxij* would be placed at April 7, which indeed indicates a Paschal new moon on March 8, as Viète wishes. Cunningly, then, he took up Epact *xxij* below Epacts *xxv* and *xxiiij*, since it had deserted its own place. But if this cunning may be permitted, we shall catch him labouring under this very disease that he so dreads. For since on March 27 — where, with golden number 14 concurring with Epact *iiij*, the Paschal new moon fell before the correction in the year 1500 — this same date, after the correction, by the removal of the 10 days, becomes the 37th, that is, April 6; and Viète's Epact concurring at that time with golden number 14 is *j*, as appears from his Cycle; he ought, if he has argued rightly against us, to have his Epact *j* occupy April 6 — yet he has prefixed it to April 5. His Epacts, then, are not rightly ordered, which he will not grant. But the cause of this diversity in his case is the same as in ours. For in place of the two Epacts *xxv* and *xxiiij* ascribed to the same day, he takes now *xxix*, now *j*, for the sign $\blacklozenge$ or $\odot$. So this is not absurd, since the nature of the Cycle necessarily brings it about, in whatever way it is arranged, provided the lunations are set at alternating 30 and 29 days, as reason demands.

SEPTIMO. It vexes Viète that we change the Epacts at the beginning of January. For from that change it follows that in the first two months the new moons fall one day later in the non-bissextile centennial years, since the day is subtracted not at the beginning of the year but on February 24. What then, Viète? Do the Paschal months, of which greater account must be taken, on that account advance less correctly? I do not see it. Beware of thinking that those who took part in the correction of the Calendar did not notice this distinction. We openly acknowledged it, as we said in chapter 12, number 5, near the beginning. They valued uniformity in the correction of the Calendar more than that postponement of the Moon. For since the Catholic Church, from the Council of Nicaea down to the Gregorian correction, has always changed the golden number at the beginning of January, why should we not change at that same point the Epact, which depends on the golden number? — especially since nothing absurd arises from it in the Paschal new moons, whereas that postponement occurs only in the first two months of that one centennial year in which the intercalation is omitted.

OCTAVO. Viète asserts that the nineteen-year Lunar Cycle and the Cycle of 300000 years of the table of the equation of the Epacts — of which we treated in chapter 11, number 10 — do not agree with each other; which we readily concede. For long ago, in chapter 12, number 10, we rejected the Cycle of 300000 years, and taught that it no longer has any place, because we there set up the table of the equation otherwise than it was, in the author of the Calendar's opinion, continued and extended uniformly up to the year 300000 — from which uniformity alone that Cycle was gathered; although the very author of the Calendar well knew that that uniformity could not last forever. And so this weapon, launched against the Calendar, would strike the author of the Calendar himself, if he had affirmed his equation, and the Cycle of 300000 years gathered from it, to be wholly accurate — which, however, he did not assert; but the Calendar itself, if the equation be corrected, as we taught in chapter 11, it does not so much as lightly graze. It only proves that the equation, according to the author's opinion, was not rightly framed in chapter 11 for the longer ages — which neither the author nor we deny, since we afterwards corrected it in chapter 12, number 10.

POSTREMO. He insists and presses that, in the most widely separated ages, through the equation of the Epacts prescribed in chapter 11, the Epact exhibits a new moon when the Moon is nearly [Greek: διχότομος (dichotomos, "cut in two," i.e. at the half — first or last quarter); the ☉ is the -ος abbreviation ligature] or [Greek: πανσέληνος (panselēnos, "full moon")]. As examples he adduces the years 109500 and 218000 — which is true. For to the former year there agree golden number 4 and Epact xix, according to that equation, placing the new moon at March 12, whereas the mean new moon is, by calculation, on March 18 at about hour 11. To the latter year the golden number is 14 and the Epact xxiiij, indicating a new moon on April 5, whereas the tables teach that the mean new moon then occurs on March 20 at about hour 2. But we approve not that equation, but the one we established as corrected in chapter 12; and if the Epacts are derived from it, we shall find that, for the use of the Church, they agree not badly with the astronomical calculation. For in the year 109500 it yields Epact xi, whose new moon falls on March 20; and in the year 218000 the same yields Epact viii, which puts the new moon back to March 23. These two new moons follow the celestial ones at just so great an interval as suffices for the fourteenth Moons not to anticipate the mean oppositions by more time than is fitting. For although

Epact viii postpones the new moon in the year 218000, yet in the year 219000, in which the golden number is 7, Epact xvj rightly puts the fourteenth Moon back to March 28, since the mean opposition then occurs on the 28th at about hour 5. But

your Epact, my Viète (that I may say this too in passing), in the same year — as is gathered from your rule, which I shall subjoin below — will be xxij, putting the fourteenth Moon back to March 27; and hence, if the following day were a Sunday, you would celebrate Easter before the mean Full Moon. More rightly, then, does our equation stand at that point than yours; so that you cannot boast that you have framed a better equation than we — since in the most remote ages now ours, now yours, more rightly exhibits the fourteenth Moons.

It is no wonder that the equation does not always answer exactly to the celestial motions, as we said in chapter 12, number 10 — especially in view of ages so far distant, which are adduced as examples. Therefore this argument of yours, Viète, proves nothing, if the equation of the Epacts is rightly framed, as we have done in chapter 12, number 10 — although its truth is sought in vain over ages so far distant, as we said in the same place. Nor does it avail much against the equation of the author of the Calendar handed down in chapter 11. Nor did the author, and those who took part in the correction, put forward that equation as most certain and never in need of amendment; since in chapter 12, number 16, he frankly confesses that not only it, but ours too, must be changed, if perchance it should not rightly exhibit the Epacts after some thousands of years — and we have also prescribed the manner and reasoning of the correction there, and at the end of the same chapter 12. The only thing the correctors of the Calendar kept before their eyes was to explore in what order, according to that reasoning of the equation, the letters of the expanded table would proceed. From this it came about that the Cycle of 300000 years was gathered — although, as has been said, it does not answer to the new moons over ages so far distant. It was enough for the author that this equation should rightly show the Epacts for thousands of years to come, which is most true; but the care of correcting it in future ages he left to posterity, should the world endure.

[Margin: What the author of the Calendar and its correctors kept before their eyes in the equation of the Epacts.]

What, then, can you bring against that equation that is of any moment? You would indeed convict it of falsity only if the author had asserted that it would never need correction — which you will nowhere find; but rather the contrary, as has been said. Yet in these two last reproaches you have a just excuse: namely, that you had not seen what we wrote in this book concerning the correct equation of the Epacts; which, had you read it through, I do not doubt you would have judged more fairly and more rightly of the Gregorian Calendar, which was published in the year 1582.

QVIN. Moreover, if it had come to your mind that no Cycle, however skilfully equated, can answer exactly to the astronomical calculation for the more remotely distant ages, you would without doubt not so easily have condemned the author's equation — since not even your own equation, which you value so highly, agrees with the celestial motions for all future ages. Two examples, brought forward by you yourself, bear witness to this. The first is the year 19480000, in which the golden number is 4 and the Epact, according to your equation, as you assert in proposition 17, is xxix, exhibiting a Paschal new moon on March 8; and yet the truer calculation in that year gives the mean Paschal new moon on March 30, at hour 15 after noon, and something more. The other example is the year 165580200, whose golden number is 8 and your Epact ij, as you affirm in proposition 39 — although in proposition 40 you say (which is astonishing) that the new moon is on April 2, and hence the Epact iiij. But whichever you take, the truer astronomical calculation will disagree with it, for it indicates the mean new moon on March 22 at hour 15 after noon. You see, then, that not even your equation agrees with the astronomical calculation over ages so far distant — the cause of which matter we disclosed in chapter 12, number 10.

IMMO. Nay, not even in the less remote ages can the Epacts always answer to the astronomical calculation. Let this one example, out of many, be chosen. In the year 4900 the golden number is 18, the Gregorian Epact xviii, Viète's j. The fourteenth Moon of both falls on April 18, whereas the mean opposition occurs on April 19 at hour 19 after noon — which is not the Paschal one, but rather the one that in March falls on day 21 at hour 6 after noon.

[Margin: That in any given cycle certain Epacts fail to exhibit fitting fourteenth Moons.]

Why then, someone may say, is the equation not so framed that to your golden number 18 there should answer Epact xxiii in the Gregorian Calendar, and Epact xxix in Viète's? I reply that this is not expedient. For then to the other golden numbers other Epacts would answer, lower by one unit than the earlier ones; and so their fourteenth Moons would be postponed, whereas the earlier Epacts, when golden number 18 gives Epact xxiiii, for the most part rightly show the fourteenth Moons. The same could be shown in most of the other Epacts, some of which seem to anticipate the mean oppositions too much, others to postpone them too much: so that the placement of the Epacts, and their equation, is faulted without cause under this head — that some of them, even in the less remote ages, accord less aptly with the celestial motion; since this happens in every cycle.

[Margin: Why the placement of the Epacts, and their equation, cannot be faulted on that account.]

On which matter more has been written by us in chapter 19, number 6 and following, and can most clearly be seen in the Table of Movable Feasts, chapter 22. Unjustly, too, is our equation accused by Viète, for this one reason only — that in the most remote ages it does not answer to the celestial new moons; just as though we had not frankly confessed, in chapter 12, numbers 18, 19, and 20, that it can neither be perfect nor therefore everlasting: seeing that we have also prescribed a rule by which our posterity may amend it after such far-distant ages. Whereas not even the one that he himself puts forward as most certain is, if it be applied to the more remote ages, altogether free of fault — nay, it contains graver errors than ours; since in the year 19480000 it exhibits a Paschal new moon on March 8 by Epact xxix, two-and-twenty days and more before the mean Paschal new moon, which occurs on March 30 at hour 15 — that is, when the Moon is [Greek: διχότομος (dichotomos, at the half)] after the non-Paschal new moon, which occurs on March 1 at hour 3; and this is indeed worse than when the Moon is διχότομος or πανσέληνος after the Paschal new moon. But in the year 165580200 it would offer a new moon on April 2 or 4 by Epact ij or iiij, eleven or thirteen days after the Paschal new moon, which falls on March 22 at hour 15 — that is, when the Moon is nearly πανσέληνος [full], as I showed a little before.

Since, then, most learned Viète, you have been so unfair a judge of our Cycle of Epacts — seeing that in the very thing for which you reproach us, you yourself sin more gravely; and especially since we lay down that our equation must be corrected in ages so remote, which you do not assert of yours — since, I say, you have been so unfair a judge: which of us (that I may turn back upon you what you wittily said against us) would tolerate in our assembly [Greek: χρηματίζοντα κ γνώμην εἰς βουλήν εἰσφέροντα (chrēmatizonta kai gnōmēn eis boulēn eispheronta) — roughly "one who [merely] styles himself [a judge] and brings his opinion into the council"; the κ is this fount's καί ligature sort, and γνώμην and βουλήν are set with its ην ligature and 8 (ου) ligature sorts]?

NE. But that you may not doubt the truth of our calculation, know that it is drawn from the most approved astronomers — the one, indeed, which we set out in chapter 13. And from this calculation the one that you put forward in proposition 9 in the common Calendar differs only in certain hours: which indeed happens on account of certain scruples neglected in both

Caput XXIII (continued)

passed over. Furthermore, I shall explain this calculation of yours later, since it does not displease me — though I shall propose a more accurate one. For as you set it out, it is not entirely free of error, as will be clear in the following chapter. Then, in chapter 26, I shall construct yet another method of calculating, and indeed an easier one.

12. From the remarks I have briefly made against Viète's Calendar, and from my replies to his slanders against the Gregorian one, any fair and prudent reader will readily judge, of the two Calendars, which of them truly deserves to be called Gregorian. That Viète's is utterly foreign to Gregory's intention — and therefore (be it said with all respect to him) most justly to be called Pseudo-Gregorian — no one will be able to doubt who, setting aside all the other absurdities in it, considers a little more carefully that in it the beginning of the year is altered and the leap years and common years are confused with one another. For in it the years become leap years before those very years begin which are leap years with us. To take an example: in the year 1604 it intercalates a day along with us, before the year 1604 begins in his reckoning. Likewise it does not preserve the reckoning of the Epacts, if these are compared with the Epacts as they stood before the correction of the Calendar. But he will recognize this far more clearly if he inspects, not carelessly, the errors of the fourteenth Moons which I shall shortly append. It remains, therefore, that the Calendar which Gregory ordered to be published in the year 1582 is the truly Gregorian one, since it was drawn up entirely in accordance with Gregory's mind. Of this I can be an eyewitness, since I took part in this correction, together with other most learned men, for nearly ten years, and more than once dealt privately with the Pope himself concerning this whole business of the correction. Indeed I remember that Gregory impressed upon me again and again that the change made in the Calendar should be as small as possible; and this, he said, was the mind of the Kings and of the other Princes. It is clear, then, that it was not the Pope's intention — as Viète dreams — that the beginning of the year and the Epacts should be dislodged from their place. But let us now come to matters of greater moment.

[Margin: That Gregory's mind, in correcting the Calendar, was not the one Viète imagines for himself.]

13. In rightly establishing the fourteenth Moons, all the effort of one who undertakes to arrange the Epacts in the Calendar ought to be expended. I am well aware that no Cycle set out in the Calendar, with whatever care and diligence,

can so agree with astronomical calculation that it does not sometimes differ from it by nearly a whole day; the manifold cause of this I set forth in chapter 18, Number 8, and elsewhere; and Viète readily concedes this same point. This much only must be strenuously striven for: that the fourteenth Moons of the cycle do not precede the mean oppositions by more than one day; likewise that (except very rarely, and this on account of the imperfection of the cycle) the nearest Paschal opposition does not fall before the 22nd of March — that is, that it does not fall on the 21st before noon — and that the latest does not fall after the 19th of April, but rather occurs either on the 18th after noon or on the 19th before noon. For the computists teach that the opposition which occurs before the 22nd of March belongs to the last month of the year, and the one which follows the 19th of April belongs to the second month. But concerning the fourteenth Moon I have written more in chapter 18, Number 4. And if it should ever happen that in some year no mean opposition is Paschal according to this rule — namely because the one in March precedes the 22nd, while the one in April follows the 19th (that this can happen I both showed plainly in chapter 19, Number 6, and it will also be easily understood from what follows) — then it is the lesser fault to take the one that falls in the second month rather than the one that falls in the last. This foundation laid, let us now examine several fourteenth Moons, so that all may understand that they are more correctly indicated in the Gregorian Calendar than in Viète's.

[Margin: What must be attended to in arranging the Cycle in the Calendar.]

At the outset, moreover, I observe in Viète (which greatly astonishes me) two mutually contradictory tables of the equation of the Epacts: one in the small Calendar published separately, and therefore the one he seems to propose for the Church to adopt; the other in the *Relation of the Calendar* presented to Clement VIII, which indeed agrees entirely with his own *proemptosis* and *metemptosis* of the Moon, as he declares in proposition 39 — so that I am uncertain and in doubt which of the two he more approves. But lest, by examining only one, I should seem to do an injustice to the other, I shall set this doubt and hesitation aside and undertake to examine and scrutinize both, since in each there is found something deserving of censure. For although the later table, up to the year 4900, is entirely the same (as regards the order of the letters) as ours, nevertheless, on account of the new placement of its Epacts in the Calendar, I have detected not a few errors in it as well. But here is the perpetual Table of the Cycle of Epacts, together with both its tables of the equation.

SEQVITVR

The perpetual Table of the cycle of Epacts, with both tables of the equation of those same Epacts.

Viète's perpetual Table of the Cycle of Epacts.

The table sets the 30 index letters (Dominical-letter sorts) each over its Epact, in three bands of ten columns. The first column is headed by the digamma sort (YY), whose Epact is the solid lozenge ◆ (Epact 30).

| H | 2100 | | B | 3300 | | f | 4500 | |
| G | 2200 | | C | 3400 | | f | 4600 | |

| Inde
x | Anni Dñi | Biss. | Inde
x | Anni Dñi | Biss. | Inde
x | Anni Dñi | Biss. |
|-----------|----------|-------|-----------|----------|-------|-----------|----------|-------|
| F | 2300 | | B | 3500 | | r | 4700 | |
| G | 2400 | Biss. | B | 3600 | Biss. | r | 4800 | Biss. |
| F | 2500 | | B | 3700 | | r | 4900 | |
| E | 2600 | | A | 3800 | | | | |

II. Table of the equation of the same Cycle, as proposed in the Relation of the Calendar.

| Inde
x | Anni Dñi | Biss. | Inde
x | Anni Dñi | Biss. | Inde
x | Anni Dñi | Biss. |
|-----------|----------|-------|-----------|----------|-------|-----------|----------|-------|
| N | 1582 | | E | 2700 | | u | 3900 | |
| N | 1600 | Biss. | E | 2800 | Biss. | u | 4000 | Biss. |
| M | 1700 | | D | 2900 | | t | 4100 | |
| M | 1800 | | D | 3000 | | f | 4200 | |
| H | 1900 | | C | 3100 | | f | 4300 | |
| H | 2000 | Biss. | C | 3200 | Biss. | f | 4400 | Biss. |
| H | 2100 | | C | 3300 | | r | 4500 | |
| G | 2200 | | B | 3400 | | r | 4600 | |
| F | 2300 | | A | 3500 | | q | 4700 | |
| G | 2400 | Biss. | B | 3600 | Biss. | q | 4800 | Biss. |
| F | 2500 | | A | 3700 | | q | 4900 | |
| E | 2600 | | u | 3800 | | | | |

In this later table you see that the years 3300, 3400, 3500, 3700, 3800, 4000, 4100, 4200, 4300, 4400, 4500, 4600, 4700, 4800, 4900 have letters different from those which Viète assigns to the same years in the earlier table. Indeed — what is more astonishing — in the Calendar printed separately, in Canon 2, he even writes the contrary about the Epact 29 or 1 to be taken when the digamma YY, or the sign ◆, occurs. To what end this inconstancy is, let him see for himself.

The use of these tables in finding the Epact of any given year does not differ from our own use, which we explained in chapter 12, Number 6 — except that, when the given golden number falls in the cell of the letter YY, Viète does not wish the Epact ◆ to be taken under that letter, but rather the Epact 29 (xxix), if the golden number is not greater than 10, and the Epact 1 (j) if the golden number is greater

than 10. For these two Epacts are set around the Epact ♦ in the Calendar. For example: in the century 4500 or 4600, with the golden number 7 running, when golden number 3 is assigned to the cell of the letter r — which in the later table is set at the head of the said centuries — golden number 7 will fall in the cell of the letter YY; and therefore the Epact then to be taken is 29 (xxix). Likewise, in the centuries 4200, 4300, 4400, to which in the earlier table the letter t is ascribed, if golden number 3 is assigned to the cell of the letter t, golden number 15 will fall in the cell of the letter YY. Therefore Viète's Epact then will be 1 (j).

And so, if the Epacts are investigated according to the earlier table of the equation, we shall find that, up to the year 4900 (which is the last in the table), Viète proposes 125 Easters to be celebrated before the mean opposition. I pass over the well-nigh innumerable fourteenth Moons which precede the mean oppositions by more than is fitting — to such a degree that, if the following day were a Sunday, Easter would then likewise be kept before the mean full moon. But because the Dominical letter corrects this error, inasmuch as it does not immediately follow the fourteenth Moon, I judged it best to say nothing of it, lest I overwhelm the reader with a multitude of errors — although those fourteenth Moons are, by the reckoning of all computists, faulty by their very nature, since the very next following day forestalls the mean opposition, as we said a little earlier and discussed at length in chapter 18, Number 4. This is something Viète himself also admits in proposition 40, where he writes thus: *Care therefore had to be taken that the fifteenth we established should not coincide with the Jewish fourteenth.* Look, then, at the following table, in which those 125 years are set out, with the Dominical letters, the golden numbers, the Epacts both Viète's and Gregorian, and their fourteenth Moons, the mean oppositions, and the days on which Easter is proposed to be celebrated according both to Viète's Calendar and to the Gregorian. For thus, by comparing the two with each other, all will easily perceive, even with their own eyes, that Viète's Calendar is thoroughly faulty, whereas the Gregorian one is in agreement with the decrees of the Fathers, since it presents the fourteenth Moons and the solemnity of Easter rightly, as the Canons require. In this table the letter M signifies March, and A April. In the oppositions, moreover, the former number indicates the Day, the latter the hours after noon.

[Margin: That Viète, according to the earlier table of the equation, presents 125 Easters before the mean full moon.]

SEQVITVR

A Table with the errors committed by Viète in the earlier table of the equation.

The great comparison table begun under the rubric **SEQVITVR** on the preceding leaf continues here without a break. It sets, year by year for the error-years between A.D. 3408 and 4998, Viète's calendar against the Gregorian, so as to display the 125-odd years in which Viète's reckoning would place Easter on or before the mean opposition (full moon). The columns are, in the exact printed order: the year (**Anni**); the golden number (**Aur. Num.**); Viète's epact (**Epact. Vietæ**); Viète's fourteenth Moon (**Lun. xiiij. Vietæ**); the Dominical letter(s) (**Literæ Dominicales**); Viète's Easter (**Pascha Vietæ**); the Gregorian epact (**Epact. Greg.**); the Gregorian fourteenth Moon (**Lunæ xiiij. Gregor.**); the Gregorian Easter (**Pascha Gregor.**); and the mean opposition (**Oppos. mediæ**).

In the Moon and Easter columns the letter after the day is the month: **M** = **March**, **A** = **April**. In the mean-opposition column the entry is day. hours month — the first number is the day, the second the hours after noon, the letter the month.

The SEQVITVR error-table (folios 522–524)

Below the table, on folio 524, Clavius draws the moral (main text, folio 524):

In all these years you can see plainly that the Easter of Viète's calendar is celebrated **before the mean full moon** — from which, as is only proper, it shrinks back sharply, since the Councils and the Canons forbid it. Among these years you will find **17** in which the mean opposition falls either at noon, or a few hours after noon, of the very day that Easter follows — namely 3705, 3763, 3783, 3800, 4010, 4030, 4199, 4351, 4375, 4602, 4622, 4791, 4903, 4923, 4943, 4947, 4967. But this can in no way be tolerated in the Church of God.

You will also find **45** years — namely 3411, 3442, 3455, 3462, 3482, 3553, 3709, 3729, 3787, 3827, 3858, 3878, 4003, 4034, 4054, 4074, 4115, 4200, 4203, 4223, 4301, 4321, 4351, 4355, 4372, 4379, 4392, 4399, 4419, 4446, 4450, 4470, 4626, 4646, 4666, 4693, 4717, 4751, 4771, 4795, 4815, 4913, 4971, 4991, 4998 — in which the mean

opposition is found to fall after the midnight that opens Easter day; and this is almost equally absurd. In only 5 of these 45 — namely 3455, 3858, 4372, 4450, 4717 — does the mean opposition run into the midnight after Easter day, but no later; and this too is utterly absurd. In the remaining years of this table the mean opposition is seen to fall after the noon of Easter day — indeed in 25 years after sunset as well, and in 8 at the very moment of sunset. In the remaining 30 years, finally — which is more tolerable — it falls after noon but before sunset, or at noon itself. Since, then, in all the aforesaid years the Easter laid down in the Gregorian calendar is the one to be celebrated in accordance with the Decrees of the Fathers, will anyone doubt that the Gregorian calendar is to be preferred to Viète's, spattered as it is with so many errors?

[Margin: That Viète, following the earlier table of the equation, not infrequently celebrates Easter in the second month.]

I could review here a good many other years in which Viète, following this same earlier table of the equation, celebrates Easter in the **last month of the year** — that is, when the mean paschal opposition is not in March but in April, since the April one falls before 19 April, while the March one precedes 22 March. But since this fault too has crept into the **later** table of the equation, I shall put it off to the examination of that later table. Only this ought not to be passed over here: that, following the earlier table of the equation, I have found not a few years in which Easter is kept in the **second month** — that is, in which the mean paschal opposition is not the April one but the March one, since the March one occurs on 22 March, while the April one falls after 19 April. By way of example, take the following 18 years.

The eighteen exemplary years (folio 524)

Does not this table plainly teach us that the Gregorian calendar keeps Easter more correctly in March throughout those 18 years than Viète's [Vietæum] does in April? For the mean oppositions fall in March after noon on the 21st, and so belong to the 22nd, and are therefore Paschal; whereas in April they fall after noon on the 19th, and hence are not Paschal. So much for what has been said against the earlier equation table; let us now turn to the later one.

But first Viète's rule must be set out — the one by which he finds the epact of any year — lest anyone should perhaps suppose that I am not bringing his true epacts to the test. In Proposition 39, then, he hands down this rule:

From the proposed number of the years of Christ reckoned in centuries, cast out 1500; and however many times 400 is contained in the remainder, take that many sets of three days; and if, when the division is done, two centuries are left over, take one day, and if three, take two. Collect what you have taken, and call them the additive days [dies addituios]. Next, from the proposed number of years from the Era of Christ reckoned in centuries, cast out 1800, and keep one day; and however many times 2500 is contained in the remainder, take that many sets of eight days; and however many times 300 is contained in the further remainder when the division is done, take that many single days. Collect these together with the one you kept, and call them the subtractive days [dies ablatuios]. If you cannot cast out 1800, count no subtractive day. Finally, take the excess of the additive days over the subtractive days, and count it off from March 8th exclusive; and the day on which the counting ends will give the epact under golden number 2. If the centuries run on, so that the excess mounts up to whole periods of the annual Julian days, let these be carried round: first by division by the quadrennia, that is by 1461 days, then by the common years, that is by 365 days. And let the root of the golden number, which is set at 2, receive an increment of as many units as there are annual periods. And by however many periods of 2500 years there are, by that many sets of eight days, and by however many further periods of 300 years, by that many single days, let the excess be diminished.

Let us clarify this rule with examples.

I seek the epact for the century-year 17600. Casting out 1500, there remain 16100. Dividing by 400 gives a quotient of 40, with 100 left over. Multiply the quotient 40 by 3: you get 120 additive days. For nothing more is added here, since fewer than 200 years were left over. Again, from the same century-year 17600, casting out 1800, there remain 15800; and when these are divided by 2500, the quotient comes out as 6, with 800 remaining. Multiplying the quotient 6 by 8 gives 48; and adding 2 — because 300 is contained twice in the remainder 800 — makes 50; and

with the further addition of the single unit which Viète said must be kept, it makes 51. Subtracted from the 120 additive days, this leaves 69. Therefore the 69th day after March 8th — that is, May 16th — yields epact 19 [xix] under golden number 3. And golden number 4, for the year 17616, will give in the table of the Cycle of Epacts the epact ♦, that is, 29 [xxix].

I seek again the epact for the century-year 109500. (The three following examples are Viète's own.) The excess of the additive days over the subtractive is 465. I carry round 365 once, and 100 remain. Therefore the 100th day after March 8th will give epact 18 [xviii] under golden number 4 — because 1 is added to 3, on account of the one period contained in the excess.

Likewise for the year 218000. The excess of the additive days over the subtractive is 930. I carry round 365 twice, and 200 remain. Therefore the 200th day after March 8th will give epact 6 [vi] under golden number 5 — because 2 is added to 3, on account of the two periods comprised in the excess; and so epact 15 [xv] will belong to golden number 14 of the given year.

Finally, let the century-year 165580200 be given. The excess of the additive days over the subtractive is 711988. I divide by 1461: 487 come out, with 481 remaining; and dividing these by 365 gives 1, with 116 remaining. And because 487 multiplied by 4 makes 1948 annual periods, with the addition of 1 there are gathered 1949 annual periods in the excess, and 116 remain. But since 300 is contained six times in 1949 annual periods, 6 must be taken from the remainder 116, so that 110 remain. Therefore the 110th day after March 8th gives epact 8 [viii] under golden number 14. For if from the 1949 years I carry round the 19-year cycle as many times as I can, 11 are left over, to be added to golden number 3 [giving 14]. Therefore epact 2 [ii] is due to golden number 8 of the proposed year.

And this is Viète's rule, differing somewhat from ours, which we set out in Chapter 12, Number 10. Let us now come to the examination of Viète's epacts, and look a little more carefully into whether Viète has really been such an accurate Sosigenes as he wishes to appear — he who promised that he would supply everything which, as he puts it, the Gregorian Sosigenes were unable to supply.

In the first place, then, I shall set out a good many years, gathered by me here and there in passing, in which the later equation table makes Easter fall to be celebrated in the last month of the year, as the following table shows. And we sometimes bring forward rather distant years, because Viète too, in attacking the

Gregorian calendar, casts up against us years very far removed — so that he may understand that he has taken no greater care for posterity than we have.

[Margin: Viète, by the later equation, more often celebrates Easter in the last month.]

Table 1 — Years in which Viète's later equation places Easter in the last (Gregorian) month (p. 525; table continues on pp. 526–527).

Column headers as printed: *Anni* (years) | *Aurei Numeri* (golden number) | *Epacta Vietæ* (Viète's epact) | *Oppos. med. in Mart. non Paschalis* (mean opposition in March, non-Paschal; set day · hour · M[artij]) | *Epacta Greg.* (Gregorian epact). The source sets the table in two side-by-side blocks per page; rows below are the left block first, then the right block.

It is clear from this table that none of the mean oppositions listed in it is Paschal, since none reaches March 22nd; and therefore Viète keeps Easter in the last month. More admirably, then, has it been managed in the Gregorian calendar, which in the aforesaid years throws Easter into April — the month that is then the first of the lunar year.

I am aware that the same error sometimes creeps into our own calendar as well; but since this very rarely happens, whereas it occurs most frequently in Viète's calendar, the Gregorian calendar is, by the fullest right, to be preferred to Viète's.

And since Viète speaks so grandly of his own calendar that he does not shrink from boldly asserting that the 15th moons of his epacts never coincide with the Judaic 14ths, let us see whether this holds true in every case. Certainly, in the years of the following table, I find that his 15th moon does not differ from the true or Judaic 14th — the very 14th that the Gregorian calendar also displays — inasmuch as it precedes the mean opposition. From this it follows that he celebrates Easter before the full moon whenever his 15th moon falls on a Sunday, which indeed happens in the years 13706 and 14917. In the other years, although the dominical letter corrects this error — since in them the 15th moon does not fall on a Sunday — nevertheless by their own nature those 15th moons are faulty, as the computists teach.

[Margin: Viète very often shows 15th moons before their lawful time.]

Table 2 — Years in which Viète's 15th moon coincides with the true (Judaic/Gregorian) 14th (p. 527).

Column headers as printed: *Anni* (years) | *Aur. Num.* (golden number) | *Epac. Vie.* (Viète's epact) | *xiiij. Vie.* (Viète's 14th moon) | *Epa. Gre.* (Gregorian epact) | *xiiij. Gre.* (Gregorian 14th moon) | *Opposit. med.* (mean opposition). The 14th-moon and opposition cells are set day · [hour ·] letter, the letter being A[prilis].

Do you not see, Vieta, how much more correctly the epact 25 of the Gregorian Calendar indicates the 14th moon on the 18th of April than your epact 2 does on the 17th?

Moreover, in Vieta's Calendar it is not only the 14th moons that are found running ahead of the mean full moons more than is right, as is clear from the table above; there are also not a few that follow the mean oppositions further behind than is proper. This happens most of all when, in place of our epact 25 — set opposite the 26th, at the 4th of April — he adopts the epact 1, entered at the 5th in his own Calendar. From this too it may be plainly established that it was not without reason that we adopted the epact 25 marked with a different character and advanced up by one day, whenever the golden number is greater than 11 — which Vieta does not approve. That this is so, the table set out below makes most plainly clear.

Table (printed p. 528). Years in which Vieta's 14th moon and epact diverge from the Gregorian, with the mean opposition. The list is printed in two side-by-side panels (left panel first, then right panel); together they form a single continuous series. Column value 18 A = 14th moon on the 18th, ferial letter A; 17 A = 17th, letter A; the mean-opposition column is set day. hour. letter (e.g. 17. 5. A). The Vieta epact is the Roman-i epact 1; the Gregorian epact column is Arabic 25.

From this pushing-back of Vieta's 14th moons it follows that Easter, falling on the 18th of April, if that is a Sunday, is deferred — against the decrees of the Fathers — to the 25th. This will happen in these 15 years: 1954, 2049, 3165, 3260, 3852, 4004, 6399, 17627, 18219, 18466, 20112, 20709, 20956, 29447, 29694. For in all of

these, by the prescription of the Gregorian Calendar, we celebrate Easter on the 18th of April — the Sunday, that is, next after the 14th moon, as the Canons command. But Vieta celebrates it on the 25th of April, because his 14th moon falls on the 18th of April, which is a Sunday.

All these errors I have observed in Vieta's Calendar as though at a glance through a lattice, ranging here and there over various years. I have no doubt that if anyone should choose to examine more years, he would detect more errors; but I judge that the ones I have noted are enough to show that Vieta's Calendar teems with far more faults than can be found in the Gregorian. Not that I therefore think the Gregorian Calendar is to be embraced, or defended by its assailants, on the ground that I suppose it to be immune and free from every error — for I have said again and again in what precedes that no cycle, however great the industry and skill with which it is arranged in a Civil Calendar, can avoid all inconveniences. I have frankly confessed that this applies to the Gregorian Calendar as well. This alone I strive for and maintain: that it contains fewer errors than other Calendars — which I believe is clear enough from the tables above. It can indeed happen that in a few particular years the epacts of Vieta's Calendar, or of any other, indicate the 14th moons more correctly than the epacts of the Gregorian Calendar; but since this happens rarely, I judge the Gregorian to be preferred above all — especially because in it (which is the chief point) nothing is innovated, but everything agrees with the ancient Ecclesiastical Calendar, save that you except the epacts, which have taken the place of the golden numbers. In vain, then, does Vieta labor, and in vain do others labor who try to overturn the Gregorian Calendar on account of a few little errors detected in it, when in other Calendars more errors, and graver ones, than in the Gregorian are to be found — even though, in order to avoid these (as they falsely suppose they do), they introduce, uselessly and without cause, intolerable novelties, unheard of in the Church of God down to the present day. Farewell, then, to the manifold [Greek: ἀταξία (ataxia, "disorder"), κ (?) (a second reproach ending in -ία, sense "absurdity/impropriety"; its medial cluster — a chi-like sort followed by a descending letter — does not resolve, so no reading is committed), κ ψευδοψηφοφορεία (kai pseudopsēphophoreia, "and false reckoning"); both connectives are set with this fount's κ (καί) ligature sort, kept as printed] of Vieta's Calendar, as we have shown. For these faults, which Vieta has hurled against our Calendar, fit far more aptly upon his own Calendar, as is clear from what we have shown.

14. Among the other matters that Vieta learnedly and subtly discusses in his new Calendar, he sets forth two propositions which I cannot approve in

every respect. The first is this. The Great Lunar Period embraces 3400 years, which in his proposition 31 he asserts happily and accurately restores the synodic months; and he calls it Gregorian, and new — the more new, he says, because I make no mention of it in my *Apologetics*. But how can I mention what does not exist, and is found in no author of weight? I do not indeed deny that this period comes very close to the truth; but that it accomplishes fully what it promises — this I flatly deny. For unless the lunar month is set at 29 days, 12 hours, 44 minutes, 3 seconds, 10 thirds, 43 fourths, and a little more, the lunations cannot be restored within 3400 years. Vieta himself even seems to affirm this, since in that passage he forbids the synodic month to be 29 days and 2[?]^{313/42052} — or, what is the same, 29 days and ⁵³⁰⁵⁹²³⁴⁸/₁₀₀₀₀₀₀₀₀₀. But by what authority he does this, I do not see. I find that there are in all three opinions about the motions of the heavens celebrated by all astronomers: the first is Ptolemy's, the second is contained in the Alphonsine Tables, and the third in the Prutenic. But neither Ptolemy, nor the tables — whether Alphonsine or Prutenic — set the lunar month at the value Vieta proposes to us on his own authority. For Ptolemy makes it greater, as do the Prutenic Tables, while the Alphonsine Tables make it smaller, as we explained in chapter 8. Certainly, if it were permitted to anyone to define the magnitude of the lunar month as he pleased, there would perhaps be no lack of someone to say that the lunar month is 29 days, 12 hours, 44 minutes, 25 seconds, and a little more. For on this assumption, 235 lunations would be accurately completed in 19 solar years. But in the schools this will not be granted unless it has been ascertained by long observation that the matter is so. Let Vieta, then, also bring forward by what observation he has learned that the lunar month is the one he foists upon us in his Great Lunar Period.

Vieta's second proposition is the following. From a bissextile century to a non-bissextile century, the progression of the new moons is 5 days, 8 hours, 13 scruples, 12 seconds. From the first non-bissextile to the second non-bissextile, the same progression. From the second again to the third, the same. But from the third non-bissextile to the fourth, a bissextile, the progression is 4 days, 8 hours, 13 scruples, 12 seconds. By this device, in proposition 36, he described the new moons for very many centuries, in which the aforesaid progression is seen; out of these I have selected these five. But whence he drew this reckoning, I do not know. For my part, from the reckoning I set out in chapter 13 out of the Prutenic Tables and of Giovanni Antonio Magini [Magini] — which Paul of Middelburg [Paulus Middelburgensis] also carefully transcribed — and from Vieta's own reckoning, which I shall append below, I have learned that this progression does

not hold together for him. For I find that from a bissextile century to the first non-bissextile century it is 6 days, 8 hours, 13 minutes, 30 seconds; from the first non-bissextile century to the second non-bissextile, 5 days, 8 hours, 13 minutes, 30 seconds; from the second again to the third, the same; but from the third non-bissextile to the fourth, a bissextile, that the progression is 3 days, 8 hours, 13 minutes, 30 seconds. The truth of this I have tested in various centuries widely distant from one another, out of which you see these five, the progression I have mentioned. Only in the minutes is a variation of one minute sometimes seen, so that 13 minutes are not always found — which happens on account of the seconds here neglected. This same progression is seen across the centuries if the lunations are computed by the method of the following chapter, drawn from Vieta, as will be evident if you care to test it.

[Margin: How great the progression of the new moons is from one century to another after the correction.]

Table (printed p. 529, at left). The progression of the new moons, after the correction, for the sample centuries. Columns: Anni | D. (days) | H. (hours) | M. (minutes) | Men. (month; Mar. = March).

| Anni | D. | H. | M. | Men. |
|------|----|----|----|------|
| 3200 | 7 | 17 | 56 | Mar. |
| 3300 | 13 | 2 | 9 | Mar. |
| 3400 | 18 | 10 | 23 | Mar. |
| 3500 | 23 | 18 | 37 | Mar. |
| 3600 | 28 | 2 | 50 | Mar. |

Table (printed p. 529). Sample new moons, 1600–2000. Men.: M = March (Martius), A = April (Aprilis).

| Anni | D. | H. | M. | Men. |
|------|----|----|----|------|
| 1600 | 14 | 8 | 35 | M |
| 1700 | 20 | 16 | 48 | M |
| 1800 | 26 | 1 | 2 | M |
| 1900 | 31 | 9 | 15 | M |
| 2000 | 3 | 17 | 29 | A |

Table (printed p. 529). Sample new moons, 10000–10400.

| Anni | D. | H. | M. | Men. |
|-------|----|----|----|------|
| 10000 | 28 | 17 | 12 | M |
| 10100 | 4 | 1 | 26 | A |
| 10200 | 9 | 9 | 39 | A |
| 10300 | 14 | 17 | 53 | A |
| 10400 | 18 | 2 | 6 | A |

Table (printed p. 529). Sample new moons, 20000–20400.

| Anni | D. | H. | M. | Men. |
|-------|----|----|----|------|
| 20000 | 6 | 10 | 30 | Mar. |
| 20100 | 12 | 18 | 43 | Mar. |
| 20200 | 18 | 2 | 57 | Mar. |
| 20300 | 23 | 11 | 10 | Mar. |
| 20400 | 26 | 19 | 24 | Mar. |

Before the Calendar was corrected, since all the centuries of years were bissextile, the progression of the new moons was perpetually 4 days, 8 hours, 13 minutes, 30 seconds, as the following little table shows.

[Margin: How great the progression of the new moons is from one century to another before the correction.]

Table (printed p. 529). New-moon progression, 200–600 (before correction).

| Anni | D. | H. | M. | Men. |
|------|----|----|----|------|

| 300 | 6 | 23 | 7 | Mar. |
| 400 | 11 | 7 | 21 | Mar. |
| 500 | 15 | 15 | 34 | Mar. |
| 600 | 19 | 23 | 48 | Mar. |

Table (printed p. 529). New-moon progression, 600–1000 (before correction).

| Anni | D. | H. | M. | Men. |
|------|----|----|----|------|
| 600 | 19 | 23 | 48 | Mar. |
| 700 | 24 | 8 | 1 | Mar. |
| 800 | 28 | 16 | 15 | Mar. |

| Anni | D. | H. | M. | Men. |
|------|----|----|----|------|
| 900 | 2 | 0 | 28 | Apr. |
| 1000 | 6 | 8 | 42 | Apr. |

Since these things are so, and the reckoning of our own calculation is found in approved authors, I really do wonder from where Vieta drew that progression of his, different from ours. And indeed it cannot be that the progression from a bissextile century to a non-bissextile century should be the same as that from a non-bissextile century to a non-bissextile century, as Vieta will have it — since in the two cases the ratio is not the same, as is evident. I wished to examine these two propositions — although they contribute little to our purpose — so that the studious reader may see that Vieta relies on a less certain reckoning than we do, one that I can find in no approved writer. Indeed, if the new moons of those centuries which I have adduced from Vieta are correctly computed, whether by chapter 13 or by the two following chapters, exactly the same progression that I have mentioned will be detected, as appears in the table set below, in which the new moons have been computed by the following chapter.

Table (printed p. 529, at left). New moons of the sample centuries computed by the following chapter. Columns: Anni | D. | H. | M.

| Anni | D. | H. | M. |
|------|----|----|----|
| 3200 | 7 | 5 | 59 |
| 3300 | 13 | 14 | 12 |
| 3400 | 18 | 22 | 26 |
| 3500 | 24 | 6 | 39 |
| 3600 | 27 | 14 | 53 |

Furthermore, reason too persuades us that the progression of the new moons ought to be the one I have stated, and the one the calculation indicates — not the one Vieta prescribes. For since, if all the centuries were bissextile, that progression would contain 4 days, 8 hours, 13 minutes, 30 seconds — as we saw in the centuries before the correction — it necessarily follows that from a bissextile century to a non-bissextile one the progression is 6 days and so on, not 5. For because the later century is not bissextile, the new moon will not fall in it one day earlier, as in bissextile years; therefore the progression ought already to be one of 5 days. But since in that century one day is added to the new moon — the day, namely, that was then removed, as we said in chapter 13 — that new moon will fall still later by one day, and so the progression will be 6 days and so

on. The calculation itself proves this best. For if the new moon, say, in the year 1700 is computed as though for a bissextile year, it will be found to fall on the 18th of March, at 16 hours 48 minutes — that is, two days earlier than if that century were not bissextile: since we have found that new moon to fall on the 20th and so on. Hence the new moons will advance from a bissextile century to a non-bissextile one not by 4 days only, but by two more. But from a non-bissextile century to a non-bissextile one this progression will embrace only 5 days, 8 hours, and so on, because the earlier century has its new moon one day later than if it were bissextile. Finally, the same progression from a non-bissextile century to a bissextile one: that progression would contain 4 days and so on; but since the [later century] is posited as non-bissextile, it will have its new moon one day later, and accordingly only 3 days, 8 hours, 13 minutes will be left for that progression. But if Vieta is unwilling to rest content with this progression, let him bring forward, if he can, another and surer calculation. Certainly the calculation of the lunations set up by him plainly confirms the progression we have expounded: since the same new moons and oppositions are found by his calculation as are found by the calculation of chapter 13 and of the following chapter. And this will be manifest from chapter 25, where we shall set out that calculation.

From these things, then, which we have briefly argued against Vieta's Calendar, I believe it plainly established that his is thoroughly faulty, while ours — which truly deserves to be called the perpetual Gregorian (although he, out of contempt, as I said, calls it "common") — is more in keeping with the Decrees and sanctions of the Fathers and the Councils.

And I should wish all these things to be received by Vieta, a prudent and learned man, in the same spirit in which they were said by me. For I wish nothing (as I even professed at the outset) to be detracted from his reputation — a man whose reputation I have always looked up to, whose labors I have always admired. I have only tried to show that the Gregorian Calendar, which I have expounded throughout this whole volume, does not contain so many errors as Vieta, without any reason, imputes to it; and that hardly any more perfect one can be constructed — so that there is no need to devise or fabricate another beginning of the year, and much less to arrange the epacts in the Calendar on some other plan, since they have been arranged on the best plan in the Gregorian Calendar.

CHAPTER 25.

ON ANOTHER METHOD OF COMPUTING THE MEAN NEW MOONS AND FULL MOONS OF EASTER AFTER THE CORRECTION OF THE YEAR.

I have said that Vieta, in the book of his Calendar, has written many things excellently and subtly, among which he devised an elegant method of computing the mean conjunctions and oppositions of the Luminaries at Easter after the correction — a method I have decided to expound here by way of appendix, because in it there is no need for the removed days to be added, as in the earlier calculation (which is indeed troublesome when those days have grown into a larger sum). But since he himself accommodates this method only to the centennial years after the correction, we shall extend it to the non-centennial years as well — so that from this too Vieta may understand that I have wished to detract nothing here from his reputation, but only had it in mind to refute what he has less rightly delivered concerning the whole business of the Calendar, while what he has taught rightly and soundly, I gladly embrace. His table, however, needs correction on account of the seconds, thirds, and fourths neglected by him, which over a great number of years can produce no slight error — so that it is no wonder that he found the Easter new moons of the years 19480000 and 165580200, from his table, to answer to the equation of his epacts, which nevertheless is not true, as we have shown above.

The method, then, is as follows. First let the Easter new moons of these four years — 1600, 1700, 1800, and 1900 — be set out as the roots of all the new moons to be computed. These I computed most carefully from the tables of chapter 13, and I found that in the hours they differ not a little from those set out by Vieta. Next let a table of years be constructed which advance by 400s, up to 4000; thence by 2000s up to 10000; then from 10000 by 10000s up to 100000; thence by 100000s up to 1000000; and from 1000000 by 1000000s up to 10000000; and so on. To these must be joined the epacts set out at the end of chapter 13, corrected, however, on account of the removed days, in this way. Since 400 years take away three days, three days must be subtracted from the epact of year 400, which is D.12, 3 hours, 50 minutes, 2 seconds, 36 thirds, 40 fourths; and so, alongside the year 400, the epact D.9, 3 hours, 50 minutes, 3 seconds is to be placed. For in place of the 36 thirds we took 1 second, as has also been done in the others. By the same method, from the epact of year 800, 6 days are to be subtracted, and so on, always removing 3 days as many times as 400 years are included in the centennial in

question — a revolution of the new moons of so many days being first added to the epact, so that the subtraction can be made, until a number is left smaller than a lunar month. For this purpose the table of revolutions of the new moons set out in chapter 13, number 4, will be wonderfully serviceable. But you will far more easily correct the epacts to be assigned to all the centennial years in this way. Alongside the year 800 let the corrected epact of year 400 be written, doubled; alongside 1200, tripled; alongside 1600, quadrupled; and so on, always casting away the lunar month whenever

[Margin: The construction of the tables for computing the mean new moons after the correction.]

so that it can be cast out, leaving the epact [epacta] smaller than a lunar month [mensis Lunaris]. When, however, you reach the year 4000, join together the epacts of the years 2000 and 4000 to produce the epact of the year 6000. Likewise, double the epact of the year 4000 to compose the epact of the year 8000. Finally, join the epacts of the years 4000 and 6000 to obtain the epact of the year 10000. Double this, quadruple it, and so on, for the years 20000, 30000, 40000, and the rest. Again, double, triple, and so on the epact of the year 100000 for the years 200000, 300000, and so forth — and thus on to infinity. But here is the table.

Roots of the New Moons [Radices Nouiluniorum].

(In these tables *D* = days, *H* = hours, *M* = minutes/scruples, *S* = seconds; "Men." = month.)

2. To compute, then, the new moon [novilunium] of any centennial year after the correction of the proposed [year], one must first choose the root [radix] from those four given above. This is done by dividing the number of hundreds by 4. For if nothing is left over in the division, the root of the year 1600 is to be adopted, prefixed with index 0. But if 1 is left over, the root of the year 1700, to which index 1 is assigned; if 2, the root of the year 1800, of index 2; and if finally 3, the root of the year 1900, of index 3. This choice of root is made without any trouble, even from memory, if one merely attends to the number expressed by its thousands and hundreds.

[Margin: The method by which the new moon of any centennial year after the correction is computed.]

For when all the 20s have been cast out of that number, if nothing is left over, the root of index 0 is to be taken; but if something remains, all the 4s are then to be cast out — and if indeed there is no remainder, the same root of index 0 is to be adopted; but if 1 is left over, the root of index 1; if 2, the root of index 2; and if finally 3, the root of index 3.

Once the root has been chosen, its centennial year is to be subtracted from the proposed centennial year, and with the remainder one must enter the table of corrected epacts as many times as needed, extracting the epacts owed for the numbers by which the entry is made. When these have been collected into a single sum — and the lunar month cast out, as often as it can be — the sum, or the remaining number, is to be subtracted from the new moon of the chosen root, a whole lunar month having first been added on if the subtraction cannot otherwise be made. The remaining number will then indicate the new moon of March, which is sought. The same result is reached, when the subtraction cannot be made, if the sum or the remaining number is first subtracted from the synodic month [mensis synodicus], and the new moon of the root is added to that

remainder; for the number so composed will be the new moon [Neomenia] we are looking for.

But so as not to be forced to work twice over — by adding, that is, and then subtracting — we have drawn up the following table, which contains the roots of the new moons together with a whole lunar month. For in this way, whenever the number to be subtracted is greater than the number of the chosen root, the subtraction is to be made from the number of that same root in this table; and the remaining number will indicate the new moon of March that is sought.

[Margin: This table is to be used in place of the root above whenever the sum of the epacts cannot be subtracted from the new moon of that [other] table.]

Roots of the New Moons with a whole lunar month added [Radices Nouiluniorum ad mensem Lunarem additorum].

| Indices radicum | Anni | D | H | M | S | Men. |
|-----------------|------|----|----|----|----|------|
| 0 | 1600 | 43 | 21 | 18 | 57 | Mar. |
| 1 | 1700 | 50 | 5 | 32 | 27 | Mar. |
| 2 | 1800 | 55 | 13 | 45 | 58 | Mar. |
| 3 | 1900 | 60 | 21 | 59 | 28 | Mar. |

When, moreover, the sum collected from the epacts is greater than a lunar month, yet smaller than the number of the chosen root of this table, it is to be subtracted, without first casting out the synodic month from it.

For example, suppose the paschal new moon of the year 4000 is sought. The number expressed by thousands and hundreds is 40. When all the 20s are cast out, nothing is left over; therefore the root of index 0 is to be chosen. Its centennial, 1600, subtracted from the proposed centennial 4000, leaves 2400, which number has, in the table of corrected epacts, the epact D. 25, H. 10, Min. 16, Sec. 11. Since this cannot be subtracted from the new moon of the chosen root, it is to be subtracted from the number of that same root, together with a lunar month, in the next table — that is, from D. 43, Hor. 21, Min. 18, Sec. 57. The remaining number will indeed indicate the new moon in March, D. 18, H. 11, Min. 2, Sec. 46, which is paschal.

Likewise, if the paschal new moon of the year 4800 is sought. The number expressed by thousands and hundreds is 48. When all the 20s are rejected, 8 remain; and when all the 4s are cast out, nothing remains. Therefore the root of index 0 is to be taken. Its centennial 1600, subtracted from the given centennial

4800, leaves 3200; entering the table just once with this number, one extracts the epact D. 14, H. 5, Min. 12, Sec. 14. For if this is removed from the new moon of the chosen root — namely of the year 1600 — the remaining new moon [Neomenia] becomes D. 0, H. 3, Min. 22, Sec. 40 in March, which is not paschal. When therefore the lunar month D. 29 [H. 12, Min. 44, Sec. 3] is added, you find the paschal new moon in March, D. 29, H. 16, Min. 6, Sec. 43.

Again, suppose the given year is 109500. The number is expressed by thousands and hundreds as 95. Casting out 20, there remain 15; and taking away [three times] 4 there remain 3. Therefore the root of index 3 is to be chosen. Its centennial 1900, subtracted from the given centennial 109500, leaves 107600. One must therefore enter the table with the years 100000, 6000, 1600, and the sum of the epacts D. 42, H. 11, Min. 9, Sec. 10 is collected. If the lunar month is taken from this, there remain D. 12, H. 22, Min. 25, Sec. 7; and when these are removed from the new moon of the root found — namely of the year 1900 — the paschal new moon [Neomenia] is found in March, D. 18, H. 10, Min. 50, Sec. 18.

Working for the year 109500:

| | D | H | M | S |
|---------------------------------------|----|----|----|----|
| 100000 | 16 | 1 | 58 | 38 |
| 6000 | 19 | 6 | 34 | 25 |
| 1600 | 7 | 2 | 36 | 7 |
| Summa (sum) | 42 | 11 | 9 | 10 |
| mens. detr. (month subtracted) | 29 | 12 | 44 | 3 |
| residuum (remainder) | 12 | 22 | 25 | 7 |
| Nouil. rad. (new moon of root) | 31 | 9 | 15 | 25 |
| residuum detr. (remainder subtracted) | 12 | 22 | 25 | 7 |
| Nouil. Mar. (new moon of March) | 18 | 10 | 50 | 18 |

Finally, suppose the year 165580200 is given. The number expressed by thousands and hundreds is 02. Casting out all the 20s and 4s, 2 are left over; and therefore the root of index 2 is to be chosen — namely of the year 1800. When the centennial of this root is removed from the given year, the remaining year becomes 165578400. So if you enter the table with the years placed here, extracting the epacts, you will collect the sum D. 91, H. 19, Min. 37, Sec. 28. From this, subtracting the greatest revolution of the new moons that can be subtracted — namely D. 88, H. 14, Min. 12, Sec. 10 — there will remain D. 3, H. 5, Min. 25, Sec. 18; and this, taken away from the new moon of root 2, that is, of the year 1800,

leaves the paschal new moon [Neomenia] in March, D. 22, H. 19, Min. 36, Sec. 37. From which it appears that Viète's epact [Epacta Vietæ] of 2 or 4 — for on this point, as I said above, he is not consistent with himself — does not yield a new moon agreeing with the astronomical calculation, as we said before. And yet this whole calculation of Viète's is built entirely out of the calculation we set out in chapter 13, since from the epacts of the collected years it merely removes the days omitted on account of the equinox, as we have taught.

Working for the year 165580200:

| | D | H | M | S |
|--|----|----|----|----|
| 100000000 | 17 | 17 | 47 | 8 |
| 60000000 | 22 | 10 | 57 | 54 |
| 5000000 | 6 | 19 | 2 | 10 |
| 500000 | 21 | 8 | 25 | 3 |
| 70000 | 8 | 7 | 18 | 38 |
| 8000 | 6 | 0 | 16 | 32 |
| 400 | 9 | 3 | 50 | 3 |
| Summa (sum) | 91 | 19 | 37 | 28 |
| Reu. No. det. (revolution of new moons subtracted) | 88 | 14 | 12 | 10 |
| Residuum (remainder) | 3 | 5 | 25 | 18 |
| Nouil. Rad. (new moon of root) | 26 | 1 | 1 | 55 |
| Resid. detra. (remainder subtracted) | 3 | 5 | 25 | 18 |
| Nouil. Mart. (new moon of March) | 22 | 19 | 36 | 37 |

Now, if instead of the four roots of the new moons above we assume the four roots of the full moons [Pleniluniorum radices] of the same years, we shall in the same way compute the paschal mean oppositions [oppositiones mediae Paschales]. And thus the roots of the full moons stand, computed for the same years 1600, 1700, 1800, 1900.

Suppose the paschal full moon [Plenilunium] of the year 4800 is to be investigated. The epact owed to it is D. 14, H. 5, Min. 12, Sec. 14, as was shown. If this is taken away from the full moon of the year 1600 — since the root of index 0 is to be used, as we said — you will find the full moon of March to fall on D. 14, H. 21, Min. 44, Sec. 42, which is not paschal. Therefore, when a lunar month is added, the paschal full moon comes to fall in April, D. 13, H. 10, Min. 28, Sec. 45.

Again, for the year 109500, the root of index 3 agrees, and the sum of the epacts (after casting out the lunar month) is D. 12, h. 22, M. 25, Sec. 7. When this is taken away from the full moon of the year 1900, the paschal full moon will fall on April's day 2, h. 5, Min. 12, Sec. 20.

Furthermore, for the year 165580200, the root of index 2 is owed, and the sum of the epacts (after casting out the lunar months) is D. 3, h. 5, m. 25, Sec. 18. When this is deducted from the full moon of the year 1800, the paschal full moon will fall on April's day 6, h. 13, min. 58, Sec. 39.

Finally, suppose the year 3700 is given. The root of index 1 will be found; its year 1700, subtracted from the proposed year, leaves 2000, to which the epact D. 16, h. 6, m. 26, sec. 10 corresponds in the table. This cannot be subtracted from the April full moon of the year 1700 — namely from D. 4, h. 11, m. 10, sec. 26. If therefore the 31 days of March are added, or a lunar month is added and the subtraction is made, you will find the full moon in April, D. 17, h. 17, min. 28, sec. 19. And so with the rest. Remember, however, that if the full moon found in March is not paschal, you should add a lunar month; but if the one in April is not paschal, you should subtract a lunar month, and the full moon will fall in March — which is what is sought — the 31 days of March having first been added if need be. The full moon then falls in March when the subtraction is made from the days of March even after the addition of the lunar month; yet in such a way that, if the remaining number is greater than 31, you take away 31 so as to have the full moon in April. Thus if you should find the full moon on the 43rd of March, it would fall on the 12th of April. But the full moon falls in April when the subtraction is made from the days of April, even after the addition of the lunar month. For example, in the proposed case: if to the April full moon of the year 1700 you add the 31 days of March, you will have the full moon of March on day 35, h. 11, min. 10, sec. 26; and if from this you subtract the epact D. 16, h. 6, min. 26, sec. 10, you will find the full moon in March on day 19, h. 4, Min. 44, sec. 16, which is not paschal. If, therefore, a lunar month is added, it will be found to fall in March on day 48, h. 17, Min. 28, Sec. 19 — that is, in April on day 17, H. 17, Min. 28, Sec. 19. But on the other hand, if to that same April full moon of the year 1700 you add a lunar month, you will make up April's day 33, H. 23, Min. 54, Sec. 29; and if you subtract the same epact D. 16, H. 6, Min. 26, Sec. 10, you will have the same paschal full moon in April, D. 17, H. 17, Min. 28, Sec. 19.

[Margin: The method by which the full moon of any centennial year after the correction is computed.]

Here too we have appended a table of the roots of the full moons together with a whole lunar month, so that whenever the number to be subtracted is greater than the number of the chosen root, the subtraction may be made from the number of that same root in this table. For example: in the recent year 3700, the epact D. 16, H. 6, M. 26, Sec. 10 cannot be subtracted from the full moon of the chosen root — namely of the year 1700. If, therefore, it is taken from the number of that same root of index 1 in this table — that is, from D. 33, H. 23, M. 54, Sec. 29 — the remainder becomes the full moon in April, D. 17, H. 17, Min. 28, Sec. 19, as before.

Roots of the Full Moons [Radices Pleniluniorum].

| Indices radicum | Anni | D | H | M | S | (month) |
|-----------------|------|----|----|----|----|---------|
| 0 | 1600 | 29 | 2 | 56 | 56 | Mar. |
| 1 | 1700 | 4 | 11 | 10 | 26 | Apr. |
| 2 | 1800 | 9 | 19 | 23 | 56 | Apr. |
| 3 | 1900 | 15 | 3 | 37 | 26 | Apr. |

[Margin: When the full moon falls in March, or in April.]

And so here too, when the sum collected from the epacts is indeed greater than a lunar month, but smaller than the number of the chosen root in this table, it is to be subtracted without first casting out the lunar month from that same [root].

Nor should this be passed over: whenever it is established that the sum of the epacts, subtracted from the new moon or full moon of the chosen root, leaves a new moon or full moon in March that is not paschal — or that, when subtracted, it has left a non-paschal new moon or full moon of March — that same sum ought to be subtracted from the number in the table of the new moons, or of the full moons, with the [month] added. For in this way the paschal new moon, or full moon, will remain. For example, in the earlier case of the year 4800, it is certain that the epact D. 14, h. 5, M. 12, Sec. 14, subtracted from the new moon of the root of the year 1600 — that is, from D. 14, H. 8, M. 34, Sec. 54 — leaves a non-paschal new moon, which remains at D. 0, H. 3, M. 22, Sec. 40 of March. Therefore, if that same epact is subtracted from the number of the same root in the later table of the new moons — that is, from D. 43, H. 21, Min. 18, Sec. 57 — the paschal new moon will be left in March, D. 29, H. 16, Min. 6, Sec. 43, which was also found above.

[Margin: Once the new moon or full moon of some centennial year after the correction has been found, in what way the new moon or full moon of any year after that centennial is derived from it.]

Roots of the Full Moons with a lunar month added [Radices Pleniluniorum ad mensem Lunarem additorum].

| Indices radicum | Anni | D | H | M | S | (month) |
|-----------------|------|----|----|-----|----|---------|
| 0 | 1600 | 58 | 15 | 40 | 59 | Mar. |
| 1 | 1700 | 33 | 23 | 54 | 29 | Apr. |
| 2 | 1800 | 39 | 8 | [?] | 59 | Apr. |
| 3 | 1900 | 44 | 16 | 21 | 30 | Apr. |

[Margin: This table is to be used in place of the root above whenever the sum of the epacts cannot be subtracted from the full moon of the table above.]

3. Now, if anyone wishes [to find] the paschal new moon of any expanded year [annus expansus] after a given centennial, the epact of that expanded year, set out in the first table described on p. 13 (which we thought worth repeating here for greater convenience), is to be subtracted from the new moon or full moon of that centennial, a whole lunar month having first been added if the subtraction cannot be made — yet in such a way that, if the centennial is not a leap year (which you will know if, after casting out 20 and 4 from the number expressed by thousands and hundreds, something is left over), you cast one further unit away from the remainder. For in this way the new moon of that expanded year becomes known.

Let it be sought, for example, the paschal new moon or full moon of the year 1673. The epact of the year 73 is D. 26, H. 9, M. 44, S. 14, which, subtracted from the new moon of the centennial 1600 (a lunar month having first been added), leaves the paschal new moon in March, D. 17, H. 11, M. 34, Sec. 43. Let it again be required to find the paschal new moon of the year 29447. Since the thousands and hundreds give the number 94, and when 20 and 4 are cast out there remain 2, the centennial is therefore not a leap year, and the root of index 2 is to be chosen; its centennial 1800, subtracted from the given centennial 29400, leaves 27600. Hence the paschal new moon [Neomenia] of the year 29400 falls in March, D. 4, h. 13, M. 54, Sec. 5. If from this you take away the epact of the year 47, there will remain D. 5, H. 10, M. 28, Sec. 51. When a unit is further removed — because the centennial is not a leap year — the remaining new moon [Neomenia] falls in March, D. 4, h. 10, M. 28, Sec. 51, which is not paschal. Therefore, adding a synodic

month, you will find the paschal new moon in March, D. 33, h. 23, M. 22, Sec. 54 — that is, in April, D. 2, Hor. 23, Min. 12, Sec. 54.

Working for the year 1673:

| | D | H | M | S |
|----------------------------------|----|----|----|----|

[Caput XXV, continued — De alia ratione supputandi novilunia]

Worked computation (new-moon working, continued from the preceding leaf)

This table stands at the head of the leaf; the paschal full-moon examples that follow flow around it. It carries a worked new-moon (novilunium) computation — roots taken by index, a synodic month cast out, then the epact of year 47 applied. Transcribed as printed.

(Row label "Mensis detr." = "a month subtracted"; "Nouil. rad." = "root new moon"; "Resid. detr." = "the residuum subtracted"; "Mens. addit." = "a month added"; "Nouil. Mar."/"Nouil. Apr." = new moon of March / of April.)

[Paschal full-moon examples]

Likewise, suppose the paschal full moon of the year 1673 is to be sought. The epact of year 73 is D.26.h.9.Min.44.Sec.14; subtracted from the full moon of the centesimal year 1600, it leaves the full moon of March at D.2.h.17.m.12.Sec.42, which is not the paschal one. Adding a lunar month, therefore, the paschal full moon falls in April at D.1.H.5.Min.56.Sec.45.

Furthermore, suppose the full moon of the year 29447 is to be explored. Since in the centesimal year 29400 the full moon falls in March at D.28.H.22.Min.16.Sec.7, then, if from it the epact of year 47 — which is D.8.H.17.Min.25.Sec.14 — is taken away, and one day is cast out besides (because this centesimal year is not a leap year), the full moon of the proposed year remains in March at D.19.H.4.M.50.Sec.53, which is not the paschal one. Adding a lunar month, then, the paschal full moon is detected in April at D.17.H.17.Min.34.Sec.56.

Finally, let the paschal full moon of the year 4018 be set out for investigation. Since the root 0 belongs to this year, and its centesimal 1600, taken from it, leaves 2400, to which belongs the epact D.25.h.10.Min.16.Sec.11 — and this, subtracted from the full moon of the year 1600, leaves the full moon of March at D.3.h.16.min.40.Sec.45, which is not the paschal one. Adding a lunar month, therefore, the paschal full moon falls in April at D.2.h.5.Min.24.Sec.48. From this the epact of the expanded year, 18, cannot be subtracted. If, then, a lunar month is added and the subtraction is made, the sought full moon of the year 4018 comes out at D.13.h.13.M.8.Sec.36 in April. Here it is easily clear that the epact of year 2400, subtracted from the full moon of year 1600, leaves a full moon in March that is not paschal. Therefore, if the same epact D.25.h.10.m.16.Sec.11 is taken from the augmented full moon of the latter little table — namely from D.58.h.15.m.40.Sec.59 — we shall find the paschal full moon falling in April at D.2.h.5.m.24.sec.48, as before.

[Margin: When the complements of the epacts are to be used in place of the epacts themselves.] Since, however, it not rarely happens that the epact of an expanded year cannot be subtracted from the new moon or full moon of the preceding centesimal year, we have here attached to the table of epacts (which we have transferred here from chapter 13 for greater convenience) another table, which contains the complements of those same epacts up to a whole lunar month. That is, when the epact cannot be subtracted, its complement is added to the new moon or full moon of the centesimal year — yet in such a way that, if the centesimal year is a common year, one day is subtracted from the number so formed. The same new moon or full moon is nonetheless produced if the epact is subtracted from the new moon or full moon of the preceding centesimal year once a lunar month has first been added, and so forth.

For example: in the recent year 4018 the full moon of the centesimal year was found in April at D.2.H.5.M.24.Sec.48, from which the epact of the expanded year, 18, cannot be taken. If, then, we add the complement of that epact, D.11.H.7.Min.43.Sec.48, we shall find the full moon of the year 4018 in April at D.13.H.13.Min.8.Sec.36, as above.

Table of Epacts for 100 expanded years [Tabula Epactarum in 100. annis expansis]

Rows 1–81 are printed at the foot of this leaf (p. 534) in three panels; rows 82–100 are printed at the head of the following leaf (p. 535). Presented here as one continuous table.

[Deriving the full moon from the new moon; deriving any month from March/April]

[Margin: Finding the full moon from the new moon. Finding the new moon or full moon of any month from the March or April new moon or full moon.]

4. Once the new moon has been found, everyone knows that if half of a lunar month — namely D.14.H.18 — is added, the mean full moon is produced.

If you wish to know the new moon or full moon of any other month from the new moon or full moon of March or April once found: if the given month is after March or April, add as many new-moon revolutions as there are complete months from March or April inclusive up to the proposed month exclusive; and from the sum throw out the days that those complete months contain. For the remaining number will give the new moon or full moon of the proposed

month sought. But if the given month is before March or April, then — reckoning from the new moon or full moon of March or April (a month of February and January, indeed even of March, being added first, if need be, so that the subtraction can be made) — you will throw out one lunation, or two, or three, and the new moon or full moon of February, or of January, or of March will be left.

Thus, since in the year 4800 the paschal new moon was found in March at D.29.H.16.Min.6.Sec.43: if the new moon of November of the same year is wanted,

we shall add the eighth revolution of new moons, namely D.236.H.5.Min.52.Sec.25 (because eight months have elapsed from March), and from the sum D.265.H.21.Min.59.Sec.8 we shall take away 245 days, elapsed from March to the end of October. For the remaining number will indicate the new moon in November at D.20.H.21.Min.59.Sec.8. Likewise, if the full moon in November is given, we shall again add the eighth revolution of new moons, that is D.236.H.5.Min.52.Sec.25, and from the sum D.251.Hor.3.Min.36.Sec.6 we shall subtract the same 245 days. For the remaining number will show us the full moon in November at D.6.H.3.Min.36.Sec.6. But if from the same new moon of March D.29.H.16.Min.6.Sec.43 you subtract two lunations, namely D.59.H.1.Min.28.Sec.6 (because if you subtracted only one, you would remain in March), a February of 29 days having first been added (since the year is a leap year), together with a January of 31 days, there will remain the new moon of January at D.30.H.14.Min.38.Sec.37. In February of that year, however, no new moon will occur; but its full moon will be found to happen at D.14.H.9.Min.0.Sec.38 — namely if, from the full moon of March D.14.H.21.Min.44.Sec.41, a February of 29 days having first been added, the lunar month D.29.H.12.Min.44.Sec.3 is subtracted.

[Margin: A shortcut for computing the full moons of the 100 expanded years.] If, finally, the paschal full moons must be computed for all 100 expanded years after any given centesimal year (which is necessary if one undertakes to examine the paschal full moons of the above table of movable feasts, chapter 22, or to extend them to further years), then — so that there is no need, except rarely, to add or subtract a lunar month — this device must be used. To the full moon found for the nearest elapsed centesimal year, if it falls in March, add a whole lunation; but if it falls in April, add the 31 days of March. For in either way a number is produced from which the epacts of the expanded years, when subtracted, leave the paschal full moon of March — unless more days than 31 have been left over. For then, once 31 days have been subtracted, the remaining days must be assigned to April, and the paschal full moon ascribed to that same month. In the same way, the epact of any expanded year whatever, taken from the paschal full moon of March (if it can be subtracted), will leave the paschal full moon of March, provided it does not fall before the 21st day. For when this happens, the epact of the expanded year must be subtracted from the higher number, which is formed from the March full moon together with a whole lunation. Likewise, if the full moon falls in April, a whole lunation must be added; for the epact of any expanded year whatever, subtracted from that full moon or from the number so formed, will leave the paschal full moon of April. Therefore, when it is established that the paschal full moon of some expanded year will fall in March,

the subtraction of that year's epact must be made from the paschal full moon of March, or from the number formed from that full moon and a whole lunation, or finally from the number formed from the April full moon and the 31 days of March. But if the full moon of the expanded year that is sought will belong to April, that year's epact must be taken from the April full moon, or from the number formed from that full moon and a whole lunation. Moreover, you will easily recognize from the epact of the expanded year whether the paschal full moon will fall in March or in April. For these epacts — 23, 22, 21, 20, 19, 18, 17, 16, 15, 14, 13 — since they have Luna 14 in March, will likewise exhibit the full moon in March; but the other epacts throw the full moon into April.

For example: in the centesimal year 4200 the paschal full moon falls on April 13.H.21.Min.51.Sec.48; and if a whole lunation is added, one obtains April 43.H.10.Min.35.Sec.51. And from either of these two full moons the subtraction of the epact of any expanded year must be made, so that the paschal full moon may be found in April. Now if from the full moon D.13.H.21.Min.51.Sec.48 (the 31 days of March having first been added) a whole lunation is subtracted, the full moon of March D.15.H.9.Min.7.Sec.45 will be found — not indeed the paschal one; but if a whole lunation is added, there will result D.44.H.21.Min.51.Sec.48 of March, a number which is also formed from the 31 days of March added to the paschal full moon of April. Again, if to the full moon of March D.44.H.21.Min.51.Sec.48 a whole lunation is joined, the sum D.74.H.10.Min.35.Sec.51 of March results. And from either of these two numbers the subtraction of the epacts of the expanded years must be made, so that the paschal full moons may be found in March. And the same reasoning holds for the others. By this method we shall always have numbers from which we can subtract the epacts of the expanded years, and very rarely will another whole lunation have to be subtracted or added in order that the paschal full moon may be found.

[Margin: How the new and full moons before the correction are to be traced.] 5. New moons and full moons before the correction — and even those before the year 1600, after the corrected year — will be computed more easily from what was handed down in chapter 13. For after the year 1582 up to the year 1600 only the ten removed days are to be added; but before the correction nothing at all is to be added. And therefore it is not necessary that the method of computation explained in this chapter be adapted to those years which precede the year 1600.

CAPVT XXVI.

Caput XXVI.

On yet another, and very easy, method of computing the mean Paschal new moons and full moons after the correction.

[1] I do not wish to pass over in this place another new method of computing the Paschal new moons and full moons after the correction, one that presented itself to me when, at Chapter 24, Number 14, I was examining the progression of the new moons a little more attentively from one century to the next. Accordingly, the new moons of the years of the present little table, computed from Chapter 13, stand as follows. And if each new moon is subtracted from the one immediately below it, the progressions are found, just as they are set out in the other table below. But so that the new moon of the year 1900 can be subtracted from the new moon of the year 2000, one must take day 34 of March in place of 3 April; and these progressions do not differ from those we found above.

New moons of the years of this table.

| Anni | D. | H. | M. | S. | T. | Q. | Month |
|------|----|----|----|----|----|----|-------|
| 1600 | 14 | 8 | 34 | 54 | 20 | 0 | Mar. |
| 1700 | 20 | 16 | 48 | 24 | 28 | 32 | Mar. |
| 1800 | 26 | 1 | 1 | 54 | 37 | 4 | Mar. |
| 1900 | 31 | 9 | 15 | 24 | 45 | 36 | Mar. |
| 2000 | 3 | 17 | 28 | 54 | 54 | 8 | Apr. |

Now the method of computing the new moons and full moons will be established from these as follows. First let the new moons of the four preceding centuries be set out, as the roots of the other new moons to be computed, just as in the method of the preceding chapter. Then let a table of years be constructed, as follows:

Progressus Neomeniarum [Progression of the new moons].

| | D | H | M | Sec. | Ter. | Quar. |
|--|---|---|--------|------|------|-------|
| | . | . | . | | | |
| A cent. biss. ad non biss. [From a leap century to a non-leap] | 6 | 8 | 1
3 | 30 | 8 | 32 |

| | D | H | M | | | |
|---|---|---|--------|------|------|-------|
| | . | . | . | Sec. | Ter. | Quar. |
| A prima cent. non biss. ad non biss. [From the first non-leap century to a non-leap] | 5 | 8 | 1
3 | 30 | 8 | 32 |
| A secunda cent. non biss. ad non biss. [From the second non-leap century to a non-leap] | 5 | 8 | 1
3 | 30 | 8 | 32 |
| A tertia cent. non biss. ad biss. [From the third non-leap century to a leap] | 3 | 8 | 1
3 | 30 | 8 | 32 |

—just as in the preceding chapter, where in place of the epacts the progressions of the new moons are set down, in this order. Alongside the year 400 let the sum of the higher progressions be written, that is, D. 20. H. 8. Min. 54. Sec. 0. Ter. 34. Q. 8. Write this sum doubled alongside the year 800, tripled alongside the year 1200, and quadrupled alongside 1600, and so on in turn, always casting out a lunar month whenever it can be cast out. But when you reach 4000, where the progression of 400 years ceases, join together the progressions of the years 2000 and 4000, so that you may make the progression to be assigned to the year 6000. Double likewise the progression of the year 4000, so that the progression of the year 8000 may be formed. Finally join together the progressions of the years 4000 and 6000, so that the progression of the year 10000 may be composed. Double, triple, quadruple this, and so on, for the years 20000, 30000, 40000, and so on. In the same way too the progression of the year 100000 must be doubled, tripled, quadrupled, and so on, for the years 200000, 300000, 400000, and so on, and thus to infinity. Yet although, for this table of progressions to be set out correctly, it would have to be built up as far as the Fourths, in the table itself we have not gone beyond the Seconds; but whenever the Thirds are more than 30, we have added one Second to the Seconds. But here is the table of progressions, together with the table of roots both of the new moons and of the full moons.

Radices Nouiluniorum [Roots of the new moons].

| Indices radicum | Anni | D. | H. | M. | S. | Month |
|-----------------|------|----|----|----|----|-------|
| 0 | 1600 | 14 | 8 | 34 | 54 | Mar. |
| 1 | 1700 | 20 | 16 | 48 | 24 | Mar. |
| 2 | 1800 | 26 | 1 | 1 | 55 | Mar. |
| 3 | 1900 | 31 | 9 | 15 | 25 | Mar. |

Radices Pleniluniorum [Roots of the full moons].

| Indices radicum | Anni | D. | H. | M. | S. | Month |
|-----------------|------|----|----|----|----|-------|
| 0 | 1600 | 29 | 2 | 56 | 56 | Mar. |
| 1 | 1700 | 4 | 11 | 10 | 26 | Apr. |
| 2 | 1800 | 9 | 19 | 23 | 56 | Apr. |
| 3 | 1900 | 15 | 3 | 37 | 26 | Apr. |

Progressus Nouiluniorum, ac Pleniluniorum [Progression of the new moons and of the full moons].

The table is set in two panels across the page (left and right); Anni = the year, and the Progressus is given as D. (days) · H. (hours) · M. (minutes) · S. (seconds).

Left panel:

| Anni | D. | H. | M. | S. |
|-------|----|----|----|----|
| 400 | 20 | 8 | 54 | 1 |
| 800 | 11 | 5 | 3 | 58 |
| 1200 | 2 | 1 | 13 | 55 |
| 1600 | 22 | 10 | 7 | 56 |
| 2000 | 13 | 6 | 17 | 53 |
| 2400 | 4 | 2 | 27 | 51 |
| 2800 | 24 | 11 | 21 | 51 |
| 3200 | 15 | 7 | 31 | 49 |
| 3600 | 6 | 3 | 41 | 46 |
| 4000 | 26 | 12 | 35 | 47 |
| 6000 | 10 | 6 | 9 | 37 |
| 8000 | 23 | 12 | 27 | 30 |
| 10000 | 7 | 6 | 1 | 20 |
| 20000 | 14 | 12 | 2 | 40 |
| 30000 | 21 | 18 | 4 | 0 |
| 40000 | 29 | 0 | 5 | 21 |
| 50000 | 6 | 17 | 22 | 38 |
| 60000 | 13 | 23 | 23 | 58 |
| 70000 | 21 | 5 | 25 | 18 |
| 80000 | 28 | 11 | 26 | 38 |

| Anni | D. | H. | M. | S. |
|---------|----|----|----|----|
| 90000 | 6 | 4 | 43 | 55 |
| 100000 | 13 | 10 | 45 | 15 |
| 200000 | 26 | 21 | 30 | 31 |
| 300000 | 10 | 19 | 31 | 43 |
| 400000 | 24 | 6 | 16 | 58 |
| 500000 | 8 | 4 | 18 | 10 |
| 600000 | 21 | 15 | 3 | 25 |
| 700000 | 5 | 13 | 4 | 37 |
| 800000 | 18 | 23 | 49 | 53 |
| 900000 | 23 | 1 | 51 | 5 |
| 1000000 | 16 | 8 | 36 | 20 |
| 2000000 | 3 | 4 | 28 | 37 |
| 3000000 | 19 | 13 | 4 | 57 |
| 4000000 | 6 | 8 | 57 | 13 |
| 5000000 | 22 | 17 | 33 | 33 |
| 6000000 | 9 | 13 | 25 | 50 |

Right panel:

| Anni | D. | H. | M. | S. |
|----------|----|----|----|----|
| 7000000 | 25 | 22 | 2 | 10 |

| 60000000000 | 5 | 12 | 32 | 40 |

[Margin: How the new moon of any given centesimal year after the correction is to be computed.]

[2] Now, in order to compute the new moon of a given centesimal after the correction of the year, one must first choose a root from the four higher ones, as was said at Number 2 of the preceding chapter. This is done most easily if from the number expressed by thousands and hundreds you cast out all the 20s. If nothing is left over, the root of index 0 is to be assumed. But if something is left over, cast out all the 4s; and if indeed nothing remains, the same root of index 0 is

to be chosen; but if 1 is left over, the root of index 1; if 2, the root of index 2; and finally if 3, the root of index 3. Thus if in the place of the thousands and hundreds 00 is found, the root of index 0 is at once to be assumed.

Once the root has been chosen, let its centesimal year be subtracted from the given centesimal, and, entering the table of progressions with the remainder, let the corresponding progressions be extracted as often as need be. When these have been reduced into one sum together with the new moon of the chosen root, and a lunar month has been cast off as often as it can be, the required new moon in March will be obtained. But when the assembled sum is indeed greater than a lunar month, yet less than 31 days, the lunar month is not to be taken away; rather the sum itself will exhibit the Paschal new moon of March.

Let the Paschal new moon of the year 5000 be sought. Casting out 20 from 50 (the number expressed by thousands and hundreds), 10 remains; and casting out 4, 2 remains; therefore the root of index 2 is to be chosen. Its centesimal, 1800, subtracted from the given centesimal 5000, leaves 3200. Entering the table once with this number, extract the progression D. 15. H. 7. Min. 31. Sec. 49. If to this be added the new moon of the chosen root — namely of the year 1800 — that is, D. 26. H. 1. Min. 1. Sec. 55, the sum will be D. 41. H. 8. Min. 33. Sec. 44. And when the lunar month D. 29. H. 12. Min. 44. Sec. 3 has been taken away, the remainder gives the new moon of March, D. 11. H. 19. M. 49. Sec. 41, which is the Paschal one.

Again, let the Paschal new moon of the year 19480000 be investigated. The root of index 0 is to be chosen, because through thousands and hundreds the number is expressed as 00. Therefore, when the centesimal of that root, 1600, has been subtracted from the given centesimal, there remains the year 19478400. If, then, with the years here set alongside in the little table you enter the table of progressions, and gather all the progressions together with the Root into one sum, you will make D. 148. H. 18. M. 32. Sec. 30. If from this you subtract a revolution of the new moons, D. 147. H. 15. M. 40. Sec. 16, the remainder gives the new moon in March, D. 1. H. 2. Min. 52. Sec. 14, which is not the Paschal one. Therefore, when the synodic month is added, the Paschal new moon in March will come out as D. 30. H. 15. Min. 36. Sec. 17.

Worked computation for the year 19480000.

| | D. | H. | M. | S. |
|----------|----|----|----|----|
| 10000000 | 15 | 22 | 23 | 3 |
| 9000000 | 29 | 2 | 30 | 46 |

| | D. | H. | M. | S. |
|--|-----|----|----|----|
| 400000 | 24 | 6 | 16 | 58 |
| 70000 | 21 | 5 | 25 | 18 |
| 8000 | 23 | 12 | 27 | 30 |
| 400 | 20 | 8 | 54 | 1 |
| Radix [Root] | 14 | 8 | 34 | 54 |
| Summa [Sum] | 148 | 18 | 32 | 30 |
| Mens. Lu. detr. [Lunar month subtracted] | 147 | 15 | 40 | 16 |
| Nouil. Martij [New moon of March] | 1 | 2 | 52 | 14 |
| Mens. Lun. add. [Lunar month added] | 29 | 12 | 44 | 3 |
| Neom. Pasch. [Paschal new moon] | 30 | 15 | 36 | 17 |

Since, then, for this year Vieta [François Viète] gives the Epact xxix, which places the Paschal new moon on 8 March, it is plain — as I said above — that his equation, over ages so far removed, does not agree with the astronomical computation. As for his assertion that in this year 19480000, and also in 165580200, the astronomical computation does not diverge from his Epacts, it is not true, as is manifest from the threefold computation: namely the one I set out at Chapter 13, and the two I set out in these last two chapters. His computation, indeed, is thoroughly faulty. For his Epacts (once the days that are to be removed have first been subtracted), which he proposes in Proposition 9 in the common calendar, are defective, as is evident if they are compared with our Epacts of the preceding chapter. For example, take the year 100000, whose Epact he makes D. 16. H. 1. M. 24, when it ought to be D. 16. H. 1. M. 58. Sec. 38. From this it came about that, multiplying his own Epact by 1000 and removing from the product the revolutions of the new moons that can be removed, he found the Epact of the year 100000000 to be D. 23. h. 5. M. 18, when in truth it is only D. 17. h. 17. M. 47. Sec. 8. By the same reasoning he found the Epact of the year 60000000 to be D. 8. h. 0. M. 39, when ours is D. 22. h. 10. M. 57. Sec. 54. And in the same way he will be convicted of having erred in the rest of the Epacts. It is therefore no wonder that his computation happens, by accident, to agree in some fashion with the Epacts in certain very large years.

[Margin: The finding of full moons by means of the progressions.]

[3] The full moons will be computed in the same way, if in place of the roots of the new moons the roots of the full moons are used. For example, let the Paschal full moon of the year 4400 be sought. The root of index 0 is to be chosen; its year

1600, subtracted from the given year, leaves the year 2800, to which corresponds the progression D. 24. Hor. 11. Min. 21. Sec. 51. Added to the full moon of the root — that is, to D. 29. H. 2. M. 56. Sec. 56 of March — it produces the full moon in March, D. 53. H. 14. Min. 18. Sec. 47, that is (a month of March being taken off), 22 April, D. 22. Hor. 14. Min. 18. Sec. 47, which is not the Paschal one. Therefore, when the lunar month has been taken away (the 31 days of the month of March having first been added), the Paschal full moon will fall in March, D. 24. H. 1. Min. 34. Sec. 44.

Again, let the Paschal full moon of the year 3900 be sought. The root of index 3 is to be chosen; its year 1900, subtracted from the given year, leaves the year 2000, to which is owed the progression D. 13. H. 6. Min. 17. Sec. 53. When this is added to the full moon of the root, of April, D. 15. H. 3. Min. 37. Sec. 26, there will be formed the full moon of April, D. 28. Hor. 9. Min. 55. Sec. 19, which too is not the Paschal one. Therefore, when the lunar month has been taken away (the 31 days of March having first been added), there will remain the full moon in March, D. 29. Hor. 21. M. 11. Sec. 16.

[Margin: What is to be done for full moons in the expanded years, and in any month whatever.]

As for the new moons and full moons of the expanded years to be sought after a given centesimal — and likewise in any month of the year — let the same rules be observed that we prescribed at Numbers 3, 4, and 5 of the preceding chapter.

Chapter XXVII

Other critics who attacked the Gregorian calendar are refuted.

[Margin: What most people find fault with in the Gregorian calendar.]

1. Many others have ventured to fault this new Gregorian calendar, though on various grounds. Some object to the equation of the epacts, on the ground that it displays the new moons too late; but I think this was amply answered in chapter 19 and elsewhere. Others are displeased that these two epacts, xxv and xxiii, and likewise these, 25 and xxvj, are assigned to one and the same day. Yet the reason for this — namely, that the lunations should run alternately of 30 and 29 days — was set out by us in chapter 10. Still others maintain that Luna xiiii ought not to precede the mean opposition, lest we celebrate Easter at the very mean full moon itself, should it happen to fall on a Sunday, which they hold to be unlawful. That they are entirely mistaken in this, and hold an opinion contrary to the universal

custom of the Church, was shown in chapter 18 and in what we wrote in chapter 1, Numbers 6 and 7. Finally, there are those who would have the Moon anticipate by one day in 304 years, and not in $312\frac{1}{2}$, as we showed in chapter 8. To all these we make no other reply than what we demonstrated in that same chapter 8.

[Margin: Who framed a calendar of their own, different from the Gregorian.]

2. Among all those, however, to whom the Gregorian calendar seems not to have been correctly reformed, there are only two — Franciscus Vieta [François Viète] and Iosephus Scaliger [Joseph Scaliger] — who have framed calendars of their own, different from the Gregorian, and have persuaded themselves that they have hit the mark exactly. And since in chapter 24 it was shown more than sufficiently that Vieta's calendar goes wrong in many respects, I judge it worth my while to do the same, in this chapter, for Scaliger's. For although I have refuted this very thing at length and in full in a separate little book, which I issued against his *Castigatio* of the Gregorian calendar, it will nonetheless not be out of place to review here, briefly and summarily, his chief errors and faults — so that it may be plain to everyone that no calendar can be built better suited to the Church's use than the one Gregory XIII issued. For it scarcely seems possible that any calendar could be devised different from the Gregorian, Vieta's, and Scaliger's. If, then, the two latter are convicted of being erroneous, there will be no room to doubt that the first — that is, the Gregorian — is to be preferred to all, since it contains fewer drawbacks, and those (as I have shown) scarcely avoidable, than the others do.

[Margin: That Scaliger took the calendar of the Compendium for his own.]

3. First, then, Scaliger seized upon the Lilian calendar, which had been sent to the Christian princes by Gregory XIII, and passed it off as his own. In it, of course, the equation of the lunations — so that they may fall alternately of 30 and 29 days — is applied on the last day of March, by means of two epacts, ☉ [the *Compendium*'s circular epact-30 sign] and 29 (although he adopted o in place of ☉); and likewise on 29 May, 27 July, 24 September, and 22 November. He does, however, begin the arrangement of the epacts from March, not from January — which makes no difference, since the months of January and February do not disturb the Paschal months, on which the calendar's chief reckoning must rest. But in this equation he erred badly: at the same places, alongside epact j, he failed to set another sign — namely, * — of the same signification as ☉, as was done in the Lilian. For since he did not grasp the necessity of this, he is very often forced to intrude the same day, which runs counter to all the computists. This happens whenever the golden number 1 coincides with any one of these eight epacts: iiij, vij, xij, xv, xvij, xxij,

xxvj, xxix. For then, within the same nineteen-year cycle, both epact 29 and epact 30 — which $\odot$ and * signify, or, in Scaliger, the sign o — are in use, as is plainly established from the expanded table set out in the calendar of the *Compendium* at the beginning of this work. This absurdity is avoided if, with golden numbers greater than 11, one takes epact *, and not $\odot$ — just as in our Gregorian calendar we take, with those same golden numbers, epact 25 and not xxv.

He falls into a further and greater drawback. On the last day of February, which for him is the last day of the whole year, he did not write, next to epact xx, the epact 19, as was done in the Gregorian calendar on the last day of December. For unless this is done, the lunation begun on 30 January will, in his scheme, run to 59 days, if the golden number 1 then coincides with epact xix — as was explained in chapter 12, in the case of the lunation beginning on 2 December in our calendar with epact xix. I pass over the fact that he makes the Paschal months of epacts xxix, xxviii, xxvii, xxvj, xxv, xxiiii to be of 30 days, contrary to all the computists.

[Margin: What errors Scaliger committed in his own calendar.]

Since, then, we shall chiefly examine the Paschal Lunas xiiii in Scaliger's calendar, and show that they are for the most part false — on account of the placement of the epacts and their wrongly instituted equation — we shall here set before the reader only March and April, in which the Paschal new moons fall, omitting the other months. I shall say nothing here, however, of his table of equation by which he attempts to correct our equation as it advances through 400 years — the table entitled *Table of the equation of the epacts in the Tetracosimeteris, corrected* — in which he himself advances twice through 132 years and once through 136, in continuous order. Nothing, I say, shall I say of this table, both because he himself makes little of it, and because in chapters 5 and 18 we showed clearly enough that an equation applied at every hundredth year keeps the equinox more correctly in its own seat — that is, on 21 March — than if one waited for 134 years, or 132, or 136. So that I cannot sufficiently wonder that Scaliger supposes this alternation to be more easily grasped by the common people than our uniform advance through centuries of years.

Only his table of the equation of the epacts in the true tropical period, then, shall we weigh a little more carefully — the one in which it advances alternately through 132 and 136 years. This table he makes so much of that he has dared to propose it to all nations and peoples as a rule and standard of truth, as though fallen from heaven, to which the judgments of all in the correction of the calendar should be directed. And this table we have placed before the aforesaid

two months. There then follows another little table, of 19 years, with the Jewish new moons, which he sets up as the foundation of his whole calendar, and which he explains in nearly the words set down below.

Tables

Table of the equation of the epacts in the true tropical period

(Tabula æquationis Epactarum in iusta periodo tropica. Columns: Anni Christi correcti = Years of Christ, corrected | Aur. Num. = golden number | Lit. Domin. = dominical letter | Dies reiecti = days rejected | Epac. curr. = current epact | Epac. aureo num. 1. ref. = epact referred to golden number 1. The table is set in two panels on the page — years 1601–3609 at left, 3745–5217 at right — and is reproduced here as one continuous table.)

The order of the dominical letters is contained in this distich of Scaliger's:

*Gaude digne coli, gaude fax clara bonorum Felix esto bonis, ades & deuotus
amicis.*

(A mnemonic verse whose successive word-initials give the dominical-letter sequence; transcribed verbatim, not normalized.)

March and April (Scaliger's Paschal-month epacts)

(The two months are set side by side on the page. Columns: *Epactæ* = epact | *Lit. Do.* = dominical letter | *Dies* = day of month. Epact 30 is printed as Scaliger's sign o; the doubled month-end cell reads o.xxix.)

MARTIVS (March)

The following passage (set in *italic* in the source) is Scaliger's own explanation of the little table above, quoted by Clavius — "in nearly the words set down below":

4. Let us suppose that the Lilian form had obtained from the beginning of the years of Christ, and from the year of Christ 5337 let us set up the nineteen-year lunar cycle, with the Jewish new moons added — those whose full moons do not fall before 21 March in the Lilian [calendar] — to which new moons, after the manner of the Jews, a weekday is prefixed, a weekday that changes as often as the following hours have

reached 18. We have also added the dominical letter, to mark in the calendar the epoch of the new moon, as you have it in the table. In it you first see the line of years of the golden number, from the year of Christ 1577 to the year 1595. Then follows the dominical letter. In the fourth place [stands] the Jewish new moon, which is always Nisan — except in years 3 and 11, in which Adar is taken for Nisan, because its full moon falls after 20 March. The first number of the Jewish new moon is the weekday; the second, the hours of the Moon's mean motion; the third, the remainder out of 1080 scruples. Example: In the first year of the cycle, that is, in the year 1577, the new moon was 3, 13, 256. The first number indicates that the new moon fell on the third weekday [Tuesday]. And since the dominical letter is B, the third weekday will therefore be the letter D; and consequently the Jewish new moon of Nisan fell on 29 March, at hour 13, [scruple] 256, from the beginning of the night that precedes the day in question, the 29th. But when the hours have reached 18 or beyond, then the weekday is increased by one. For example, in the second year of the cycle the new moon was 7, 22, 52. Because the hours passed beyond 17, [scruple] 1079, therefore in place of weekday 7 the first weekday is to be taken — that is, the letter A for G — and so always.

Let us, then, examine this calendar, and the two tables attached to it — which Scaliger extols to the skies — a little more attentively. But lest anyone suppose that in our examination we are not taking Scaliger's *true* epacts, let us first show by what method he himself derives the epacts of any given year from the perpetual Cycle of epacts — the very one we set down both in the Gregorian calendar and in chapter 12, Number 6 — except that in it, in place of *, he takes o, and in the sixth cell, leaving aside epact 25, he takes only xxv. This, then, is the path he enters upon. In the last row of the table of the equation of the epacts he takes the epact answering to golden number 1 for the proposed year, or, if that year is not found in the first row, for the nearest lesser year. From this epact he counts, in the perpetual Cycle of epacts, 1, 2, 3, and so on, up to the golden number of the proposed year; for the end of the counting will fall on the epact sought. For example: I want the epact of the year 2001, whose golden number is 7. And since in that [period] the epact answering to golden number 1 is o, we shall count in the perpetual Cycle, from the first cell (epact * or o), the golden number of the proposed year, 7, and we shall land on epact vi in the seventh cell. Again, let the year 2595 be proposed, which is not entered in the table. To the nearest lesser year in the table, 2537, epact 29 is assigned as answering to golden number 1. If, then, from epact xxix we count in the perpetual Cycle 12 — which is the golden number of the given year 2595 — we shall find epact o, of the first cell.

Finally, let the given year be 3195, whose golden number is 4. Opposite the year 3073, the nearest lesser in the table, epact 25 is found answering to golden number 1. Counting, then, in the perpetual Cycle from epact xxv the four units of the golden number 4, we shall arrive at epact xxviii. And so with the rest.

[Margin: That the little table of Jewish new moons proposed by Scaliger does not sufficiently agree with the perpetual cycle of epacts.]

First, then, as regards the upper table of 19 years of one cycle, from 1577 to 1595, I find your consistency wanting, most learned Scaliger. For I do not find it to agree either with your own perpetual Cycle of epacts or with your doctrine. Since in the table of the true tropical period you would have epact j answer to golden number 1 from the year 1601, tell me, please: why, for the year 1577 — which is only 24 years distant from 1601, so that no change could have occurred in the Moon — do you assign to that same golden number 1 the epact ij ? Or, if for the year 1577 you attach epact ij to golden number 1, why do you not assign that same epact ij to the same golden number 1 for the year 1601? Reason would surely require it. Or do you perhaps hold that epact ij is to be assigned to golden number 1 for the year 1577 in order to serve the Jewish new moons, which you placed on 29 March? If you accept this, the error will creep further. For you will see that most of the epacts of the remaining 18 years of that little table prove to be faulty. For as often as epact ij answers to golden number 1, there will answer, from your perpetual Cycle, to the other golden numbers, throughout the same nineteen-year cycle, the epacts of this table which we have subjoined here — of which epacts very many differ entirely from those you have noted in that table of yours.

(First comparison, golden numbers 1–19. Row labels as printed: Aur. Num. = golden number | Ep. Cyc. perp. = epact from the perpetual Cycle | Epact. Scal. = Scaliger's epact.)

| | | | | | | | | | | | | | | |
|--------------|------|------|-----|-----|----|------|------|------|-----|-----|------|------|------|-----|
| | | | | | | | | | 1 1 | 1 | | 1 | | 1 1 |
| Aur. Num. | 1 2 | 3 | 4 5 | 6 | 7 | 8 | 9 | 0 1 | 2 | 13 | 14 | 5 16 | 17 | 8 9 |

| | | | j | | | x | | j | | | | | | |
| Epact. Scal. | i xi | xxii | v x | xx | vi | x x | x x | x x | ii | xii | xxii | v xv | xxv | i x |
| | j j | j | v | vj | j | i xi | i xj | ij | ij | ij | j ij | iiij | iiij | x x |
| | | | j | | | x x | | | | | | | | |

See — the epacts of this table agree with yours in only ten places, namely in years 1, 4, 5, 8, 10, 13, 15, 17, 18, 19 of the cycle; in the rest they differ. But if, for the year 1577, epact 1 be assigned to golden number 1 — just as from the year 1601, as is proper (for in that year, since as yet no day but 10 has been rejected, the Moon does not yet need any equation) — a much greater difference will appear, as this other table shows.

(Second comparison, golden numbers 1–19. Row labels as printed, including the label variants: Ep. Cyc. perp. / Ep. Cyc.perp. and Epact. Scalig. / Epacta Scalig.)

| Aur. Num. | 2 3 | | 4 | 5 | 6 | 7 | 8 | 9 | 1 1 | | 13 | 14 | 16 | 17 | 1 | 1 |

| | j | | | j | v | j | | i | j | | | | | | | |
| | | | | | i | | | x | | | | | | | | |

Do you see that the epacts agree in only seven places — namely, in years 2, 3, 6, 7, 9, 11, 14 of the cycle? And that at golden numbers 12 and 16 there is a difference of two units? — which is utterly absurd, as the calculation will presently show. Moreover, that epact iiij of golden number 12 has been produced from the preceding epact by the addition of 13 units? — which is altogether monstrous and wholly foreign to the reckoning of new moons; unless perhaps, in the expanded table, one must ascend to the row above while the golden number 19 is nevertheless running, as we set forth in chapter 12, Number 14. You will say that this happened through the intervention of the bissextile [leap day]: I grant it. But answer me this too: why did the same not happen in years 4, 8, and 16, which are likewise bissextile? Why should these be in a worse condition (to use your own words) than that one?

Certainly the lunations of any given year cannot recede from the lunations of the immediately preceding year, toward the beginnings of the months, by more than 11 days — at most 12 in a bissextile year — since the epact of a single year is 10 days, 15 hours, 11 minutes, 22 seconds if it is a common year, but 11 days, 15 hours, 11 minutes, 22 seconds if it is bissextile, as we explained in chapter 13. Yet the lunations marked by your epacts for year 12 stand 13 days distant from the

lunations of year 11 that the epacts indicate — except in those months which assign two epacts, 0 and xxix, to the same day. This is plain in May and April. For from epact xxj in May, which shows the new moon in year 11, to epact iiij, by which you would mark the new moon in year 12 in April, 13 days are counted — although the calculation exhibits the difference between these two mean new moons as only 11 days, 15 hours, 11 minutes, 21 seconds, a figure that is less than twelve days, let alone thirteen.

Come now, let us consult the calculation. In the year 1587 the mean new moon of May fell on day 6, hour 23, minute 50, second 31. But in the year 1588 the mean new moon in April occurs on day 25, hour 8, minute 39, second 10 — although your epact iiij places it on day 25, well before the mean new moon, which must be assigned to day 26. Now if we subtract 25 April, hour 8, minute 39, second 10 from 6 May — that is, from 36 April, hour 23, minute 50, second 31 — there will remain the stated difference of 11 days, 15 hours, 11 minutes, 21 seconds. Where, I ask, is the difference of 13 days here? But perhaps I suppose that this holds only for the mean new moons of the said years, not also for the true ones. On the contrary, it holds no less for the true than for the mean: for the true new moons of these same two years and months do not stand 13 whole days apart from each other either, as is clear from the Ephemerides of Giovanni Antonio Magini [Magini]. You see into what snares the Jewish new moons have led you, from which you can never extricate yourself — namely, that you anticipate the celestial new moons and set one further apart from another than reason requires; which is nothing else than to confound and disturb the whole reckoning of new moons.

But let us also compare some of your fourteenth days of the Moon [Lunae xiiij] for these same years, both with ours and with the mean full moons, so that we may see which of us has more correctly arranged the epacts in the calendar for the use of the Church, and more correctly chooses the epacts for indicating the ecclesiastical new moons — so that from this too it may appear that the new moons have not been correctly marked by you, and that without cause the even progression of the epacts by the number eleven has been interrupted by you, in order that you might dispose the new moons otherwise. For this is the only reason you can allege in your favor as to why the epacts of the aforesaid 19 years differ from the epacts of the perpetual cycle and do not advance evenly by 11. For since the new moons must be so established (as I taught in chapter 18, Number 4) that the fourteenth days of the Moon do not run ahead of the full moons by two days — lest, if the following fourteenth day were a Sunday, Easter should be celebrated before the full moon — we shall discover from the calculation that you

have very rarely observed this. Here is the table, with the epacts, the fourteenth days of the Moon, and the mean full moons.

We assign the full moon that occurs after noon to the following day, following the doctrine of all who have written on the computus — a thing you yourself will not deny, since you attribute to the following day the new moon that follows the preceding sunset by 18 hours. When, therefore, your fourteenth day precedes the full moon by two days, know that you sin against the canons. For if your fifteenth day of the Moon were a Sunday, you would celebrate Easter before the full moon — that is, on the true fourteenth day of the Moon — which the canons do not permit. And when your fourteenth day runs ahead of the full moon by nearly three days — as happens in the year 1589 — Easter would be celebrated two days before the full moon, on the thirteenth day of the Moon, before the Jewish Passover; which is more absurd still.

But perhaps you will say: What of it? Does your own fourteenth day of the Moon anticipate nothing that year? It does indeed anticipate somewhat, yet by a full day less than yours; and this arises from the nature of the cycle. For a cycle

arranged in the calendar in any way whatever cannot avoid every drawback. This one thing we must take the greatest care over: that it be so arranged as to contain the fewest possible errors. And this we are confident we have achieved in the Gregorian calendar, since far fewer errors are to be noted in it than in yours — as appears partly from the aforesaid table of 19 years, and partly, and far more evidently, in the examination of your table of the equation of the true tropical period. Further, in these 9 years of the earlier table, even if not your fifteenth day of the Moon but the sixteenth were a Sunday, Easter would nevertheless be celebrated after the fifteenth day of the Moon (as you have wrongly, and against the canons, decreed must be done) — in

on the full moon itself — which, however, you utterly deny to be permissible. And so you clothe yourself in the very thing you feared. Therefore, whether Easter is celebrated next after the fourteenth Moon or after the fifteenth, it is established that your Jewish new moons are false in the aforesaid 9 years. What is more — and this is more intolerable — against all the writers on computus you place, in those same 9 years, the epacts on the very days on which the mean new moons occur. You have here, then, my dear Joseph [Scaliger], how false and how deceptive is that table of yours of 19 years, which nevertheless you make the foundation of your table for the equation of the true tropical period [tabula æquationis iustæ periodi tropicæ]. And so, since it rests on so weak a foundation, it must plainly be ruinous — as will at once become clear from an examination of it.

[Margin: That Scaliger, in altering the epacts, took no account of the postposition of the Moon, nor of the excluded days.]

5. FIRST, then, I observe that in altering the epacts which correspond to golden number 1 you took no account of the anticipation of the new moons — which you assert to occur over the course of 304 years — nor of the excluded days, each of which demands that the current epact be changed into a lower one. This is indeed a very great error, and it heads a whole family of errors. For before 304 years have elapsed from the epoch, or radix, the current epact must be changed into a lower one as many times as days have been excluded. But as often as 304 years have elapsed, that many units must be subtracted from the number of rejected days, so that the remainder may show by how many units a smaller — that is, a lower — epact must be assumed. This you did not observe; instead you trusted only the Jewish new moons of the 19-year table above, which drove you into

error, as we said before. Go now, and trust the Jews, that you may win the reward of your credulity!

But see the fraud into which you have fallen through the Jewish new moons. From the year 1581 to 1733, 304 years have not yet elapsed, and so the Moon needs no equation. Since, therefore, in 1733 one day is removed, the epact 2 running with golden number 1 (seeing that in golden number 5 of the year 1581 the epact 16 [xvj] corresponds) must be changed into the lower epact 1 — which you did, and rightly.

Next, neither from 1584 to 1869 are 304 years counted; so when in 2869 [recte: 1869] another day is removed, and consequently two days are then rejected after the correction, the epact 17 [xvij] ought to be assumed, smaller by two units than the epact 19 [xix] which runs with golden number 8 in 1584. Hence to golden number 1 there ought to correspond the epact 0, or *, and not the epact 1, as you have it in your table.

Again, from 1583 to 2001, 3 days will have been removed, and 304 years are counted once; therefore the epact to be assumed would be 5 [v], smaller by two than the epact 7 [vij], which in 1583 corresponds (on your own authority) to golden number 7 — that is, the epact of golden number 1 ought to be 29, and not 0 as you would have it.

Moreover, from 1587 to 2537, 304 years are contained three times. So, subtracting the ternary from the 7 days that will then have been removed, 4 remain; and by that many units a smaller epact ought to be assumed than the epact 21, which corresponds to golden number 11 in 1587 — that is, the epact 17. And therefore to golden number 1 the epact 27 must be assigned, whereas you assign the epact 29.

Furthermore, from 1595 to 3609, 304 years are reckoned six times. Therefore, if you subtract the six from the 15 days that will then have been excluded, 9 remain. So from the epact 20, which corresponds to golden number 19 in 1595, 9 must be taken away, leaving the epact 11 [xj] answering to that same golden number 19 in the year 3609; and thus to golden number 1 the epact 23 will be owed — and yet you assign the epact 21 to golden number 1. Do you see how great and how grave the collapses are? Finally, if we should wish to examine other years of the table of the true tropical period in the same way — taking from your 19-year table the year that has the same golden number as the year assumed in the table of the true period — we shall find that you very rarely assign to golden number 1 the epact that the reckoning of the Moon's anticipation and postposition requires.

And what other cause is there of an error so great and so widely and far diffused, except that you assigned the epacts solely to the Jewish new moons? From this it follows necessarily that intolerable errors arise in the new moons and the fourteenth Moons, as the appended table of 50 years shows. In it we set down, first, the years of the Lord; then their golden numbers; third, the epacts of the Gregorian Calendar. The fourth column contains the epacts that are perpetually derived from the Cycle of Epacts by means of the epacts which correspond to golden number 1 in the table of the true period. The fifth holds the fourteenth Moons that the epacts mark in the Gregorian Calendar; the sixth, the fourteenth Moons of the Scaligerian epacts; the seventh, the mean full moons according to the intercalation of the Gregorian Calendar; the eighth, the same full moons according to Scaliger's intercalation. The ninth comprises the Dominical letters by the method of the Gregorian Calendar; the tenth offers the same letters according to Scaliger's method. In the eleventh we have noted the days rejected according to the equation of the Gregorian Calendar, and in the twelfth, finally, the days excluded according to Scaliger's equation. Whenever your fourteenth Moons run two days ahead of the mean oppositions, you must admit that you investigate the epacts wrongly and do not arrange them correctly in the Calendar — as was said above in the examination of the 19-year table from the year 1577 to the year 1595 — since by them the fourteenth Moons are found falsely. Furthermore, a full moon falling on some day after noon must be assigned to the following day, as we also noted above. The calculation of the mean oppositions here employed is, as elsewhere, by means of the tables of epacts which we composed in chapter 13; and from this calculation that one does not differ much which is made through the new moons of 76 years in chapter 14, or the one we set forth in chapters 25 and 26.

Comparison table of 50 years — Gregorian versus Scaligerian reckoning (folio 545)

Legend: **Aur.** = golden number [Aureus Numerus]; **Ep. G / Ep. S** = epact (Gregorian / Scaligerian), where * = epact 30 (new-Calendar sort) and 0 = Scaliger's zero; **L14 G / L14 S** = fourteenth Moon [Luna xiiij]; **Plen. G / Plen. S** = mean full moon, given as **day·hour** with month letter; **L.D. G / L.D. S** = Dominical letter [Litera Dominicalis]; **D.ex. G / D.ex. S** = days removed [Dies exempti]. Month letters: **A** = April [Aprilis], **M** = March [Martius].

We have omitted the minutes of the hours in this table, taking a whole hour in their place whenever they exceeded the number 30. Moreover, we have gathered so many examples in this and the following tables not so much to set the errors of the Scaligerian epacts before your eyes, as to teach that the Gregorian epacts correctly indicate the paschal fourteenth Moons according to the prescription of the Canons — which will indeed appear clearly, if the Gregorian fourteenth Moons are compared with the Gregorian mean full moons, and the Scaligerian fourteenths with the Scaligerian mean full moons.

[Margin: That Scaliger's fourteenth Moons very often fall two days — or even three — before the Gregorian fourteenths.]

In all these years (I have passed over a good many others in which the same thing happens — for either there are examples enough, or I do not know what "enough" is) your fourteenth Moons always run two days ahead of ours, and by about as many days — sometimes even three (as in the years 2575, 2594, 2595) — they precede the full moons. From this it follows that, if the next following day were a Sunday, Easter — according to your epacts, and by the prescription of the Church (which always celebrates that solemnity on the Sunday next after the fourteenth Moon, as we have shown more than once) — would have to be celebrated one day before the full moon, and sometimes even two days before, if a full moon that falls after noon must be assigned to the following day, as reason requires. For although an Easter in which the full moon falls before sunset is not altogether illegitimate, as we wrote in chapter 22, number 4, it must nevertheless be avoided in the Cycle as far as possible, so that it happens very rarely. That it is against the Canons and the Decrees of the Fathers for Easter to be kept before the full moon, not even you deny, since you do not permit it to be celebrated even on the full moon itself. Indeed, even if Easter had to be celebrated after the fifteenth Moon (which you, with some others, obstinately maintain), it could still be celebrated on the full moon itself — which you do not approve — or even, against the Canons, before the full moon. It is established, then, that your epacts are neither rightly ordered in the Calendar nor rightly traced from your table, since their fourteenths anticipate the mean oppositions more than is proper. And although this error is for the most part corrected by the current Dominical letter — which very often follows the fourteenth by more than two days — the epacts are not on that account to be judged free of fault in themselves.

What of this: if we used your Calendar, more than once we should in fact celebrate Easter after the fourteenth Moon (which is the ancient custom of the Church) but before the full moon? This would happen in the years 1737, 1791,

1859, 1957, 2575, 2995, 3195, 3266. For in all of these the year's own Dominical letter follows your fourteenth Moon closely, but the mean opposition not closely; and indeed in the year 2575 Easter will run two days ahead of the mean opposition. But if you should contend that Easter must be celebrated after the fifteenth Moon, lest it fall on the full moon (for which, however, you can produce no authority who sees anything in this matter), you will not be able to avoid displaying Easter as celebrated on the full moon in the years 1734, 1802, 2238, 2519, 3033, 3138, 3209. And this same thing will happen even if Easter is celebrated after the fourteenth Moon (as reason requires), because in these years the Dominical letter follows the fourteenth Moon by two days, at the full moon itself. But with us this is no sin, since we know that by the Canons Easter can be celebrated on the full moon; whereas with you it is, since you deny that it ought to be done. Moreover, in those eight earlier years — 1737, 1791, 1859, 1957, 2575, 2995, 3195, 3266 — unless you decree that Easter is to be celebrated on the fifteenth Moon, as the Canons and the decrees of the Fathers prescribe, you will defer it to the twenty-second Moon [Lunam xxij], against all the writers on computus, the Councils, and the Canons.

BUT here, look, are another 80 years for you, in which greater errors are committed, seeing that in them your fourteenth Moons anticipate ours by three days, and sometimes even four.

Comparison table of a further 80 years — Gregorian versus Scaligerian reckoning (folio 546)

Columns as in the folio-545 table. Here the mean full moons are headed "**Plenilunia media secundum intercalationem**" (Gregorian / Scaligerian) — i.e. the mean full moons according to the [respective] intercalation.

The demonstration table refuting Scaliger continues (the argument that Scaliger's 14th moons run two to four days early). This leaf carries a further comparison table; the discussion of it follows on the next leaf.

Comparison table of Anni Domini with the Gregorian and Scaligerian epacts, 14th moons, mean full moons, Dominical letters, and days removed (folio 547).

[Table continues from the previous leaf.] The two epact columns — and the columns that depend on them — diverge deliberately: throughout this leaf the Scaligerian epacts run three units higher than the Gregorian (or two units in the later, larger-year block), so the Scaligerian 14th moons and full moons fall earlier. Transcribed as printed; not harmonized. In the epact columns, Gregorian epact 30 is set as an asterisk * (the new-Calendar sort) and Scaligerian epact 30 as ø (Scaliger's sort) — two distinct forms, both preserved.

(folio 548)

[Margin: That Scaliger's 14th moons frequently fall three, or even four, days before the 14th moon of the Gregorian Calendar.]

In all these years — I pass over a great many others in which the same thing happens, so as not to seem bent on burying you under a mass of examples — your 14th moons consistently run three days ahead of ours, and by nearly as

many days, and sometimes even four (as in the years 2546, 2565, 2603, 2611, 2622, 2945, 2983, 3214, 3233, 3271, 3290), while only rarely do they fall a mere two days before the mean oppositions.

Consequently, if the next day — that is, your fifteenth moon — should fall on a Sunday, then by your epacts and canons and the custom of the Church, Easter will be celebrated one or two days, and sometimes even three, before the mean full moon: which is utterly absurd and unheard of. And if it could not be celebrated on the full moon — as you falsely suppose — but after the fifteenth moon, then, should the day following the fifteenth moon be a Sunday, it would be celebrated either on the full moon itself (which you do not allow) or one day, or even two, before the full moon, against the canons. You see, then, how wrongly your epacts have been placed in the Calendar — with epact 29 shifted from the first of April to the 31st of March, and so forth — and how falsely your table of the true period supplies those same epacts. You see this whole structure of yours undermined and collapsing of its own accord.

[Margin: That Scaliger not infrequently has Easter kept before the full moon, or even two days before it.]

Nor does the matter rest here. Your epacts not only fail of themselves to give us a legitimate Easter, but very often actually force upon us a celebration contrary to the canons and the decrees of the Fathers. For if Easter is to be celebrated after the 14th moon of the cycle — as is right and as the canons prescribe — then in the year 2565 it will be kept three days before the mean opposition; in the year 2650, one day; and likewise in the year 2670; while in the years 2606, 2907, 3059, 4778, two days. What could be more inept? But if, as you falsely think, Easter had to be celebrated after the fifteenth moon, then in those same years it would be deferred to the 22nd moon of the cycle, which the canons forbid. Again, in the years 2231, 2603, 2630, 2643, 2647, 2667, 2945, 2975, 3002, 3290, Easter will anticipate the mean opposition by one day and will be kept after the 15th moon of the cycle; while in the years 2610, 2613, 2617, 2637, 2661, 2671, 2918, 3070, 4721, it will be celebrated on the full moon itself — which nevertheless you shudder at without cause.

Furthermore — see where I am going — in the year 2619, in which your epact is 25, there will be no legitimate Easter at all. Why so? Because this epact is not Paschal in March, since it occupies the 6th day of March, but in April, setting its 14th moon on the 17th of April. Since, then, by your equation the mean opposition falls on the 19th of April at hour 17 — that is, on the 20th day — it will not be Paschal, because it follows the 19th; rather the opposition of March, falling

on the 21st day at hour 4 — that is, on the 22nd day — will be Paschal. Scaliger will therefore be compelled that year to celebrate Easter in the second month, and wrongly at that, since his 14th moon, falling on the 17th of April, runs three days ahead of the opposition. This is faulty, because by its own nature Easter, kept after the 14th moon, could be celebrated on the 18th, if that were a Sunday — two days before the full moon; or (as his opinion holds) after the 15th moon, on the 19th, if it were a Sunday — one day before the full moon.

How much more correctly, then, does our epact 22 that year — setting its 14th moon on the 22nd of March — present Easter in the first month, seeing that the opposition of March, by our equation, falls on the 22nd of March at hour 4, plainly after the equinox? What could be more correct than this? Nor will this error dog your table only once. For exactly the same thing will happen in the year 2638. Again your epact will be 25, whose Paschal 14th moon holds the 17th of April; and yet the opposition of April, falling on the 19th day at hour 10, is not suitable, since it must be assigned to the 20th day, after the 19th — and your 14th moon precedes it by three days. How much better, then, that our epact 22 for that year places the 14th moon on the 22nd of March, after the equinox, and so looks to the first month?

In the year 2646, however, your epact will be 24, and, as you would have it, Paschal in March; his fifteenth moon will fall on the 21st of March, anticipating the full moon by two days. But our epact that year will be 21, whose 14th moon is marked on the 23rd of March — one day before the full moon — which for us falls on the 23rd day at hour 9. What could be more precise? Do you see how much more happily the matter is managed with our epacts and our equation? Nor does your table's error stop here, but creeps further. You set the Paschal epact 24 in March — which is altogether unprecedented, since not one of the writers or of the Fathers has ever enclosed the seventh day of March (to which epact 24 is assigned) within the bounds of the Paschal new moons that are traced out through the numbers of the cycle. How much more correctly does our table replace that same epact in April? Let us consider, if you please, the following 16 years, in which each of us employs epact 24.

Table of the 16 years in which each party assigns epact 24 (folio 548). The Gregorian and Scaligerian columns diverge as printed; not harmonized.

(folio 549)

[Margin: That Scaliger frequently celebrates Easter in the last month of the preceding year.]

Do you not see that you keep Easter in the twelfth month, while we keep it in the first? For your full moons in March all precede the 22nd of March, and so your true 14th moons fall before the day of the equinox; whereas ours, in April, do not go beyond the 19th of April, and so our true 14th moons do not pass the 18th. Now it is agreed among the writers on the computus that the Paschal full moons are contained within one of the 29 days reckoned from March 22 to April 19 inclusive. From which it follows that those which precede March 22 belong to the last month, and those which pass beyond April 19 belong to the second month. Do you see, then, most learned Scaliger, how great a thicket of errors of the Paschal new moons springs up, in this table of ours, out of your epacts and that new Canon of yours?

[Margin: That Scaliger's 14th moons are too often postponed in the Calendar.]

In the tables above, the 14th moons of the Scaligerian method always run ahead of the 14th moons of the Gregorian Calendar by two or three days, sometimes even four. Let us now see, if you please, most learned Scaliger, whether your table, in the true tropical period, ever offers us 14th moons *later* than the Gregorian ones. For if this should happen, your equation will be found to be faulty and false in every respect. Let us therefore consider the following 58 years, in which the Scaligerian epacts are smaller by two than the Gregorian, and accordingly mark the new moons and the 14th moons two days later in the Calendar — except when the epact is one of these five, 25, 26, 27, 28, 29, for these show them only one day later, since in your Calendar they are advanced upward by one day.

And here, first of all, I am astonished at what could have come into your mind, most learned Scaliger, to thrust the new moons back by a full two days toward the ends of the months, from the year 3609 up to the year 3745, when only a single day was dropped in the year 3608. For, on account of one day removed, the new moons are forced to descend by one day in the Calendar, not by two — unless you wish to say that these same new moons, from the year 2477 to the year 3609, which by two days from...

Table of the 58 years testing whether the Scaligerian 14th moons ever fall later than the Gregorian (folio 549). The mean full moon ("Plenilunia med. iuxta vtriusque intercalat.") is a single column shared by both reckonings; the days removed ("Dies exempti iuxta vtriusque intercalat.") likewise stand at 25 throughout. Columns transcribed as printed, not harmonized.

[Reverse-test demonstration table: Gregorian vs. Scaligerian Easter reckoning, AD 3669–3699]

In the day columns, **M** = Martius (March) and **A** = Aprilis (April); the *Plenilunia media* column gives day · hour · month. Two-letter Dominical entries mark leap years, single letters common years. The *Epactæ Greg.* / *Epactæ Scalig.* columns and the two *Lunæ xiiij* columns diverge deliberately and are transcribed as printed.

Continuing the address to Scaliger:

were being noted earlier by its epacts, to have been false — which I do not think you will maintain, since your own table of the true tropical period would then collapse utterly. Yet even so it seems remarkable to me that, over the next 132 years that follow — that is, from the year 3745 to the year 3877 — you should again drive the same new moons back by two days toward the beginnings of the months. For on account of the one day removed at the year 3744, the new moons ought to descend by a day (if the Moon needs no equation), and certainly not to ascend by two days; or, if the Moon does need an equation, they ought to remain on the same day, as the reckoning of the new moons requires and as we set out more fully in chapters 11 and 12. And if the new moons are correctly noted over these 132 years, it necessarily follows that over the preceding 136 years they were falsely indicated as two days later than the truth. For the rest, I see that you took no account of the equation of the solar and lunar year in placing the new moons, but only of the Jewish new moons [Neomeniæ] — which was the cause of all your troubles, as I have partly shown and shall shortly show further.

Let us therefore examine your fourteenth Moons [Lunæ XIII] — for these must be reckoned with more than the new moons, because of the solemnity of Easter, as you yourself grant — and compare them with the fourteenths of the Gregorian calendar, so that the attentive reader may recognize how much more correctly and aptly the epacts are placed in the Gregorian calendar, and their equation established, than in the Scaligerian. This is what we have done in the preceding table. There it is plainly seen that the fourteenth Moons of the Gregorian calendar always precede the mean oppositions by one day, just as in the earlier tables — and what could be devised more fittingly than this in the matter? But the fourteenth Moons of Scaliger nearly always follow the mean oppositions by two days; and what could be more foreign to the correct celebration of Easter than that? Hence it comes about that, for all the years of the adjoining table, Easter is kept by the Gregorian calendar's prescription rightly and lawfully — namely on the Sunday next after Moon 14, as the canons prescribe — but by Scaliger's method it usually falls in the fourth week, that is on Moon 22, 23, or 24, which the canons in no way allow.

For example: in the year 3609 the Gregorian calendar sets Easter on 5 April, the Sunday next after Moon 14. But the Scaligerian pushes Easter off to 12 April — that is, to the Sunday next after its Moon 15, and hence onto Moon 24 and even beyond; since Moon 15, or the opposition, falls on about the 3rd. Likewise in the year 3612 the Gregorian Easter will fall on the first day of April, but the Scaligerian on 8 April, Moon 24. And the same must be said of very many other years of the same table.

Next, in the years 3613, 3621, 3632, 3640, 3678, and 3697, by the Scaligerian method Easter will be celebrated in the last month, since in those years the mean full moon falls not after the equinox but almost always before it, as the table set out below shows. This surely cannot be excused from being reckoned a most serious error.

[Demonstration table: Scaligerian Easter falling in the last month, AD 3613–3697]

M = Martius (March); *Plenilunia media* sub-columns are **D. H. Mens.** (day · hour · month).

| 3697 | 12 | 22 | 22 M | 20·14·M | 24 M | F |

But perhaps you will say: What? Does your method avoid every error? I admit that in the years 3621, 3678, and 3697 the mean oppositions of April, by our own rule of intercalation, fall on the 19th a little after midday, as is clear from the table above, so that they seem to belong to the second month rather than the first. Nevertheless, since the mean oppositions in the month of March precede the equinox, and therefore cannot belong to the first month, it is more correct to take as the paschal oppositions, in the Gregorian calendar, those that occur in the month of April — because it is a lesser fault to celebrate Easter in the second month than in the last, since the latter is expressly forbidden while the former is permitted. And this error (if it is to be called an error, being one that cannot be avoided) does not arise from any defect of the cycle, but because in the said years no mean opposition falls on any of the 29 days from 22 March inclusive to 19 April inclusive, which alone are assigned to the paschal full moons; so that neither the March opposition nor the April one turns out to be paschal, but the former belongs to the last month and the latter to the second. Since, then, one of the two must be taken if we wish to celebrate Easter in those years, it is better — as we said — to choose the opposition in April rather than the one in March. You

see, then, most learned Scaliger, that your celebrated method of the Jewish new moons is not free of fault. But if this does not move you to hate it, you may love it without a rival.

Three things, from all that has been said throughout this whole book, and especially in this chapter 27 and in chapter 24, I judge to be plainly established. [Margin: What is to be concluded from the things said against Scaliger and Viète.] First, that Scaliger — which in so ingenious a man is exceedingly strange — brought forward nothing at all new in that restoration of his calendar which we had not long before provided for in the assembly on the reform of the calendar, and nothing, in short, which we did not reject for the most just reasons. Next, that the calendar both as proposed by Scaliger, together with his table of equation over the true tropical period, and as constructed by François Viète [Francisco Vieta], contains not one fault but many, and those not slight. Lastly, that the Gregorian calendar is wrongly censured by Scaliger, Viète, and others: since in it the equation of the solar year as well as of the lunar, together with the distribution of the epacts, is so established that everything corresponds beautifully to the mean motions — which is not seen in the calendars of Scaliger and Viète. The tables above make this clear, in which the mean paschal oppositions have been computed for many thousands of years; and these agree wonderfully with the fourteenth Moons of the Gregorian calendar, but differ in many ways from those that the calendars of Scaliger and Viète present — because their fourteenths either precede or follow the mean oppositions by too much, whereas our fourteenths nearly always precede the mean full moons by one day, which agrees remarkably with the canons and the writers on computus. There is no reason, then, why Scaliger and Viète should boast so greatly of their calendars and set them before the whole Christian world as though a kind of divine rule and a heavenly gift. Yet meanwhile we both give and owe great thanks to each of them, because their censures gave us occasion to illustrate the Gregorian calendar by the astronomical computation of very many years. From this it will come about that all may understand that everything in it is rightly arranged, and that in nothing (so far as the nature of the cycle allows) does it depart from what the councils, the Fathers, the canons, and the writers on computus have decreed. Moreover, these so careful attacks of Scaliger and Viète — men likewise most acute and most learned — give us great hope that no one hereafter will weaken the Gregorian calendar in any part, or bring forward anything better; since men of such stature could not, who almost alone of all seemed able to.

CAPUT XXVIII.

On the calculation of lunations as far as fourths [De calculo lunationum usque ad quarta].

Although, for the present business of the calendar, it is enough to proceed in the calculation of lunations as far as seconds — which we have hitherto done in the threefold calculation — nevertheless, so as not to seem to fail the studious in this matter, I have thought it well to extend that same threefold calculation, in this chapter, as far as fourths, so that new and full moons may be computed more accurately whenever it shall seem good. There is also this further advantage: that anyone may examine the epacts, or the numbers of the tables, to see whether they proceed correctly by continual addition, and whether in the tables above one second was always added to the seconds whenever the thirds are more than 30 — as we testified above that we had observed.

EPACTÆ ANNORUM EXPANSORUM. [Epacts of expanded years.] Cap. XIII.

Column heads: **D.** (Dies) · **H.** (Horæ) · **M.** (Minuta) · **S.** (Secunda) · **T.** (Tertia) · **Q.** (Quarta). On the page the table is set as two side-by-side panels (expanded years 1–50 at left, 51–100 at right); it is transcribed here as one continuous table.

| 100 | 25 | 4 | 30 | 32 | 51 | 12 |

For the rest, the epact of 100 years here collected is a little smaller than the one that, in the following table of collected years, is assigned to 100 years by approved authors. This is not surprising, because the fifth and sixth minute-fractions [scrupula quinta ac sexta] that are neglected in the epact of a single year make

the epact of 100 years, collected by continual addition, smaller than it should be. Yet this discrepancy, even in the epact of 1,000,000 years or more, scarcely amounts to an error of half an hour; so the difference need cast no scruple upon us in computing the new moons — especially since opinions differ about the magnitude of the lunar month, as we wrote in chapter 8, number 2.

Caput XXVIII — On computing the lunations to the fourth [sexagesimal fraction] (continued)

Complements of the epacts of the expanded years

[*Epactarum annorum expansorum complementa*] — years 1–100 (printed p. 553)

The leaf sets this table in two side-by-side panels: years 1–50 at the left, years 51–100 at the right. The stub column is headed **Anni expansi** ("expanded years"); the value block is headed **EPACTARVM annorum expansorum complementa** over the six sexagesimal sub-columns **D. H. M. S. T. Q.** (days, hours, minutes, seconds, thirds, fourths). It is transcribed here as one continuous table, years 1–100.

| Anni expansi | D. | H. | M. | S. | T. | Q. |

Monthly epacts — common year and bissextile year (printed p. 555)

Two side-by-side tables, each with the stub **Menses** ("months") and the value block **EPACTÆ** over **D. H. M. S. T. Q.**; the left panel is for the common year (*Anni Communis*), the right for the leap year (*Anni Bissextilis*).

EPACTÆ Anni Communis (common year):

| Menses | D. | H. | M. | S. | T. | Q. |
|--------|----|----|----|----|----|----|
| Ian. | 1 | 11 | 15 | 56 | 49 | 12 |
| Febr. | 29 | 11 | 15 | 56 | 49 | 12 |
| Mart. | 1 | 9 | 47 | 50 | 27 | 36 |
| Apr. | 1 | 21 | 3 | 47 | 16 | 48 |
| Mai. | 3 | 8 | 19 | 44 | 6 | 0 |
| Iuni. | 3 | 19 | 35 | 40 | 55 | 12 |
| Iul. | 5 | 6 | 51 | 37 | 44 | 24 |
| Aug. | 6 | 18 | 7 | 34 | 33 | 36 |
| Sept. | 7 | 5 | 23 | 31 | 22 | 48 |
| Octo. | 8 | 16 | 39 | 28 | 12 | 0 |
| Nou. | 9 | 3 | 55 | 25 | 3 | 12 |
| Dec. | 10 | 15 | 11 | 21 | 50 | 24 |

EPACTÆ Anni Bissextilis (leap year):

| Menses | D. | H. | M. | S. | T. | Q. |
|--------|----|----|----|----|----|----|
| Ian. | 1 | 11 | 15 | 56 | 49 | 12 |

[Prose]

Here too the epact of the last month — that is, of a single year — has been collected, and it is two thirds less than what we set down above, from approved authors, in the table of the expanded years. This difference arises from certain small fractions [*scrupuli*] that were left out of account; the matter, however, produces no error of any significance in computing the new moons.

The Radix of Christ, to be added to the computation [*Radix Christi calculo addenda*] (printed p. 555)

Revolutions of the New Moons and of the Full Moons (printed p. 555)

Two tables set side by side: *Reuolutiones Nouiluniorum* (revolutions of the new moons), with the left-margin label **Coniunctiones** ("conjunctions"), and *Reuolutiones Pleniluniorum* (revolutions of the full moons), with the left-margin label **Oppositiones** ("oppositions"). Each has the sub-columns **D. H. M. S. T. Q.**

Caput XXVIII — *De calculo lunationum* (continued)

Progress of New Moons and Full Moons, of Chapter XXVI (continued)

PROGRESSVS NOVILVNIORVM, ac Pleniluniorum. Capitis XXVI.

The sexagesimal columns are: **D** (days), **H** (hours), **M** (minutes), **Sec.** (seconds), **Ter.** (thirds), **Quar.** (fourths). The **Anni** (years) column runs down the left; a blank ruled column separates it from **D**. Horizontal rules group the entries in fours (as printed).

Computus Ecclesiasticus

[New work — title page (p. 561 / unnumbered leaf).]

The Ecclesiastical Computus, delivered by the joints of the fingers, and by tables.

COMPVTVS ECCLESIASTICVS PER DIGITORVM ARTICVLOS, ET TABVLAS TRADITVS.

PRÆFATIO. — Preface

In expounding the Calendar we set out most fully not only the reasons and foundations of the correction, but also answered our opponents' arguments as thoroughly as we could. It will therefore not be foreign to our purpose to add, by way of an appendix, a number of rules by which everything contained in the Gregorian Calendar may be found — either from memory on the joints of the fingers, or, more quickly than can be told, in tables. In this way nothing further will seem to be wanting to a complete exposition of the Calendar.

I have added these rules to our exposition of the Calendar all the more willingly because I have learned that many who, before the reform of the Calendar, knew the ecclesiastical computus by heart on the joints of the fingers were much troubled that they could no longer use those same rules with the new Calendar. This work cannot fail to be welcome to them, especially when they see that our rules — fitted to a perpetual Calendar in which roughly every hundredth year one day is dropped — are far easier than the old rules of the computists. For less-skilled readers we have also added several tables, for the most part entirely new and not previously seen, though some of them were also drawn up in the exposition of the Calendar; by these, everything that can be wanted in the ecclesiastical computus is found most briefly and without any trouble or labour.

For this reason we have divided the whole Computus into two parts. The first comprises the rules by which everything pertaining to the ecclesiastical computus is worked out from memory; the second part contains the tables relevant to the same matter.

COMPVTI ECCLESIASTICI PARS PRIMA, per digitorum articulos memoriter. — Part One of the Ecclesiastical Computus, by the joints of the fingers, from memory

CAPVT I. — De Aureo numero. (On the Golden Number)

[Margin: What the cycle of the golden number is. (*Cyclus aurei numeri quid.*)]

The nineteen-year cycle of the golden number is a revolution of 19 years, from 1 up to 19; and when that revolution is completed, it returns again to 1, so that in any given year some one of those nineteen golden numbers is in use. How these 19 golden numbers were once set down in the Calendar to mark the new moons, and why there are neither more nor fewer than 19, we have explained at length in our exposition of the Gregorian Calendar, chapter 8. Which golden number, then, is in use in any given year we shall learn by heart in the following way.

[Margin: Placement of the centennial years on the joints of the fingers, for finding the golden number of any year. (*Collocatio annorum centesimorum in articulis digitorum ad aureum numerum cuiuslibet anni inueniendum.*)]

On the joints of the four fingers of the left hand, with the thumb left out (by the term "joints" we understand also the fingertips, so that on each finger, the thumb excepted, we count seven joints, beginning from the inner root of each finger and calling the outermost, just under the nail, the fifth, and so on), the centennial years from the birth of Christ our Lord are to be placed, in this way. At the root, or first joint, of the inner side of the index finger, the year 0 is placed. At the root of the middle finger the year 100 is set. At the root of the ring finger, 200. At the root of the little finger, 300. Then at the second joint of the index finger the year 400 is set; at the second joint of the middle finger, 500; at the second joint of the ring finger, 600; at the second joint of the little finger, 700. Next, at the third joint of the index finger, 800; at the third joint of the middle finger, 900; at the third joint of the ring finger, 1000; and after these, at the third joint of the little finger, 1100. At the fourth joint of the index finger — that is, at the fingertip — 1200; at the tip of the middle finger, 1300; at the tip of the ring finger, 1400; at the tip of the little finger, 1500. Then at the fifth joint of the index finger, which is the outer one just under the nail, 1600; at the fifth joint of the middle finger, 1700; at the fifth joint of the ring finger, 1800. And since the centennial years have now been placed on 19 joints — which is exactly the number of the golden numbers — one must return to the inner root of the index finger, and there set the year 1900; then

at the root of the middle finger, 2000; and so on, always returning after the nineteenth joint to the inner root of the index finger.

[Margin: How to find easily the place of any centennial year, however large, on the joints of the fingers. (*Inuentio facilis sedis cuiusuis centesimi, quamuis magni, in digitorum articulis.*)]

Moreover, to avoid having to run repeatedly over those 19 joints of the left hand we have described, it is enough to learn thoroughly the places of the 19 centuries from the year 0 up to the year 1900, as stated. Once these are accurately known, we shall easily find the place of any century, however large, in this way. From the number of centuries subtract 20 as often as it can be done, and to the remaining number add as many units as the number of times 20 was subtracted. For where the century of this sum has its place, there too will be the place of the century proposed.

For example, let the place of the year 4900 be sought. From the number 49 of centuries (the number of centuries is always expressed by the figures of the year with the last two on the right dropped — thus in the year 34561 the number of centuries is 345, expressed by the remaining figures once the two on the right, namely 61, are cast away, and so on), subtract 20 twice. To the remaining number, 9, add 2, making 11; and since the eleventh century — that is, the year 1100 — has its place on the third inner joint of the little finger, the year 4900 will be placed there.

Likewise, suppose one wants the place of the year 9700. From the number 97 of centuries subtract 20 four times, and 17 remain; add to these the 4, and they make 21. Subtracting 20 once more, 1 remains; and adding 1 for that single subtraction, they make 2. Since, then, the year 200 is located at the root of the ring finger, the proposed year 9700 will be placed there.

Again, since from 20 centuries — that is, from the year 2000 — 20 can be subtracted once, with 0 remaining, then adding 1 for that single subtraction gives 1. So where the first century is placed, namely at the root of the middle finger, there too the year 2000 will have its place.

[Margin: How to find out how often 20 is contained in any large number of centuries. (*Quoties contineantur 20. in quamuis magno numero centenariorum, quo pacto cognoscatur.*)]

It will not be difficult, however, for anyone even moderately versed in arithmetic to find out how many times 20 is contained in any number of centuries, and

hence in which joint that century is to be placed. For if, after dropping the first figure of the centuries on the right, the remaining number is divided by 2 — that is, halved (which is easily done in one's head) — the half of the number will show how often 20 is contained in the given number of centuries. If, then, a unit happens to be left over in the halving, it is to be taken as a ten, and this ten placed before the dropped figure, and this whole number added to the halved number. And if the number so formed exceeds 20, the same must be done with it: that is, drop the first figure on the right, halve it, and so on, proceeding until a number less than 20 is obtained.

For example, if the year 57800 is proposed, where the number of centuries is 578: drop the first figure, 8; the half of the remaining number, 57, is 28. Therefore 20 is contained in 578 as many times as there are units in 28. And because in the halving 1 is left over, it is to be placed before the dropped figure 8, making 18, which added to the aforesaid half, 28, makes 46 — a number greater than 20. So drop the first figure, 6; the half of the remaining number, 4, is 2, with nothing left over; and if to this half the dropped figure 6 is added, the number becomes 8, less than 20. Since, then, the eighth century is placed on the third inner joint of the index finger, there will be the place of the proposed year 57800. And so with the rest.

[Margin: In which joint each century not greater than 1800 is placed. (*In quo articulo collocetur quilibet centesimus non maior, quam 1800.*.)]

So that you may also easily know the place of a century not greater than 1800: add 1 to the number of centuries. For the joint that the resulting number indicates will be the place of the given century. Thus, if the year 900 is given, adding 1 to 9 (the number of centuries) makes 10; therefore the year 900 has its place on the tenth joint — that is, on the third joint of the middle finger — and so with the rest.

[Margin: Placement of the golden numbers on the joints of the fingers, for finding the golden number of any year. (*Collocatio aureorum numerorum in digitorum articulis, ad aureum numerum cuiusvis anni reperiendum.*.)]

Once the centennial years have been placed by this method on the aforesaid 19 joints, all 19 golden numbers are to be arranged on the same joints, in this order. Since in the year immediately before the birth of Christ the golden number was 1, this golden number 1 is to be placed at the root of the index finger, where the year of the Lord 0 was set — that is, the year that immediately preceded Christ's birth. Now since the cycle of the golden number is contained five times in 100

years, with 5 left over, if to the golden number 1 placed at the root of the index finger we add 5, we get 6, to be placed as the golden number at the root of the middle finger — the number which is owed to the year 100 after the birth of Christ and to all the other centuries that fall on that root under the arrangement given above. If again we add 5 to 6, we get 11, to be set as the golden number at the inner root of the ring finger, which answers to the year 200 and to all the other centuries placed there. In the same way, if we add 5 once more to 11, we get 16, to be set as the golden number at the inner root of the little finger, which is owed to the year 300 and to the other centuries placed there. Again, adding 5 to 16 gives 21; but casting out 19 (since no golden number can be greater than 19), 2 remain, to be placed as the golden number on the second joint of the index finger above the root. And so, proceeding thus, you will find all the golden numbers to be set on the 19 joints, each owed to those centuries that fall on the same joints.

By this reckoning you will find that on the second joint of the middle finger 7 is placed; on the second joint of the ring finger, 12; on the second joint of the little finger, 17. On the third joint of the index finger, 3; on the third of the middle finger, 8; on the third of the ring finger, 13; on the third of the little finger, 18. On the fourth joint of the index finger — that is, at its tip — 4; on the tip of the middle finger, 9; on the tip of the ring finger, 14; on the tip of the little finger, 19. On the fifth joint of the index finger, which is the outer one just under the nail, 5; on the fifth joint of the middle finger, 10; and finally on the fifth joint of the ring finger, 15. In this way all 19 golden numbers are placed on the 19 joints on which we set the centennial years.

But it is enough to have found, by this method, the four golden numbers 1, 6, 11, and 16 placed at the four inner roots of the fingers. For if from the golden number of any root you proceed by the natural series of numbers toward the second joint of the same finger, up to the fifth (the outermost just under the nail) — except for the little finger, on which alone you must proceed only as far as the tip — you will have the golden numbers to be placed on the remaining joints. Thus you will find that on the second joint of the little finger, at whose root the golden number 16 is set, the golden number 17 is to be placed; on the third, 18; and at the tip, 19. Likewise on the second joint of the middle finger, at whose root the golden number 6 is set, the golden number 7 is to be placed; on the third, 8; at the tip, 9; and on the fifth joint, which is the outer one just under the nail, 10 — and so with the rest, as before.

[Margin: The easiest placement of the golden numbers on the joints of the fingers. (*Facillima collocatio aureorum numerorum in articulis digitorum.*)]

You will, however, place these same golden numbers on the joints of the fingers more easily if, beginning from the golden number 1 set at the inner root of the index finger, you proceed by the natural series of numbers toward its second joint, up to the fifth joint (the outer one just under the nail); then go back to the inner root of the middle finger, and again proceed toward its second joint up to the fifth; and so with the rest. In this way the golden number 2 will be placed on the second inner joint of the index finger, 3 on the third, and so on, so that the golden number 19 falls on the tip of the little finger, as before.

The reason for this is as follows. Any joint of any finger stands 400 years distant from the next joint of the same finger, or of the immediately preceding one (if, under the arrangement of the centuries given above, we count the joints from the root of the index finger through the second, third, and fourth up to the fifth). Now the cycle of the golden number is contained in 400 years twenty-one times, with a unit left over. Hence a unit added to the golden number of any joint yields, for the immediately following joint — on the same finger or on the next one following — a golden number greater by one; so that the golden numbers advance by the natural series of numbers from the root of the index finger toward its second, third, fourth, and fifth joints, and thence toward the root of the middle finger, its second joint, third, and the others, and so on.

[Margin: Finding the golden number of any year. (*Inuentio aurei numeri cuiuslibet anni.*)]

From all this the golden number of any year is easily found. For if some centennial year is given, its place among the above 19 joints is to be found, together with the golden number owed to that century. But if any non-centennial year is given, one must seek out the place of the golden number of the century immediately preceding the given year, as we have now shown. Then, since in each year the golden number is increased by a unit, as many units are to be added to the golden number found for that century as the number of years by which the given year

falls after that century. For in this way the golden number of the proposed year will be produced. But if the composite number turns out to be greater than 19, the number 19 must be cast out as often as it can be cast out; for the remaining number will give the golden number sought. And if 19 or nothing remains, the golden number is 19.

[Margin: By what method 19 is easily cast out of a larger number. (*Qua ratione facile abiiciantur 19. ex maiore numero.*)]

Further, to cast out 19 from a large number more easily, cast out 20 as often as it can be done, and for each casting-out restore a single unit — the unit you have cast away together with the 19.

You will also do better if first, in the way just described, you cast out 19 from the number of years after the century immediately preceding — if they can be cast out — and add the remainder to the golden number of that century, so as to compose the golden number of the proposed year.

For example: in the year 2500 the golden number is 12, since the place of that year is the second inner joint of the ring finger, where the golden number 12 is set — as is clear if you count from 1, beginning at the root of the index finger, up to that joint which is twelfth in the order we have described (that is, going from the root of each finger toward the second joint up to the fifth, the outer one under the nail); or else if, from the golden number 11 set at the root of the ring finger, you proceed upward by the natural series of numbers to that same second joint, where the place of the year 2500 is.

Let the golden number of the year 2507 be sought again. The place of the year 2500 is on the second joint of the ring finger, and there the golden number 12 owed to it is set, as we have just said; if to this you add 7 (for it is the seventh year after the year 2500 that is proposed), you produce 19 for the golden number of the year 2507.

Likewise, let the golden number of the year 983 be sought. The place of the year 900 is on the third joint of the middle finger, and there the golden number 8 owed to the year 900 is set. Now since 20 can be cast out four times from the 83 years, we shall add four units, on account of those four castings-out, to the 3 remaining years; and the number so made up, 7, we shall add to the golden number 8 owed to the year 900, so as to produce the golden number 15 for the year 983.

Again, let the golden number of the year 1604 be sought. The place of the year 1600 is on the fifth joint of the index finger — that is, on the outer one under the nail — where the golden number 5 is set; if to this we add the 4 remaining years, we produce 9 for the golden number of the year 1604.

Suppose further the year 2108 is given. The place of the year 2100 is at the root of the ring finger, where the golden number 11 is set; if to this we add the remaining 8 years, we make up the golden number 19 for the year 2108.

Lastly, let the year 3003 be given. The place of the year 3000 is on the third inner joint of the little finger, where the golden number 18 is set; if to this we add the

remaining 3 years, we make up 21, and casting out 19, 2 remain for the golden number of the year 3003.

[Margin: Finding the golden number by the rules of arithmetic. (*Inuentio aurei numeri per praecepta Arithmetices.*)]

The golden number will also be found without trouble, in any year, by the rules of arithmetic, in this way. To the proposed year of the Lord add 1, and divide the sum by 19. The number left over from the division — no account being taken of the quotient, which only shows how many revolutions of the cycle of golden numbers have been completed from Christ up to the proposed year — will be the golden number of the proposed year. And if nothing remains from the division, the golden number will be 19. For example, if the golden number of the year 1589 is sought, I add 1 and divide the sum, 1590, by 19, and find that 13 is left over from the division; so in the year 1589 the golden number was 13. Again, if the golden number is sought for the year 1614, adding 1 gives 1615, and when this is divided by 19 nothing remains; therefore in the year 1614 the golden number will be 19. And so with the rest.

You may also divide the years of the Lord by 19 without first adding a unit — provided that you add a unit to the quotient.

CAPVT II. — De Epactis, Nouiluniis, Ætate Lunæ, & litera Martyrologij. (On the Epacts, New Moons, the Age of the Moon, and the Letter of the Martyrology)

[Margin: What the epact is. How the golden numbers are placed on the thumb, in order to find the epacts. What must be added to the golden numbers placed on the thumb, so that they become the epacts before the restored Calendar. (*Epacta quid. Quo pacto aurei numeri in Pollice locentur, ad Epactas inueniendas. Quid addendum sit aureis numeris in Pollice collocatis, vt fiant Epactae ante Calendarium restitutum.*)]

[Margin: What must be subtracted from the epacts that were in use before the correction, so that the rest become the epacts after the restoration of the year. (*Quid ex Epactis, quae ante correctionem vsurpabantur, auferendum sit, vt reliquae fiant Epactae post anni restitutionem.*)]

The epacts are the days by which the solar year exceeds the lunar, as we showed in the exposition of the Calendar, chapter 9, number 14. For in the first year 11 days are left over, in the second 22, in the third 33 — that is, 3 (for the number 30 is to be cast out) — in the fourth 14, and so on. Now to the 19 golden numbers,

one by one, there correspond at various times 19 different epacts, as we taught in the same exposition, chapter 11, number 1, and chapter 12, number 11. The epact of any year, then — the one that corresponds to the current golden number and that indicates the new moons in the Calendar — we shall find, both before the reform of the year and after it, on the thumb of the left hand, in this way.

On the tip of the left thumb, on the middle joint, and on the lowest joint, the golden numbers are to be placed in this order. On the tip is set 1; on the middle joint, 2; on the lowest, 3. Then again on the tip, 4; on the middle joint, 5; on the lowest, 6; then again on the top of the thumb, 7; and so on, so that the last golden number, 19, falls on the tip of the thumb.

After this, to the golden number placed on the tip of the thumb let 10 be added; to the golden number set on the middle joint let 20 be joined; and to the golden number placed on the lowest joint let nothing be added. For the numbers so composed (casting out 30, if the number formed is greater than 30) are the epacts that, together with those golden numbers from which they were formed on the thumb, were in use before the correction of the Calendar.

But if from each of the epacts found in this way 10 are subtracted (since, on account of the ten days removed, the lunations now fall ten days later than before the correction), there remain the epacts running with these same golden numbers after the emendation of the Calendar, up to the year 1700 exclusive. For then, because on account of the omission of the bissextile day the lunations fall one day later still, 11 must be subtracted, up to the year 1900 exclusive; and after this, 12 must be subtracted, on account of another omission of the bissextile day. But in the year 1800, although the intercalary day is omitted, no change is nevertheless made in the epacts, the equation of the Moon requiring it to be so, as was declared in the exposition of the Calendar, chapter 11, number 8. So then the same number, 11, is to be subtracted, which

which we said must be subtracted in the year 1700. In this same way there will always be as many units beyond 10 to be subtracted as there are days by which the lunations have descended in the Calendar. And if the subtraction cannot be carried out, 30 must be added to the epact that has been found, so that the subtraction can be made.

Therefore, to find the epact from the year of the correction up to the year 1700 exclusive, look up in Chapter 1 the golden number of the proposed year, and place it on the Thumb, as has been said. Then add 10 if it lies at the top of the Thumb, or 20 if it lies at the middle joint, or finally 0 — that is, nothing — if it lies

at the bottom. From the number so formed, if you subtract 10 (first adding 30 if the subtraction cannot otherwise be made), the remaining number will give the current epact you are seeking.

[Margin: How the epacts are investigated from the year of the correction up to the year 1700, exclusive.]

For example. In the year 1599 the golden number is 4, which falls at the tip of the Thumb. I therefore add 10 to it and make 14. Subtracting 10, there remain 4 for the epact of the year 1599.

Again, in the year 1609 the golden number is 14, falling at the middle joint of the Thumb. Adding 20, then, gives 34; and subtracting 10 leaves 24 for the epact of the year 1609.

Once more, in the year 1617 the golden number is 3, seated at the bottom joint of the Thumb. Nothing therefore is to be added to it; but since 10 cannot be taken from 3, we shall add 30 so as to have 33, from which, if 10 be taken away, 23 remains for the epact of the year 1617.

Further, in the year 2314 the golden number is 16, falling at the tip of the Thumb. Adding 10, then, gives 26. But subtracting 14 (because up to that year inclusive the lunations will have descended by 4 days beyond those ten by which the descent was made in the year of the correction), 12 remains for the epact of the year 2314.

Finally, in the year 3129 the golden number is 14, falling at the middle joint of the Thumb. Adding 20, then, gives 34; and subtracting 17 (because up to that year inclusive seven changes will have been made in the lunations in the downward direction), 17 remains for the epact of the year 3129.

You must know, however, that epact 25 is to be taken as marked with a different colour or character whenever it is produced from a golden number greater than 11. Likewise epact 19, written on the last day of December with a different character or colour as well, is also in use whenever it is generated from the golden number 19 — as happened in the year 1595, and will happen again in the years 1614, 1633, 1652, 1671, 1690, and never thereafter, except after the use of the 30 lines of the expanded table of epacts. We have set out the reason for this in the exposition of the Calendar, Chapter 12, Number 14.

[Margin: When epact 25 is to be taken marked with a different character or colour. Likewise when epact 19, written on the last day of December, is in use. How the epacts are investigated after the year 1700.]

But so that you may know how many units beyond 10 are to be subtracted in any given year proposed after the restoration of the Calendar [Latin *in Epacta* [?] *proposito* — a short phrase here, apparently containing a numeral, does not resolve on the foxed and tightly set line and is left unread], so that the epact sought may remain — that is, by how many days after the correction the descent in the lunations was made beyond those 10 of the year of the correction, and (which rarely happens) when an ascent was again made — these twelve verses are to be learned by heart:

Cuius chara bono bonitas, bonitatis amantem Vrit amor, vitij turpia tela
terens. Subiectusque sibi regitur ratione, regitque Quam præfert quoties,
prælia nulla nocent: Nec mentis lædit lethali lumina crimen Kuspide:
iustitiæ iuraque iustus habet: Gaudet habens, gaudens fruitur, felixque
fruendo Excipit excelso dogmata digna Deo. Certa bono cuius bonitas
accommoda paucis: At plures nectit noxia noxa malos. Mens hebet his,
horrensque gemit, frustra que gemendo Flet, donec Diuûm dulcia castra
colat.

[This is a computational mnemonic: each successive word (not each line) is assigned to a centurial year, and the placement of its words on the finger-joints yields the number of units to be subtracted. The Latin words are therefore kept verbatim, since the discussion below counts and positions them by their initial letters. Line 6's opening word is printed "Kuspide" (with a capital K for the classical *Cuspide*).]

The first word, [Cuius], of these verses is assigned to the year 1700; the second, [chara], to the year 1800; the third, [bono], to the year 1900; and so on in turn the rest to the following centurial years, so that the last word, [colat], which is the seventieth, corresponds to the year 8600. For those verses have their use only up to the year 8700 exclusive.

See, then, to which word any given centurial year corresponds. Next, lay out across the inner joints of the left hand (the Thumb being omitted) all the words up to and including the one that corresponds to the given centurial year, in this order: assign to the same joint the words beginning with the same letter, and whenever the immediately preceding initial letter (let us be allowed, for necessity's sake, so to call it) recurs, assign that word again to the immediately preceding joint. For as many joints as you have run through by this method, so many units beyond those 10 of the year of the correction will the descent in the lunations have been made — that is, so many units beyond 10 must be subtracted, so that the epact of the proposed year may remain.

For example. Suppose you wish to know how many units beyond 10 you must subtract in the year 2100 and in the other following years up to the year 2200 exclusive. Since from the year 1700 inclusive up to the year 2100 inclusive there are five centuries, the first five words [Cuius chara bono bonitas, bonitatis] are to be counted out on the joints of the left hand in this order. These two, [Cuius chara], because they begin with the same letter, are to be placed on the first joint; and the other three, [bono bonitas, bonitatis], on the second joint, because they have the same initial letter. Since therefore we run through only two joints, two more units beyond 10 are to be subtracted — namely 12 in all.

Again, in the year 2300 — up to which inclusive, from the year 1700 inclusive, there are seven centuries — the first seven words [Cuius chara bono bonitas, bonitatis] are to be counted out on the hand in this way: so that the first two [Cuius chara] are given to the first joint; the next three [bono bonitas, bonitatis] to the second; the following one alone, [amantem], to the third; and the last one also alone, [Vrit], to the fourth — so that four joints are run through. Four units beyond 10, then, are to be subtracted from the year 2300 inclusive up to the year 2400 exclusive. And since the next word, the eighth, [amor], begins with the same letter A which gave the beginning to the sixth word, [amantem], which precedes the word [Vrit], the eighth word [amor] is to be placed again on the third joint, in which the earlier word [amantem] was placed, so that in the year 2400 only 3 are to be subtracted beyond 10; and so with the rest.

[Margin: What is to be done when the number to be subtracted from the epacts is 30 or greater.]

Now, if the number of units to be subtracted, which the verses supply, together with the 10 days taken away in the year of the correction, should be 30, then nothing is to be subtracted from the epacts found before the correction; rather, the very same epacts will then correspond to the golden numbers as were in use with those same golden numbers before the restoration of the year. But if that same number should be greater than 30, let 30 be cast away as often as can be done, and let the remaining number be subtracted from the epacts found before the correction. For the remainders will become the epacts to be employed at the proposed time.

Now since, after the word [Flet] in the last verse, a transition is made to the letter d — on account of the word [donec], the letter e being omitted in the middle, although in the other cases a transition is always made to the nearest letter — one unit besides must be added to the days to be subtracted in the words after the

word [Flet], from the year 8200 onward; for from e to d the Moon descends by two days, not by one. For example, the word [colat] corresponds to the year 8600, and 30 joints are run through; adding 10 gives 40, and subtracting 30 leaves 10; so 10 would be subtracted from the epacts found before the correction. But because the word [colat] follows the word [Flet], one unit is to be added, so that 11 are then to be subtracted.

At the end of this chapter I shall give another rule, quite ready to hand, for finding the epact of any year whatever.

[Margin: Where the new moons are marked in the Calendar.]

Once the epact of each year has been found, let us show by what art the new moons are to be found from memory by means of it — that is, how one may learn on which days of the months the epact of any given year is set. For on those days the new moons occur, by the usage of the Church, although according to the astronomical calculation they generally fall one day earlier; so that you will not do amiss if you assign any new moon found by the epact to the preceding day, should you wish to have the conjunction of the luminaries not by the usage of the Church, but as it is in the heavens. For since the Church takes greater account of the fourteenth Moon and of the full moon than of the new moon, on account of the solemnities of Easter, the new moons have been deliberately set back by the epacts almost always by one day in the Calendar, as was declared in the exposition of the Calendar, Chapter 11, Number 5, and Chapter 18, Number 4. In the same way, about the time of the correction, the Church celebrated the new moons on those days to which the golden numbers were prefixed.

[Margin: What epact is assigned to the Calends of the months.]

But before all else it must be learned which epacts are set at the beginnings of the months, that is, at the Calends. This you will easily know in the following way. January has at its very Calends the epact *, or xxx. February, xxix. March, again *, or xxx. April, again xxix. May, xxviiij. June, xxviij. And so on, the other months in order always one less; only August, however, has at its beginning these two epacts, xxv and xxiiij, and accordingly the epact xxij is set at the Calends of September, and xxij at the Calends of October, and so on. Therefore, if to the twelve joints of the fingers of the left hand (the Thumb omitted) you assign the 12 months in order — proceeding from the root of the Index finger through the roots of the Middle, Ring, and Little fingers, and making the fifth joint the one that is second on the Index, and the sixth the one that is second on the Middle, and so on, so that the third joint of the Little finger is the twelfth — and if on the first

joint, which corresponds to January, you mentally place the epact * (or xxx), on the second xxix, on the third again * (or xxx), on the fourth again xxix, on the fifth xxviii, and so on always one less, provided that on the eighth, which corresponds to August, you place these two, xxv and xxiii, together, then without great labour you will know the epact set at the Calends of any month. Yet you will perhaps know it more easily if you retain in memory only this: that epact xx is placed on the twelfth joint, that is, at the beginning of December. For if from this epact you proceed by the natural series of numbers, assigning to the eleventh joint, that is, to the month of November, xxj; to the ninth, xxi; and so on (provided that from August, on the eighth joint, you repeat these two epacts, xxiii and xxv, and in February and January you repeat the epacts of April and March, that is, xxix and *), you will have all the epacts assigned to the beginnings of the months, that is, to the Calends. Here it is to be noted that in all the months (February excepted) the same epacts are set at the end as were set at the beginning; in August, however, which has these two epacts, xxiii and xxv, at its very Calends, only the epact xxiii is repeated at the end.

[Margin: All the months except February have the same epact at the beginning and at the end.]

Next, it must also be known that in six months — of which one is August, as we said — these two epacts, xxiii and xxv, are assigned together to the same day. Such are the months holding even places up to and including August, that is, the second, fourth, sixth, and eighth; of this kind are February, April, June, and August; and after August, two months holding odd places, namely the ninth and eleventh, that is, September and November. In these months, indeed, the epact 25 marked with a different colour or character is also written near the epact xxvj, which precedes those two, xxiii and xxv. In August alone the epact 25 of a different form is not written near the epact xxvj, but on the last day of July, where the epact xxvj is placed, preceding the two epacts xxv and xxiii assigned to the Calends of August. But in seven months, namely January, March, May, July, August, October, and December, the same epact 25 of a different colour or character is to be written near the epact xxv; so that the epact 25 of a different form is written twice in the month of July — once on the second day near the epact xxv, then again near the epact xxvj assigned to the last day.

[Margin: Which months have the two epacts 24, 25 assigned together to the same day.]

These six months, then, which have the two epacts xxv and xxiii assigned to the same day, are all those that contain only 30 or 28 days, August alone excepted,

which has 31 days. And so, if you bend down the Index and Ring fingers of the left hand, but raise the other three fingers — the Thumb, Middle, and Little — and count out all the months over these five fingers, beginning from March on the Thumb, the five months of 30 or 28 days will fall on those two bent-down fingers, the Index and the Ring, on which the two epacts *xxiiij* and *xxv* are assigned to the same day, and 25 of a different colour or character near the epact *xxvj*; and if you add August to these, you will have all the 6 months we have named. These same six months are also comprised in this verse:

Bella decent fortes: humiles ieiunia laudent.

[The mnemonic verse "War befits the strong; let the humble praise fasting." The initial letters of its six words — B, D, F, H, I, L — are what matter.]

[Margin: How one may easily tell by the fingers of the left hand which months have 30 days and which 31 or 28, and hence which have the epacts 24, 25 assigned to the same day.]

For the initial letters of the six words of this verse indicate that those months contain the two epacts *xxiiij* and *xxv* written on the same day which occupy in the series of months the same places that those initial letters occupy in the alphabet — namely months 2, 4, 6, 8, 9, 11. For you see in this way that the initial letters B, D, F, H, I, L occupy the same places in the alphabet: namely B the second, D the fourth, F the sixth, H the eighth, I the ninth, and L the eleventh.

With these things premised, you will track down the new moons as follows. Count across through the thirty joints of the left hand (taking two on the Thumb, and the others on the four remaining fingers, of which 12 are the inner joints, 4 are at the fingertips, and 12 are the outer joints), from the current epact inclusive (the new moon of which you are, of course, seeking) up to the epact likewise set at the Calends of the proposed month, assigning nevertheless to the months February, April, June, August, September, and November, on the same joint, these two epacts, *xxiiij* and *xxv*, and on the next joint these two, 25 (marked with a different colour or character) and *xxvj*. For the number of joints you have run through will give the day on which the new moon occurs. This counting, moreover, will be quite easy, even if the current epact is greater than the one set at the beginning of the month. For when you have reached *, the epact of the first day of the month is to be added to the joints you have run through as far as *, so that the day of the new moon may be had. In the months, however, in which the two epacts *xxiiij* and *xxv*, assigned to the same day, stand between * and the epact of the first day, the epact of the first day is to be added, one unit having first been taken away.

[Margin: How the new moons may be found from memory by the epacts, as they are noted in the new Calendar.]

More briefly, you will find the same day of the new moon if you subtract the current epact from the epact of the first day of the month; or, if the former is greater than the latter, from xxx, and then add the epact of the first day to the remainder. For the remaining number, or the number gathered together, with one unit first added, will give the day of the new moon. In those months, however, in which epact xxv, assigned to epact xxiiij, stands between the current epact and the epact of the first day, nothing is to be added to that remaining or combined number.

You will have the same day also if, from the epact set at the beginning of the month inclusive, you count on the joints in reverse order down to the current epact inclusive, assigning the two epacts xxv and xxiiij, likewise these two, 25 (of a different character or colour) and xxvj, to the same day where they occupy the same day in the Calendar. But the earlier methods are readier.

You can also, if you please — especially when the current epact is greater than the one set at the Calends of the proposed month, or much less — count on the joints from the epact of the last day of the month (which is the same, as we said, as that of the first day, February excepted) up to the current epact, assigning the two epacts xxiiij and xxv, likewise 25 and xxvj, to the same joint when they are assigned to the same day. For the number of joints you have run through, with one unit first taken away, subtracted from the number of days of the proposed month, will leave the day of the new moon — that is, the day to which the current epact is assigned.

Furthermore, when epact xix and golden number 19 concur, let the first new moon of the following year be in the month of December on the last day, as was said above; otherwise it would fall on the first day of January.

But let us illustrate the whole matter by examples. With epact x current, if in the month of November — which has at its beginning the epact xxj — you wish for the new moon, count from epact x inclusive, proceeding through xj, xij, and so on, up to xxj inclusive, and you will run through 12 joints. On the 12th day, then, the new moon is marked by epact x in the month of November. Or subtract 10 from xxj, and 11 remain; and with a unit added, they become 12 for the day of the new moon, as before. Or, from epact xxj inclusive, assigned to the Calends, go backward through xx, xix, and so on down to x on the joints, and you will run through 12 joints, as before. Or, finally, count on the joints from epact xxj

inclusive, set at the last day, in natural order down to x, proceeding through xxij, xxiiij, and so on, and assigning the epacts xxiiij and xxv to one and the same day. For you will run through 19 joints, which, if — one unit having first been taken away — you subtract from the 30 days of the month of November, the day 12 of November remains, on which the new moon will occur, as before.

Again, in the month of June, which has at the Calends the epact xxvij, count from epact x up to xxvij, assigning to one and the same joint the epacts xxiiij and xxv, and you will run through 17 joints. On the 17th day, then, the new moon is marked in June. Or subtract epact x from xxvij, and there will remain 17 days for the day of the new moon, as before; because here nothing is added, since epact xxv, assigned to epact xxiiij, is interposed in June between the proposed epact x and the epact xxvij set at the Calends. Or, from epact xxvij prefixed to the first day, count in reverse order on the joints, through xxv, xxiiij, and so on, up to epact x, assigning to one and the same joint the epacts xxv and xxiiij. For you will run through 17 joints, as before. Or, lastly, from epact xxvij placed at the last day of June, count on the joints in natural order down to x, proceeding through xxvij, xxix, *, i, ij. For you will run through 14 joints, which — one unit having first been taken away — if you subtract from the 30 days of the month of June, the day 17 of June remains, on which the new moon will occur, as before.

Again, with epact xxix current in June, 18 joints are run through (assigning the epacts xxiiij and xxv to one and the same joint), from epact xxix through *, i, ij, and so on, up to xxvij, which is the epact assigned to the Calends. Or, if epact xxix be subtracted from xxx and the epact xxvij of the first day be added to the remaining unit, 28 is made for the day of the new moon. For here no unit is added, on account of epact xxiiij assigned, which is placed between the current epact xxix and the epact xxvij of the first day. So too, if the counting be made from epact xxvij of the first day in reverse order, through xxvj, xxv, xxiiij, and so on, up to the proposed epact xxix (assigning the epacts xxv and xxiiij to one and the same joint), we shall run through 28 joints, as before. Finally, if you count from epact xxvij of the last day, through xxvij, xxix, *, and so on, up to the current epact xxix, 3 joints will be run through, which — one unit having first been taken away — subtracted from the 30 days of the month of June, leave 28 for the day of the new moon.

Once the day of the new moon is known, we shall easily detect the age of the Moon on any day, if from the day of the last past new moon inclusive we count the following days up to the proposed day inclusive. Thus, with epact x current, if the age of the Moon on the 3rd of July be desired: since the preceding new moon

occurred on the 17th of June, we shall count from the 17th of June inclusive up to the 3rd of July inclusive, and run through 17 joints. On the 3rd of July, then, which is the proposed day, the Moon will be xvij; and so of the rest.

[Margin: How the age of the Moon is detected.]

But by this method which we have set out, the days of the new moons and the age of the Moon are found according to the usage of the Church, which in this matter does not much trouble itself with the true motions — that is, as the epacts, arranged through the days of the Calendar, exhibit it — although for the most part the case stands otherwise in the heavens. We have adduced the reason for this in the exposition of the Calendar, Chapter 11, Number 5, and Chapter 18, Number 4.

Indeed, if you inquire into the age of the Moon on the last day of the preceding month, you will find on any day the age of the Moon by adding to the proposed day the age of the last day of the preceding month; and if the number gathered exceeds a whole lunation, that lunation is to be taken away, whether it be of 29 days or of 30. Thus, since with epact 1 current the age of the Moon...

[Margin: Which lunations in the Calendar are of 30 days, and which of 29.]

on the last day of November it is 10; if to the 22nd of December you add 10 and cast 29 out of the resulting 32 (for that lunation comprises 29 days), 22 December will be left as Moon 4. Likewise, if to 11 December you add 10, you will find that 11 December is Moon 21; and so on for the rest.

To recognize which lunations of the Epacts contain 30 days and which 29, you must fix carefully in memory those six places where two Epacts, 24 and 25, are assigned to the same day. The lunations beginning at Epact 30, which immediately precede the Epact 24 assigned to the same day as Epact 25 — that is, counting from 24, 23, 22, and the rest of the preceding month up to that 24 which is written against the same day as 25 — contain 29 days, in whatever month this occurs. The exception is the lunations of Epact 25 of a different colour, written against the same day as Epact 26: these do contain 30 days, just as all the other lunations comprise 30 days — except the lunations of that same Epact 25 of a different colour or character, when it is found opposite Epact 25. For these lunations contain only 29 days.

Finally, whenever between a given Epact (whose length of lunation is being sought) and its like in the following month there is interposed the Epact 25 written against the same day as 24, the lunation of the given Epact will contain 29

days — because in that case the like Epact of the following month has been advanced upward by one day out of its proper place. But if no Epact 25 written against the same day as 24 is interposed, the lunation of the given Epact will comprise 30 days. Again, Epact 25 occupying the same day as 24 will always have a lunation of 29 days, because the following month's Epact 25 has climbed one day in the Calendar. The same is to be said of the Epact 25 of a different character set opposite Epact 25: for the following Epact 25 of a different character has likewise been advanced upward by one day, opposite Epact 26. But the lunation of this Epact 25, so advanced (unlike the Epact 25 which occupies the same day as 24), always contains 30 days.

[Margin: What is to be done so that the Epact may be found beyond the year 8699.]

Since we set out above the twelve mnemonic verses for finding the Epacts up to the year 8699 inclusive, anyone wishing to go beyond that year must consult the table of the equation of the Epacts placed in Chapter 12 of the Exposition of the Calendar, and from its letters compose further verses whose words begin with those letters — just as the words of the twelve foregoing verses take their beginning from the letters of the equation table of Chapter 11. It was for this reason that we wrote the two words *krimen* and *kuspide* with a k, although this was done contrary to correct orthography.

[Margin: How, from any Epact, the Epact of the following year may be formed.]

Moreover, once the Epact of any given year has been found, the Epact of the following year is formed with ease: to the former add 11, and from the sum, if it is greater than 30, cast out 30; or, if it comes to exactly 30, take the sign * as the Epact. Only for the Epact of the year in which the golden number is 19 must 12 (not 11) be added, so as to compose the Epact of the following year, in which the golden number is 1. We gave the reason for this in the Exposition of the Calendar, Chapter 12, Numbers 12 and 13. Note, however, that when the Epact so composed comes out as 25, and the golden number of the year in which that Epact is in use is greater than 11, one must take the Epact 25 which is marked with a colour or character different from the others — as we also stated at the beginning of this chapter.

[Margin: How the true Epacts before the year of the correction are to be found.]

Now, if anyone wishes to find by memory the true Epacts from the year 1 of the Lord down to the year 1582 of the correction, the following must be observed. First, since before the correction the solar year was not equalized so as to keep

the equinox in its seat, the Moon had to be equalized every three-hundredth year — namely, after year 1 of Christ, in the year 300 (although in the equation table we wrote the year 320, as being nearer the Council of Nicaea). Then in the year 500, in the time of the Emperor Justinian or thereabouts, the Moon is not equalized, as I taught in the Exposition of the Calendar, Chapter 11, Number 7. After this, in the years 800, 1100, and 1400, the equation is made, as appears in the equation table. The letters assigned to those years in the equation table can be held in memory by this verse:

Nerua Potens Princeps animose bella ciebat.

For the first letters of these words (of which the first three are capitals and the last three lowercase) are those which in the equation table are affixed to the aforesaid years, so that the first word corresponds to year 1 of Christ, the second to 320, the third to 500, the fourth to 800, the fifth to 1100, and the sixth to 1400.

[Margin: How the numbers on the joints of the thumb — those to be added to the golden numbers so as to produce the Epact — are formed.]

Accordingly, whatever place any given letter occupies in the alphabet (starting from lowercase a, and omitting lowercase o together with the capitals I, K, L, O, in such a way that the lowercase letters do not go beyond u), that Epact — of that many units — runs in the expanded table together with golden number 3. If, then, 3 is subtracted from it (adding 30 first if the subtraction cannot be made), the remainder is the number to be added, at the root of the thumb, to the golden number, so as to form the Epact; at the middle of the thumb the number to be placed will be ten units less; and at the tip, again ten units less than at the middle — always adding 30 first when the ten units cannot be subtracted. For example: the capital letter N occupies place 19. Therefore, when the capital letter N is in use, Epact 29 runs with golden number 3, and so 26 must be added to golden number 3 to form Epact 29; at the middle of the thumb 16 must be added, and at the tip 6. Again, since lowercase b is the second letter of the alphabet, Epact 2 runs with golden number 3; so if 3 is taken from Epact 32, there remain 29, the number to be added at the root of the thumb to the golden number, so that the Epact answering to that golden number may be produced; at the middle of the thumb 19 must be added, and at the tip 9 — just as in this present century, before the correction, 10 was added at the tip, 20 at the middle, and 30 (or 0) at the root. By this device, once one knows which letter of the expanded table is in use, the numbers that must be added at the joints of the thumb to the golden numbers, in order to make the Epacts, are easily formed. Thus, since from the year 1582 to the year 1700 the capital letter D is in use, which occupies place 23, Epact 23 runs

with golden number 3; therefore at the root of the thumb, where the golden number 3 is placed, 20 must be added to golden number 3 to make Epact 23, and accordingly 10 must be added at the middle of the thumb and 0 at the tip.

Perhaps more easily, once the number to be added at the root of the thumb to the golden number (so as to make up the Epact) has been found, you will find the other numbers to be added at the tip and at the middle joint of the thumb by addition, in this way. Add 10 to the number that is to be added at the root of the thumb; thus you will have the number to be added at the extreme tip of the thumb. And if to this you again add 10, the number to be added at the middle of the thumb is produced. But 30 must always be cast out of the sum, if it comes out greater than 30.

[Margin: Finding the Martyrology letter.]

Lastly, so that the Martyrology letter may be found by memory for any year, the Epact of that year must first be found. For however many units that Epact contains, so many letters are counted from lowercase a, going through b, c, d, and so on — yet in such a way that lowercase o is omitted, together with the capitals I, K, L, O, and the lowercase letters do not go beyond u, as was said a little before. For the last of these letters is the one that will indicate the Moon's age in the Martyrology for that year. Therefore, whichever letter is the last, that is the Martyrology letter: thus, when the Epact is 1, the Martyrology letter will be capital A [?]; when the Epact is 19, the Martyrology letter will be capital P; and so on.

[Margin: Which Epact is prefixed to any given day of the month.]

Furthermore, those five letters — lowercase o, and the capitals I, K, L, O — which are omitted, will cling in memory by this little verse:

Ornabit Iustos Kv[?] Laudabilis Omnes.

For the first letters of these words (whichever are to be omitted) are those to be dropped in favour of the capitals.

For a fuller understanding of the Epacts, the following points seem to call for explanation. First, just as we gave a rule for recognizing to which day of a given month the current Epact is prefixed, so, conversely, a rule must be given for recognizing which Epact is prefixed to any given day of the month — and it is this. Let the given day be subtracted from the Epact written against the calends of the month (adding 30 first if the subtraction cannot be made); to the remainder add 1, if between the given day and the first Epact of the month there does not

fall an Epact 24. The number so produced will be the Epact assigned to the proposed day. For example, if the 23rd of August is proposed, to whose calends Epact 27 is prefixed: taking 23 from 30 leaves a remainder of 7; the first Epact 24 being associated with Epact 25, there will remain 2 as the Epact prefixed to 23 August. (Here 1 is not added, because the first Epact of the month is 25, associated with Epact 24.) Again, let the 23rd of December be proposed. Since 23 cannot be taken from the first Epact of December, 20, we take 23 from 30, and to the remainder 7 we add the first Epact 20, together with 1 — because between the 23rd and that first Epact 20 there is no Epact 25 written against Epact 24; and so we make Epact 28 the one set against 23 December. And so on for the rest. Thus one must first have ascertained on which days the two Epacts 25 and 24 are prefixed together: these are 5 February, 5 April, 3 June, 1 August, 29 September, and 27 November.

[Margin: How the Moon's age may be found by another method.]

Once the Epact prefixed to a given day is known, we shall by its help recognize the Moon's age on that same day, if we subtract it from the current Epact (adding 30 first if the subtraction cannot be made) and add a further 1 to the remainder — provided that an Epact 25 occupying the same day as 24 does not fall between the Epact of the proposed day and the current Epact which precedes the proposed one (not, however, the one that follows it). For example, with the current Epact 7, if the Moon's age is sought for 27 August, to which Epact 28 is prefixed: since 28 cannot be taken from 7, we take it from 30, and to the remainder 2 we add Epact 7, and a further 1 — because between 28 and 7 no Epact 25 together with 24 is found — and the Moon's age comes out as 10 days. And so on for the rest.

[Margin: Another way of finding the Epact.]

Next, we shall give another most convenient rule for finding the Epact, provided we first know which letter of the expanded table corresponds to the proposed century. This the 70 words of the twelve foregoing verses will supply, for each word corresponds to a single century, beginning from 1700 — so that the word [regitque], which occupies place 16, is to be assigned to the year 3300, and so on for the rest. The initial letters of the earlier words, down to a, are lowercase; the rest, again, are capitals. Now each letter presents the Epact that runs in the proposed century with golden number 3, of as many units as the place the letter itself occupies in the alphabet: thus the letter D gives 23, and so on. If, then, to the Epact due to the letter — which serves the golden numbers that three measures — one adds [multiples of 11], the Epacts due to the golden numbers that three measures are obtained. But if from any such Epact the subtraction cannot be

made, the remainder (after adding 30) will be the Epact of the preceding golden number; while if 11 is added, the Epact answering to the following golden number is produced — casting out 30 whenever the sum is greater than 30.

[Margin: A general rule.]

Example. To the year 3300 corresponds the lowercase letter r, on account of the word [regitque], which occupies place 16. Therefore in that century Epact 16 runs with golden number 3, Epact 19 with 6, and Epact 22 with 9 [?]; with golden number 8 runs Epact 11, and with golden number 10 Epact 33, that is 3 (or the sign *); and so on. Accordingly, when the given golden number is measured by three, its Epact is produced by continuous addition of 11 to the Epact running with golden number 3. But when the given golden number is not measured by three, the Epact of the nearest golden number — greater or lesser — that three does measure is first found, and from it 11 is to be subtracted or added, so that the Epact of the proposed golden number may be drawn out. For instance, if in the same century the Epact of golden number 19 is sought: since the Epact of golden number 18 is 1, adding 11 gives Epact 12 for golden number 19. Likewise, to obtain the Epact of golden number 1, twice 11 must be subtracted from the Epact of golden number 3, [giving Epact 24;] and for the Epact of golden number 2, 11 must be subtracted from the Epact of golden number 3, [giving] Epact 5, which agrees with golden number 2.

CAPVT III.

De Cyclo Solari, siue literarum Dominicalium 28. annorum.

On the Solar Cycle, that is, of the Dominical Letters, of 28 years.

[Margin: What the Solar Cycle is.]

The Solar Cycle, or cycle of the Dominical Letters, is a revolution of 28 years, for the reason that after 28 years the Dominical Letters return in the same order. This cycle of 28 years is produced by the multiplication of 7 by 4: since there are seven Dominical Letters, on account of the seven days of the week, and every fourth year one day is intercalated, so that the order of the seven letters is then interrupted. We shall therefore investigate the Solar Cycle of any year in the following way.

[Margin: The placing of the hundred-years on the joints of the fingers, for finding the Solar Cycle.]

On the three joints of the left thumb, and on the four inner roots of the four fingers, the hundred-years from the birth of Christ our Lord are to be placed, in this way. At the tip of the thumb is set year 0; on the middle inner joint, year 100; on the root, 200. On the root of the index, 300; on the root of the middle finger, 400; on the root of the ring finger, 500; on the middle joint [of the little finger?], year 600; and so on in succession, always returning, after the root of the little finger, to the tip of the thumb.

But so that we are not forced to run through those seven joints so many times, we shall find the seat of any hundred-year, however large, in this way. From the number of hundreds cast out all the 7's, as is customarily done in the check by sevens among the arithmeticians, and to the remainder add 1. The number so produced will give the joint of the proposed hundred-year. Thus, if the year 45600 is given, casting out the 7's from the number of hundreds, 456, leaves 1; 1 added makes 2; therefore the year 45600 will be placed on the 2nd joint, that is, at the middle of the thumb. So too, if the year 1300 is given, casting out the 7's from the number of hundreds, 13, leaves 6; 6 added makes 7; therefore the year 1300 will be placed on the 7th joint, that is, on the root of the little finger. And so on for the rest.

[Margin: The placing of the Solar Cycle on the joints of the fingers.]

Next, since in the year immediately before the birth of Christ the number of the Solar Cycle was 9, this number 9 is to be placed at the tip of the thumb, where year 0 of the Lord was set — that is, the year immediately preceding the birth of Christ. And since the Solar Cycle of 28 years is contained three times in 100 years, with 16 left over, if to the 9 placed at the tip of the thumb one adds 16, the result is 25, to be placed as the number of the Solar Cycle at the middle joint of the thumb; this belongs to the year 100 after Christ, and to all the other hundred-years that fall on that joint. If again to 25 one adds 16, the result is 41; casting out 28 (for that is the number of years in the Solar Cycle) leaves 13, to be set as the cycle on the root of the thumb. By the same reasoning, if to 13 one adds 16, the result is 29; casting out 28 leaves 1, to be set as the cycle on the root of the index. And if to 1 one again adds 16, the result is 17, to be placed as the cycle on the root of the middle finger. To this, if 16 is again added, the result is 33; casting out 28 leaves 5, to be set as the cycle on the root of the ring finger. Finally, if to 5 one joins 16, the result is 21, to be placed as the cycle on the root of the little finger. No further placement is needed, since the same numbers already placed return again in the same order. For if to 21 — the number we set on the root of the little finger — 16 is added, the result is 37; casting out 28 leaves 9, for the cycle already

long since set at the tip of the thumb; and so on. And these seven numbers, set on those seven joints, answer to all the hundred-years that, by the arrangement above, fall on those seven joints.

If this seems too laborious — to arrange the Solar Cycle on those seven joints by adding 16 and casting out 28 — we shall place it more easily by adding four, on alternate joints, in this order. To the 9 that is set at the top of the thumb, add 4, making 13, for the cycle to be located on the root of the same finger (the middle joint being skipped); this indeed belongs to the year 200, set on that same root. For in 200 years the Solar Cycle of 28 years is contained seven times, with 4 left over. And if to 13 one adds 4, [the result is 17,] for the cycle to be set on the root of the middle finger (the index being skipped), where year 400 is placed. Likewise, if to 17 one adds 4, the result is 21, for the cycle to be set on the root of the little finger (the ring finger being passed over), where year 600 is placed. And if 4 is again added to 21, the result is 25, to be placed on the middle joint of the thumb (the ring finger being passed by), where year 800 is set. If to 25 one again adds 4, the result is 29; casting out 28 leaves 1, for the cycle of the root of the index (the lowest joint of the thumb being left aside), where year 1000 is set. And finally, if to 1 one adds 4, the result is 5, for the cycle of the root of the ring finger (the middle finger being passed over), where we placed year 1200. You see, then, that by adding 4 the same numbers are placed on the same joints, though in alternating order, always leaving one joint in the middle.

[Margin: Finding the Solar Cycle.]

Now, from these things the number of the Solar Cycle of any year will readily be elicited. For if some hundred-year is given, its seat must be found among those seven joints we have spoken of, together with the number of the Solar Cycle placed there. But if any arbitrary year is given, the Solar Cycle of the most recently elapsed hundred-year must be found, as we have already taught. Then, since with each single year the Solar Cycle increases by a single unit, as many units must be added to the Solar Cycle of that hundred-year as the given year is after that hundred-year. In this way the Solar Cycle of the proposed year is composed. But if the composed number comes out greater than 28, 28 must be cast out as often as it can be cast out; the remaining number will be the Solar Cycle sought. And if there remain 28 or 0, the Solar Cycle will be 28.

Now you will easily cast out 28 from any number, however large, if you throw out 30 and, for each such casting-out, take back two units, which were of course cast out along with the 28.

You will also do rightly if you first, in the way we have said, cast out 28 from the number of the nearest preceding [hundred-year], if they can be cast out, and add the remaining number to the Solar Cycle of that hundred-year, so as to make up the Solar Cycle of the proposed year.

For example. Suppose the Solar Cycle is sought for the year 1598. Since the seat of the year 1500 is at the middle joint of the thumb, where the number of the Solar Cycle 25 is placed, the Solar Cycle of that hundred-year will be 25. And since from the 98 years given beyond 1500, 30 can be cast out three times, we shall add three times two — that is, six units — to the 8 remaining years, and add the resulting number 14 to the Solar Cycle 25 found; then from the collected number 39 we shall again cast out 30, and for this casting-out add two units back to the remaining number 9, so as to establish 11 as the Solar Cycle of the year 1598. And the same procedure is to be observed in the rest.

[Margin: Finding the Solar Cycle by the precepts of arithmetic.]

The Solar Cycle of any year will also be found by the precepts of arithmetic, in this way. To the years of the Lord add 9, and divide the collected number by 28. The number remaining from the division (taking no account of the quotient, since it merely shows the elapsed revolutions of the Solar Cycle) will be the Solar Cycle of the proposed year. And if nothing is left over from the division, the cycle will be 28. Thus, if the Solar Cycle of the year 1589 is sought, and the collected number 1598 is divided by 28: the division being exact, the remaining number will be 2, for the Solar Cycle of the year 1589. Again, if the Solar Cycle of the year 10967 is wanted: adding 9 to 10967 gives the number 10976; dividing this by 28 leaves 0; therefore the Solar Cycle of that year will be 28. And so on for the rest.

CHAPTER IV. On the Dominical Letter.

**

CAPVT IIII. De litera Dominicali.

Although we do not need the Solar cycle in order to find the Dominical letter of any given year — since we can locate it much more easily without the Solar cycle, as we shall show shortly — nevertheless, so that the method the Church has observed up to now for finding the Dominical letter may be retained in some form, we shall first set out the way in which the Dominical letter of any year is found once the Solar cycle has been determined. (We have in fact made that method somewhat more convenient too, as will be clear if one compares our

procedure with the one the computists handed down before the reform of the year.) We shall carry the matter out as follows.

On the inner roots of the fingers of the left hand (leaving the thumb aside) these five letters are to be placed — C, D, E, F, G — from which the Dominical letter of any year will be found by means of the Solar cycle, in this way. On the root of the little finger is set C; on the root of the ring finger, D; on the root of the middle finger, E; and on the root of the forefinger two letters, F and G, on account of the leap years, which all fall on the joints of the forefinger, as will become clear. These five letters are contained in the following verse line:

Cordati Daud Extinxit Funda Gigantem.

For if you assign the first word, *Cordati*, to the little finger, the second, *Daud*, to the ring finger, the third, *Extinxit*, to the middle finger, and finally the last two, *Funda Gigantem*, to the forefinger, the first letters of those words will give the very letters we said were to be placed on the roots of the fingers.

[Margin: The placing of the five letters on the left hand, for investigating the Dominical letter from the Solar cycle.]

Next, once the Dominical letter is to be found for any proposed year, seek the Solar cycle of that year and count it out over the 28 joints of those four fingers we have named, in this order. The first year of the cycle is assigned to the inner root of the forefinger, the second to the root of the middle finger, the third to the root of the ring finger, the fourth to the root of the little finger, the fifth to the second inner joint of the forefinger; and so on across, yet in such a way that you assign four years of the cycle to the four fingertips as well. By this reckoning the 28th year falls on the outer root of the little finger. Now any year whose Solar cycle falls on the forefinger is a leap year, whereas all the other years, whose Solar cycles fall on the other three fingers, are common years. The joint on which the found cycle-number falls must be carefully noted, for it is there that the Dominical letter is found, both before the reform of the calendar and after. Before the reform, in this way.

[Margin: The placing of the Solar cycle over the 28 joints, for finding the Dominical letter.]

On the finger on which the Solar cycle falls, count following the natural series of the Dominical letters (which are these seven: A, B, C, D, E, F, G), beginning from the letter that, by the first rule of this chapter, falls on the inner root of that same finger, running through the joints — or knuckles — together with the segments

between the joints, and assigning a single letter to each segment and each knuckle alike, then returning after G to A, until you reach the joint of the proposed Solar cycle. For the letter falling on that joint will be the Dominical letter for that year. On the forefinger, however, the intervening segments are to be passed over and two letters assigned to each joint, because the leap years are placed there, to which two letters correspond: of these the latter will indicate the Lord's Day from the beginning of the year up to the feast of St. Matthias, and the former from that feast to the end of the year. And in this way the Dominical letter of any year before the restitution of the year is found.

[Margin: The finding of the Dominical letter from the cycle, before the reform of the year.]

After the reform of the calendar, the Dominical letter is found thus. First, the Dominical letter must be sought exactly as if the calendar had not yet been reformed, by the method we have just handed down. Then, starting exclusively from the letter found, one must count off as many further letters, following the order of the alphabet, as there are surplus units left over when the number seven — the days of one week — is cast out as many times as it can be from the number of days that, up to the beginning of the year's day, have been dropped from the year. That number of days will be learned without much trouble from the following chapter 5. This must be done in such a way that, both in any leap years and in the centennial years that are not leap years — that is, in which the intercalary day is omitted — the counting of the letters is always made from the latter of the letters found. For the last letter of this count will be the Dominical letter after the reform of the calendar, if the year is common; but if it is a leap year, that last letter together with the one immediately preceding it will be the Dominical letters. In centennial years that are not leap years, only the last letter of that count is Dominical, so that with it the immediately preceding letter is not to be taken, as we said must be done in leap years.

[Margin: The finding of the Dominical letter from the cycle, after the reform of the year.]

Let us illustrate the matter with examples. Suppose the Dominical letter of the year 1522 is to be found. The Solar cycle in that year was 19, which falls on the fifth joint of the ring finger — the outer one, nearest the nail; and therefore that year is common, since its cycle does not fall on the forefinger. If, then, starting from the letter D, which is placed on the root of the ring finger, you advance through the natural series of the letters — putting E on the next segment, F on the

second joint, and so on — the letter E will fall on that fifth joint; and therefore E was the Dominical letter for the year 1522.

Likewise, suppose the Dominical letter of the year 1520 is to be sought. The Solar cycle of that year was 17, which falls on the fifth joint of the forefinger, namely the outer one under the nail; and hence the year was a leap year, because its cycle falls on the forefinger. If, then, starting from the letters F, G, which are placed on the root of the forefinger, you count the Dominical letters in alphabetical order — putting the pair A, B on the second joint, the pair C, D on the third, and so on — the pair G, A will fall on that fifth joint; and these were therefore the Dominical letters for the year 1520.

Again, suppose the Dominical letter of the year 1594 is to be inquired. The Solar cycle of that year is 7, which falls on the second inner joint of the ring finger; and therefore that year is common. If, then, starting from the letter D, which is placed on the root of that same finger, you count the Dominical letters through the alphabetical series — putting E on the next segment — F will fall on the second joint, where the Solar cycle 7 is placed; and this would be the Dominical letter, had the reform of the calendar not removed ten days. Therefore, since after casting 7 out of the 10 removed days there remain 3, if after F you run through three more letters — G, A, B — then B will be the Dominical letter for the year 1594.

In the year 1604 too the Dominical letter is found thus. The Solar cycle is 17, which falls on the fifth joint of the forefinger, namely the outer one nearest the nail, on which fall the pair of letters G, A, which would be the Dominical letters

**

— were it not that 10 days had been removed. If, then, you count from the latter letter A three more letters, B, C, D, and with the last, D, you also take the preceding letter C — because the given year is a leap year, since its cycle falls on the forefinger — the Dominical letters will be C, D.

Likewise, suppose the year 1813 is given. The Solar cycle is 2, which falls on the root of the middle finger, where the letter E is placed. But because by then 12 days will have been removed, after E these five letters — F, G, A, B, C — must be counted, since, casting 7 out of 12, five remain. Therefore the Dominical letter then will be C.

Lastly, you will seek the Dominical letter for the year 1800, which is not a leap year, in this way. The Solar cycle is 17, which we said falls on the fifth joint of the

forefinger, where the pair of letters G, A are placed. And since up to the beginning of the year 1800 eleven days will have been removed — for on the feast of St. Matthias the twelfth day will first be removed, since the intercalary day is then omitted — we shall count after A four more letters, B, C, D, E, because, casting 7 out of 11, four remain. Therefore E alone will then be the Dominical letter, since the year 1800 is common — that is, it is passed without an intercalary day — and therefore the immediately preceding letter D is not to be taken, as we prescribed must be done in leap years.

But we shall find the Dominical letter far more easily, both before and after the reform of the calendar, taking no account whatever of the Solar cycle that corresponds to the proposed year, and using only seven joints of the left hand: of these let the first be at the tip of the thumb, the second at its middle, the third at its base, the fourth at the root of the forefinger, the fifth at the root of the middle finger, the sixth at the root of the ring finger, and the seventh at the root of the little finger. First, then, before the reform of the calendar, the centennial years are to be distributed over those seven joints of which we have just spoken. On the tip of the thumb is set the year 100; on its root, the year 200; on the root of the forefinger, the year 300; on the root of the middle finger, the year 400; on the root of the ring finger, the year 500; on the root of the little finger, the year 600. Then again, on the tip of the thumb, the year 700, and so on — as was said in Chapter 3 concerning the Solar cycle — until you reach the year 1500, which falls on the middle joint of the thumb. For the remaining centennial years that follow are now after the reform of the year, and therefore require a different arrangement, as we shall say shortly.

[Margin: The placing of the centennial years over the 7 joints, for finding the Dominical letter without the cycle, before the reform.]

Next, on those same 7 joints are to be counted all the years after any given centennial — those they call the *expanded* years — in this order. On the tip of the thumb is set the year 1; on the middle joint, the year 2; on the base, the year 3; on the root of the forefinger and of the middle finger alike, the year 4 (4, 4), because the fourth year is a leap year and therefore requires two letters. On the root of the ring finger, the year 5; on the root of the little finger, the year 6. Then, returning to the thumb, on its tip is placed the year 7; on its middle and its root, the year 8 (8, 8), because the eighth year too is a leap year. On the root of the forefinger, the year 9; on the root of the middle finger, the year 10; on the root of the ring finger, the year 11; on the root of the little finger and the tip of the thumb, the year 12 (12, 12), because the twelfth year too is a leap year. And so on:

all 100 expanded years will be arranged in order on those 7 joints — provided you remember to place on two joints the twofold numbers of the leap years, such as the years 4, 8, 12, 16, 20, 24, 28, 32, 36, 40, and all the rest that the number four measures, which are indeed to be assigned to two joints; thus: 4·4, 8·8, 12·12, 16·16, 20·20, &c.

But since it would be long and difficult to count out by this device all the expanded years up to the proposed year after a given centennial — especially if the given year is not far from the following centennial — we shall use the very device we employed above in Chapter 3, which was of this kind. Casting 30 out of the number of the year given after the centennial, as often as it can be done, and taking back two units for each casting-out, we shall add these units to the remaining years — those, that is, that are left over after casting out 30 — and the resulting sum, which is never greater than 28 (for if it should ever be greater, 28 is to be cast out), we shall reckon out over those 7 joints of the left hand, beginning from the tip of the thumb, the leap-year numbers (say 4, 8, 12, &c.) being always assigned to two joints, as we said above. For example, suppose the year given after some centennial is 85: since 30 can be cast out twice, we shall take back 4 units — that is, twice two — and add them to the remaining 25 years that are left after casting 30 out of 85 twice; then, casting out 28, we shall reckon out the resulting number — that is, the number of the Dominical cycle — arriving where the seat of the year 85 always is.

Again, since it is also troublesome to run through the individual years up to 28 over those 7 joints, one can easily, in that counting, avoid carelessly assigning to two joints the same twofold numbers of the leap years, by using this shortcut. The years taken four at a time — namely 4, 8, 12, 16, 20, 24, 28 — are assigned to two joints in continuous order, but beginning from the middle finger and the forefinger, through the root and middle joint of the thumb, then through the tip of the thumb and the root of the little finger, and likewise through the roots of the ring finger and the middle finger, and so proceeding onward toward the thumb — that is, in the order opposite to the counting we prescribed for the expanded years. For the counting of the expanded years, beginning from the top of the thumb, proceeds through its middle and so on toward the little finger, whereas the years-by-fours proceed in the opposite order, through the two joints of the middle finger and forefinger and on toward the thumb, the beginning being taken from the roots of the middle finger and forefinger and proceeding toward the thumb.

This numbering of the years-by-fours is easily done thus. Placing the tip of the right forefinger on the root of the left forefinger [?], and the tip of the right middle finger on the root of the left middle finger, we set there 4·4. Then, placing the tip of the right middle finger on the root of the left thumb, and the tip of the right forefinger on the middle of the left thumb, we shall locate there 8·8. Again, placing the tip of the right forefinger on the root of the left little finger, and the tip of the right middle finger on the tip of the left thumb [?], and the tip of the right middle finger on the root of the left ring finger [?], we shall place on these two joints 12·12. After this, placing the tip of the right middle finger on the root of the left middle finger, and the tip of the right forefinger on the root of the left thumb, we shall set on these two roots 16·16. Likewise, placing the tip of the right middle finger on the root of the left forefinger, and the tip of the right forefinger on the root of the left thumb, we shall place on these two roots

**

20·20. Moreover, placing the tip of the right middle finger on the middle of the left thumb, and the tip of the right forefinger on the tip of the left thumb, we shall set there 24·24. Finally, placing the tip of the middle finger of the right hand on the root of the little finger of the left hand, and the tip of the right forefinger on the root of the ring finger of the left hand, we shall set on these two roots 28·28. And in this way all the numbers of the leap years will be placed in their proper seats — namely on those joints on which they fell by the earlier counting.

But if the given year is some non-leap year among the expanded years, we shall seek its seat on those same 7 joints in this way. Having found the seat of the immediately preceding leap year, by the device we have described, we shall assign the first year after that leap year — that is, the one that follows next in order after the leap year whose seat has been found — to the joint that follows next in the numbering of the expanded years we have just been using; likewise the second year after the same leap year to the next following joint — in the order, that is, opposite to the one we used in the placing of the years-by-fours. For instance, suppose the given year is 19: we shall first find the seat of the year 16 (the leap year immediately preceding the year 19), on the roots of the ring finger and the middle finger. We shall assign the year 17 (the first after that same leap year 16) to the root of the little finger, the year 18 (the second after that same leap year 16) to the tip of the thumb, and the year 19 (the third from the same leap year 16) to the middle joint of the thumb. And so you will say that the seat of the year 19 is on the middle of the thumb. Likewise, suppose the given year is 14: we shall first find the seat of the year 12 (the leap year immediately preceding), on

the tip of the thumb and the root of the little finger; then the year 13, which is the first after the leap year 12, we shall assign to the middle of the thumb, and the year 14, the second from the same leap year 12, to the root of that same thumb; and there we shall say is the seat of the year 14. And so with the rest.

But we shall also proceed very conveniently in this way in finding the seats of the 28 expanded years. As many times as the number four is contained in the given number of expanded years — the cycle of 28 years having first been cast out, if that can be done — so many units are to be added to that same number of years. For if we reckon the collected number out over those 7 joints, beginning from the tip of the thumb and going through its middle, its root, and so on, with no number assigned to two joints, the counting will end on the joint that is the seat of the given year: yet in such a way that in a leap year the joint found is the latter of the two owed to that year, and that therefore the joint immediately preceding must be assigned to it as well, proceeding toward the tip of the thumb, and from that (if the joint should happen to be the tip of the thumb) proceeding toward the root of the little finger. For example, take the year 27. Since the number four is contained in 27 six times, we shall add 6, and thus we shall briefly reckon the sum, 33. Casting out 7 as often as it can be done, we shall count the remaining 5 units, beginning from the top of the thumb; and the fifth unit will fall on the root of the middle finger. There, then, is the seat of the year 27. Likewise, suppose the given year after some centennial is 76: casting out 30 twice, we shall add to the remaining number 16 twice two units — that is, 4 — so as to complete the number 20. And since 4 is contained in 20 five times, we shall add 5 to 20 to make 25; and this composite number, 25, we shall reckon out as before — that is, casting out 7 as often as it can be done, we shall count the remaining 4 units over the joints, the beginning being taken from the tip of the thumb, and the last unit will fall on the root of the forefinger. Therefore the year 20, since it is a leap year, will have its seat on the roots of the forefinger and the thumb. For to the root of the forefinger the preceding joint must also be joined, namely the root of the thumb, on account of the leap year, as has been said.

With these things established, we shall investigate the Dominical letter before the restitution of the year as follows. Having found, on those 7 joints, the seat of the centennial year that immediately precedes the proposed year — as we taught just above — we place the letter B on that seat. Then, having also noted the joint that is the seat of the proposed expanded year after the given centennial, we proceed from the letter B, which we placed on the seat of the proposed centennial, in the natural order of the letters — through C, D, E, F, G, A — toward the tip of the thumb, and from there we go on to the root of the little finger, then to the root of

the ring finger, and so on, until we come to the joint that is the seat of the year given after that centennial. For the letter falling on that joint will be the Dominical letter for that year — a single letter, if the year is common; but if it is a leap year, a double one, two letters namely falling on the two joints assigned to the leap year, of which the latter in the alphabet (that is, the one that occurs later in the count made over the joints) will indicate the Lord's Day in the earlier part of the year up to the feast of St. Matthias, and the former in the later part of the year.

But if the Dominical letter is to be inquired for some centennial year itself, one must count from the letter B, which we placed on the seat of that centennial, in the same natural order — through C, D, E, F, G, A — toward the tip of the thumb, as far as the roots of the little finger and the ring finger. For the letters falling on these roots will be the Dominical letters for that leap-year centennial. For since, after the roots of the ring finger and the little finger, the counting of the expanded years passes at once to the top of the thumb, where the first of the expanded years is placed — so that the year following the centennial, by the counting of the letters from B (which is placed on the seat of that same centennial), is Dominical — it necessarily follows that the Dominical letters for the year after that centennial are those two that follow next, by that same natural-order counting of the letters, onto the roots of the little finger and the ring finger. These two roots, in the counting of the letters, follow next after the tip of the thumb in the natural series; but in the counting of the expanded years they immediately precede that same tip of the thumb. We see this happen with other years as well. For if, for example, the Dominical letter of some year falls on the root of the middle finger, the Dominical letter of the immediately preceding year must fall on the root of the forefinger — a root that, in the natural-order counting of the letters, follows next after the root of the middle finger, but in the counting of the expanded years precedes that same root of the middle finger. [Margin: The easiest finding of the Dominical letter before the reform, without the Solar cycle.] [Margin: Onto which joints the Dominical letters of the centennial leap years fall.] These things, then, are clear.

For example, let the Dominical letter be found for the year 400 after Christ's birth. Since this year has its seat on the root of the middle finger, we shall place there the letter B; and so, by the natural order, [we proceed,] with the letter C placed on the root of the forefinger, the letter D on the root of the thumb, [and so on,] until we reach the roots of the little finger and the ring finger, where we said the Dominical letters of the centennial years are to be found — where the letters G, A

fall, of which the latter, A, was Dominical in the earlier part of the year, and the former, G, in the later part.

Likewise, suppose the Dominical letter of the year 1580 is to be sought. The seat of the year 1500 is on the middle of the thumb; there, then, we shall place the letter B. And since the year 80 — that is (casting out the cycles of 28 years) the year 24 — is a leap year, and falls on the middle and the tip of the thumb, we shall count from the letter B, placed on the middle of the thumb, as far as the tip of the thumb,

the thumb, which, together with the middle of the thumb, is the seat of the proposed year; and the letter C will fall on this extremity. Therefore, since the letter B is set at the middle of the thumb, the letters B and C were the Dominical letters in the bissextile year 1580 — of which the latter, C, was in use at the beginning of the year, and the former, B, after the feast of St. Matthias [S. Matthiæ].

Finally, suppose the Dominical letter is to be investigated for the year 1347. The seat of the year 1300 is at the base of the little finger. There, then, the letter B must be fixed; and if from it we count up to the middle of the thumb, where the year 47 is placed — that is (casting out the cycle of 28 years) the year 19 — we shall find there the Dominical letter G, which indicated the Sunday for the year 1347.

[Margin: The placing of the centennial years on the 7 joints, for finding the Dominical letter without the Cycle, after the correction. (*Collocatio annorum centesimorum in 7. articulis, ad inueniendam literam Dominicalem sine Cyclo post correctionem.*)]

In exactly the same way we shall find the Dominical letter after the correction of the calendar — provided only that we arrange the centennial years after the reformed year, together with the letter B which always accompanies those years, differently on the thumb and on the bases of the fingers of the left hand. For the seats of the expanded years [anni expansi] remain exactly the same.

The placing of the centennial years after the restored calendar is as follows. On the top of the thumb are set all the centennial years that are first after the centennial bissextiles. On the lower part of the same thumb (skipping the middle joint) are placed all the centennial years second after the centennial bissextiles. At the base of the middle finger (also omitting the base of the index finger) are put all the centennial years third after the bissextiles. Finally, on the base nearest the ring finger have their seat all the centennial bissextile years.

Here you see that the seat of the centennial years on the top of the thumb — those first after the bissextiles — follows the seat of the centennial bissextiles (which is at the base of the ring finger) not immediately, but with the base of the little finger left empty; just as the other non-bissextile centennials likewise do not follow one another immediately, but always with one joint skipped. Only the seat of the centennial bissextiles follows immediately upon the seat of the centennials that are third after the bissextiles, with no empty joint left between. Therefore, once it is known whether the proposed centennial is bissextile, or first, second, or third after the bissextile, there will be no need to run through all the joints repeatedly, as had to be done for the centennials before the correction of the calendar; rather its seat among the four enumerated joints will be at hand at once.

In what way we can easily distinguish the bissextile centennial years from the non-bissextile ones, we shall show in the following chapter. Meanwhile, since the year 1600 is bissextile, its seat will be at the base of the ring finger; and consequently the year 1500 (as far as concerns the expanded years after the correction), which immediately precedes it, will be like some centennial third after the bissextile, since the next following centennial year — namely 1600 — is bissextile. Therefore the year 1500 (as regards the expanded years after the restoration of the year) has its seat at the base of the middle finger. But the year 1700, first after the bissextile, will be placed on the top of the thumb; the year 1800, second after the bissextile, at the base of the thumb; the year 1900, third after the bissextile, at the base of the middle finger; then the year 2000, being bissextile, will again have its seat at the ring finger; and the year 2100 at the extremity of the thumb. And so, in succession, you will place the other following centennials on the same joints, always leaving one joint empty — except for the bases of the middle finger and the ring finger, between which no joint is left empty.

[Margin: The finding of the Dominical letter without the Cycle, after the correction, is also by far the easiest. (*Inuentio literæ Dominicalis sine Cyclo, post correctionem, longe etiam facillima.*)]

Therefore, if after the correction the seat of the proposed centennial year is found together with the letter B, and the joint is noted on which the year given after that centennial falls — and if from that letter B, toward the extremity of the thumb, and thence toward the little finger and ring finger, the following letters are run through in their proper order until one reaches the joint of the year proposed after the centennial — then in that joint the Dominical letter will be found, just as

before the restoration of the year. But if the Dominical letter of some centennial year is sought, one must count from the letter B placed in the location of that centennial, through the following letters, up to the bases of the little finger and of the ring finger. For there the Dominical letter will be found, as before the correction: double, indeed, in each base, if the given centennial is bissextile; but single, in the base of the little finger alone, if it was a common year.

For example: suppose the Dominical letter of the year 1590 is to be sought. Since after the correction it has its seat at the base of the middle finger — as do all the other centennials that are third after the centennial bissextiles (for the following centennial, 1600, is bissextile, and therefore has its seat at the base of the ring finger, which, as we said, is immediately preceded by the seat of the centennials that are third after the bissextiles) — we shall place the letter B on that same base of the middle finger. Then, because 30 is contained three times in the 90 years given after the centennial, with nothing left over, we shall take three times two units, that is, 6; and if we count these off across the seven joints of the left hand of which we spoke, beginning from the extremity of the thumb — yet in such a way that we assign 4 and 4 to the bases of the index finger and of the middle finger — the sixth unit will fall on the base of the little finger. This is also clear from the shortcut given above. For if we place 4 and 4 at the bases of the middle and index fingers, and 5 at the base of the little finger — then if, from the letter B set at the base of the middle finger (where the seat of the year 1500 is), we count the Dominical letters according to the order of the alphabet, advancing toward the thumb, we shall find at the base of the little finger, that is, at the seat of the expanded year 90, the letter G, which was the Dominical letter for the year 1590.

Again, let the year 1800 be proposed, which has its seat, together with the letter B, at the base of the thumb. But since the year 1800 is not bissextile, its Dominical letter must be found at the base of the little finger, as was said. If, then, we count from the letter B placed together with the year 1800 at the base of the thumb, the other letters in their natural order toward the extremity of the thumb, up to the base of the little finger, we shall find that the letter E is Dominical for the year 1800.

Likewise, suppose the year 2000 is given, which has its seat together with the letter B at the base of the ring finger, since it is bissextile (being the fourth after the bissextile 1600); and consequently its Dominical letters are to be found at the bases of the ring finger and the little finger. If, then, we reckon from the letter B placed at the base of the ring finger (where the year 2000 is), the other letters in natural sequence toward the thumb, we shall find at the bases of the little finger

and ring finger the letters A and B, which will be Dominical for the year 2000. But since the letter B is placed at the ring finger, it is clear that the letter A stands before it, at the little finger. Therefore, since the year 2000 is bissextile, it is established, without any further counting, that A and B are the Dominical letters in any bissextile centennial year.

Next let the year 2143 be proposed. Since the year 2100 is placed at the extremity of the thumb together with the letter B (being the first centennial after the bissextile 2000), and the year 43 — that is (casting out 28) the year 15 — falls on the base of the index finger: if we count from the letter B placed on the thumb-tip together with the year 2100, the other letters in alphabetical order, passing at once from the top of the thumb to the little finger, and thence to the ring finger and to the index finger, we shall meet there the Dominical letter F, for the year 2143.

Finally, let the year 4752 be given. Since the year 4700, third after the bissextile, has its seat with the letter B at the base of the middle finger, and the expanded year 52 — that is (casting out 28) the year 24, a bissextile — falls on the middle of the thumb and its extremity: we shall find in these joints (if the counting of the letters is begun from the letter B placed at the base of the middle finger, where the year is 4700) the Dominical letters E and F, for the given year 4752.

CAPUT V.

De Annis Bissextilibus, Communibusque tum centesimis, tum non centesimis, & numero dierum ob æquationem anni Solaris vsque ad datum quodcunque tempus exemptorum.

(Chapter V. On Bissextile and Common Years — both centennial and non-centennial — and on the number of days removed, on account of the equation of the solar year, up to any given time.)

[Margin: How non-centennial bissextile and common years may be recognized. *(Anni non centesimi bissextilis, & communes qua ratione sciuntur.)*]

You will recognize the non-centennial bissextile and common years as follows. Given any year, cast out all the thousands and hundreds, and likewise from the rest cast out the number 20 as many times as you can. Then from the remaining number cast out 4 as often as it can be done. For if nothing remains, the proposed year is bissextile; if 1 is left over, it will be the first after the bissextile; if 2 remain,

the second after the bissextile; if finally 3, the third after the bissextile. In the same way, if after casting out all the 100s or 20s nothing remains, the year is bissextile.

For example: let the year 1589 be proposed. Casting out the years 1500 (which are centennial) and 20 from the remaining 89 as many times as can be done, and from the residual 9 years subtracting all the 4s, there remains 1. Therefore the year 1589 is a common year, and the first after the bissextile.

Likewise, suppose the year 5960 is given. Casting out 5900 (that is, the centennial years) and 20 from the remaining 60, nothing is left. Therefore the year 5960 is bissextile.

Finally, let the year 6456 be given. Casting out the centennial years, that is 6400, and 20 twice from the remaining 56, and 4 four times from the remaining 16, nothing remains. Therefore the given year 6456 is bissextile.

[Margin: In what manner the centennial bissextile and non-bissextile years may be known. (*Anni centesimi bissextiles, & non bissextiles quo pacto cognoscantur.*)]

By the same method we shall distinguish the centennial bissextile years from the non-bissextile ones. For, given any centennial year, let there be cast out all the tens of thousands (to speak in the manner of the arithmeticians) — that is, the years 10000, 20000, 30000, 40000, 50000, 60000, 70000, 80000, 90000, 100000, 200000, and finally all the years measured by the number 10000, such as all those found beyond the fourth place of their number (proceeding from right toward left); for all these are bissextile. And with the number of the remaining centennial years — which will always be less than 100 (since 100 centennials make 10000) — one proceeds as if they were simple, expanded years, and not centennials. For a centennial year is bissextile when, after casting out all the 20s or 4s from the number of thousands and hundreds (without regard to the tens of thousands), nothing remains; if 1 is left over, it is the first centennial after the bissextile; if 2, the second; and if 3, the third. But if the given year has, as its first four figures — proceeding from right to left — 0000, it too will be bissextile.

Therefore, if a number of centennials, however large, written out in its figures, is proposed, one need consider only the number expressed by the two figures found in the fourth and third places — that is, in the place of thousands and of hundreds — and one must proceed with that number as was said concerning non-centennial years. For instance, if the year 27000 is given, the number 70 is to be noted, since the figure 7 occupies the place of thousands and the figure 0 the place of hundreds. But if the given year is 30900, account is to be taken of the

hundreds-figure 9 alone, since the thousands-figure 0, placed before it in this way, adds nothing. Thus (so that the force of this precept may be seen even in the largest numbers of years) in the year 946700000 nothing is to be considered, because in the place of thousands and of hundreds the figure 0 stands; rather, the proposed year is bissextile. Finally, in the year 6789200, account must be taken of the number 92, and so on.

For example: let the year 1900 be given. Since it is less than 10000, we shall cast out nothing, but only the number of thousands and hundreds expressed in it is to be noted — that is, the number 19. From it, if all the 20s are removed, 19 remain; and if from these all the 4s are taken away, 3 remain. Therefore the year 1900 is a common year; and though it is a centennial, it is the third after the bissextile centennial.

Let the year 30400 also be given. Casting out 30000 — that is, considering only the hundreds-figure 4, since the thousands-figure is 0 — if all the 4s are cast out of 4, nothing is left. Therefore the year 30400 is bissextile.

Likewise, suppose the year 407600 is given. Casting out 400000, there remain 76 centennials, which alone are to be considered. From these, if 20 is cast out, 16 remain; and if all the 4s are taken away from these, nothing is left. Therefore the proposed year 407600 is bissextile.

Finally, let the year 580600 be offered. Casting out 580000, there remain 6 centennials. And casting out 4 once from 6, there remain 2. Therefore the given centennial year 580600 is a common year, and the second after the bissextile centennial.

Very conveniently, therefore, the correction of the calendar falls in a year contained between 1500 and 1600 — such as the year of the correction, 1582 — since in this way the centennial bissextile and common years retain the rule of the non-centennial bissextile and common years.

[Margin: By what art it may be known how many intercalary days have been omitted up to any centennial year inclusive. (*Quot dies intercalares omissi sint vsque ad quemcunque annum centesimum inclusiue qua arte cognoscatur.*)]

Now, how many intercalary days — beyond those 10 removed in the year of correction — have been omitted up to any given centennial year inclusive, you will find out in this way. Having subtracted 1600 from the number of the proposed centennial year, divide the remaining centennial years by 4. Multiply the quotient number (as the arithmeticians say) by 3 (because in every span of

400 years three intercalary days are omitted), and to the resulting number add the remainder of the division, if there is any (since the units of the remaining number, which will always be fewer than 4, are common centennial years); and you will produce the number of days removed up to that time, beyond the 10 days that were removed in the year of correction.

For example: if someone should wish to know how many days have been removed from the time of the correction up to the year 6790 inclusive, let him subtract 1600 from 6700 (for only the centennials are reckoned), so that there remain 5100 — that is, 51 centennial years; and if these are divided by 4, the quotient will be 12, with remainder 3. If, then, the quotient 12 is multiplied by 3, and to the produced number 36 are added the 3 centennial years left over from the division, there will result 39 days subtracted up to the year 6790 inclusive; and if to these are added the 10 days removed in the year of correction, there will be in all 49 days.

Thus, from the year of correction up to the year 8800 inclusive, 54 days will have been removed. For, taking away the years 1600 from 8800, there remain 7200 years — that is, 72 centennial years — which, if divided by 4, give a quotient of 18, with nothing left over from the division. Multiplying, then, the quotient 18 by 3, the number of days removed becomes 54. And adding the 10 days of the year of correction, 64 days in all will have been removed.

Perhaps we shall attain the same result more conveniently if we divide all the centennial years by 4 without subtracting 1600, and from the quotient (keeping meanwhile the remainder of the division, if there is any) we take away 4 — because 4 is contained four times in the 16 centennials, that is, in the 1600 years, which we ought to have taken away. For if we multiply the remaining number by 3, and add to the resulting number the remainder of the division, we shall gather the number of days removed beyond those 10 days of the year of correction.

For example: let the year 8800 be proposed. Dividing the 88 centennials by 4, the quotient becomes 22. Taking away 4, there will remain 18; and these, multiplied by 3, produce 54. So there will then be that many days removed beyond those 10 of the year of correction — the same as we had found by the earlier way.

Again, let the year 634700 be proposed. Dividing the 6347 centennial years by 4, the quotient becomes 1586, and 3 will remain. Taking away 4 from the quotient, and multiplying the remaining number 1582 by 3, there is produced the number 4746; and adding the 3 that were left over, the number of days removed becomes 4749 — besides those 10 that were removed in the year of correction.

And this knowledge of the number of removed days is altogether necessary if we wish to investigate the Dominical letter by means of the solar cycle — namely, so that we may understand how many letters are to be counted after the Dominical letter has been found, as we taught at the beginning of chapter 4. This knowledge of the same days is likewise most necessary in order that the celestial motions may be computed from the astronomical tables for any year given after the correction of the calendar.

CAPUT VI.

De Festis Mobilibus.

(Chapter VI. On the Movable Feasts.)

[Margin: The placing of the 7 Dominical letters on the fingers, for finding the movable feasts. (*Collocatio 7. litterarum Dominicalium in digitis ad festa mobilia inuenienda.*)]

To find the movable feasts, both before and after the restoration of the calendar, all 7 Dominical letters must first be placed on each of the 4 fingers of the left hand (the thumb omitted), and again on the little finger of the right hand, in this way. On the inner base of each of those 5 fingers is put D; on the second joint, E; on the third, F; on the fourth — that is, at the tip — G; on the fifth, which is on the outer side under the nail, A; on the sixth, B; on the seventh, C. This placement is contained in the following verse:

Donec Erat Fortis, Gens Africa Bella Ciebat.

For if, beginning from the inner base, you run through all 7 joints of each of those five fingers, and assign to each joint the successive words of that little verse, the first letter of each word will show the letter that is placed on the corresponding joint.

[Margin: The placing of the 30 epacts on the left hand, for finding the movable feasts. (*Collocatio 30. Epactarum in sinistra manu, ad festa mobilia inuenienda.*)]

Next, in order that the movable feasts after the correction of the year may be found (for we shall deal a little later with finding them before the restored year), the 30 epacts must be arranged on the left hand in this order. On the palm of the hand is placed epact xxij. On the inner base of the index finger, xxij. On its second joint, xxj; and so on in succession, keeping the epacts in retrograde order — yet in such a way that from the outer base of each finger you jump at once to

the inner base of the following finger: that is, from the seventh joint of the index to the first of the middle finger, and from the seventh of this to the first of the ring finger, and finally from the seventh of this to the first of the little finger. This procedure being observed, epact xv will fall on the inner base of the middle finger, epact viij on the base of the ring finger, and epact j on the base of the little finger. Further, on the penultimate joint of the little finger must also be placed epact 25 (marked with a different colour or character), together with epact xxvj. But on the last joint, the two epacts xxv and xxiiij, as is done in the calendar.

But perhaps the same epacts will be placed on the hand more easily in the natural order of the numbers, if the beginning is made from the outer last joint of the little finger; and there you place epacts xxiiij and xxv together, and proceed toward the penultimate joint, and the antepenultimate joint, and so on, up to the inner base of the index finger and the palm of the hand: that is, on the penultimate joint of the little finger you put xxvj and 25; on the antepenultimate, xxvij; at the tip, 28; and so on in succession. For in this way epact xxij will at last fall on the palm of the hand, where the beginning was made before.

But we shall discover the seat of any epact far more easily in this way. To the proposed epact let 6 be added; and the accumulated number, if it is less than 30 — or else, if it is not less, the number by which that accumulated total exceeds 30 — is to be placed on the lower part of the left thumb. Then, if from this number inclusive a counting is made according to the natural series of the numbers, through the palm of the left hand and through the joints, both inner and outer, of the index and the other fingers, up to 30 — or, if the epact is the 25 of a different colour or character, or xxiiij (each of which climbs one day higher in April, and therefore has its lunation, begun in March, of 29 days), up to 29 — this counting will end at the seat of the proposed epact.

For instance, if to epact x we add 6, they make 16. Setting, then, 16 at the base of the thumb, 17 on the palm of the hand, 18 at the base of the index, and so on, the number 30 will fall on the penultimate joint of the middle finger, which is the outer one. There, then, is the seat of epact x.

Likewise, if to epact 25 (marked with a different character or colour) 6 is added, they make 31, which number exceeds 30 by one unit. If, then, we place 1 at the base of the thumb, and 2 on the palm of the hand, and 3 at the base of the index, and so on, the number 29 will fall (when...

(For when the epact is 25, marked in a different colour or character, the count must be carried only as far as 29, because its lunation, beginning in the month of

March, contains only 29 days) — into the penultimate joint, that is, the sixth joint of the little finger [Auricularis]. There, then, is the place of epact 25, which is customarily written in a different colour or character.

Again, if 6 is added to epact xxiiij, the result is 29. So if we place 29 at the base [radix] of the thumb [Pollex], the number 30 will fall into the palm [vola] of the hand. Epact xxiiij will therefore be set in the palm of the hand.

Finally, if 6 is added to epact xxiiij, the result is 30, a number that exceeds 30 by nothing. So if we set 0 at the base of the thumb, 1 in the palm, and 2 at the first joint of the index finger [Indicis], the number 30 will end — for when the epact is xxiiij, the count too must go only as far as 29, since its lunation likewise, beginning in March, is of only 29 days — at the last joint of the little finger. There, then, is the seat of epact xxiiij.

Thirdly, the roots of the movable feasts [radices festorum Mobilium] must be carefully committed to memory: that is, the days of the months before which the movable feasts can never be celebrated, though they are sometimes celebrated on those days themselves. The principal movable feasts are Septuagesima, Ash Wednesday [dies Cinerum], Easter [Pascha], the Lord's Ascension, Pentecost, and the feast of Corpus Christi. The intervals between these feasts never change among themselves; the same number of days is always interposed. The Lord's Advent [Aduentus Domini], however, even though it too is a movable feast, follows a different reckoning, as will be said below. [Margin: What the movable feasts are, and what their roots are.] The root of Septuagesima, then, is 18 January; of Ash Wednesday, 4 February; of Easter, 22 March; of the Lord's Ascension, 30 April; of Pentecost, 10 May; and of Corpus Christi, 21 May. For feasts of this kind can be celebrated on these days of their roots, but not before them. These roots will perhaps be more easily retained in memory by the following verses:

*Octodecim Ianus. Februus sed quatuor optat. Viginti duo Mars: Triginta
poscit Aprilis: Bis quinque at Maius: Ter septem postulat idem.*

For these roots correspond to the feasts named above in the order recited, so that the first root belongs to the first movable feast, that is, Septuagesima; the second to the second, that is, Ash Wednesday; and so on.

Accordingly, if you are about to find any one of those movable feasts in any given year, look first into which joint the epact of that year falls, according to the arrangement set out above. Then look into which joint the dominical letter of that same year is placed, after the epact has already been fixed in its own place, in the

order we prescribed at the beginning of this chapter — with this proviso: that if the dominical letter falls into the same joint as the epact, the same letter is to be taken in the corresponding joint of the next finger. [Margin: Finding the movable feasts.] The same is to be understood of the two letters of a leap year [Bissextilis]. For if either of them occupies the same joint as the epact, the same two letters are to be taken in the corresponding joints of the following finger. Thirdly and last, count from the root of the proposed feast the days of the months, starting the reckoning from the base of the index finger (placing, of course, at the first joint of the index finger the number of the root of the proposed feast-day), at the second the next-greater number, and so on in succession — provided you remember that January has 31 days, February 28 both in the common and in the leap year (as far as the present business is concerned), March 31, April 30, and May 31 — as far as the joint in which the dominical letter has been placed after the seat of the current epact. For the day of the month at which the reckoning ends will be the day on which the proposed feast is to be celebrated. [Margin: How the Hebrew Passover, or the 14th of the Paschal moon, is found.] Here it is also to be noted that, in the search for Easter, the day of the month that falls in the joint of the current epact is the day on which the 14th of the Paschal moon, or the Hebrew Passover [Pascha Hebræorum], occurs. So if anyone wants the Hebrew Passover or the 14th Paschal moon, he must count from the root of Easter — that is, from 22 March — as far as the joint in which the current epact has its seat.

Moreover, in a leap year all the movable feasts must be investigated by means of the later dominical letter [litera Dominicalis posterior], which is of course the one in use after the feast-day of St. Matthias; but under this rule: that to the day found for Septuagesima one day is always to be added, whereas to the day of Ash Wednesday one day is likewise added only when it has been found in the month of February and not in the month of March. [Margin: What is to be done in a leap year on account of the two dominical letters.] For since before St. Matthias's day the earlier dominical letter is in use — the one that is of course later in the alphabet, and therefore follows by one day in the calendar the later dominical letter, which holds the earlier place in the alphabet — it comes about that Septuagesima and Ash Wednesday, before that same feast-day of St. Matthias, are celebrated one day later than is indicated by the later dominical letter then current (that is, by the one earlier in the alphabet). For this reason one day must then be added to the day found by means of the later letter. But after St. Matthias's feast, although the later letter is now in use, a further day must nonetheless then be added to the day of Ash Wednesday found in the month of February, on account of the intercalary day added on the sixth of the Calends of March, which is not written in the calendar. For it is because of this intercalary

day that 24 February is called 25 in the calendar, 25 is called 26, 26 is called 27, and here 28, and here 29. From this it follows that Ash Wednesday, found for example on 26 February by the later dominical letter, is in reality the 27th in the counting of the days; and so of the rest. But if Ash Wednesday falls in March in a leap year, nothing is to be added to the day found, just as neither at the feast of Easter nor at the other feasts following it, because then both the later dominical letter is in use and the days of the months answer to their proper numbers, since the intercalary day has been added to February — so that the first day of March is called the first, the second the second, and so on. Why in a leap year the feasts must be sought by the later letter has been declared in Canon 6 of the Gregorian Calendar, which is prefixed to the explanation of that same calendar.

By way of example: let all the movable feasts of the year 1589 be investigated, in which, by the foregoing rules, the epact is xiiij and the dominical letter A. And since epact xiiij has its seat in the third joint of the middle finger [*digitus Medius*], and letter A, occupying the joint next below it, is placed in the fifth joint of the same finger, all the movable feasts will fall into this fifth joint of the middle finger. So if from the root of Septuagesima — that is, from 18 January inclusive — you count, beginning from the base of the index finger and proceeding toward the second joint and the others, until you reach the fifth joint of the middle finger, you will find that Septuagesima falls on 29 January. But if in the same way, beginning from the root of Ash Wednesday, that is, from 4 February, you count until you reach the same fifth joint of the middle finger, you will find that Ash Wednesday was celebrated on 15 February; and so of the rest.

Likewise in the year 1605, in which the epact is x, falling into the penultimate joint of the middle finger, which is the sixth. And because the dominical letter B of that year falls into that same joint, letter B is to be taken in the same sixth joint, the ring finger [*Annularis*]. For into that joint all the movable feasts of that year will fall. Therefore, if you count the number from the root of Easter — that is, from 22 March, beginning at the first joint of the index finger — you will find in the penultimate joint of the ring finger the day 10 April, on which Easter will be celebrated in the year 1605.

Again, in the leap year 1588 the epact was ij, falling into the last joint of the ring finger, which is the outer one. The dominical letters were C, B. And since letter B, the later one in use (although it is the earlier in the alphabet), by which all the feasts are to be traced, as we have said, immediately precedes that last joint of the ring finger, the same letter B is to be taken in the penultimate joint of the little finger. You will find that Septuagesima falls on the 13th, but, one day added, on

14 February. And you will find that Ash Wednesday falls on 2 March, and therefore that nothing is to be added; and so on.

Next, in the leap year 1596 the epact is j, falling on the inner root of the little finger. The dominical letters are G, F, of which F, the later in use, falls into the third joint of the same little finger. So if from the root of any feast you count as far as that joint, you will find that Septuagesima falls on 10 February. With unity added, then, you will find that it was celebrated on the 11th. And you will find that Ash Wednesday falls on 27 February; with unity added, then, you will say that it was celebrated on the 28th — which in the calendar is indeed the 27th, but is called the 28th on account of the intercalary day added on the sixth of the Calends of March. [The month here as printed reads "Maij"; recte "Martias" (Calends of March).]

Furthermore, in the year 1535 the epact is 25, marked with a colour or character different from the others, but having its seat in the penultimate or sixth joint of the little finger. The dominical letter F, which falls after the epact, into the third joint of the little finger of the right hand. Hence Septuagesima will fall on 17 February, Ash Wednesday on 6 March, Easter on 21 April, and so on.

Besides, in the non-leap year 1700 the epact is ix, whose seat is in the last joint of the middle finger, that is, on the outer root. The dominical letter C falls into that same joint, so that letter C is therefore to be taken in the last joint of the ring finger. So if the reckoning is made from the root of the Ascension — that is, from 30 April — the Lord's Ascension will be found on 20 May.

To these, in the leap year 2096 the epact is v, having its seat at the tip [extremitas] of the ring finger. The dominical letters are A, G; and the movable feasts are all to be sought by the later of them, G — which is later, that is, in use, but not in the order of the dominical letters, since in the order of the letters A immediately follows G, and not the reverse, G following A. But since letter G falls at the same tip of the ring finger, the same letter G is to be taken at the tip of the little finger, in which place you will find that Septuagesima falls on the 11th — that is (with unity added) on 12 February; Ash Wednesday on the 28th, that is (with unity added) on 29 February, which in the calendar is the 28th; Easter on 15 April; the Lord's Ascension on 24 May; Pentecost on 3 June; and finally the feast of Corpus Christi on 14 June.

Finally, in the leap year 1612 the epact is xxvij, whose seat is in the fifth joint of the little finger, which is the outer one, nearest the nail. The dominical letters are A, G, of which A, the earlier in use, falls into that same joint, and the later, G, is set

before that joint at the tip. Hence the same letters are to be taken in the following finger — that is, in the little finger of the right hand — and the movable feasts are to be sought by the later, G, which falls at the tip of the little finger of the right hand. For you will find at the top of the little finger that Septuagesima is to be celebrated on 18 February, that is (with unity added) on the 19th; Ash Wednesday on 7 March; Easter on 22 April; the Lord's Ascension on 31 May; Pentecost on 10 June; and Corpus Domini on 21 June. And the same procedure is to be observed in all other years.

Furthermore, we shall very conveniently find these same movable feasts without any arrangement of the epacts and dominical letters on the hand, in the following way. Let the Paschal new moon [Nouilunium Paschale] be found, as we taught in Chapter 2. To the day of the new moon let 13 be added, so that the 14th Paschal moon [Luna xiiij Paschalis] is obtained. Then let the day of the week on which the 14th moon falls be investigated — which will be done with the greatest ease by the means we shall hand down in Chapter 9. Thirdly, see how many days are counted after the day of the 14th moon up to and including the Sunday. For the number of these days added to the day of the 14th moon will give the day of Easter. [Margin: How Easter and the other feasts may be found otherwise, without the epacts on the hand, etc.]

Example. When the epact is vij and the dominical letters are c, b in some leap year: epact vij subtracted from 30, which is ascribed to the Calends of March, leaves 23; and with 1 added, the result is 24, for the day of the Paschal new moon. With 13 added, the result is 37 — that is (casting off the 31 days of March) 6 April — for the 14th moon, falling on a Wednesday, after which 4 days are counted up to Sunday. Therefore Easter will be celebrated on 10 April. Again, with epact xxvj current and the dominical letter A, the new moon will be found on 4 April and the 14th moon on 17 April, falling on a Monday, after which six days are counted up to Sunday. Therefore Easter will be celebrated on 23 April.

But in order that any other movable feast may be found, Easter must first be investigated, as has been said. Then it must be seen how many days after the root — that is, after 22 March — it is celebrated, observing that in March 9 days remain over. So, by adding the day of Easter, if it is celebrated in April, the number of days after the root of Easter will be had. And since the other feasts are the same number of days distant from their roots, if you add that number of days to the root of each feast, you will have the day on which it ought to be celebrated. In leap years, however, unity must further be added to the day of Septuagesima and of Ash Wednesday — yet in such a way that, when Ash Wednesday would be

the 29th or greater, unity is not added, but 28 is subtracted, so that the remainder gives Ash Wednesday in March. For example: in the latter example Easter fell on 23 April. With 9 added, its distance after the root — that is, after 22 March — becomes 32 days; and these added to the root of Septuagesima, that is, to 18 January, make 50; and, the 31 days of January removed, there will remain 19 February for Septuagesima. In the same way Ash Wednesday will be found on the 36th — that is, subtracting the 28 days of February, on 8 March. The Ascension on the 61st of April — that is, taking away the 30 days of April and the 31 of May, on 1 June; and so on. But in the former example, of a leap year, Easter is distant from its root by 19 days; and this distance, added to the root of Septuagesima, makes Septuagesima fall on the 37th of January — that is, on 6 February — and, with 1 added, on the 7th. Ash Wednesday on the 23rd of February — that is, with 1 added, on the 24th, namely on the vigil of St. Matthias; and so on. [Margin: The placing of the golden numbers on the hand.]

Now, if in place of the epacts the golden numbers [aurei numeri] are arranged on the left hand, all the movable feasts from the Council of Nicaea up to the year of the restitution of the calendar will be found in the same way as was said above concerning the epacts. And the golden

numbers will be placed on the left hand thus. In the palm of the hand 16 is set. With 8 added, and 19 cast off from the sum of 24, the golden number 5 remains, to be located at the inner root of the index finger, after the palm of the hand. With 8 added again, the golden number 13 is produced, for the third joint of the index finger, the second being left empty. For in this arrangement the lesser golden number always follows the greater at the next joint, but the greater follows the lesser not at the next but at the joint beyond — which must be carefully observed, so that all the golden numbers are set in their proper places. With 8 added again to golden number 13, set at the third joint of the index finger, and 19 cast off from the sum of 21, the golden number 2 is produced at the tip of the index finger, since it is set at the first joint of the index finger, which is less than 13. Again, with 8 added to golden number 2, the golden number 10 is produced, greater than the preceding, and therefore to be placed at the sixth joint of the index finger (the fifth being left empty). If to this 8 is again added, the golden number 18 is produced, again greater than the preceding 10, and therefore to be placed at the root of the middle finger (the last joint of the index finger being omitted as empty). With 8 further added to golden number 18, set at the root of the middle finger, and 19 taken from the sum of 26, there remains the golden number 7, which, being less than 18, is to be placed at the next joint of the middle finger, that is, at the second. And by this device all 19 golden numbers will

be placed on the left hand, provided only that you remember that the lesser is to be located next after the greater, but the greater after the lesser not next, but with one joint left empty. Now that golden number is always less than the preceding one which remains after casting off 19 — which happens when, from adding 8 to the preceding golden number, a sum greater than 19 is produced. But that golden number is greater than the preceding one when 19 is not to be cast off from the sum produced by adding 8 to the preceding golden number — which happens only when that sum is not greater than 19.

The same golden numbers will also be arranged on the left hand in this way. When the preceding golden number is greater than 11, subtract 11, and let the remaining number be set at the next following joint; but when it is not greater than 11, add 8, and the number produced is [set in the palm of the hand. If the number thus produced] is greater than 11, cast off 11, and the lesser remaining number 5 is to be located at the next joint, that is, at the root of the index finger. With 8 added to 5, the golden number 13 arises — not at the second joint of the index finger, but at the third, the second being left empty. Subtracting 11 again from 13, the number 2 remains, the lesser, to be set at the next joint, that is, at the tip of the index finger; and so of the rest.

Moreover, we shall find the seat of each golden number on the left hand by means of the epact which corresponded to that golden number before the correction year, even if the preceding golden numbers are not yet located, in this way. To the epact which is elicited from the given golden number before the restitution of the year — as was handed down at the beginning of Chapter 2 — let 3 be added; and the number collected, if it is less than 30 (or, if it is not less, the number remaining after 30 is cast off), assign to the thumb; the next-greater number to the palm of the hand; the next-greater in turn to the root of the index finger; and so on in succession, until you reach 30. For into whatever joint the number 30 falls, there will be the place of the golden number. Thus if the seat of golden number 8 is sought, to which epact 28 corresponded before the correction of the year, let 3 be added to epact 28, to make the sum 31. With 30 removed, 1 remains. So if you set 1 on the thumb, 2 in the palm of the hand, 3 at the root of the index finger, and so on in succession, 30 will fall into the outermost joint of the little finger. There, then, is the seat of golden number 8.

Likewise, because before the restored year epact x_j corresponded to golden number 1, if to this epact you add 3 and set the collected number 14 on the thumb, 15 in the palm of the hand, 16 at the first joint of the index finger, 17 at

the second, and so on in succession, the number 30 will fall into the first joint of the ring finger. There, then, is the seat of golden number 1; and so of the rest.

Accordingly, if from the root of any movable feast, set at the first joint of the index finger, you count the following days of the month, until, after the seat of the current golden number, you reach the joint where the proposed dominical letter [Margin: Finding the movable feasts by the golden numbers, before the correction of the year.] is set, you will find in that joint the day of the month on which the feast was celebrated. For example, if you wish to know on what day Easter was celebrated in the year 1450, whose dominical letter was D and golden number 7, having its seat in the second joint of the middle finger, you will do it in this way. Since the dominical letter D, following the second joint of the middle finger, is set at the root of the ring finger, if from the root of Easter, set at the first joint of the index finger — that is, from 22 March — you count as far as the root of the ring finger, you will find that Easter in the year 1450 was celebrated on 5 April. And the same reckoning holds in the other cases.

CAPUT VII.

De Aduentu Domini.

[On the Advent of the Lord.]

On what day of the month the first Sunday of Advent is celebrated, we shall learn most expeditiously as follows. Since the beginning of the Lord's Advent is always celebrated on that Sunday which is nearest to the feast of St. Andrew, or falls on the feast itself, it is manifest that the first Sunday of Advent can be celebrated three days before that feast and three days after. So if you keep in memory that letter F is prefixed to the Calends of December (which, however, Chapter 9 will easily teach), you will clearly understand that letter G is prefixed to the second day of December, and letter A to the third day; but to the last day of November, which is the 30th, letter E is affixed, which of course precedes letter F ascribed to the first day of December; while letter D is affixed to the 29th, letter C to the 28th, and finally letter B to the 27th. And hence we shall understand that Advent is to be celebrated on the day to which the dominical letter of the proposed year is prefixed [Margin: Finding the first Sunday of Advent.] — which will be evident if from letter F, ascribed to the Calends of December, you go back as far as D. Thus, since in the year 1598 the dominical letter was D, which fell on 29 November (which will be evident if from letter F ascribed to the Calends of December you go back as far as D), you will say that Advent in that year began on 29 November,

which precedes St. Andrew's holy day. And so, as you see, it is enough if you keep in memory that letter F is prefixed to the Calends of December.

Caput VIII — On the number of Sundays between Pentecost and Advent

[Margin: How many Sundays there are between Pentecost and Advent in any given year.]

You will find the number of Sundays between Pentecost and Advent most briefly and easily by this method. See how many Sundays there are after Easter up to and including the feast of St. George, which falls on 23 April — that is, how many times the number 7 is contained in the days after Easter up to and including that day sacred to blessed George. That is the number of Sundays to be added to 24 in order to complete the count of Sundays between Pentecost and Advent. But if no Sunday is found after Easter up to and including that feast of St. George — that is, if there are fewer than 7 days after Easter up to St. George's day, or if Easter itself falls on that feast day — then there will be only 24 Sundays. And finally, if Easter is celebrated after St. George's day, there will be only 23 Sundays between Pentecost and Advent.

For example: if Easter falls on 22 March, you will look for the number of Sundays between Pentecost and Advent thus. After Easter — that is, after 22 March — up to and including St. George's day, or 23 April, there are 32 days: 9 to the end of March (for when 22 is subtracted from the 31 days of March, 9 remain), and another 23 in April up to the 23rd. Since the number 7 is contained four times in 32 days, 4 Sundays must be added to 24, so that the whole count of 28 Sundays between Pentecost and Advent is completed.

Likewise, if Easter falls on 3 April, there are 20 days after Easter — that is, after 3 April — up to the 23rd, since when 3 is taken from 23, 20 remain. And because the number seven is contained twice in 20, 2 Sundays must be added to 24. There will then be 26 Sundays, and so on. Exactly the same reasoning holds in the other cases.

Caput IX — From what day of the week any day of the month is to be named, in any proposed year, whether it is the first day or not

[Margin: What Dominical letter is written against the Kalends of each month.]

In the first place, you must learn what Dominical letter is set in the Calendar against the first day of each month. This you will easily recognize from the twelve words of these verses:

Astra dabit Dominus, gratisque beabit egenos Gratia Christicolæ feret aurea dona fideli.

For the first word, *Astra*, is assigned to the first month, that is, January; the second, *Dabit*, to the second, February; and so on in order — with this reservation, that the fourth word, *Gratisque*, is taken as one word only. Now the first letter of each word is the Dominical letter that is set in the Calendar against the Kalends of the month which that word represents. Thus January has the letter A written against its very Kalends, February D, March likewise D, April G, May B, June E, July G, August C, September F, October A, November D, and December F.

[Margin: What Dominical letter is written against the Kalends of each month.]

Once the first Dominical letter of any month is known, you will easily understand from what weekday that month begins. For if on the joints of the fingers you count, starting inclusively from the Dominical letter of the proposed year, the following letters in alphabetical order up to the letter that is set against the Kalends of the given month (returning, if need be, from the letter C to the letter A), the number of joints you have run through on the fingers will indicate the number of the weekday from which the proposed month takes its beginning.

[Margin: From what weekday each month begins in any given year.]

For example: in the year 1592, a leap year, in which the Dominical letters are E, D — since the letter A is set against the Kalends of January, on account of the first word *Astra* assigned to the first month — if from the current Dominical letter E (for this one is in use up to St. Matthias's day) you count the other letters in the natural order of the alphabet up to A, in this way, E, F, G, A, you will run through four joints. January therefore begins from the fourth weekday, that is, from Wednesday. For if the letter E indicates Sunday, then F will signify Monday, or the second weekday; G, Tuesday, that is, the third weekday; and A, the fourth weekday, or Wednesday.

Next, because the letter D is written against the Kalends of February — on account of the second word *Dabit*, which belongs to February — if from the same current Dominical letter E you count the other letters up to D, in this way, E, F, G, A, B, C, D, seven joints of the fingers will be run through, and therefore the month of February takes its beginning from the seventh weekday, that is, from Saturday;

for the seventh weekday is usually called the Sabbath, just as the first is called Sunday.

Again, because the month of March begins from the Dominical letter D, as the third word *Dominus* denotes, and the later Dominical letter D is then in use, you will pronounce the first of March to be a Sunday, or the first weekday.

Lastly, since May begins from the letter B, because the fifth word *Beabit* corresponds to it, and the later Dominical letter D is then in use, you must count from D up to B, in this order, D, E, F, G, A, B; and since six finger-joints are run through, the first day of May will be Friday, or the sixth weekday.

[Margin: What Dominical letter is written against a proposed day of any month, and from what weekday that same day is to be named.]

Now if from the number of any day in any month whatever you cast out 7 as often as possible — in such a way, however, that if nothing remains you take 7 as the remainder — and if, starting inclusively from the first Dominical letter of the proposed month, you count on the finger-joints the following letters in natural order (returning from G to A) until you have run through as many joints as there are units in that remainder, then the last letter (the one that falls, of course, on the last joint counted) will be set against the proposed day of the month. And so, if you again count from the current Dominical letter the following letters up to the letter assigned to the proposed day (the one just found), you will recognize, in the same way as you recognized the weekday of the first day of the month, the weekday from which the proposed day of the month takes its name.

For example: in the same year 1592, whose Dominical letters are E, D, suppose someone wishes to know what Dominical letter is set against 22 February — on which the Church celebrates the Chair of St. Peter at Antioch — and what weekday it then is. Since the word *Dabit* indicates that the letter D is set against the Kalends of February, and since when 7 is cast out three times from 22 there remains 1, the first letter of the month, D, must be counted on one single joint, thus: D. Therefore the letter D is assigned to 22 February. Accordingly, since the earlier Dominical letter E is then in use, if we count inclusively up to D the 7 letters E, F, G, A, B, C, D, we shall find that the proposed day, 22 February, is the seventh weekday, that is, the Sabbath.

Again, I wish to know what letter is set against the sixth of December, which is sacred to St. Nicholas. Since the last word *Fideli* shows that the letter F is set against the first day, we shall count from F six letters, thus: F, G, A, B, C, D —

because 7 cannot be cast out from 6. Therefore D is set against the sixth day, and consequently that day will be a Sunday, since the Dominical letter is then D.

Likewise, if the question concerns 21 December, sacred to St. Thomas: when all the sevens are cast out, nothing remains. Therefore 7 letters must be counted from F, in this order, F, G, A, B, C, D, E, so that E falls on the 21st. And if the count is made from the Dominical letter D, thus, D, E, you will find that this day is the second weekday.

Next, let it be asked what letter is set against the anniversary day of St. Matthias, which falls on 24 February, and what weekday it is. Count from the first letter of the month, namely D, three letters in this order, D, E, F (for when 7 is cast out from 24 as often as possible, namely three times, 3 remain), for the last, F, is assigned to the 24th. But since the later letter D is now to be used, if you count from D up to F, in this way, D, E, F, you will find that the feast of St. Matthias — that is, 24 February, which is then really the 25th on account of the added intercalary day — falls on the fourth weekday, that is, on Tuesday.

[Margin: What to do in a leap year, when the proposed day falls after the feast of St. Matthias.]

By the same reasoning, if in a leap year any day whatever in February after the feast of St. Matthias is proposed, you must seek the letter set against the day whose number is next smaller than the number of the proposed day, and the weekday must be investigated by means of the later Dominical letter. For instance, if the 28th is proposed, you must seek the letter of the 27th, because the intercalated day is not written in the Calendar. So you see that just above, for the feast of St. Matthias, the letter of the 24th was sought, even though in a leap year that feast is celebrated on the 25th.

Finally, let it be asked on what weekday the anniversary day of the Apostle St. James — that is, 25 July — falls. Since the seventh word *Gratia* shows that the letter G is written against the Kalends of July, and since when 7 is cast out three times from 25 there remain 4, four letters must be counted from G, thus, G, A, B, C; for the last, C, is set against the 25th. If then, from the later Dominical letter D, which is then in use, the count is made up to C, just found, in this order, D, E, F, G, A, B, C, you will find that the feast of St. James — that is, 25 July — falls on the Sabbath, or the seventh weekday.

The reason why 7 must be cast out from the number of the proposed day as often as possible is that after the 7th day of any month, and after the 14th, 21st, and 28th, the same letter recurs that is set against the Kalends.

Caput X — On the Nones, Ides, and Kalends

The first day of each month takes its name from the Kalends. For on the first of January we usually say "on the Kalends of January"; on the first of February, "on the Kalends of February"; and so in the rest. But all the other days are customarily marked from the Nones or Ides of the same month, or from the Kalends of the following month — in such a way that the day which is four days distant, inclusively, from the Nones, Ides, or Kalends (that is, with two days interposed) is to be called "the fourth before the Nones," "the fourth before the Ides," or "the fourth before the Kalends," counting inclusively.

Now in order to know how to name correctly any day of the proposed month from the Nones, Ides, or Kalends, you must diligently commit to memory the days on which the Nones and Ides of each month fall. These can easily be grasped from the number of the Nones and Ides of each month. For since 4 months — March, May, July, October — have 6 Nones, while the other 8 months — January, February, April, June, August, September, November, December — have only 4, the Nones fall in the first 4 months on the 7th, but in the other 8 on the 5th. For to the number of the Nones must be added the first day, which takes its name not from the Nones but from the Kalends, so that the day of the Nones is obtained. And since each month has 8 Ides, if 8 be added to the day of the Nones, the Ides fall in the first 4 months on the 15th, but in the other 8 on the 13th. And to aid the memory these two little verses have been composed:

Maius sex Nonas, October, Iulius, & Mars. Quatuor at reliqui: dabit Idus quilibet octo.

[Margin: How many Nones and Ides each month has, and on what day both the Nones and the Ides fall.]

[Margin: How the days of the months are to be named from the Nones, Ides, and Kalends.]

And so, before you name a proposed day of any month from the Nones, Ides, or Kalends, first see whether that month is one of the first 4 or not. If it is one of them, and the proposed day is the 7th, you will call that day the Nones; but if the given day is the 15th, you will call it the Ides of that month. If, however, the offered day comes before the 7th, or after it but before the 15th, subtract its number, first diminished by a unit (namely the number of the day that precedes the proposed day in the Calendar), from 7 or from 15, and name the remaining number from the Nones or Ides, according as the proposed day falls before the

15th. But if the given day comes after the 15th, subtract its number, first diminished by a unit (namely the number of the day that immediately precedes the given day in the Calendar), from the number of days of the whole proposed month — provided you have first added a unit to the day of that month (namely the first day of the following month, on which its Kalends fall) — and name the remaining number from the Kalends of the following month.

You will observe exactly the same procedure in the other 8 months, provided that in place of the 7th for the day of the Nones and the 15th for the day of the Ides you take the 5th and the 13th, on which days the Nones and Ides of those months fall.

For example: let 3 March be named — the day which precedes the Nones, the 7th. Take away 2 (the number one less than 3, the number of the proposed day) from 7; 5 remain. So you will call 3 March "the fifth before the Nones of March," that is, the fifth day before the Nones of March, counting inclusively.

Again, let the 10th of the same month be given. Since the Ides fall on 15 March, and the proposed 10th is after the Nones and before the Ides, take 9 from 15, so that 6 remain. You will therefore call the 10th "the sixth before the Ides of March."

Furthermore, let 23 June be offered. Since the Ides have passed, and the Kalends of the following July fall on the 31st day counted from the Kalends of June (because June has 30 days), we shall take 22 from 31, so that 9 remain. On 23 June, therefore, one must say "the ninth before the Kalends of July."

Lastly, let the given day be 10 August. Since the Nones have passed, but the Ides fall on the 13th, if 9 be taken from 13, 4 will remain. You will then say "the fourth before the Ides of August."

Note, however, that when the remaining number is 2, one must not say "the second before the Nones," or Ides, or Kalends, but "the day before the Nones," or Ides, or Kalends (*Pridie*).

[Margin: How the days of the months may be recognized from the Nones, Ides, and Kalends.]

Now if a day is proposed named from the Nones or Ides of some month, or from the Kalends of the following one, and we wish to know what day of the month it is, the number of the naming, less one, must be subtracted from the number of the day on which fall the Nones, the Ides, or the Kalends of the following month

— according as the day is named from the Nones, Ides, or Kalends. The remaining number will give the day of the month that is sought.

For example: suppose certain letters are dated "the fifth before the Ides of January." Since the Ides of January fall on the 13th, the number 4 (one less than the number of "the fifth before the Ides") must be taken from 13, so that 9 remain. The day on which the letters were written, therefore, was 9 January.

Likewise, suppose other letters are dated "the day before the Nones of October." Since the Nones of October fall on the 7th, we shall take away 1 (the number one less than that of "the second before the Nones," which is expressed by *Pridie*) from 7, and there will remain 6 October.

Lastly, suppose other letters are written "on the eighteenth before the Kalends of July," a day which lies in the month of June. Since the Kalends of July fall on the 31st day counted from the Kalends of June — June having 30 days — if 17 be subtracted from 31, 14 remain. Those letters, therefore, were written on 14 June, namely the day immediately after the Ides.

Caput XI — On the Indiction

[Margin: What the Indiction is.]

The Indiction is a cycle of 15 years, from 1 up to 15; when this cycle is finished, one returns again to 1. And since the Indiction is frequently used in papal Bulls and diplomas and other public documents, it will not be out of place to explain in a few words by what method the Indiction of any year can be found; this is done as follows.

[Margin: The placing of the hundred-years on the hand, to find the Indiction.]

On the tips of the thumb, index, and middle finger of the left hand, the centurial years must first be arranged, in this way. On the thumb place 0; on the index, 100; on the middle finger, 200. Again on the thumb, 300; on the index, 400; on the middle finger, 500; on the thumb, 600; and so on.

When a large number of centurial years is proposed, you will readily find the seat of that century thus. Cast out 3 from the number of the proposed century as often as possible — which is easily done if you collect the figures expressing the centurial number into one sum in order, always casting out 3, just as arithmeticians cast out 9 in the proof by nines. For if, after the removal of all the 3s, you add 1 to the remaining number, the centurial year must be placed on the finger indicated by the number produced (which will never be greater than 3).

For example, if the year 4716 is given: from 47 (the number of centurial years), when 3 is cast out, there remain 2. (This casting-out is done thus: cast 3 from the figure 4, and 1 remains; added to the figure 7, it makes 8; and when 3 is cast out, 2 are left.) If you add 1 to these, they make 3. On the third finger, therefore, that is, on the middle finger, the year 4700 must be placed. Again, let the year 1589 be given. When 3 is cast from 15 (namely from the number of centuries), 0 remains; adding 1 makes 1. Therefore on the first finger, namely the thumb, the year 1500 must be placed.

[Margin: The placing of the three Indictions, to find the Indiction of any year.]

Next, on the same three finger-tips the three numbers of three Indictions must be set, by this reasoning. Since Christ the Lord was born after the 3rd year of the Indiction, the Indiction 3 will be placed on the thumb, where the year 0 is located — that is, the year immediately preceding the birth of Christ. And since the cycle of 15 years of the Indiction is contained six times in 100 years, with 10 remaining, if we add 10 to 3, the Indiction 13 is produced, to be placed on the second finger. Adding 10 again to the next Indiction, 13, the sum 23 is obtained; and if from it the cycle of the Indiction — that is, 15 — be cast out, the Indiction 8 will remain, to be placed on the third finger. And these Indictions belong to those centurial years which, by the arrangement above, are placed on those finger-tips. These three numbers of the Indictions, which we have set on the finger-tips of the years, are comprehended in this little verse:

Da tria primo, alij tredecim, deinde octo sequantur.

For by this verse it is indicated that 3 is assigned to the first finger, 13 to the second, and 8 to the third.

Now if to the Indiction of any centurial year — which is placed on the finger on which that century is set — you add the extra years given after that century, and from the sum cast out 15 as often as possible, you will produce the Indiction of the proposed year.

For example: let the year 1589 be given. Since the year 1500 falls on the thumb, or the first finger (because, when 3 is cast from 15, the number of centurial years, 0 remains, and with 1 added it becomes 1), the Indiction 3, set on that same thumb, belongs to the year 1500. If to it the extra years 89 are added, and from the sum, 92, all the 15s are cast out, there will remain the Indiction 2 for the year 1589.

Again, for the proposed year 4716, which falls on the middle finger, or the third — because when 3 is cast from 47

Computus Ecclesiasticus — Pars Prima (concl.) and Pars Secunda (opening)

(Caput XI, De Indictione, concluding — worked examples continued.)

that is, of the number of the hundreds of years, 2 remain; and if 1 is added to these, they make 3.) There the Indiction 9 is found. If the 16 expanded years are added to this, the sum 24 is collected. From this, once the 15-year cycle of the Indiction has been cast out, the Indiction 9 of the proposed year 4716 remains. And so for the rest.

We shall also readily find the **Indiction** by the rules of arithmetic, if we add 3 to the years of the Lord and divide the resulting number by 15. For the number left over from the division will be the Indiction sought; or if nothing remains, the Indiction sought will be 15. For example, suppose the Indiction is sought for the year 1589. Adding 3, and dividing the resulting 1592 by 15, the number 2 remains, which is the Indiction for the year 1589. Again, suppose the Indiction of the year 3462 is wanted. Add 3 to the 3462 years, and divide the resulting number, 3465, by 15: here 0 will remain. Therefore the Indiction of the year 3462 will be 15. The same procedure is to be observed in all remaining cases. [Margin: Finding the Indiction by the rules of arithmetic.]

CAPUT XII.

De loco Solis in Zodiaco.

(On the place of the Sun in the Zodiac.)

So that you may know in which sign and degree of the Zodiac the Sun dwells on any given day, more or less, you must first know which sign the Sun enters in each month. For this purpose these two little verses, long ago composed by the astronomers, must be learned:

Sunt Aries, Taurus, Gemini, Cancer, Leo, Virgo: Libraque, Scorpius,
Arcitenens, Caper, Amphora, Pisces.

For these twelve signs correspond, in the same order, to the twelve months of the year, taking the beginning from March. Thus the Sun enters the first sign, namely Aries, in the month of March; the second, which is Taurus, in April; and so on in succession — so that it enters the eleventh, namely Amphora (that is, Aquarius),

in the month of January, which is the eleventh month from March; and in the month of February, Pisces, the twelfth sign. [Margin: Into which sign the Sun enters in each month.]

Next, you must learn on what day of the month the Sun enters the sign assigned to that month. So that this may be more easily held in memory, these two further verses have been devised:

Inclyta Laus Iustis Impenditur: Hæresis Horret Garrula: Grex Gratus
Faustos Gratatur Honores.

For the twelve words of these verses correspond, in the same order, to the twelve months of the year — though here the beginning is made from January, so that the first word, *Inclyta*, is assigned to January; the second, *Laus*, to February; and so on.

Therefore, to obtain the day on which the Sun enters the sign of its own month, look at the position, in the alphabet, of the first letter of the word that corresponds to the proposed month. For if you subtract from 30 as many units as the place that letter occupies in the alphabet, the remainder will be the number of the day on which the Sun enters the sign of that month. [Margin: On what day the Sun enters each sign.]

For instance, suppose you wish to know on what day of the month of March the Sun enters the sign of Aries. Since to March — that is, to the third month — belongs the third word, *Iustis*, whose first letter I is the ninth in the alphabet, we subtract 9 from 30, so that 21 remain. Therefore on the 21st of March the Sun held the beginning of Aries.

Likewise, if I wish to know on what day of November the Sun enters the sign of the Archer, or Sagittarius: since to November — that is, to the eleventh month — corresponds the eleventh word, *Gratatur*, whose first letter G is the seventh among the letters of the alphabet, 7 must be taken from 30, so that the 23rd of November is left as the day on which the Sun enters Sagittarius.

Now if you add the same units that the first letter of any month offers to the number of the proposed day of that same month, you will collect a number that will indicate in what degree of the sign the Sun stands on that day — with this proviso, however: if the collected number is less than 30, the degree found is to be referred to the sign of the *preceding* month, since the Sun will not yet have reached the proper sign of the proposed month. But if that same number is greater than 30, you should say that the Sun dwells in the degree that remains

after 30 is cast out of the resulting number, this within the proper sign of the month. And finally, if the sum comes to exactly 30, you should declare that the Sun holds either the 30th degree of the sign of the preceding month, or the beginning of the proper month's sign. [Margin: In what degree the Sun stands each day.]

For example, suppose someone wishes to know where the Sun stands on the 10th of April. Let him add 9, on account of the first letter I of the fourth word, *Impenditur*, which is owed to the fourth month, that is, April; let him add, I say, 9 to the proposed 10th day, to make 19, which number is less than 30. Therefore the Sun has not yet entered the sign of Taurus, which is assigned to April, but stands in the 19th degree of Aries, the sign, that is, of the preceding month, March.

Again, suppose someone wishes to learn in what degree the Sun stands on the 27th of September, which is the ninth month, and to which therefore belongs the ninth word, *Gratus*, whose first letter G occupies the seventh place among the letters of the alphabet. If then I add 7 to the proposed day 27, I shall make 34, a number greater than 30, from which I understand that the Sun has already entered Libra, the sign of the month of September. And when 30 is taken from 34, there remain 4 degrees of Libra, in which the Sun then stands.

Finally, suppose you wish to know where the Sun dwells on the 22nd of May: since to May, the fifth month, corresponds the word *Hæresis*, whose first letter H is the eighth in the alphabet. Therefore, adding 8 to the day 22, the sum 30 is produced. So on the 22nd of May the Sun will stand in the 30th degree of Taurus, or at the beginning of Gemini.

Even so, the true place of the Sun cannot be known by this method with complete precision — both on account of the leap years and the common years, and because the Sun does not run through exactly one degree in the Zodiac each day, so that an error of half a degree, or of a whole degree at most, is committed. Thus, more or less, we do attain the place of the Sun, but not so surely and exactly that we could rely on it in the use of clocks, in which we must necessarily know the hours; for that, the place of the Sun in the Zodiac must be had precisely — which is also required for the use of the other instruments that astronomers employ.

CAPUT XIII.

De loco Lunæ in Zodiaco, & quot horis noctu luceat.

(On the place of the Moon in the Zodiac, and how many hours it shines by night.)

Computists gather what place of the Zodiac the Moon occupies on any given day — that is, in which sign and degree it stands, more or less — roughly in this way. They take the age of the Moon found in the Calendar, first adding one unit (because the Moon is usually conjoined with the Sun one day earlier than the Epacts show: and so, since any Epact indicates the Moon to be, say, 16 days old, we rightly say it is 17 days old in the heavens); this they double, and divide the resulting number by 5. For the quotient will indicate by how many whole signs the Moon is distant from the Sun, following the succession of the signs; and the remaining units, if there are any, will give fifths of one sign (so that for each single unit they take six degrees), by which, beyond the whole signs, the Moon is distant from the Sun in the succession of the signs.

For example: on the 7th of December in the year 1588, the Moon will be found to be 18 days old, but more truly it will then contain 19 days. Double 19, then, and divide the resulting number, 38, by 5: the quotient will be 7, with 3 units remaining. The Moon will therefore then be distant from the Sun by 7 signs and, in addition, 18 degrees — that is, by three fifths of one sign. Since, then, on the 7th of December the Sun holds the 15th degree of Sagittarius, as is clear from the preceding chapter, if after Sagittarius we count seven signs — Capricorn, Aquarius, Pisces, Aries, Taurus, Gemini, Cancer — the 15th degree of Cancer will be distant seven signs from the place of the Sun, that is, from the 15th degree of Sagittarius; and if we add another 18 degrees, we shall find that the Moon then occupies about the 3rd degree of Leo.

By this rule you will learn that the Moon, at the first quadrature — namely when it is $7\frac{1}{2}$ days old — is distant three signs from the Sun; at the full moon, when it is 15 days old, is six signs distant from the Sun; and finally at the second quadrature, when it is about $22\frac{1}{2}$ days old, has receded nine signs from the Sun. For twice $7\frac{1}{2}$ makes 15, which, divided by 5, yields 3 signs. Likewise, twice 15 makes 30, which, divided by 5, yields six signs. Finally, twice $22\frac{1}{2}$ is 45, which, divided by 5, gives 9 signs.

We shall also be able to investigate this same place of the Moon in the Zodiac in the following way. Since the Moon moves from west to east with a mean motion

of about 13 degrees, as is clear from the Theorics, if we multiply the age of the Moon by 13 and divide the resulting number by 30, the quotient will indicate the number of signs by which the Moon, following the succession of the signs, is distant from the place where it was at the new moon; and the remaining number will give the degrees. Therefore, once the place of the Sun at the time of that new moon is found, you will easily find the place of the Moon.

Thus on the 7th of December in the year 1588 the Moon is 19 days old, which, multiplied by 13, makes 247 degrees — that is, 8 signs and 7 degrees. Since, then, on the 19th of November, when the new moon occurred in the heavens (although the Epact ij throws it back to the 20th day), the Sun, and hence the Moon too, stood in the 26th degree of Scorpio, the Moon on the 7th of December will stand in about the 3rd degree of Leo — that is, it will be distant about 8 signs and 7 degrees from the 26th degree of Scorpio.

By this rule too you will learn that the Moon at the full moon is 6 signs distant from the Sun, at the first quadrature 3 signs, and at the second 9 signs. For, multiplying 15 by 13, there result 195 degrees — that is, 6 signs and 15 degrees. When, therefore, the Sun has completed 15 degrees from the new moon up to the full moon, the Moon will be distant 6 signs from the Sun. At the first quadrature, if the $7\frac{1}{2}$ days are multiplied by 13, there result $97\frac{1}{2}$ degrees — that is, 3 signs and $7\frac{1}{2}$ degrees. Since, then, the Sun from the new moon up to the first quadrature has completed $7\frac{1}{2}$ degrees, the Moon will be distant 3 signs from the Sun. Finally, at the second quadrature, if the $22\frac{1}{2}$ days are multiplied by 13, there are produced $292\frac{1}{2}$ degrees — that is, 9 signs and $22\frac{1}{2}$ degrees. Hence, since the Sun from the new moon up to the second quadrature has completed about $22\frac{1}{2}$ degrees, the Moon will be distant 9 signs from the Sun.

Now the computists ascertain how long the Moon shines by night roughly in this way. They take the age of the Moon that has been found (again first adding one unit) if it is not more than 15 days; or, if it is greater than 15, its complement to 30; and they multiply this by 4 and divide the number thus produced by 5. For the quotient will indicate the unequal hours, and the remaining units, if there are any, the fifths of one hour, for which the Moon shines. These hours are to be counted after sunset while the full moon has not yet come; but after the full moon they are to be counted before sunrise — so that while the Moon is waxing its shining is in the evening, but while it is waning, in the morning. [Margin: How many hours the Moon shines by night.]

For example: on the 7th of December in the year 1588 the age of the Moon will be found to be 18 days, and, one unit added, 19 days. Its complement to 30 is 11;

when this number is multiplied by 4, and the product 44 is divided by 5, the quotient becomes 8 with four fifths. For that many unequal hours, then — that is, for eight twelfth-parts of the whole night, and in addition four fifths of one twelfth-part — the Moon will shine that night before sunrise.

Further, by this rule you will find that the Moon at the full moon shines 12 hours, that is, the whole night; at either quadrature 6 hours, that is, half the night; when the Moon is 5 or 25 days old, 4 hours, that is, a third part of the night. Finally, when the Moon is 4 or 26 days old, about 3 hours, or a fourth part of the night.

And so, once the length of the proposed night is known, if it is divided into 12 equal parts, the equal hours for which the Moon shines will also be known. Thus, since on the 7th of December the night contains about 14 hours 55 minutes at the latitude of 42 degrees, and the Moon by the given rule shines for 8 unequal hours with four fifths, while a twelfth part of the night comprises 1 hour 14 minutes with 7 twelfths, the eight twelfths of the night, together with four fifths of one twelfth-part, will comprise about 10 equal hours 56 minutes, and a little more, for which the Moon will then shine.

But for many reasons neither the place of the Moon in the Zodiac nor the time of its shining can be found exactly to the mark by these rules — both because the minutes are neglected in them, and because the Moon is not carried uniformly beneath the Zodiac, from which some error is necessarily committed in investigating its place; and also because the Moon's time is increased when the Moon is swift in its motion and northerly, but diminished when it is slow and southerly, so that in inquiring after that time one must necessarily stray from the truth. To this is added that neither the age of the Moon is found precisely by the Epacts, nor the place of the Sun in the Zodiac — which cannot but induce an error of several degrees. It is enough that by these rules one may find, more or less, the sign in which the Moon stands on the proposed day, even though sometimes, for the causes we have mentioned, we stray by several degrees from its true place.

COMPUTI ECCLESIASTICI

Pars Secunda per Tabulas.

(Ecclesiastical Computus — Second Part, by Tables.)

Aurei numeri inuentio ex tabula 1.

(Finding the Golden Number from Table 1.)

If the proposed year is one of the hundreds, look for it among the centesimal years. For descending straight down, opposite it, you will find the Golden Number belonging to that hundred, in the single column of Golden Numbers.

But if the given year is not a centesimal one, you will find its Golden Number opposite the expanded year, beneath the hundred, that most nearly precedes the given expanded year.

For example: suppose the Golden Number of the year 9600 is sought. Since this year, found among the hundreds, has the number 6 written beneath it, we shall say that the Golden Number of the year 9600 is 6; and this same Golden Number is also owed to the years 100, 2000, 39000, and so on. Likewise for the years 300, 2200, 4100, and so on, you see that the Golden Number 16 agrees.

Again, suppose the Golden Number of the year 1604 is to be investigated. Since, beneath the year 1600, opposite the expanded year 4, the number 9 is found, we shall say that the Golden Number of the year 1604 is 9. Likewise for the year 4738 you will discover the Golden Number to be 8, opposite the expanded year 38 beneath the hundred 4700; and so for the rest.

Epactæ inuentio ex tabula 2.

(Finding the Epact from Table 2.)

Let the Golden Number of the proposed year be sought from Table 1. Then, in the little table of equation of Table 2, take the proposed year — or, if it is not present, the next-smaller year — together with the letter, whether capital or small, placed to its left. Finally, in the cycle of Epacts note that same letter, and to the cell which, counting inclusively from that letter toward the left, is the third, assign Golden Number 1; and to the next cell to the right, the next Golden Number 2; and so on. For in the cell into which the Golden Number of the proposed year falls, you will find the Epact owed to that year. But if you should run through the whole little table of the cycle before you reach the Golden Number of the given

year, you must return to the beginning of the little table. Likewise, when the Golden Number of the given year falls into the cell of the capital letter F: if that Golden Number is not greater than 11, the Epact xxv is to be taken; but if it is greater than 11, the Epact 25 is to be taken, written in a different colour or character.

By way of example: let the proposed year be 1597, whose Golden Number is 2. Since to the year 1582, which in the little table of equation is the next-smaller than 1597, the capital letter D is prefixed, then if in the cycle of Epacts you assign Golden Number 1 to the cell of the capital letter a — which is the third from the cell of the capital letter D, counting inclusively toward the left — the Golden Number 2 of the given year will fall into the cell of the small letter m, beneath which the Epact xij is found, which is in use for the year 1597. Again, let the given year be 4300, whose Golden Number is 7, and to which in the little table of equation the small letter l is prefixed. If, then, you assign Golden Number 1 to the cell of the small letter u — which is the third toward the left from the cell of the small letter l — and Golden Number 2 to the next cell, of the capital letter P, and so on, the Golden Number 7 will fall into the cell of the capital letter F, in which the Epact xxv is found. Therefore the former xxv is to be taken, because the Golden Number 7 is not greater than 11. But for the year 3393, whose Golden Number is 12, greater than 11, the Epact will be 25, marked with a different character: because into the same cell of the capital letter F the Golden Number 12 falls, if Golden Number 1 is assigned to the cell E, capital, which is the third, inclusively, from the cell of the small letter r prefixed to the year 3300. Again, to the year 4218 in the little table of equation the small letter l corresponds, and the Golden Number is 1. Therefore, if in the cycle of Epacts you assign Golden Number 1 to the cell of the small letter u, which is the third from the cell of the letter l toward the left, you will find the Epact xix for the given year 4218. Moreover, to the year 1710 the capital letter C corresponds in the little table of equation, and again the Golden Number is 1. If you assign this to the cell P, capital, which is the third from the letter C, capital, you will find the Epact * for the year 1710. Finally, to the year 1912 the capital letter B corresponds in the little table of equation, and the Golden Number is 13. Therefore, if in the cycle of Epacts you assign Golden Number 1 to the cell of the capital letter N — which is the third from the cell of the capital letter B — and 2 to the next cell, and so on, the Golden Number 13 will fall on the Epact xi, which is to be used for the year 1912.

Literæ Martyrologij inuentio ex cyclo Epactarum perpetuo.

(Finding the Letter of the Martyrology from the perpetual cycle of Epacts.)

The letter which, in the cycle of Epacts, is placed above the Epact of any year will indicate the age of the Moon in the Martyrology; and for that reason it is customarily called the letter of the Martyrology. Thus in the year whose Epact is xij, the letter of the Martyrology will be the small m, which is ascribed to that Epact. Likewise to the Epact * corresponds the letter of the Martyrology P, capital, and so on.

Nouiluniorum, & ætatis Lunæ inuentio ex tabula 3.

(Finding the new moons and the age of the Moon from Table 3.)

The day of the new moon is found more quickly than words can tell, opposite the Epact under the given month. Thus in the year whose Epact is 12, the new moon will fall on the 17th of April, and likewise on the 17th of May. But when the Epact 20 is current, the new moon of March will fall on the 11th; while in December the same will happen both on the 1st and on the 31st.

[continued from the preceding leaf]

The new moon likewise falls, in any given month, on the day to which the current epact is assigned in the Calendar. Thus, when the epact 12 is running, the new moon occurs in June on the 15th and in November on the 10th, because on those days the epact 12 is entered in the Calendar.

If, beginning from the day of the new moon inclusive, you count the following days on the joints of the hand up to and including the day whose lunar age you are seeking, you will say that the Moon's age is as many days as the joints you have counted through. Thus, when the epact 7 is running, the Moon's age on 10 February will be 18 days, because from 24 January inclusive — on which the new moon falls — up to 10 February inclusive, 18 days are counted.

In the last column of this same Table 3, on the right, you will find which epacts constitute an embolismic lunar year, containing 13 lunations, and which constitute a common year, comprising only 12 lunations. There you see that the epact xviii is ambiguous [indifferens], since it sometimes makes a common year and sometimes an embolismic one, as we explained in the exposition of the Calendar, chapter 17, number 10.

The Finding of the Solar Cycle from Table 4 [Cycli Solaris Inuentio ex tabula 4]

If the year for which the Solar Cycle is sought is one of the centesimal years, you will find its Cycle beneath that year among the centesimal years, in the single row of the Solar Cycle.

But if the given year is not centesimal, you will find its Solar Cycle opposite the given expanded year, beneath the centesimal year that most nearly precedes the given expanded year.

For example: in the year 1500 the Solar Cycle is 25; in the year 2100 it is 9; and finally in the year 1697 the Cycle is 26, opposite the expanded year 97, in the Cycle row beneath the year 1600; and so on.

The Finding of the Dominical Letter, both from Table 5 and from Table 6 [Literæ Dominicalis inuentio tum ex 5. tum ex 6. tabula]

Once the Solar Cycle has been found, you will find in Table 5, opposite it, the Dominical Letter in the descending column beneath the proposed centesimal year. If a single letter occurs, the year is common; but if a double letter, it is bissextile [leap]. For example: in 1697 the Solar Cycle is 26, opposite which, in the descending column beneath the centesimal year 1600, you will find the Dominical Letter f. But in 1812 the Cycle is 1, opposite which, in the descending column beneath the centesimal 1800, you will find the Dominical Letters d, e. Now in non-bissextile centesimal years both letters are not to be taken, but only the one that stands first in the alphabet. Thus in 1900 the Cycle is 5, opposite which, in the descending column beneath the centesimal year 1600, you will find the Dominical Letters g, A; of these, g alone is Dominical that year, because g is the earlier — since in the order of the letters one must pass from g to A, seeing that g is the last of the 7 Dominical Letters.

Before the reformed year [i.e. before the calendar reform], the Dominical Letter is found in the same way from the Solar Cycle, in the single row 5, whose topmost letters are f, g. For example, in the year 325, in which the Solar Cycle is 26, you will find in row 5 the Dominical Letter c. But in 1582, before the month of October — in which the year was reformed — where the Solar Cycle is 23, you will meet the letter g.

From Table 6 you will find the Dominical Letter more expeditiously, without the aid of the Solar Cycle, in this way. If the given year is one of the centesimals, seek it among the centesimal years. For opposite it, in the row where two letters are written, you will find the Dominical Letters running in that centesimal year, provided it is bissextile — as are all the centesimals before the reformed year, but after the correction of the Calendar only those set down in the sixth cell, where the years 1600, 2000, 2400, etc. stand. But if the proposed centesimal year is common — as, after the correction, all are alike except those in the sixth cell — the Dominical Letter will be single, namely the one of the two that is placed to the right, which also holds the earlier place in the alphabet.

But if the proposed year is not centesimal, you will find its Dominical Letter above the given expanded year, in that row of Dominical Letters which is set opposite the centesimal after which the given expanded year falls. And if the given year, among the expanded years, is doubled [geminatus], the year is bissextile, and two Dominical Letters correspond to it. For example: in 2000 you see that the Dominical Letters are b, A; but in 1700 that c alone is Dominical; likewise in 1615 that the Dominical Letter is d; and finally in 1604 that the Dominical Letters are d, c; and so of the rest.

The Finding of the Indiction from Table 7 [Indictionis inuentio ex tabula 7]

If the given year is one of the centesimals, you will find its Indiction below it in the single row of Indictions.

But if the given year is not centesimal, you will find its Indiction opposite the given expanded year, in the row of Indictions situated beneath the centesimal most nearly preceding that year.

For example: in the year 1700 the Indiction will be 8; in 1606 it will be 4; and in 1200 you will find the Indiction 3; and so on.

The Finding of the Movable Feasts from Table 8 [Festorum mobiliu inuentio ex tabula 8]

On the left-hand side, take the epact of the year whose feasts you seek, and, in the column of Dominical Letters, the Dominical Letter of that same year — but below the epact taken — so that if the Dominical Letter of the proposed year is found opposite the epact, the next Dominical Letter below is to be taken, leaving aside the one written opposite the epact. Opposite this Dominical Letter, below the

epact taken, are contained all the movable feasts, the Sundays after Pentecost, and the first Sunday of the Lord's Advent, as the headings written at the top of the table indicate.

In a bissextile year the same feasts are to be investigated by means of the later Dominical Letter, which in the alpha-

-bet stands first, and has its use after the feast of St. Matthias — so that we may not be in doubt as to which of the two letters is to be taken for seeking this or that feast; yet in such a way that, for Septuagesima and also for Ash Wednesday [dies Cinerum], if it falls in February, one day is added. This too being observed: that if one of the two Dominical Letters stands opposite the epact, two other like letters are to be taken, the ones occurring next below them.

In the same way the movable feasts are to be investigated before the reformation of the year, if in place of the epact one takes the golden number of the proposed year — written to the left of the epacts.

For example: in 1597 the epact is 12 and the Dominical Letter e; having found this below epact 12, you will find opposite it Septuagesima on 22 February, Ash Wednesday on 19 February, Easter on 6 April, the Lord's Ascension on 15 May, Pentecost on 25 May, Corpus Christi [Corpus Domini] on 5 June, the Sundays between Pentecost and Advent, 26 in number, and finally the first Sunday of Advent on 30 November.

Again, in 1612 the epact is 27, the Dominical Letters A, g. And since the letter A stands opposite epact 27, the same letters next below are to be taken. For opposite the letter g — which is the earlier in the alphabet (since A follows g), though the later in use — you will find Septuagesima on the 18th, and, adding a unit, on 19 February; Ash Wednesday on 7 March (for here 1 is not added, since it falls in March, not in February); Easter on 22 April; and so on.

So too in the year 2096 the epact will be 5, and the Dominical Letters again A, g. And because the letter g is found opposite epact 5, two other letters A, g are to be taken, the ones occurring next below those. If, then, the feasts are investigated by the later g, you will find Septuagesima on 18 February and Ash Wednesday on 28 February; but if to each feast one day is added, because each was found before March, Septuagesima will fall on the 12th and Ash Wednesday on 29 February, and Easter on 15 April; and so on.

Finally, in the year 347 the golden number was 6 and the Dominical Letter d. If, then, on the left of the table you take the golden number 6, and below it the

nearest Dominical Letter d, you will find opposite this letter Septuagesima on 8 February, Ash Wednesday on 25 February, Easter on 12 April, the Ascension on 21 May, Pentecost on 31 May, Corpus Christi on 11 June, the Sundays between Pentecost and Advent, 25 in number, and finally Advent on 29 November. And in this state were the movable feasts in that year.

Moreover, this Table 8 agrees entirely with the arrangement of the epacts, golden numbers, Dominical Letters, and days of the months which we set forth in the first part, in chapters 6, 7, and 8. For the golden number 16 and the epact xxiii correspond to the hollow of the left hand [*vola manus sinistrae*]. Then the whole following row corresponds to the first joint of the Index [*forefinger*], where we placed the golden number 5 and the epact xxii together with the roots of the movable feasts. The next row following corresponds to the second joint of the Index, and so with the others. And so in this table both the epacts and the golden numbers are set down opposite those days on which the Paschal fourteenth Moons [*Lunæ xiiii*] fall, and which in the other movable feasts serve as the fourteenth Moons — just as in the arrangement above, both the golden numbers and the epacts fell on those same fourteenth Moons on the hand, as we said. Opposite the epact xxiii alone the fourteenth Moons are not marked in the table; yet anyone will understand them, since they are less by a unit than the roots of the movable feasts. Thus the Paschal fourteenth Moon of epact xxiii is 21 March; that of Septuagesima, 17 January; that of Ash Wednesday, 3 February; and so of the rest.

The Finding of the Time during which the Moon Shines at Night, from Table 9 [*Inuentio temporis, quo Luna noctu lucet, ex tabula 9*]

Before the full moon, the Moon's age is to be taken on the left-hand side; but after the full moon, on the right. The hours during which the Moon shines are in the middle; these indeed are to be counted after sunset, if the full moon has not yet arrived, but after the full moon is past, before sunrise.

For example: when the Moon's age is 10 days, it will shine for 8 unequal hours after sunset — that is, for two-thirds, or 8 twelfths, of the night. But when the Moon's age is 20 days, it will shine likewise for 8 hours before sunrise.

So too, when the Moon's age is $3\frac{3}{4}$ days, its shining after sunset will be 3 unequal hours — namely for a quarter of the night. And when the Moon's age is $26\frac{1}{4}$ days,

it will shine likewise for a quarter of the night, before the Sun rises, namely for 3 unequal hours. And so of the rest.

TABLE I OF THE GOLDEN NUMBERS [TABVLA I. AVREORVM Numerorum]

Years of the Lord, collected by hundreds [Anni Domini per 100. collecti]

The grid below is a lookup table of century-values. Each of the 19 columns corresponds to one golden number; the eight cells stacked in a column are the century-marks (multiples of 100) that share that golden number, differing by 1900 (= 100×19). In the source the golden-number key is printed **below** the eight rows, under the rubric *Aurei numeri annorum per 100. collectorum*; it is reproduced here as the header row for legibility. To the right of the 19 columns the source prints the note *Et sic in infinitum* ("and so on to infinity"), i.e. the pattern continues beyond 15100.

[illegible]

Golden numbers of the years collected by hundreds [Aurei numeri annorum per 100. collectorum] (printed as the row above; in the source it stands beneath the grid): 1 · 6 · 11 · 16 · 2 · 7 · 12 · 17 · 3 · 8 · 13 · 18 · 4 · 9 · 14 · 19 · 5 · 10 · 15

Expanded years [Anni expansi]

Years 1–100, arranged in six columns (five columns of 19 rows, then a short column for 96–100):

| Anni expansi (i) | (ii) | (iii) | (iv) | (v) | (vi) |
|------------------|------|----------------|------|-----|------|
| 1 | 20 | 39 | 58 | 77 | 96 |
| 2 | 21 | 40 | 59 | 78 | 97 |
| 3 | 22 | 41 | 60 | 79 | 98 |
| 4 | 23 | 42 | 61 | 80 | 99 |
| 5 | 24 | 43 | 62 | 81 | 100 |
| 6 | 25 | 44 | 63 | 82 | |
| 7 | 26 | 55 [recte: 45] | 64 | 83 | |
| 8 | 27 | 46 | 65 | 84 | |
| 9 | 28 | 47 | 66 | 85 | |
| 10 | 29 | 48 | 67 | 86 | |
| 11 | 30 | 49 | 68 | 87 | |
| 12 | 31 | 50 | 69 | 88 | |
| 13 | 32 | 51 | 70 | 89 | |
| 14 | 33 | 52 | 71 | 90 | |
| 15 | 34 | 53 | 72 | 91 | |
| 16 | 35 | 54 | 73 | 92 | |
| 17 | 36 | 55 | 74 | 93 | |
| 18 | 37 | 56 | 75 | 94 | |
| 19 | 38 | 57 | 76 | 95 | |

Golden numbers of the expanded years [Aurei numeri annorum expansorum]

A 19-column cyclic matrix. The header row repeats the golden-number key of the collected centuries; each column descends by +1 (with 19 rolling over to 1), and the 19 data rows correspond to the expanded years. (This is a modular-arithmetic

reference matrix; its cyclic regularity is inherent and correct. It was verified directly against the leaf: columns 1–3 were read out in full, as was the final row, which closes the cycle back to the header.)

| | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 |
| 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 |
| 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 |
| 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 |
| 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 |
| 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 |
| 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 |
| 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 |
| 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 |
| 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 |
| 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 |
| 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 |
| 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 |
| 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 |
| 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 |
| 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 |
| 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 |
| 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 |
| 19 | 5 | 10 | 15 | 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 |
| 1 | 6 | 11 | 16 | 2 | 7 | 12 | 17 | 3 | 8 | 13 | 18 | 4 | 9 | 14 | 19 | 5 | 10 | 15 |

TABVLA II. INVENTIONIS EPACTARVM.

(Table II. Finding the Epacts.)

Cyclus Epactarum perpetuus. — (*The perpetual cycle of Epacts.*)

Each index letter (upper- and lower-case sorts, plus the asterisk *) is paired with its epact value. The three ranks below reproduce the three stacked rows of the printed table. Note the doubled epact under letter F, printed both in Roman and Arabic figures (xxv. 25.).

Tabella æquationis cycli Epactarum perpetui. — (*Little table for the equation [adjustment] of the perpetual cycle of Epacts.*)

The printed table sets four side-by-side columns, each headed **Anni Dñi.** (Years of the Lord), pairing the index letter with the year at which that epact-letter takes effect; Biſſ. marks a bissextile (leap) year. Read down each column in turn.

Column 1 (Anni Dñi.):

| Cyclus | Anni Dñi. |
|--------------------------|----------------------------------|
| N | 1 |
| P | 320 Biſſ. |
| P | 500 Biſſ. |
| a | 800 Biſſ. |

TABVLA III. INVENTIONIS NOVILVNIORVM.

(Table III. Finding the New Moons.)

For each epact (left column) the table gives the day of the (ecclesiastical) new moon in each month. An entry such as 1.31 or 1.30 means the new moon falls on both listed days of that month; the Februarius cell for epact * is blank (no new moon). The final column classifies the year as *communis* (common), *Embol.* (embolismic), or *Indifferens*; for the lower rows this column is blank and the leaf runs the vertical rubric **Anni communes.** ("common years"). Note the doubled epact printed once in Roman (xxv) and once in Arabic (25), whose month-values differ.

Quando Epacta xxix. & aureus numerus 19. concurrunt, incidit aliud Nouilunium in diem 31. Decembris. (*When epact 29 and golden number 19 concur, another new moon falls on 31 December.*)

TABVLA IIII. CYCLI SOLARIS.

(Table IIII. Of the Solar Cycle.)

ANNI CENTESIMI. (*Centesimal years.*)

Vertical stub-label: **CYCLVS SOLARIS centesimorum Annorum** ("The solar cycle of the centesimal years"). Read each of the seven columns downward to obtain the centennial years; the phrase **Et sic in infinitum.** ("and so on to infinity") heads the last three columns in place of a fixed value. The final row gives the solar-cycle number for each column.

| — | — | — | — | Et sic in infinitum. | | |
|------|------|------|------|----------------------|------|------|
| 7700 | 7800 | 7900 | 8000 | | | |

| 6300 | 6400 | 6500 | 6600 | 6700 | 6800 | 6900 |
| 5600 | 5700 | 5800 | 5900 | 6000 | 6100 | 6200 |
| 4900 | 5000 | 5100 | 5200 | 5300 | 5400 | 5500 |
| 4200 | 4300 | 4400 | 4500 | 4600 | 4700 | 4800 |

| — | — | — | — | Et sic in infinitum. | | |
|----------|-----------|-----------|-----------|----------------------|----------|-----------|
| 3500 | 3600 | 3700 | 3800 | 3900 | 4000 | 4100 |
| 2800 | 2900 | 3000 | 3100 | 3200 | 3300 | 3400 |
| 2100 | 2200 | 2300 | 2400 | 2500 | 2600 | 2700 |
| 1400 | 1500 | 1600 | 1700 | 1800 | 1900 | 2000 |
| 700 | 800 | 900 | 1000 | 1100 | 1200 | 1300 |
| 0 | 100 | 200 | 300 | 400 | 500 | 600 |
| 9 | 25 | 13 | 1* | 17 | 5 | 21 |

CYCLVS SOLARIS Annorum expansorum. (*Solar cycle of the expanded years.*)

At the far left, the narrow index block **ANNI EXPANSI** ("expanded years") lists the years 1–100 in four columns:

| | | | |
|----|----|----|-----|
| 1 | 29 | 57 | 85 |
| 2 | 30 | 58 | 86 |
| 3 | 31 | 59 | 87 |
| 4 | 32 | 60 | 88 |
| 5 | 33 | 61 | 89 |
| 6 | 34 | 62 | 90 |
| 7 | 35 | 63 | 91 |
| 8 | 36 | 64 | 92 |
| 9 | 37 | 65 | 93 |
| 10 | 38 | 66 | 94 |
| 11 | 39 | 67 | 95 |
| 12 | 40 | 68 | 96 |
| 13 | 41 | 69 | 97 |
| 14 | 42 | 70 | 98 |
| 15 | 43 | 71 | 99 |
| 16 | 44 | 72 | 100 |
| 17 | 45 | 73 | |
| 18 | 46 | 74 | |

| | | |
|----|----|----|
| 19 | 47 | 75 |
| 20 | 48 | 76 |
| 21 | 49 | 77 |
| 22 | 50 | 78 |
| 23 | 51 | 79 |
| 24 | 52 | 80 |
| 25 | 53 | 81 |
| 26 | 54 | 82 |
| 27 | 55 | 83 |
| 28 | 56 | 84 |

The main grid gives the solar-cycle value: its 28 rows correspond to the expanded year (1–28, first column of the block above) and its 7 columns to the centesimal base of the same page. Row 28 reproduces the centesimal solar-cycle row 9 25 13 1 17 5 21.

| | | | | | | |
|----|----|----|----|----|----|----|
| 10 | 26 | 14 | 2 | 18 | 6 | 22 |

Table of the Dominical Letters with the Solar Cycle (continued)

(Continuation of Tabula V, begun on the preceding leaf; folio 592. The page carries no fresh "TABVLA" rubric — only the two part-headings "ANNI CENTESIMI" and "LITERÆ DOMINICALES," with the side-label "ANNI CYCLI SOLARIS.")

ANNI CENTESIMI [Centesimal (century) Years]

The century-year argument, arranged in seven columns; column *k* of centuries stands above the dominical-letter column *k* of the grid below. "& sic infinitum." (and so on to infinity) heads the fourth column, marking continuation of the series beyond the tabulated centuries.

| I | II | III | IV | V | VI | VII |
|------|------|------|------------------|------|------|------|
| 8100 | 8200 | 8400 | & sic infinitum. | 7700 | 7800 | 8000 |

LITERÆ DOMINICALES [Dominical Letters]

Side-label (reading up the left edge): **ANNI CYCLI SOLARIS** [Years of the Solar Cycle], numbering the 28 years of the solar cycle down the leftmost column. Each cell gives the year's Dominical letter; leap-year rows (1, 5, 9, 13, 17, 21, 25) carry two letters.

| Cycle yr | I | II | III | IV | V | VI | VII |
|----------|-----|-----|-----|-----|-----|-----|-----|
| 1 | b c | c d | d e | e f | f g | g A | A b |

(Folio 593.)

TABVLA VI. LITERARVM DOMInicalium sine cyclo Solari.

Table VI. Of the Dominical Letters, without the Solar Cycle.

ANNI CENTESIMI [Centesimal (century) Years] — argument block

The century-year argument for this table sets each century as a numeral **rotated 90°** within a dense two-band staggered grid (an upper and a lower band). "Et sic in infinitum." (and so on to infinity) heads the block, marking continuation beyond 5400; "detract. x. dieb." (*detractis decem diebus*, "ten days having been subtracted") is attached at the 1400/1500 reform boundary. The individual century numerals are legible, but the block's two-dimensional assignment of each century to one of the seven dominical-letter rows does **not** resolve reliably on the scan; the centuries read (grouped roughly as printed, order within a band approximate) are given below, while the assignment of each century to its letter-row is left unresolved.

- **Upper band:** 5400 · 5100 · 5200 · 4700 · 4800 · 4300 · 4400 · 3900 · 4000 · 3500 · 3600 · 3100 · 3200 · 2700 · 2800 · 2300 · 2400 · 1900 · 2000 · 1500 · 1600 · 1100 · 1200 · 1300 · 600 · [*Et sic in infinitum.*]
- **Lower band:** 5300 · 4900 · 5000 · 4500 · 4600 · 4100 · 4200 · 3700 · 3800 · 3300 · 3400 · 2900 · 3000 · 2500 · 2600 · 2100 · 2200 · 1700 · 1800 · 1400 [*detract. x. dieb.*] · 1000 · 900 · 700 · 800 · 500 · 400 · 300 · 200 · 100 · 0

Together the two bands enumerate every century year from 0 to 5400 (step 100), each assigned to its dominical-letter class.

Dominical-letter grid (7 rows × 9 columns)

Read against the ANNI CENTESIMI class (row) and the ANNI EXPANSI argument (column) below. Letters lower-case except capital A.

| Row | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
|-----|---|---|---|---|---|---|---|---|---|
| 1 | c | b | A | g | f | e | d | c | b |
| 2 | b | A | g | f | e | d | c | b | A |
| 3 | A | g | f | e | d | c | b | A | g |
| 4 | g | f | e | d | c | b | A | g | f |
| 5 | f | e | d | c | b | A | g | f | e |
| 6 | e | d | c | b | A | g | f | e | d |
| 7 | d | c | b | A | g | f | e | d | c |

ANNI EXPANSI [Expanded (elapsed-within-century) Years]

The expanded-year argument, seven columns; multiples of 4 (leap years) are entered **twice** to carry the intercalary shift. Values transcribed as printed.

| | | | | | | |
|----|----|----|----|----|----|----|
| 1 | 2 | 3 | 4 | 4 | 5 | 6 |
| 7 | 8 | 8 | 9 | 10 | 11 | 12 |

(Folio 594.)

TABVLA VII. INDICTIONVM.

Table VII. Of the Indictions.

ANNI CENTESIMI [Centesimal (century) Years]

Side-label reads up the left edge: **ANNI CENTESIMI**. The century years 0–6900 (step 100) in three columns; "& sic in infinitū." (and so on to infinity) heads the block. The three columns feed the three base indictions given immediately below.

| I | II | III |
|------|--------------------|------|
| 6900 | & sic in infinitū. | |
| 6600 | 6700 | 6800 |
| 6300 | 6400 | 6500 |
| 6000 | 6100 | 6200 |
| 5700 | 5800 | 5900 |
| 5400 | 5500 | 5600 |
| 5100 | 5200 | 5300 |
| 4800 | 4900 | 5000 |
| 4500 | 4600 | 4700 |
| 4200 | 4300 | 4400 |
| 3900 | 4000 | 4100 |
| 3600 | 3700 | 3800 |
| 3300 | 3400 | 3500 |
| 3000 | 3100 | 3200 |
| 2700 | 2800 | 2900 |
| 2400 | 2500 | 2600 |
| 2100 | 2200 | 2300 |
| 1800 | 1900 | 2000 |

| I | II | III |
|------|------|------|
| 1500 | 1600 | 1700 |
| 1200 | 1300 | 1400 |
| 900 | 1000 | 1100 |
| 600 | 700 | 800 |
| 300 | 400 | 500 |
| 0 | 100 | 200 |

Indictiones centesimorum. [Indictions of the centesimal years]

The base indiction of each century column above.

| I | II | III |
|---|----|-----|
| 3 | 13 | 8 |

Indictiones annorum expansorum. [Indictions of the expanded years]

The three columns correspond to the three century-indiction bases (3, 13, 8); each row adds the expanded-year contribution (1–15). Columns I and II are reduced modulo 15 (values wrap 15→1); column III is left as the raw sum (base 8 + 1...15 = 9...23, un-reduced), as printed.

| I | II | III |
|----|----|-----|
| 4 | 14 | 9 |
| 5 | 15 | 10 |
| 6 | 1 | 11 |
| 7 | 2 | 12 |
| 8 | 3 | 13 |
| 9 | 4 | 14 |
| 10 | 5 | 15 |
| 11 | 6 | 16 |
| 12 | 7 | 17 |
| 13 | 8 | 18 |
| 14 | 9 | 19 |
| 15 | 10 | 20 |
| 1 | 11 | 21 |

| I | II | III |
|---|----|-----|
| 2 | 12 | 22 |
| 3 | 13 | 23 |

ANNI EXPANSI [Expanded (elapsed-within-century) Years]

Side-label reads up the left edge: **ANNI EXPANSI**. The expanded years 1–100 laid out in seven columns of fifteen (last two columns run short).

| | | | | | | |
|----|----|----|----|----|----|-----|
| 1 | 16 | 31 | 46 | 61 | 76 | 91 |
| 2 | 17 | 32 | 47 | 62 | 77 | 92 |
| 3 | 18 | 33 | 48 | 63 | 78 | 93 |
| 4 | 19 | 34 | 49 | 64 | 79 | 94 |
| 5 | 20 | 35 | 50 | 65 | 80 | 95 |
| 6 | 21 | 36 | 51 | 66 | 81 | 96 |
| 7 | 22 | 37 | 52 | 67 | 82 | 97 |
| 8 | 23 | 38 | 53 | 68 | 83 | 98 |
| 9 | 24 | 39 | 54 | 69 | 84 | 99 |
| 10 | 25 | 40 | 55 | 70 | 85 | 100 |
| 11 | 26 | 41 | 56 | 71 | 86 | |
| 12 | 27 | 42 | 57 | 72 | 87 | |
| 13 | 28 | 43 | 58 | 73 | 88 | |
| 14 | 29 | 44 | 59 | 74 | 89 | |
| 15 | 30 | 45 | 60 | 75 | 90 | |

TABLE VIII. OF THE MOVABLE FEASTS

TABVLA VIII. FESTORVM MOBILIVM. **

The table is keyed by the golden number of the old (Julian) calendar and by the epact. For each Dominical letter it gives the calendar dates of the principal movable feasts: Septuagesima Sunday, Ash Wednesday, Easter Sunday, Ascension, Pentecost, Corpus Christi, the number of Sundays after Pentecost, and the First Sunday of Advent. Month abbreviations are transcribed as printed (Ian.

= January, Febr. = February, Mar. = March, Apr. = April, Maij = May, Iunij = June, Nou. = November, Dec. = December).

Column headers, verbatim (with gloss):

1. **Aur. Num Calend. vet.** — Golden number, old calendar
2. **Epactæ** — Epacts
3. **Lit. Dom.** — Dominical letter
4. **Dominica Septuagesimæ** — Septuagesima Sunday
5. **Dies Cinerum** — Ash Wednesday
6. **Dominica Paschæ** — Easter Sunday
7. **Dies Ascensionis** — Ascension Day
8. **Dom. Pentecostes** — Pentecost Sunday
9. **Corpus Christi** — Corpus Christi
10. **Dom. post Pentecost.** — Sundays after Pentecost
11. **Dominica prima Adventus** — First Sunday of Advent

TABLE IX. OF FINDING THE TIME DURING WHICH THE MOON SHINES BY NIGHT

** The whole table is set within a decorative border of printer's ornaments;
FINIS. stands within the frame at its foot.

Tabula ix. inventionis temporis, quo Luna noctu lucet. — "Table 9, of finding the time during which the Moon shines by night." (The chapter numeral is set as lowercase ix.)

Column headers, verbatim (with gloss):

1. **Ætas Lunæ ante Plenilunium.** — Age of the Moon before full moon; sub-head **Dies** (days)
2. **Horæ inæquales, quibus Luna lucet** — Unequal (seasonal) hours during which the Moon shines; sub-head **H. inæqu.**

3. **Ætas Lunæ post Plenilunium.** — Age of the Moon after full moon; sub-head **Dies** (days)

| Ætas Lunæ ante

FINIS.

(This FINIS. closes the tabular Second Part — and with it the whole Exposition of the Calendar. The chapter index follows.)

INDEX OF CHAPTERS of the Exposition of the Calendar

INDEX CAPITVM Explicationis Calendarij. **

(Ornamental initial E.)

[E]PISTOLA to the Reader.

PREFACE to the whole work. — Page 1

A compendium of the new method of restoring the Calendar, sent by Gregory XIII to the Christian princes and the more renowned universities, in the year of our Lord 1577. — 3

The perpetual **GREGORIAN CALENDAR**, set before the whole Christian world by Gregory XIII, Supreme Pontiff, in the year 1582. — page 13

- **I.** What Scripture prescribes concerning the celebration of Easter, and what the holy Fathers and Councils have decreed about it. — 53
- **II.** Why the Calendar had to be corrected, and in what its correction consists. — 63
- **III.** Why the vernal equinox was brought back specifically to 21 March, and by what reasoning. — 64
- **IIII.** Why the Church, setting aside the true or apparent motions, employs in the celebration of the movable feasts only the mean (that is, equal) motions — or rather the cycles. — 66
- **V.** What method of intercalation is applied so that the equinox may be kept near 21 March, to which it has been brought back. — 69
- **VI.** On the period of the anomaly of the equinoxes and of the inequality of the years, from the doctrine of Nicolaus Copernicus [Nicolai Copernici]. — 75
- **VII.** Various doubts are resolved concerning the formula for equating the solar year prescribed in the new Calendar. — 81
- **VIII.** How the nineteen-year cycle of the golden number equalizes 19 solar years. — 75
- **IX.** How the golden numbers are arranged in the Calendar, and why, once they are removed, the epacts are substituted in their place. — 88
- **X.** By what device the epacts are set out in the Calendar. — 101

- **XI.** The construction of the expanded table of epacts, and of the table for equating those same epacts, according to the mind of the Calendar's author. — 105
- **XII.** The finding of the golden number and of the epact for any given year; likewise the correction of the equation-table set out in the preceding chapter according to the view of Lilius [Lilij; Aloysius Lilius]. — 133
- **XIII.** On the calculation of the new moons and full moons by means of the true epacts. — 168
- **XIIII.** On an easier calculation of the mean new moons and full moons, by means of the mean new moons computed over 76 years. — 174
- **XV.** On the thirty calendars of golden numbers, answering to the thirty lines of the expanded table of epacts. — 254
- **XVI.** The lunations of all thirty cycles of the expanded epact-table, resolved into their quantities throughout the whole year in the order they keep in the Calendar month by month. — 304
- **XVII.** On the embolisms, and on the "leap" of the Moon, as they call it. — 335
- **XVIII.** What the fourteenth Moon is; and why the epacts are so arranged and equated in the Calendar that their mean new moons for the most part follow the true conjunctions of the luminaries. — 346
- **XIX.** Various doubts are resolved concerning the setting-out of the epacts in the Calendar and their equation; and at the same time it is the more confirmed that the epacts have been most correctly set out and equated in the Calendar. — 353
- **XX.** Finding the solar cycle for any given year. — 361
- **XXI.** Finding the Dominical letter. — 365
- **XXII.** Finding the movable feasts. — 375
- **XXIII.** That the most holy Easter is to be celebrated on one and the same day in all parts of the world. — 505
- **XXIIII.** The calendar of François Viète [Francisci Vietæ] is examined and refuted. — 505
- **XXV.** On another method of computing the mean Paschal new moons and full moons after the correction of the year. — 530
- **XXVI.** On yet another new and very easy method of computing the mean Paschal new moons and full moons after the correction of the year. — 537
- **XXVII.** Others who assailed the Gregorian Calendar are refuted. — 540

- **XXVIII.** On the calculation of the lunations up to the fourths [usque ad Quarta(s)]. — 551

Index

Index of the Chapters of the First Part of the *Computus Ecclesiasticus*

[INDEX CAPITVM PRIMÆ PARTIS Computi Ecclesiastici.]

(Page references are transcribed verbatim; additive Roman forms — e.g. *IIII* — are kept as printed.)

- Preface [*Praefatio*]. — **562**
- I. Chapter. On the golden number [*De aureo numero*]. — **562**
- II. On the epacts, the new moons, the age of the Moon, and the Martyrology letter [*De Epactis, Nouilunijs, Ætate Lunæ, & Litera Martyrologij*]. — **564**
- III. On the solar cycle, that is, the cycle of Dominical letters of 28 years [*De Cyclo Solari, siue literarum Dominicalium 28. annorum*]. — **569**
- IIII. On the Dominical letter [*De litera Dominicali*]. — **571**
- V. On bissextile years and common years — the centesimal ones as well as the non-centesimal — and on the number of days exempted, for the equation of the solar year, up to any given time whatever [*De annis bissextilibus, communibusque tum centesimis, tum non centesimis, & numero dierum, ob æquationem anni Solaris, usque ad datum quodcunque tempus exemptorum*]. — **575**
- VI. On the movable feasts [*De festis mobilibus*]. — **576**
- VII. On the Advent of the Lord [*De Aduentu Domini*]. — **579**
- VIII. On the number of Sundays between Pentecost and the Advent of the Lord. — **580**
- IX. From what day of the week any given day of the month is named in any proposed year, whether that day comes earlier or not. — **580**
- X. On the Nones, the Ides, and the Kalends [*De Nonis, Idibus, & Calendis*]. — **581**
- XI. On the Indiction [*De Indictione*]. — **582**
- XII. On the place of the Sun in the Zodiac [*De loco Solis in Zodiaco*]. — **583**
- XIII. On the place of the Moon in the Zodiac, and for how many hours it shines at night. — **584**

Index of the Rules and Tables of the Second Part of the *Computus Ecclesiasticus*

[*INDEX REGVLARVM, ET TABVLARVM secundæ partis Computi Ecclesiastici.*]

- Finding the golden number from Table 1. — **585**
- Finding the epact from Table 2. — **585**
- Finding the Martyrology letter from the perpetual cycle of epacts. — **585**
- Finding the new moons and the age of the Moon from Table 3. — **585**
- Finding the solar cycle from Table 4. — **586**
- Finding the Dominical letter, both from Table 5 and from Table 6. — **586**
- Finding the Indiction from Table 7. — **586**
- Finding the movable feasts from Table 8. — **586**
- Finding the time at which the Moon shines at night, from Table 9. — **587**
- I. Table for finding the golden numbers. — **588**
- II. Table for finding the epacts. — **589**
- III. Perpetual table for finding the new moons of the whole year. — **590**
- IIII. Table for finding the solar cycle. — **591**
- V. Table for finding the Dominical letters from the solar cycle. — **592**
- VI. Table for finding the Dominical letters without the solar cycle. — **593**
- VII. Table for finding the Indiction. — **594**
- VIII. Table for finding the movable feasts. — **595**
- IX. Table for finding the time at which the Moon shines at night. — **596**

Index of the Principal Matters Explained in Each Chapter

[*INDEX RERVM PRÆCIPVARVM quæ in quolibet capite explicantur.*]

In the Letter to the Reader [*In Epistola ad Lectorem*]

(*These entries carry no page references in the source.*)

- Aloysius Lilius [Luigi Lilio] the first author of the new Gregorian calendar.
- Why the author of this book dissents from Aloysius Lilius in most matters.
- What in particular the author of this book has added to the calendar of Aloysius Lilius.
- Why this burden of writing was imposed on the author of this book above all others.

In the Prooemium [*In Prooemio*]

- Two kinds of feast days are celebrated by the Church. — **Page 1**
- For celebrating the immovable feasts, only the use of the solar months is necessary. — **1**
- For celebrating the movable feasts, both the solar and the lunar months are necessary. — **1**
- Why both the solar and the lunar year needed correction. — **1**
- That many Roman Pontiffs and Councils desired no small correction of the calendar. — **1**
- Who chiefly detected the errors of the calendar of the Council of Nicaea, and wrote on their emendation. — **1**
- That no one before Gregory XIII attained a perfect correction of the calendar, and why. — **1**
- That most held that a perpetual lunar cycle could not be described in the calendar, nor a stable seat be assigned to the equinox. — **1**
- That Aloysius Lilius alone, whom Gregory XIII followed, described a perpetual lunar cycle in the calendar and at the same time assigned a stable seat to the equinox. — **1**
- The order which the author of this book follows. — **2**

In the Compendium of the New Method of restoring the Calendar, [issued] by Gregory XIII, Supreme Pontiff, sent to the Christian Princes and to the more celebrated Academies, in the year of the Lord 1577

[*In Compendio Novæ Rationis restituendi Calendarium à Greg. XIII. P. O. M. ad Principes Christianos, celebrioribusq; Academiis missum, anno Domini 1577.*]

- For what reason Gregory XIII sent this Compendium of the new method of restoring the calendar to the Princes. — **3**
- When Easter is to be celebrated by the decree of the Council of Nicaea. — **3**
- That the seat of the equinox was fixed on 21 March by the Fathers of the Council of Nicaea. — **3**
- That the Fathers of the Council of Nicaea determined that the 14th moon [Luna xiiii] was to be found from the golden number. — **3**
- That the equinox had deserted its seat. — **3**
- That the 14th moon [Luna xiiii] was falsely indicated by the golden number before the correction. — **3**

- That several supreme Pontiffs attempted to emend the error of the equinox and of the 14th moon. — **3**
- That it is difficult to ascribe a stable seat to the equinox, on account of the uncertain and variable magnitude of the tropical year [*anni vertentis*]. — **3**
- What remedy Aloysius Lilius devised for affixing a stable seat to the equinox. — **3**
- The interruption of the cycle of Dominical letters, devised by Aloysius Lilius from his plan for equalizing the equinox. — **4**
- Why the golden number cannot perpetually indicate the Paschal 14th moon [Luna xiiii] in the calendar. — **4**
- That the decemnovennal [19-year] cycle of epacts can perpetually show the Paschal 14th moon in the calendar, if at certain times an equation is applied. — **4**
- The calendar of Aloysius Lilius with the cycle of epacts. — **5**
- By what means the equation of the epacts was instituted by Aloysius Lilius, according to the Alphonsine year. — **9**
- The expanded table of epacts of Aloysius Lilius, with the little table of the equation of the same epacts. — **9 & 10**
- The use of the equation of the epacts, as instituted according to Aloysius Lilius. — **10**
- A little table of some temporary epacts according to Aloysius Lilius, and their use. — **11**
- That Aloysius Lilius perfected a wholly complete table of the movable feasts. — **11**
- That the cycle of epacts inscribed in the calendar can be accommodated to any magnitude of the year whatever. — **11**
- By what reasoning the equation of the epacts is to be instituted according to the varying magnitude of the year, following the opinion of Nicolaus Copernicus [Nicolaus Copernicus]. — **12**
- An exhortation to mathematicians to devote themselves to the care of emending the calendar. — **12**
- That Gregory XIII set himself to follow the consensus of the whole Christian world in this business of correction. — **12**

In the Gregorian Calendar, perpetual, which was proposed to the whole world in the year 1582 by Gregory XIII

[In Calendario Gregoriano perpetuo, quod anno 1582. à Gregorio XIII. toti orbi propositum est.]

- The Bull of Gregory XIII on the corrected calendar. — **13**
- Canon 1. On the decemnovential cycle of the golden number. — **16**
- Finding the golden number by table. — **17**
- Finding the golden number by arithmetic. — **18**
- Canon 2. On the epacts and the new moons. — **18**
- A little table of the epacts corresponding to the golden numbers before the correction of the calendar. — **18**
- A little table of some temporary epacts corresponding to the golden numbers after the correction of the calendar. — **19**
- That by mature counsel the new moons in the calendar were placed after the celestial new moons. — **20**
- The perpetual little table of the cycle of epacts, with the table of the equation of the same cycle. — **20**
- Finding the epact from the perpetual cycle. — **20**
- Canon 3. On the solar cycle, that is, the cycle of Dominical letters of 28 years. — **22**
- Finding the solar cycle from the table which begins at the year of correction 1582. — **23**
- Finding the solar cycle by table, in any proposed year whatever. — **23**
- Finding the solar cycle by arithmetic. — **23**
- Canon 4. On the Dominical letter. — **24**
- Finding the Dominical letter from the year of correction up to the year 1700 exclusive. — **24**

- The little table of Dominical letters, perpetual from the year 1700 inclusive — provided that in every 400 years three bissextiles are omitted — together with the table of the equation of the same little table. — **25**
- Finding the Dominical letter from the aforesaid table, in any proposed year after the year 1700. — **25**
- The construction of the temporary table of Dominical letters for any proposed century. — **26**
- The old solar cycle, that is, the cycle of Dominical letters of 28 years, perpetual, with the table of the equation of the same cycle. — **27**
- Finding the Dominical letter from the perpetual solar cycle, in any proposed year. — **27**
- Canon 5. On the Indiction. — **28**
- Finding the Indiction from the year 1582. — **28**
- Finding the Indiction by table, in any year. — **28**
- Finding the Indiction by arithmetic. — **29**
- Canon 6. On the movable feasts. — **29**
- Finding Easter in the calendar by means of the epact and the Dominical letter, together with the other movable feasts. — **29**
- Finding the movable feasts from the twofold perpetual table. — **29**
- A temporary little table of the movable feasts, from the year 1582 up to the year 1631. — **32**
- The Paschal table, that is, the old table of movable feasts, reformed and perpetual. — **33**
- The Paschal table, that is, the new table of movable feasts, reformed and perpetual. — **34**
- The Gregorian calendar with the epacts distributed through the days of the months. — **36**
- A canon on the Gregorian calendar for the year of correction 1582. — **48**
- The last three months of the year of correction 1582. — **49**

- What is to be observed if the correction of the calendar does not take place in the year 1582. — 52

In Chapter I [*In Capite I*]

- The precept concerning the celebration of Easter, from Sacred Scripture. — 53
- When the Jews celebrated the Passover [*Pascha*] by divine precept. — 53
- Which is the first month of the Jews. — 54
- Why the Church preferred Easter to be movable rather than fixed. — 54
- That the first Sunday after the 14th moon [*Luna xiiij*] of the first month is to be celebrated as the Christian Easter. — 54
- The decree of St. Pius, Pope and martyr, on the celebration of Easter on the Lord's Day. — 55
- The decree of St. Victor, Pope, on the celebration of Easter on the Lord's Day after the 14th moon of the first month. — 55
- The decree of the Council of Caesarea in Palestine on the celebration of Easter after the 14th moon of the first month. — 55
- A fragment of the epistle of the Council of Nicaea on the celebration of Easter. — 55
- The decree of the Council of Nicaea on the celebration of Easter is confirmed from the Council of Antioch, of Chalcedon, and others. — 55
- That the Council of Nicaea confirmed, rather than instituted, that Easter is to be celebrated on the Sunday after the 14th moon. — 55
- The opinion of Bede [*Bede*]: that the Council of Nicaea renewed the ecclesiastical decree on the celebration of Easter after the 14th moon of the first month, on the Lord's Day. — 56
- The opinion of St. Ambrose on the celebration of Easter, from the decree of the Council of Nicaea. — 56
- That the care of the cycle of the golden number was given by the Council of Nicaea to Eusebius of Caesarea [*Eusebius of Caesarea*] and to the Alexandrians. — 56
- That the custom of celebrating Easter on the Sunday after the 14th moon of the first month began in the times of the Apostles, and is an Apostolic tradition. — 56
- That Easter has always been, and ought to be, celebrated on the first Sunday after the 14th moon, even if that Sunday falls on the 15th moon [*Luna xv*] — against certain persons who deny it. — 57

- The error of certain persons in defining the first month. — **61**
- That that month is rightly called the first whose 14th moon falls on the day of the equinox, or next follows it. — **61**
- Three things to be observed in the celebration of Easter, from the decrees of the Pontiffs and the Councils. — **62**
- That the day 21 March was assigned to the vernal equinox by the Council of Nicaea. — **62**
- How many, and which, new moons are Paschal, by the decree of the Council of Nicaea. — **62**
- On how many days of the year, and on which, Easter can be celebrated, by the decree of the Council of Nicaea. — **62**
- That the new moons arranged by golden numbers in the calendar were investigated before the correction of the year, so that all might celebrate the new moons [*Neomenias*] on the same days. — **62**
- That the cycle of Dominical letters was devised so that there should be no dissension in celebrating the Lord's Day. — **62**

In Chapter II [*In Capite II*]

- That the equinox and the new moons, at the time when the calendar was being corrected by Gregory XIII, did not fall on the same days on which they occurred at the time of the Council of Nicaea. — **63**
- What lunations — Paschal according to the Council of Nicaea — were rejected as though non-Paschal, before the correction of the calendar, on account of the error of the equinox. — **63**
- When Easter was celebrated in the second month before the correction, on account of the error of the equinox. — **63**
- That, had the calendar not been corrected, it would have come about after some years that Easter would always be celebrated in the second month, the third, the fourth, and so on, on account of the advance of the equinox toward the beginnings of the months. — **63**
- When Easter was celebrated before the correction on the 25th moon [*Luna xxv*], on account of the error of the new moons found by golden numbers. — **63**
- That, had the calendar not been corrected, Easter would have happened to be celebrated at the new moon — on the 2nd moon, the 3rd, and so on — on account of the error of the new moons which were sought by golden numbers. — **63**

- That, on account of the error of the equinox and of the 14th moon found from the golden numbers, an error of 7, or 28, or 35 days often occurred in the celebration of Easter before the emendation of the calendar. — **63**
- That an error of 42 days and more would have come to be committed in the celebration of Easter after many years, had the calendar not been corrected. — **63**
- The disadvantages for histories, for chronology, and for the principal celebrations of the year, if the calendar had not been emended. — **63**
- The necessity of the correction of the calendar. — **64**
- That the correction of the calendar consists in three things, and what these are. — **64**

In Chapter III [*In Capite III*]

- Various opinions on the restitution of the equinox. — **64**
- Which opinion Gregory XIII followed in restoring the equinox. — **65**
- The disadvantages of the other opinions on the restitution of the equinox. — **ibid.**
- By what reasoning the vernal equinox was restored to 21 March. — **ibid.**
- That the year 1582 must be called the year of correction, because in it the correction of the calendar of Gregory XIII was made. — **ibid.**
- Why 10 days were exempted at once from the year 1582, and not single days from single years or months. — **ibid.**
- Why the equinox anticipates its seat in the calendar. — **ibid.**
- The magnitude of the year according to Julius Caesar [Julius Caesar] and the Church. — **ibid.**
- The magnitude of the year according to the Alphonsines [the Alphonsine astronomers]. — **ibid.**

Index

(Continuation of the Index Rerum Præcipuarum — the subject index of "the principal matters explained in each chapter." Page references are transcribed verbatim off the leaf; "ibid." is preserved; additive Roman forms — e.g. IIII, xiiij — are kept as printed. The doubled-epact distinction is load-bearing and preserved exactly as set: Arabic 25/19/30 versus Roman xxv/xxiiij/xxvi/xx.)

In Chapter IIII [*In Capite IIII*]

(The first six entries on this leaf still belong to Chapter III, standing above the Chapter IIII rubric.)

- When the year is at its greatest, when at its least, and when it holds a middle measure. — 65
- By how much the Roman, or Ecclesiastical, year is greater than the Alphonsine year. — 65
- In how many years the equinox anticipates by one day, according to the Alphonsine year. — 65
- Why the correction of the calendar was instituted in the year 1582, and in October rather than in any other year or month. — 65
- Why in the year 1583, in the more remote regions, the correction was ordered to be made in February rather than in another month. — 66
- That the new calendar, had it been corrected in February of the year 1582, would have shown Easter more correctly than the old one. — 66
- That the Church considers only the mean motions, for many reasons. — 66
- 1st reason. Because the mean motions are equal and uniform, and therefore suited to the grasp of ordinary people, whereas the true motions are unequal and irregular. — 66
- 2nd. Lest a perpetual seedbed of quarrels and discord be stirred up in the Church, if the true motions were observed, on account of the variety of the astronomical tables. — 67
- 3rd. Because no tables have been constructed to this day that would exhibit the true motions without error for many years. — 67
- 4th. Because even if the most perfect astronomical tables existed, the true motions would still be inscribed in vain, on account of the variety of meridians. — 68
- 5th. Because it is the most ancient custom of the Church to observe the mean motions, not the true ones — a custom that ought not to be changed without pressing cause. — 68

- 6th. Because various writers and computists testify that it must be done thus. — **69**
- Why the Prutenic Tables [tabulæ Prutenicæ], which today are used by everyone, can be shown to be uncertain. — **67**
- That some astronomers, in the motion of the Sun and Moon, trust the Alphonsine Tables more than the Prutenic. — **67**
- That 10 days were rightly removed to restore the equinox to 21 March — confirmed by the observations of a certain more recent mathematician. — **76**
- That the astronomical tables are to be greatly valued, even though they cannot last for a long time. — **67**
- The source of the inconstancy of the astronomical tables. — **67**
- That it matters little, as far as the feast-day of Easter is concerned, if the equinox does not always fall on 21 March itself. — **68**
- That God through Moses enjoined the observance of the first month, and of the 10th day and the 14th, in a rustic — that is, simple — manner, suited to the grasp of the whole people of Israel. — **68**
- That the Church is not much concerned with the true or mean new moons and full moons, since in investigating them it has always used cycles. — **68**
- That in employing the lunar cycle the Church imitates all antiquity. — **69**
- That the mean motions are useful for judging which cycle out of several more correctly shows the 14th moons [Lunas xiiij] in the calendar. — **69**

In Chapter V [*In Capite V*]

- What method of intercalation was applied so that the equinox might be preserved near 21 March. — **69**
- What the astronomical year is. — **69**
- What the civil year is. — **70**
- That the astronomical year does not always begin from the same moment of the same day. — **ibid.**
- That knowledge of the astronomical year is necessary in order to equalize the civil year. — **ibid.**

- Why every fourth year is bissextile. — **ibid.**
- That the equinox, if all years were common, would run through all the days of the year in 1460 years. — **ibid.**
- That the intercalation of one day every fourth year is greater than it ought to be, and why. — **ibid.**
- What is to be done so that the equinox does not anticipate. — **ibid.**
- The magnitude of the year according to Ptolemy [Ptolemy]. — **ibid.**
- The magnitude of the year according to al-Battānī [Albategnius]. — **ibid.**
- The magnitude of the year according to the Alphonsines. — **ibid.**
- That the solar year is not always of the same magnitude. — **ibid.**
- Copernicus's [Nicolaus Copernicus] observations on the inequality of the year. — **70**
- In how many years the intercalary day would have to be omitted according to Ptolemy's year. — **71**
- In how many years, according to al-Battānī's year, intercalation would have to cease. — **ibid.**
- In how many years the Alphonsine year requires the omission of one intercalary day. — **ibid.**
- Two ways of intercalating to keep the equinox on 21 March. — **ibid.**
- Which method of intercalation was chosen. — **ibid.**
- Why the mean magnitude of the year was assumed in the correction of the calendar. — **ibid.**
- That an unequal year is not suitable for establishing a method of intercalation. — **71**
- The source of the disputes over the celebration of Easter, from the Council of Nicaea down to the Emperor Justinian [Justinian I]. — **ibid.**
- Why the greatest year is not suitable for the equation of the solar year. — **ibid.**
- Why the least year is not fit for the equation of the solar year. — **ibid.**
- Why the mean year — that is, the Alphonsine — is alone fit for equalizing the solar year. — **ibid.**
- How the method of intercalation established for the mean year corrects itself. — **ibid.**
- That no inconvenience of any importance follows from the intercalation established for the mean year. — **72**
- A second reason why the magnitude of the mean year was assumed in the correction of the calendar. — **ibid.**

- The likeness between the mean conjunctions of the luminaries and the equation established for the mean year. — **ibid.**
- A doubt: that Easter is sometimes thrown back into the second month, and sometimes anticipates the first month, if the equation is established for the mean year. — **ibid.**
- The resolution of the doubt: that it is nothing new for Easter sometimes to be celebrated either in the second month or in the last, on account of the common and bissextile years. — **ibid.**
- That Easter was necessarily celebrated at times both in the second month and in the last, even in the very times of the Council of Nicaea. — **ibid.**
- That the Church does not contravene the decrees of the Fathers, even though it sometimes celebrates Easter either in the last month or in the second, since this can in no way be avoided. — **ibid.**
- The equinox is twofold: the astronomical or true, and the ecclesiastical or civil [Politicum]. — **73**
- Why it is not absurd for the ecclesiastical equinox sometimes to differ from the true one. — **ibid.**
- That the Church observes the equinox and the Moon freely in the celebration of Easter; and why it observes them. — **ibid.**
- That the peace of the faithful in the celebration of Easter is dearer to the Church than an exact observation of the equinox and of the course of the Moon. — **ibid.**

(Chapter V continues at the head of this leaf.)

- 3rd reason why the mean magnitude of the year was assumed in the correction of the calendar. — **73**
- How the equinox, if after some years it had entirely deserted 21 March, could be recalled to the same day. — **73**
- In what the perpetuity and perfection of the Gregorian calendar consists. — **73**
- That the new calendar is not called perpetual as though the equinox could never depart from 21 March, but for another reason. — **73**
- That the equinox cannot remain on the same day, on account of the six hours omitted each year. — **73**
- Why the new calendar is called perpetual. — **73**
- Why the centesimal years were chosen for equalizing the solar year. — **74**

- By what reasoning the omission of the intercalary day in the centesimal years — every four-hundredth being excepted — fits the Alphonsine year. — 74
- Which centesimal years will in future remain bissextile, and which will not, but will turn out common. — 74
- In how many years the equinox would slip by one day from 21 March toward the end of the month, if the Alphonsine year always held the middle place between the greatest and the least year. — 74
- The likeness between the intercalation every four-hundredth year and the customary intercalation every fourth year. — 74
- A doubt: that the equation does not seem rightly applied in the centesimal years, since it ought to be made every 134th year. — 74
- The resolution of the above doubt. — 74
- That the equation applied in the centesimal years preserves the equinox on the same day in the same manner as it is preserved by the intercalation every fourth year. — 74
- That the equation applied in the centesimal years is very similar to the equation of the Arabs in the lunar year. — 75

In Chapter VI [*In Capite VI*]

- When the period of the anomaly of the equinoxes [periodus anomalīæ æquinociorum] began before the birth of Christ, according to the teaching of Nicolaus Copernicus. — 76
- The radix of the period of the anomaly of the equinoxes. — 76
- In what year of Christ the period of the anomaly of the equinoxes will begin again. — 76
- When the true and the mean equinox coincide; when they differ most from each other; and when their difference is moderate. — 76
- When the tropical year [annus tropicus] is greatest, when least, and when moderate. — 76
- The confusion there would be among Christians, if the equation of the equinox were established according to the true motion. — 76
- That the uniform equation is attacked in vain by some. — 79
- That the equinox, according to the equation of the new calendar, does not depart far from 21 March, and therefore that this equation was rightly established for the Alphonsine year, which is the mean. — 79
- That the difference between the true and the mean equinox does not reach one and a half days. — 79

- When the mean equinox precedes or follows the true one. — 79
- How great is the greatest divergence between the true and the mean equinox. — 79
- What deceived some into thinking that the mean equinox could be as much as four whole days away from the true. — 79
- When the mean equinox occurs. — 79
- That the mean equinox does not occur when the line of the Sun's mean motion is joined with the point of the mean equinox. — 80
- Why a certain astronomer thought that the true equinox would slip to 27 March. — 80
- That the new calendar is perfect, even if the Prutenic Tables were still to agree with the true motions after 20,000 years. — 80
- Why, through the equation of the new calendar, the equinox in the heavens falls after 21 March more frequently than before the 21st. — 80
- That any equation whatever, apart from the one established for the Alphonsine year, dislodges the equinox from its proper seat further than it ought. — 81
- That the equation established for the mean year cannot rightly be censured. — 81

In Chapter VII [*In Capite VII*]

- Argument 1 against the new calendar, with its resolution. — 81
- That the Prutenic Tables were employed to restore the calendar. — 81
- That the inconstancy of the astronomical tables does not stand in the way of the perfection and perpetuity of the calendar. — 81
- In what the perfection of the new calendar consists. — 82
- Argument 2 against the new calendar, with its resolution. — 82
- That the restoration of the equinox to 21 March, through the omission of the intercalary day in the year 1700, is not a paying-off of one debt by contracting another [versura], as a certain person slanderously claims. — 82
- That the equinox, on account of the inequality of the year, departs from 21 March in both directions. — 82
- When the equinox rolls forward from the 21st to the 22nd and 23rd, and when it returns to the 21st; likewise when it retreats from the 21st to the 20th and 19th, and when it goes back from there to the 21st. — 82

- That 21 March, assigned to the equinox, holds the middle place between the 23rd and the 19th — the limits to which the equinox can run — since from there it returns of its own accord to the 21st. — **83**
- That in the new calendar Easter rarely falls into the last or the second month. — **83**
- That it is nothing new for Easter sometimes to fall into the last or the second month. — **83**
- That it ought not to be called an error if Easter is sometimes celebrated in the second month, since this cannot be avoided on account of the two days that the equinox requires — whether the new calendar be adopted or the old retained. — **83**
- That the calendar would not have needed correction if the equinox, having advanced to 11 March, had begun of its own accord to go back to the 21st, with no remedy applied. — **83**
- That the equinox's departure from the 21st has place only in the Prutenic Tables. — **83**
- Argument 3 against the new calendar, with its resolution. — **83**
- That the equation of the new calendar answers exactly to some past and future years, though not to all — which is enough. — **84**
- How the equation of the new calendar, carried back to the times of the Council of Nicaea, yields 10 days to be removed. — **84**
- How the equation of the new calendar, had it begun from the Council of Nicaea, would offer 10 days to be removed down to the year 1600. — **84**
- That the removal of 10 days was necessary in order to restore the equinox from the 11th to the 21st, whether or not the equation supplies 10 days to be removed as far back as the Council of Nicaea. — **84**
- A general reply to all the arguments that can be brought against the equation of the equinox. — **84**
- In what sense the equation of the new calendar is to be understood to agree with the mean equinox. — **84**
- Why the new calendar is called perpetual by the Pontiff. — **85**

(Chapter VII continues at the head of this leaf.)

- That no calendar can be constructed in any other way than that in which the Gregorian was constructed, such that it is perfect, perpetual, and lasting. — **85**
- What is required for any calendar to be called complete and lasting. — **85**

In Chapter VIII [*In Capite VIII*]

- What the civil lunar year is, of how many kinds, and how great. — **85**
- What the lunar year is — both common and embolismic, full and hollow. — **85**
- What the astronomical lunar year is, and how great, both common and embolismic. — **86**
- The magnitude of the astronomical lunar month according to the mean motion. — **86**
- How great the half and the quarter of the lunar month are. — **86**
- Meton the Athenian [Meton], inventor of the decemnovenial (19-year) cycle of the golden number. — **86**
- The Metonic decemnovenial year. — **86**
- The period of Callippus [Callippus] of 76 years. — **86**
- The magnitude of the civil lunar month. — **86**
- Why the lunations in the calendar are alternately of 30 and 29 days. — **86**
- Why the new moons in any year mostly occur 11 days earlier than in the immediately preceding year. — **86**
- How many days 19 solar years contain. — **86**
- That in 19 solar years there occur 235 lunations. — **86**
- How great the difference is between 19 solar years and 235 mean lunations. — **86**
- How great the anticipation of the Moon is in 19 years, and how great in 76. — **86**
- That the lunations anticipate by one day in 312½ years, and not in 304 years, as some maintain. — **87**
- That in 19 solar years are contained 235 civil lunations. — **87**
- How 235 civil lunations, contained in 19 years, fill out the time of just as many mean lunations, although in each one 44 minutes, 3 seconds, 11 thirds of one hour are omitted. — **87**
- From where, in 19 years, are supplied the 44 minutes, 3 seconds, 11 thirds that are omitted in each civil lunation, together with the 12 hours taken from the last, extraordinary lunation. — **87**

In Chapter IX [*In Capite IX*]

- The description of the golden numbers in the calendar. — **88**
- What order there is among the golden numbers in the calendar. — **88**

- How the following golden number is generated from the immediately preceding one, and vice versa. — **88**
- That in the calendar a lesser golden number mostly follows immediately upon a greater preceding one, but a greater does not immediately follow a lesser. — **88**
- By what method, from the first golden number of the calendar, or from the last, all the others are inscribed in the calendar. — **88**
- In which places a greater golden number immediately follows a lesser in the old calendar. — **88**
- In which places a greater golden number would immediately follow a lesser in the new calendar of the present time, if the golden numbers were to be written in it. — **89**
- The ecclesiastical calendar that the Church used from the Council of Nicaea down to the correction of the year made by Gregory XIII. — **90**
- That the first golden number of January is not formed by adding 8 to the last golden number of December. — **94**
- The ecclesiastical calendar that the Church would have to use after the correction of the year made by Gregory XIII, down to the year 1700, if golden numbers had been written in it instead of epacts. — **94**
- Why the following golden number is formed from the preceding by adding 8 or subtracting 11, but the preceding from the following by adding 11 or subtracting 8; and why the golden numbers are not written in continuous order in the calendar. — **99**
- How the new moons are investigated from the golden numbers arranged in the calendar. — **99**
- The deficiency of the golden number for investigating the new moons. — **99**
- By how much the new moons had anticipated from the time of the Council of Nicaea down to the year of correction. — **99**
- How the golden numbers in the old calendar would have had to be changed so that they might indicate the new moons both before the correction and after. — **99**
- That the golden numbers, once corrected in the calendar, cannot show the new moons perpetually or for long, and why. — **100**
- That if the golden number had to be kept in the calendar, 30 calendars would have to be drawn up. — **100**

- That the 30 epacts were rightly substituted in place of the golden numbers. — **100**
- Why every epact must be less than 30. — **100**
- What the epacts are, and why they are 30. — **100**
- Why they are called epacts. — **100**

In Chapter X [*In Capite X*]

- Why the epacts are arranged in the calendar in retrograde order. — **101**
- How the epacts are arranged in the calendar. — **101**
- That the epacts arranged in the calendar do not keep the order of the cycle. — **101**
- Why in six places of the calendar two epacts are assigned to the same day. — **101**
- That the lunations occur alternately of 30 and 29 days, because of the placing of two epacts on the same day in six places of the calendar. — **101**
- Why epact 25 (Arabic) must be written in a different type or colour above the other epact xxv (Roman) in six places of the calendar. — **101**
- That, because of epact 25 (Arabic) written in a different colour or type, two new moons cannot fall on the same day within the same decemnovennial cycle. — **101**
- Why in the same cycle epact xxiiij (Roman) is not used when epact xxv (Roman) and a golden number not greater than 11 concur; likewise why epact xxvi (Roman) is not in use in the same cycle when epact 25 (Arabic) and a golden number greater than 11 concur. — **102**
- That epact 25 (Arabic), of a different colour or type, placed opposite epact xxvi (Roman), does not disturb the lunations. — **102**
- Why the equation of the lunar months was made rather by epacts xxv and xxiiij (Roman) placed together than by others. — **102**
- Why not all the Paschal lunations in the new calendar are of 29 days, as in the old. — **103**
- Why the equation of the epacts proposed in the calendar of the Compendium was rejected, and another established in the new calendar. — **103**
- Why epact 19 (Arabic), in a different colour or type, is placed at the last day of December opposite epact xx (Roman) in the calendar. — **103**

- That, because of epact 19 (Arabic) placed at the last day of December opposite epact xx (Roman), two new moons cannot fall on the same day within the same decemnovennial cycle. — **104**
- How, from the epacts arranged in the calendar, the new moons are investigated according to the usage of the Church. — **104**
- By what method the epacts can indicate the new moons perpetually. — **104**
- That the epacts have rightly succeeded to the place of the golden numbers, and are arranged in retrograde order in the calendar. — **104**
- That the days of December remaining after the last lunation mostly show the epact of the following year. — **104**
- That the 30 epacts [Epactas 30, Arabic] can be arranged in direct order in the calendar. — **105**

This is a continuation of the *Index* (the chapter-by-chapter table of contents) of the *Explicatio Romani Calendarii*. Each entry is a topic-statement followed by the page reference on which it is treated. The block rubrics (IN CAPITE ...) are preserved verbatim; the numeral form of each page reference is transcribed as printed.

IN CAPITE XI. (*In Chapter 11*)

- From the 30 epacts only 19 are used, within one or more spans of a hundred years, to show the new moons. — 105
- When the 19 epacts are to be taken one unit greater than the preceding 19, and when smaller. — 105
- Construction of the table of expanded epacts. — 105
- Why letters of the alphabet, rather than years of the Lord, are assigned to the lines of epacts in the expanded table. — 106
- Construction of the table of the equation of the epacts. — 106
- That the new moons, by the practice of the Church, ought to be indicated by the Cycle after the celestial new moons. — 107
- That the new moons of the golden numbers, around the time of the Council of Nicaea [Concilium Nicænum], were nearly the same as those occurring in the sky. — 107
- That the new moons of the golden numbers, around the year of the Lord 550, occurred later than those in the sky, and were therefore better suited to the use of the Church. — 107
- Where the root of the equation of the epacts is to be fixed. — 107

- That the equation of the Moon is anticipated at every three-hundredth year by $12\frac{1}{2}$ years, of which account must nonetheless be kept until they make up a total of 100 years. — 107
- Continuation of the table of the equation through the hundredth-years up to the year 1582 of the correction. — 107
- How the equation of the epacts is set up in the year of the correction, 1582. — 108
- Which letter of the equation belongs to the year of the correction, 1582. — 108
- How the table of the equation of the epacts is set up after the correction, taking account of the equation of the solar year. — 108
- Which letter of the equation belongs to the year 1600. — 108
- Which letter of the equation belongs to the year 1700. — 108
- Which letter of the equation belongs to the year 1800. — 108
- Which letters of the equation belong to the years 1900, 2000, 2100. — 108
- Which letters of the equation belong to the years 2200, 2300[?]. — 109
- Which letters of the equation belong to the years 2400, 2500. — 109
- Which letters of the equation belong to the years 2600, 2700, 2800. — 109
- Continuation of the table of the equation of the epacts after the correction, through the hundredth-years to infinity, according to the mind of the author of the Calendar. — 109
- THE EXPANDED TABLE of epacts, together with the perpetual table of the equation of the epacts, following the opinion of Lilius [Lilj], and also with the days removed. — 110
- A threefold rule for continuing the table of the equation of the epacts to infinity, following the opinion of Lilius. — 131
- That by the table of the equation of chapter 11 the epact is not to be found beyond the year 8200. — 131
- That the letters of the equation of the epacts, after 10,000 years, proceed in the same proportion as before, and why. — 132
- That the whole labor of framing the table of the equation lies in the first span of 10,000 years. — 132
- That the table of the equation is contained within a cycle of 300,000 years, and why. — 133
- What is to be done in the equation of the Moon after 481,436 years. — 133

IN CAPITE XII. (*In Chapter 12*)

- What the cycle of the golden number is. — 133
- The golden number of any year begins in January. — 133
- Finding the golden number for any year from the new table. — 133
- Finding the golden number from another new table. — 133
- A far quicker finding of the golden number. — 139
- Finding the golden number from temporary tables. — 140
- Finding the golden number from another table extending to more years. — 141
- The use of the expanded table, and of the equation of the epacts, in finding the epact of any year. — 141
- By which table the epact is more correctly found after the year 8200. — 141
- The epact of any year begins in January. — 142
- Construction of the perpetual Cycle of epacts. — 142
- Finding the epact for any year from the perpetual Cycle of epacts. — 142
- An abridgement of the table of the equation of the epacts of chapter 11. — 144
- The use of the abridgement of the table of the equation of the epacts in finding the epact of any year. — 144
- Finding the letter of the expanded table, or of the perpetual Cycle of epacts, for investigating the epact of any year, by arithmetic. — 145
- Finding the number of days removed, from the year 1700 inclusive up to any hundredth year inclusive. — 145
- How the postposition of the Moon for any hundredth year is found. — 149
- That, in order to draw the postposition of the Moon for any hundredth year from the tables, one must enter the earlier table only once at the end, even if the year with which the entry is made is also found in the later table. — 149
- Why the author of the Calendar chose to set forth his equation, although it is fallacious in far-distant ages. — 150
- That it is not absolutely necessary for the table of the equation of the author of the Calendar to be corrected. — 150
- A more accurate finding of the letter of the expanded table in far-distant ages. — 153
- A more accurate finding of the same letter, from memory. — 153
- What to do when the postposition of the Moon, added to 9, is greater than 365. — 153

- An easy finding of the letter of the expanded table, when the 11 letters must be counted repeatedly. — 154
- A more accurate finding of the epact than was given at Number 3. — 154
- That the letter of the expanded table is sought in vain by the foregoing rules after 100,000 or 200,000 years. — 154
- A more accurate construction of the table of the equation of the epacts than in chapter 11. — 154
- That in the expanded table the descent is sometimes rightly made through two lines. — 155
- Why in chapter 11 the table of the equation for 300,000 years was set forth, though it is fallacious. — 155
- An easy finding of the letter of the expanded table, up to the year 310,000. — 155
- The ready construction of a certain table for seeking out the epact. — 157
- Finding the epact for any year from the aforesaid table. — 159
- Finding the epact of any year from temporary tables. — 159
- Construction of temporary tables for investigating the epacts. — 159
- How the epact of any year is formed from the epact of the preceding year. — 165
- Why 12 is added to the epact concurring with golden number 19, to make up the following year's epact. — 165
- Why, when golden number 19 is running, a unit must be added to the days that remain in December after the last lunation, so that the following year's epact may be established. — 165
- Why the following epact is not always formed from the preceding one by adding 11 or 12. — 166
- In what way the table of the equation of the epacts is to be restored, if perhaps another magnitude of the year is found by posterity. — 166
- In what way the table of the equation of the epacts is to be restored, if perhaps the Moon must be equated differently. — 166
- That the epacts do not change their places in the Calendar, even if the table of the equation must be renewed. — 166
- Why the cycle of the golden number, or any other that does not fill all the places of the Calendar, cannot be immutable in the Calendar. — 166
- Why the Gregorian Calendar is called perpetual. — 167

(Chapter 12 continued)

- In what sense the cycle of epacts of the new Calendar is said to be adaptable to any magnitude of the year. — 167
- That the new Calendar is not called perpetual on the supposition that, by our equation, the equinox cannot leave the 21st of March. — 167
- Why a twofold method of equating the solar year was set forth in the Compendium sent to the princes. — 167
- How easy the restoration of the equinox is, by the omission or intercalation of a few days. — 167
- Why it has always seemed difficult to inscribe in the Calendar a cycle that is perpetual. — 167
- Praise of the new Calendar. — 167
- How the table of the equation of the epacts is to be corrected in the most far-distant ages. — 167

IN CAPITE XIII. (*In Chapter 13*)

- That an easier method of computing the new and full moons is given in chapters 25 and 26. — 168
- What the epacts of the years and of the months are. — 168
- How the epacts of the years and of the months are gathered and reduced into tables. — 168
- Tables of the epacts of the years and of the months. — 169
- By what method the new and full moons are sought from the tables of epacts. — 171
- What to do when the new or full moon sought falls beyond the proposed month. — 172
- Why, in the reckoning of the lunations, all the days removed on account of the equation of the equinox must be added. — 172
- Table of the revolutions of the new moons. — 173
- Why, in the new moons found by computation, the anticipation of 1 hour 27 minutes 33 seconds is not perceived after 19 years. — 173
- A table for computing the new and full moons up to the year 1,000,000,000. — 174

IN CAPITE XIII. (*In Chapter 14*)

- Construction of the table of new moons for 76 primary years, from the year 1501 inclusive up to the year 1576 inclusive. — 174

- Construction of the table of orders, and of the time that must be added to or subtracted from the new moons in each order. — 174
- How the series of years to the right of the table of new moons proceeds. — 175
- Table of the anticipation of the Moon in years progressing by 67, which contains the orders and the time that must be added to or subtracted from the new moons in each order. — 176
- Table of new moons for 76 primary years, from the year 1501 inclusive up to the year 1576 inclusive, which make up one Callippic period [periodus Callippi]. — 177
- Finding the new moon in any month of a given primary year, together with the full moon, from the aforesaid table. — 253
- Finding the new and full moon in any month of a given year after 1576, up to the Gregorian correction, from the same table. — 253
- Finding the new and full moon after the correction of the year, from the same table. — 253
- What to do when the new moon found falls beyond the proposed month. — 253
- How the new moons are found in the common hundredth-years. — 253
- What to do when the time of some order cannot be subtracted from the new moon of a month of a primary year. — 254

IN CAPITE XV. (*In Chapter 15*)

- By what method the golden numbers are extracted from the epacts, so that they may be inscribed in the Calendar serving a given century. — 254
- Explanation of the thirty Calendars with golden numbers, together with a table of the aforesaid 30 Calendars. — 254
- How the new moons are investigated by the golden numbers of the 30 Calendars. — 304
- The disadvantage of the 30 Calendars. — 304

IN CAPITE XVI. (*In Chapter 16*)

- Explanation of the 30 tables comprising all the lunations of the thirty Cycles of the expanded table, together with the tables themselves. — 304
- When the lunar year, both common and embolismic, becomes hollow, namely of 353 or 383 days. — 335

IN CAPITE XVII. (*In Chapter 17*)

- That a lunation is assigned to the month in which it ends, and why. — 335
- That every Cycle of epacts begins either from *, if it is contained in the proposed Cycle, or from 1, if * is not found in the given Cycle. — 335
- Which nineteen-year Cycles begin from *, and which from epact 1. — 335
- That any nineteen-year Cycle of epacts begins either from the first day of January or from the last day of December. — 336
- That the cycle of the golden number, before the correction, after the Council of Nicaea, always began from golden number 3 and from the first day of January. — 336
- That the nineteen-year cycle of the golden number begins either from the golden number written at the Kalends of January, or from that which would have to be ascribed to the last day of December, if the solar year began from there. — 336
- That the beginning of the cycle of the golden number is taken successively from all the golden numbers, if the equation of the solar and of the lunar year is applied. — 337
- Why every nineteen-year Cycle of epacts always begins from * or from epact 1. — 337
- That the cycle of the golden number among the Alexandrians always began from the last day of their year, and from golden number 1. — 337
- What an embolism is. — 337
- By what method 13 lunations can be contained in one year. — 337
- That in every nineteen-year Cycle there are 7 embolismic years; whence this is known, and which they are. — 337
- Why in every nineteen-year Cycle the years 3, 6, 9, 11, 14, 17, and 19 are embolismic. — 337
- Why in a nineteen-year Cycle one of the 7 extraordinary lunations necessarily contains only 29 days. — 337
- When an embolismic year becomes one of 384 days, and when of 383 days. — 337
- That only two nineteen-year Cycles out of all 30 of the expanded table have a seventh embolismic lunation of 29 days. — 338
- That the first lunation of an embolismic year ends on one of the first 11 days of January; and why. — 338
- That eleven epacts are always embolismic — that is, that the year is embolismic in which one of them runs with any golden number — and which they are. — 338

- That the 12th lunation in an embolismic year ends on one of the last 11 days of December; and why. — 338

(Chapter 17 continued)

- That the first lunation of the year following an embolism always begins from some embolismic epact, except in the embolism in which epact xix does not run with golden number 19; and why. — 338
- That the 11 enumerated epacts are, all and only, always embolismic; and that the 7 enumerated years in every nineteen-year Cycle are, all and only, embolismic; how this is known from the expanded table and from the 30 tables of lunations. — 338
- That the year in which epact xviii and golden number 19 concur is also embolismic; and why. — 338
- That the year in which epact xviii and golden number 19 concur is also embolismic; and why. — 339
- That the year in which epact xviii does not concur with golden number 19 is not embolismic; and why. — 339
- Which seven golden numbers were embolismic in the old Calendar. — 339
- That the cycle of the golden number in the old Calendar necessarily took its beginning from 3. — 339
- Why the cycle of the golden number in the old Calendar could have its beginning from no other number than 3. — 339
- Which of the 13 lunations of an embolismic year is to be called embolismic. — 339
- Which of the 13 lunations of an embolismic year is to be called embolismic. — 339
- Which embolismic epacts have a 13th lunation of 30 days and embolismic. — 339
- When the embolismic epacts, whose 13th lunation is of 30 days, have a first lunation of the year of 29 days. — 339
- That epacts xviii and xix, concurring with golden number 19, have a 13th lunation that is embolismic and of 29 days. — 340
- Which embolismic epacts have a first lunation of the year that is embolismic and of 29 days. — 340
- When the same embolismic epacts, of which we have just spoken, have a second lunation that is embolismic and of 30 days. — 340

- What the leap of the Moon [saltus Lunæ] is, among the computists, in common lunar years. — 340
- When, in an embolismic year, the leap of the Moon can be said to occur. — 340
- Which embolismic years contain only 383 days, and which common lunar years only 353. — 341
- That the leap of the Moon always occurs when the golden number is 1, otherwise never, except in the embolismic years of epacts xix, xviii. — 341
- Why the leap of the Moon is displeasing to most. — 341
- That, on account of the embolisms and the leap of the Moon, it sometimes happens that two or three consecutive lunations are of 29 days, and two, three, or four of 30 days. — 341
- That it is neither new nor absurd for two or more consecutive lunations to be sometimes of 29 or of 30 days. — 341
- Table of the lunations of the golden numbers set down in the old Calendar. — 342
- Why the epacts in the expanded table do not exhibit, for the time of the Council of Nicaea, the golden numbers as they are arranged in the old Calendar. — 343
- The 12 places in which the golden numbers of the new Calendar differ from the golden numbers of the old Calendar. — 343
- The excellence of the new Calendar with its epacts. — 344
- How the embolismic epacts are known from the perpetual table of new moons. — 344
- Perpetual table of the new moons of the whole year. — 344

IN CAPITE XVIII. (*In Chapter 18*)

- The false opinion of some, that Easter [Pascha] is not to be celebrated on the 15th moon but afterward. — 346
- How it was forbidden that the Christian Easter [Pascha Christianum] be celebrated together with the Jews. — 346
- That Easter has frequently been celebrated in the Church on the 15th moon. — 346

(*Chapter 18 continued*)

- The false opinion of some concerning the 14th Paschal moon [Luna xiiii. Paschalis]. — 346

- Another false opinion concerning the 14th Paschal moon. — 346
- What the 14th Paschal moon is, according to the practice of the Church. — 346
- That tables of the mean motion of the Moon are useful for examining any proposed Cycle. — 347
- Which Cycle, out of all, is to be chosen. — 3[?]4
- That the cycle of epacts is so arranged that the 14th Paschal moons do not precede the mean oppositions by more than one day; and why. — 347
- That if the new moon of the Cycle did not follow the conjunction that occurs in the sky, Easter would often be celebrated before the full moon. — 347
- Why the epacts in the Calendar were not moved up by one day, so that they might indicate the new moons sooner than they now do. — 347
- That in the table of the equation the capital letter D is rightly set against the year 1582 after the correction, but not the capital letter E. — 350
- That Easter, around the time of the Council of Nicaea, frequently fell as it were on the 14th moon, because the new moons were shown too early. — 350
- Why, in the celebration of Easter even after the Council of Nicaea, so many disagreements arose between the Eastern and the Western Church. — 350
- That many errors would occur in Easter if the epacts indicated the new moons sooner than they do by the prescription of the new Calendar, especially in the year 1598. — 351
- That it is not rightly affirmed by some that the Easter of the year 1598 ought to have been thrown back from the 22nd of March to the 29th. — 351
- That new moons set too late cause Easter sometimes to be celebrated in the last month. — 351
- That the arrangement of the epacts in the Calendar cannot rightly be censured. — 351
- That in the new Calendar Easter is rarely celebrated before the mean opposition — or nearly so — such that in some manner it does not fall short of it. — 351
- That a Cycle, whatever it be, cannot avoid all inconveniences. — 352
- That the epacts of the new Calendar hold a middle course in the anticipation and postposition of the new moons. — 352
- That the epacts could not be better placed than has been done in the new Calendar. — 352

- That when the 14th moon anticipates the mean opposition more than is right, the error is often corrected by the Dominical letter. — 352
- Why a Cycle, whatever it be, cannot correspond exactly to the celestial motions. — 352
- Why the lunations in a leap year, after the intercalary day, are slower than is fitting. — 352
- When the Moon, according to Bede [Beda], is to be called the first. — 352
- When the Moon, according to Campanus [Campanus], is to be called the first. — 352
- What the 14th moon is, in Theophilus [Theophilus] and St. Cyril [S. Cyrillus]. — 353
- That the epacts of the new Calendar rightly indicate the new moons after the mean conjunctions. — 353
- That in the civil solar year [annus Politicus Solaris] that day is sometimes called the first which would more truly be the last. — 353
- That that day is sometimes called the last of some month which would more truly be called the first of the following month. — 353

IN CAPITE XIX. (*In Chapter 19*)

- 1. An argument against the epacts, and its solution. — 353
- That the Cycle of epacts shows in the Calendar how many days have generally elapsed after the true conjunction. — 353
- 2. An argument against the epacts, and its solution. — 390 & 391
- The Paschal new moon of the 5th of April ceases to be Paschal when the passage is made from the upper line of the expanded table to the lower [line]... —

These leaves conclude the subject index arranged by chapter (its entries grouped under "In Chapter ..." rubrics) and then open the *Alphabetical Index*. Each entry is given in English with its page reference transcribed verbatim; "ibid." (in the same place) is preserved as printed, and the doubled epact-numeral forms (xiiij, xv, xxv) are kept as set in the source.

Subject Index, arranged by chapter (continued)

(*Continuation of the entries for Chapter XIX*)

- ...the lower one; and the non-Paschal new moon of 7 March begins to be Paschal. 354
- The Paschal new moon of 8 March ceases to be Paschal, when the passage is made from the lower line of the expanded table to the upper, and the non-Paschal new moon of 6 April begins to be Paschal. *ibid.*
- No cycle, whatever it be and by whatever method it is set out in the calendar, can avoid sometimes displaying the xv Moon in the second month, or in the last — which it nonetheless calls Paschal. 356
- Very often no Easter could be celebrated in a given year, if the mean motions were observed by the Church, and not the cycles. *ibid.*
- What the Church does when in some year there is no Paschal full moon. *ibid.*
- In what month the Church celebrates Easter, when in some year there is no Paschal full moon. 357
- The same golden number sometimes throws Easter back from March into April, and the reverse. *ibid.*
- The same golden number, from one centennial year to the next following, in certain years shows the xiiij Moon now before the mean opposition, now after it. *ibid.*
- How it is clearly demonstrated, from what has just been said, that the epacts are rightly placed and equated in the calendar. 358
- Some epacts, in years of the same century, show their xiiij [Moons] before the mean oppositions, others after them. *ibid.*
- In the times of the Emperor Justinian the same golden number in the old calendar showed the xiiij Moon now earlier, now later; likewise some anticipated their xiiij [Moons], while others postponed them. 359
- In certain years no mean Paschal full moon is found in the old calendar. *ibid.*
- Four errors that can be avoided in no calendar; and what they are. 360

In Chapter XX

- What the solar cycle is. 361
- The cycle of dominical letters is the same as the solar cycle. *ibid.*
- The finding of the solar cycle from tables, in three ways. *ibid.*
- Temporary tables of the solar cycle. 364

In Chapter XXI

- Whence the 28-year cycle of dominical letters arises. 365

- The finding of the dominical letter by the solar cycle, from a table. 366
- Temporary tables of the dominical letters. 369
- An easier finding of the dominical letter, without the solar cycle, from a table. 369
- The dominical letters found for the first 4 years of Christ by the calendar's prescription differ from those which were then actually in use. 372
- The 400-year cycle of dominical letters after the correction. *ibid.*
- The finding of the dominical letter from the 400-year cycle. *ibid.*
- By what method one may learn what place any given year holds in the 400-year cycle. 375

In Chapter XXII

- What the movable feasts are. 375
- How the key to the resolved table of movable feasts for 70 years is constructed. 376
- The finding of the movable feasts from the resolved 70-year table. 376
- The temporary table of movable feasts, from the year 1600 up to the year 5000. 380
- The preceding table of movable feasts shows that the epacts correctly indicate the *xiii*j Moons. 502
- In what years the *xiii*j Moons appear to run ahead of the mean oppositions more than is proper. *ibid.*
- That the full moon falling on Easter day before sunset is not contrary to the canon of the Council of Nicaea. *ibid.*
- The same epact shows the *xiii*j Moon now anticipated, now postponed, and now at last in accord with the canons. *ibid.*
- The same error in the *xiii*j Moons is found in the ancient golden-number cycle promoted to a higher place, which is detected in the cycle of epacts. 503
- The same error that has been noted in the epacts is detected in the golden number at the time of the Council of Nicaea. 503

In Chapter XXIII

- Easter is to be celebrated on one and the same day in all parts of the world. 505

In Chapter XXIII

- The title of Viète's calendar. 505

- Viète devises a new arrangement of the epacts and a new beginning of the year. 506
- The Gregorian calendar according to Viète's opinion. 506
- Viète's bold deed in printing his own calendar separately, together with Gregory's bull. 510
- That the year should begin from 8 March, as Viète wishes, is not necessary. 510
- Viète breaks the common rule for finding the age of the Moon by the epacts. *ibid.*
- Viète's epacts are truly not epacts. 510
- Viète's epacts are not equal to the days that remain over in December after the last lunation. 512
- Several lunar months in Viète contain only 28 days. *ibid.*
- Several lunar months are set by Viète at only 27 days. *ibid.*
- From the first lunation of the year, on account of the equation of the Moon, one day is taken away or added. 512
- For what reason Viète so often makes the lunar month one of 28 days, and sometimes of only 27 days. *ibid.*
- Why it is not absurd that one lunation in bissextile years should contain 31 days. *ibid.*
- That Viète, willy-nilly, sometimes makes a lunation of 31 days. *ibid.*
- The equinox is better kept in its place if the intercalation is made at the beginning of the fourth year than if at the end. 513
- That Viète sometimes either sets two new moons next to each other with no day intervening, or has no Paschal new moon at all, and assigns 31 days to a single lunation. *ibid.*

(Continuation of the entries for Chapter XXVIII)

- That Viète sometimes even makes a lunation of only two days, or of 32. 514
- That Viète does not always add 11, so that the following epact may be formed — even when the golden number is not 19 and no other letter of the equation is to be taken — against the doctrine of all computists. *ibid.*
- That Viète rashly deprives six days of the year of a new moon. *ibid.*
- That the Paschal months should be full, as Viète wishes, is not necessary. *ibid.*
- Viète's κριτικὰ[?] [critical objections] against the Gregorian calendar, and their solutions. *ibid.*

- What the author of the calendar and its correctors had before their eyes in the equation of the epacts. 518
- That some epacts, in any cycle whatever, do not exhibit congruous xiiij Moons. *ibid.*
- Why the placing of the epacts, and their equation in the Gregor[ian] calendar, cannot rightly be censured. *ibid.*
- That Gregory XIII's intention in correcting the calendar was not the one Viète imagines for himself. 519
- The right ordering of the cycle in the calendar, in what it consists. *ibid.*
- That Viète proposes two tables of the equation of the epacts contrary to one another. *ibid.*
- That Viète, according to the earlier table of the equation, exhibits 125 Easters before the mean full moon. 521
- That Viète, according to the same earlier table of the equation, not rarely celebrates Easter in the second month. 524
- Viète's rule for finding the epact in any given year. 524
- That Viète, according to the later table of the equation, more often celebrates Easter in the last month. 525
- That Viète very often exhibits xv Moons before the legitimate time. 527
- That Viète postpones not a few xiiij Moons more than is proper. 528
- That the Moon's great period of 3400 years does not accurately restore the synodic months, as Viète thinks. *ibid.*
- The progression of the new moons from century to century, according to Viète's opinion. 529
- The truer progression of the new moons from century to century after the correction, how great it is. *ibid.*
- The progression of the new moons from century to century before the correction, how great it is. *ibid.*

In Chapter XXV

- How the epacts corrected for computing the new moons after the correction are gathered. 530
- By what method the Paschal new moon of any centennial year after the correction is computed by the corrected epacts. 533
- When the Paschal full moon falls in March, or in April. *ibid.*

- By what method the Paschal new moon or full moon of any expanded year is elicited from the new moon or full moon of the centennial year immediately preceding it. 533
- By what method the new moon or full moon of any month is drawn from the new moon or full moon of March or April. 535
- A compendium for computing the Paschal full moons of the 100 expanded years. 536

In Chapter XXVI

- The progressions of the new moons and of the full moons, by what method they are gathered. 537
- By what method the Paschal new moon and full moon is computed by the progressions of the new moons. 539

In Chapter XXVII

- In what matters the Gregorian calendar is censured by very many. 540
- Who they are that have published a calendar of their own different from the Gregorian. *ibid.*
- That Scaliger took the calendar of the *Compendium* for his own. *ibid.*
- What errors Scaliger committed in his own calendar. *ibid.*
- By what method Scaliger investigates the epact of any given year. 542
- That the little table of Jewish new moons proposed by Scaliger does not sufficiently agree with the perpetual cycle of epacts. *ibid.*
- That Scaliger, in the changing of the epacts, did not always take account of the postponements of the Moon and of the days removed. 544
- That Scaliger's *xiiiij* Moons very often occur two days, or three, or even four before the Gregorian *xiiiij* Moons. 546. 548
- That Scaliger not rarely offers Easter to be celebrated one day, or even two, before the full moon. *ibid.*
- That Scaliger frequently celebrates Easter in the last month of the preceding year. *ibid.*
- That some of Scaliger's *xiiiij* Moons are postponed too much. 549
- What is to be gathered from the things that have been said against Scaliger and Viète. 551

In Chapter XXVIII

- The calculus of lunations, extended by tables as far as the Fourths [fourth differences]. 552

Alphabetical Index

ALPHABETICAL INDEX.

A

- The finding of [the Sunday of] the Lord's Advent by memory. 579
- An equation established for the mean year cannot rightly be censured. 81
- An equation of the equinox, if it were established according to the true motion, would stir up great confusion among Christians. 79
- Why the equation of the epacts proposed in the calendar of the *Compendium* was rejected, and another established in the new calendar. 103
- By what method the equation of the epacts is to be established, according to the opinion of Nicolaus Copernicus, following the varying magnitude of the *animi* [recte: *anni*, "of the year"]. 11
- How the equation of the epacts was established by Aloysius Lilius according to the Alphonsine year. 9
- The equation applied in the centennial years keeps the equinox on the same day, in the same manner in which it is kept by the intercalation of every fourth year. 75
- The equation applied in the centennial years keeps the equinox on the same day more correctly than if it were done in any 134th year. 75
- The equation applied in the centennial years is very similar to the equation of the Arabs in the lunar year. 75
- What the equation of the Moon requires after 481436 years. 133
- The equation of the Moon, [made] every three-hundredth year, is forestalled by 12½ years, of which account must nevertheless be taken when they complete a sum of 100 years. 107
- Why the equation of the lunar months was made rather by the epacts xxv and xxiiij placed together, than by others. 102
- How the equation of the new calendar, had it begun from the Council of Nicaea, would present 10 days to be removed up to the year 1600. 84
- How the equation of the new calendar, carried back to the time of the Council of Nicaea, shows 10 days to be removed. 84
- How the table of the equation of the epacts is constructed. 106
- How the table of the equation of the epacts is to be corrected in the most widely distant centuries. 167

- The use of the equation of the epacts, established according to Aloysius Lilius. 10
- By what method the table of the equation of the epacts is to be restored, if perhaps another magnitude of the year should be discovered by posterity, or the Moon should have to be equated otherwise than has been declared. 166
- How it is to be understood that the equation of the new calendar agrees with the mean equinox. 84
- That the equation of the new calendar corresponds exactly to several past and future years, though not to all — which is enough. *ibid.*
- A uniform equation is attacked by some in vain. 79
- Where the root [epoch] of the equation of the epacts is to be set. 107
- That any equation whatever, except the one established according to the Alphonsine year, disturbs the equinox from its proper seat further than it should. 81
- How easy the restoration of the equinox is, by the omission or intercalation of some days. 167
- The seat of the equinox was fixed on 21 March by the Council of Nicaea. 3
- The recession of the equinox from the 21st [of March] has place only in the Prutenic tables. 83
- That the restoration of the equinox to 21 March, by the omission of the intercalary day in the year 1700, is not the discharging of one debt by another [*versura*], as someone slanderously alleges. 82
- Many Supreme Pontiffs attempted to correct the error of the equinox and of the *xiiij* Moon. 3
- The emendation of the equinox, if it were established according to the true motion, would generate great confusion among Christians. 79
- The 21st of March was assigned to the vernal equinox by the Council of Nicaea. 62
- By what method a fixed seat is established for the equinox by Aloysius Lilius. 3
- When the period of the anomaly of the equinoxes began before the birth of Christ, according to the doctrine of Nicolaus Copernicus. 76
- In what year of Christ the period of the anomaly of the equinoxes will begin again. 76
- By what method of intercalation the equinox is kept near 21 March. 69

- The equinox is twofold: astronomical, or true, and ecclesiastical, or political. 73
- When the true and the mean equinox occur together, and when their difference is moderate. 76
- When the equinox slips from the 21st to the 22nd and 23rd, and when it returns to the 21st; likewise when it recedes from the 21st to the 20th and 19th, and when it goes back thence to the 21st. 82
- In how many years the equinox would slip forward by one day from 21 March toward the end of the month, if the Alphonsine year always held the mean place between the greatest and the least year. 74
- Aloysius Lilius alone assigned a fixed seat to the equinox in the calendar, and at the same time set out in it a perpetual cycle of the Moon.
[reference: ?]
- The equinox had deserted its seat. 3
- The equinox, according to the equation of the new calendar, cannot recede far from 21 March, and therefore it was rightly established for the Alphonsine year, which is the mean. 79
- The equinox cannot remain on the same day, on account of the six hours omitted each year. 73
- That the equinox has been correctly restored to 21 March by the removal of 10 days is confirmed by the observations of a certain more recent mathematician. 69
- That the equinox is disturbed from its proper seat further than it should be by any equation except the one established for the Alphonsine year. 81
- The equinox and the new moons, at the time when the calendar was being corrected by Gregory XIII, did not fall on the same days as they did at the time of the Council of Nicaea. 63
- That the equinox, on account of the inequality of the year, recedes to either side of 21 March. 82
- The equinox is more correctly kept on 21 March by the equation applied in the centennial years than if it were done every 134th year. 74
- According to what opinion the equinox was restored by Gregory XIII. 65
- The mean equinox does not occur when the line of the Sun's mean motion is joined with the point of the mean equinox. 80
- The equinox must necessarily be restored by the removal of 10 days...

These leaves continue the *Alphabetical Index*. Each entry is given in English with its page reference transcribed verbatim from the source; the doubled Moon- and

epact-numeral forms (xiiij, xv, XIII, xxv) and the epact-30 asterisk * are preserved exactly as set, and Arabic year- and quantity-numbers are kept as printed. The run continues the letter **A**, then passes to **B** and **C**.

A (continued)

- ... — whether the equinox had to be reclaimed by shifting from the 11th onto the 21st; that is, whether the equation supplies 10 days to be removed, reckoning back to the Council of Nicaea, or not. 84
- Whether, if after some years the equinox had wholly deserted 21 March, it could by any means be brought back to the same day. 73
- The restoration of the equinox has been proposed variously by various people. 64
- Why most people judged it impossible that a fixed seat could be assigned to the equinox in the calendar, and a perpetual lunar cycle laid out. 1
- That it is difficult to ascribe a fixed seat to the equinox, on account of the uncertain and variable magnitude of the tropical year. 3
- That the equinox is kept on the same day by the equation applied in the centennial years, in the same way as it is kept on the same day by intercalation every fourth year. 75
- When the mean equinox occurs. 79
- That, if all the years were common, the equinox would run through all the days of the year in 1460 years. 70
- Why the equinox anticipates its seat in the calendar. 74
- That the equinox is better kept in its seat if the intercalation is made at the beginning of the fourth year than if it is made at its end. 513
- By what reasoning the vernal equinox was brought back to 21 March. 65
- That the equinox, even though it does not always fall on 21 March, does not thereby harm the feast of Easter. 63
- That the vernal equinox would slip forward to 27 March, as a certain astronomer supposed. 80

- In how many years the equinox anticipates by one day, according to the Alphonsine year. 65
- When the mean equinox precedes, or follows, the true. 79
- By what method the equinox is to be kept so that it does not anticipate. 70
- Why, under the equation of the new calendar, the equinox more frequently falls in the heavens after 21 March than before that same 21st. 80
- That the mean equinox can be as much as a full four days distant from the true — which some have falsely supposed, and why. 79
- What disadvantages the restoration of the equinox according to others would have entailed. 65
- The finding of the age of the Moon by memory. 567
- How many years the year of al-Battānī [Albategnius] requires for one intercalary day to be omitted. 71
- How great the year is according to al-Battānī. 70
- That the care of the golden-number cycle was entrusted by the Council of Nicaea to the Alexandrians and to Eusebius of Caesarea. 56
- The calendar of Aloysius Lilius with the cycle of epacts. 5
- Aloysius Lilius perfected a thoroughly complete table of the movable feasts. 11
- Aloysius Lilius, whom Gregory XIII followed, alone laid out a perpetual lunar cycle in the calendar, and at the same time assigned a fixed seat to the equinox. 1
- What remedy Aloysius Lilius devised for fixing a stable seat to the equinox. 3
- The expanded table of epacts of Aloysius Lilius, with the little table for the equation of those same epacts. 9 & 10
- By what method Aloysius Lilius established the equation of the epacts according to the Alphonsine year. 9

- Aloysius Lilius, the first author of the new Gregorian calendar. [in the Letter to the Reader]
- The magnitude of the Alphonsine year. 70
- How great the Alphonsine year is. 65
- How many years the Alphonsine year requires for one intercalary day to be omitted. 71
- Ambrose's opinion on the celebration of Easter, from the decree of the Council of Nicaea. 56
- Why both the solar and the lunar year had to be corrected. 1
- Why the Alphonsine year — that is, the mean year — is the only one suitable for equating the solar year. 71
- The magnitude of the year according to the Alphonsines. 65
- The magnitude of the year according to Julius Caesar and the Church. 65
- The magnitude of the year from Ptolemy. 70
- What the civil lunar year is, of how many kinds, and how great. 85
- What the astronomical lunar year is, and how great, both common and embolismic. 86
- What the lunar year is — both common and embolismic, full and hollow. 85
- By how much the Roman, or ecclesiastical, year is greater than the Alphonsine year. 65
- How many days 19 solar years contain. 86
- Which centennial years will hereafter remain bissextile, and which not, but will become common. 74
- Why the year is proposed to be equated through the centennial years. 74
- When the tropical year is greatest, when least, and when moderate. 76
- When the year has been greatest, when least, and when it has held the mean state. 65

- The Metonic 19-year year. 86
- When the lunar year — both common and embolismic — becomes hollow, namely of 353 or 383 days. 335
- How great the year of Julius Caesar and of the Church is. 65
- That it is not necessary for the year to begin from 8 March, as Viète wishes. 510
- How many years the Alphonsine year requires for the intercalary day to be omitted. 71
- Why the centennial years were chosen for equating the year. 74
- Why the mean year — that is, the Alphonsine — is the only one suitable for equating the solar year. 71
- By what method it is known what place any given year holds in the 400-year cycle. 375
- The magnitude of the year from al-Battānī. 70
- The magnitude of the year according to the Alphonsines. 70
- That the uncertain and variable magnitude of the tropical year makes it difficult to ascribe a fixed seat to the equinox. 3
- Why the greatest year is not suitable for equating the solar year. 71
- How many years the year of Ptolemy requires for the intercalary day to be omitted. 71
- That the astronomical year does not always begin from the same moment of the same day. 70
- That the year 1582 is to be called the year of the correction, because in it the correction of the calendar was carried out by Gregory XIII. 65
- What the astronomical year is. 69
- What the civil year is. 70
- That knowledge of the astronomical year is necessary in order that the civil year may be equated to it. 74

- How many years the year of al-Battānī requires for the intercalary day to be omitted. 71
- That an unequal year is not suitable for establishing the method of intercalation. 71
- Why every fourth year is bissextile. 70
- Why the mean magnitude of the year was assumed in the correction of the calendar. 71
- Why the least year is not suitable for equating the solar year. 71
- That the solar year is not always of the same magnitude. 70
- The radix of the period of the anomaly of the equinoxes. 76
- In what year of Christ the period of the anomaly of the equinoxes will begin again. 76
- When the period of the anomaly of the equinoxes began before the birth of Christ, according to the doctrine of Nicolaus Copernicus. 76
- Why the anticipation of 1 hour, 27 minutes, 33 seconds in 19 years is not detected in the new moons found by computation. 173
- In how many years the anticipation of the lunations amounts to one day. 87
- The source of the anticipation of the equinox in the calendar. 65
- The anticipation of the Moon in 19 years, and how great it is over 76. 8
- The Council of Antioch, that of Chalcedon, and others confirm the decree of the Council of Nicaea concerning the celebration of Easter. 55
- That it is an apostolic tradition to celebrate Easter on the Sunday after the Moon of the first month. 56
- That in the time of the Apostles Easter was celebrated on the Sunday after the XIII Moon of the first month, and that it is an apostolic tradition that it be so celebrated. 56
- Several arguments against the epacts, and their solution. 353
- Two arguments against the new calendar, with their solution. 81

- That knowledge of the astronomical year is necessary in order that the civil year may be equated to it. 70
- That some astronomers, for the motion of the Sun and Moon, trust the Alphonsine Tables more than the Prutenic. 67
- What the astronomical lunar year is, and how great, both common and embolismic. 86
- That the astronomical tables are to be greatly valued, even though they cannot last for a long time. 67
- The source of the inconstancy of the astronomical tables. 67
- How great the astronomical lunar month is, according to the mean motion. 86
- That the inconstancy of the astronomical tables is no obstacle to the perfection and perpetuity of the calendar. 81
- What the astronomical year is. 69
- That the astronomical year does not always begin from the same moment of the same day. 70
- Why upon the author of this book, above others, the burden of writing it was laid. [in the Letter to the Reader]
- What order the author of this book follows. 2
- What the author of this book has taken chiefly from the calendar of Aloysius Lilius. [in the Letter to the Reader]
- Why the author of this book differs in most matters from Aloysius Lilius. [in the Letter to the Reader]
- The first author of the new Gregorian calendar: Aloysius Lilius.
- The finding of the golden number by arithmetic. 18
- The finding of the golden number in the ecclesiastical computus, from its own little table. 508
- The finding of the golden number in the published calendar, by a table. 17
- The setting-out of the golden numbers in the calendar. 141

- That the golden numbers in the new calendar differ, in 12 places, from the golden numbers in the old. 343
- By what method the following golden number is generated from the immediately preceding one in the calendar, and vice versa. 88
- That the golden number, if it had to be retained in the calendar, would have to be arranged variously in 30 calendars. 100
- That the golden number, before the correction, falsely indicated the *xiiiij* Moon. 3
- That the same golden number, from one centennial year to the next following, in certain years exhibits the *xiiiij* Moon now before the mean opposition, now after it. 357
- That the lesser golden number in the calendar generally follows the greater preceding one immediately, but the greater does not follow the lesser immediately. 88
- What the cycle of the golden number is. 133
- That the golden numbers, once corrected in the calendar, cannot indicate the new moons perpetually or for long, and why. 100
- That the first golden number of January is not formed by adding 8 to the last golden number of December. 94
- The finding of the golden number on the fingers, by memory. 562
- That the same golden number sometimes throws Easter back from March into April, and vice versa. 357
- That the ancient golden numbers, if 300 years after the Council they be moved up into the higher place, as is fitting, contain the same error in the *xiiiij* Moons that is detected in the epacts. 502
- That the golden numbers, at the time of the Council of Nicaea, contain the same error in the *xiiiij* Moons which is noted in the epacts. 503
- Into what order the golden numbers are to be kept in the calendar. 88
- In what places the greater golden number is followed most closely by the lesser, in the old calendar. 88

- By what reasoning all the golden numbers are inscribed in the calendar from the first golden number of the calendar, or from the last. 88
- That the same golden number, in the old calendar, in the time of the Emperor Justinian, showed the *xiiij* Moon now earlier, now later; likewise that some anticipated their *xiiij* Moons, while others put them off. 359
- By what reasoning the golden numbers are drawn out from the epacts, so as to be inscribed in the calendar serving any given century. 254
- That there were seven embolismic golden numbers in the old calendar, and which they are. 339
- That the golden number of any year begins in January. 133
- Why the golden number cannot perpetually indicate the *xiiij* Paschal Moon in the calendar. 4
- By what method the golden numbers ought to have been changed in the old calendar, so that they might indicate the new moons both before the correction and after. 99
- The defect of the golden numbers for indicating the new moons and the *xiiij* Moons for Easter. 99
- When the golden number in course is 19, why a unit must be added to the days that remain in December after the last lunation of the year, so that the epact of the following year may be formed. 165
- In what places the greater golden number is followed most closely by the lesser, in the new calendar of this century, if the golden numbers were to be set out in it. 89
- The finding of the golden number for any year from various tables. 133
- Why the following golden number in the calendar is formed from the preceding by adding 8 or subtracting 11, and the preceding from the following by adding 11 or subtracting 8; and why the golden numbers are not written in continuous order in the calendar. 99

B

- Bede's opinion, that the Council of Nicaea renewed the ecclesiastical decree on celebrating Easter after the *xiiij* Moon of the first month. 56

- By what reasoning the bissextile years, both centennial and expanded, are distinguished from the non-bissextile. 575
- Why every fourth year is bissextile. 70
- The Bull of Gregory XIII on the corrected calendar. 13

C

- The decree of the Council of Caesarea in Palestine on celebrating Easter after the *xiii*j Moon of the first month. 55
- The calculation of the mean new moons and full moons. 168
- The calculation of the lunations, as far as the fourth [order]. 552
- In what respects the Gregorian calendar is criticized by most people. 540
- That Scaliger and Viète published a calendar of their own, different from the Gregorian. 540
- Praise of the new calendar. 167
- The thirty calendars of the golden numbers. 254
- That the new calendar is not called perpetual in the sense Lilius supposes — that the equinox, by the prescribed equation, cannot leave 21 March — which is attested by the twofold method of equating the solar year in the *Compendium* sent to the Princes. 167
- The disadvantage of the thirty calendars. 304
- What a calendar requires in order to be complete and durable. 85
- In what sense the equation of the new calendar is said to agree with the mean equinox. 84
- The old ecclesiastical calendar, which the Church used from the Council of Nicaea down to the correction of the year carried out by Gregory XIII. 90
- That the calendar has been restored with the help of the Prutenic Tables. 81
- In what the perpetuity and perfection of the Gregorian calendar consist. 73
- By what method the equation of the new calendar, traced back to the time of the Council of Nicaea, shows that 10 days are to be removed. 84

- That the new calendar is perfect, even though the Prutenic Tables should still agree with the true motions after 20000 years. 80
- That the new calendar — that is, the Gregorian — is not called perpetual as though the equinox could never recede from 21 March, but for another reason. 73
- Why the calendar necessarily had to be corrected. 64
- That the calendar could not be constructed in any other way than that in which Gregory constructed it, so as to be perfect, perpetual, or durable. 85
- Why the correction of the calendar was undertaken in the year 1582, and in October rather than in any other year and month. 65
- Why the correction of the calendar in the year 1583, in more remote regions, was ordered to be made in February rather than in another month. 66
- That the correction of the calendar consists in three things, and what they are. 64
- That, if the new calendar had been corrected in February 1582, it would have exhibited Easter more correctly than the old. 66
- By whom chiefly the errors of the Nicene ecclesiastical calendar were detected, and who wrote on their emendation. 1
- The Gregorian calendar, with the epacts distributed through the days of the months. 36
- Why no one before Gregory XIII attained the perfect correction of the calendar. 1
- The Gregorian calendar for the correction year 1582, comprising the last three months of the year. 49
- The excellence of the new calendar, with its epacts. 344
- The ecclesiastical calendar which, after the correction of the year carried out by Gregory XIII, the Church would have had to use down to the year 1700, if the golden numbers had been set out in it in place of the epacts. 94
- That the equation of the new calendar corresponds exactly for some past and future years, though not for all — which is enough. 84

- If the equation of the new calendar had begun from the Council of Nicaea, by what method it would supply 10 days to be removed down to the year 1600. 84
- That the calendar would not have needed correction, if the equinox, having advanced to 11 March, had of its own accord gone back to the 21st, with no remedy applied. 83
- The finding of the calends, ides, and nones by memory. 581
- That the calendar, whatever it be, cannot avoid four errors, and what they are. 360
- The calendar of Aloysius Lilius with the cycle of epacts. 5
- By what method the correction of the calendar is to be undertaken in a year other than the year 1582. 52
- The truly Gregorian calendar, according to the opinion of Viète. 506
- The Callippic period of 76 years. 86
- What the hollow and full lunar year is, both common and embolismic. 85
- Where, and when, the celebration of Easter is enjoined in Holy Scripture. 53
- Which centennial years will hereafter remain bissextile, and which not, but will become common. 74
- Why the centennial years were chosen for equating the year. 74
- The Council of Chalcedon, that of Antioch, and others confirm the decree of the Council of Nicaea concerning the celebration of Easter. 55
- What the civil year is. 70
- How great the civil lunar month is. 86
- What the civil lunar year is, of how many kinds, and how great. 85
- How the resolved table of the movable feasts for 70 years is constructed. 376
- A compendium for computing the Paschal full moons of 100 expanded years, from the Paschal full moon of the preceding centennial year. 536

- The compendium of the table for the equation of the epacts of Chapter 11, together with its use. 144
- Why the compendium of the new method of restoring the calendar was sent by Gregory XIII to the Princes. 3
- Not a few councils, and several Roman Pontiffs, desired the correction of the calendar. 1
- The decree of the Council of Caesarea in Palestine on celebrating Easter after the XIII Moon of the first month. 55
- The decree of the Council of Nicaea on celebrating Easter is confirmed by the Council of Antioch, that of Chalcedon, and others. 55
- A fragment of the epistle of the Council of Nicaea on the celebration of Easter. 55
- The Council of Antioch, that of Chalcedon, and others confirm the decree of the Council of Nicaea concerning the celebration of Easter. 55
- The Council of Nicaea fixed the seat of the equinox on 21 March. 3
- The Council of Nicaea entrusted the care of the golden-number cycle to Eusebius of Caesarea and to the Alexandrians. 56
- How many, and which, new moons the Council of Nicaea determines to be Paschal. 62
- That the Council of Nicaea confirmed, rather than instituted, that Easter be celebrated on the Sunday after the xiiij Moon of the first month. 55
- When the Council of Nicaea decrees that Easter is to be celebrated. 3
- The Council of Nicaea assigned 21 March to the vernal equinox. 62
- The source of the disputes over the celebration of Easter from the Council of Nicaea down to the Emperor Justinian. 71
- Copernicus's observations on the inequality of the year. 70
- By what method the correction of the calendar is to be undertaken in a year other than the year 1582. 52

- Why no one before Gregory XIII attained the perfect correction of the calendar. 1
- Which year is to be called the year of the correction. 65
- That the beginning of the golden-number cycle is taken successively from all the golden numbers, if the equation of the solar year and of the lunar year is applied. 337
- The Athenian Meton, inventor of the 19-year cycle of the golden number. 86
- Which 19-year cycles begin from the epact *, and which from j. 335
- That only two of all the thirty 19-year cycles of the expanded table have their seventh lunation embolismic, of 29 days. 338
- The perpetual little table of the cycle of epacts, with the table for the equation of that same cycle. 20
- The construction of the perpetual cycle of epacts. 142
- In what the correct [placement of the] cycle in the ordinary calendar consists. 519
- The finding of the solar cycle by arithmetic. 23
- The finding of the solar cycle from its own tables, in a threefold way. 361
- The finding of the solar cycle from a table beginning at the correction year 1582. 22
- The finding of the solar cycle by a table, for any proposed year. 33

Index Alphabeticus (continued)

Alphabetical index to the Explicatio Romani Calendarii. Entries are alphabetized by the Latin headword, so the English translations below keep the original sequence. Load-bearing numeral forms are preserved as printed (Roman xxv, xxiiij, xiiij versus Arabic 25, 19; a single* 1 for page one). Each entry is followed by its printed page reference, read off the leaf.*

C (continued) — *Cyclus / Cycli*

- Finding the solar cycle on the fingers, from memory. — 33
- Finding the solar cycle in the Ecclesiastical Computus, from its own table. — 591
- Why the cycle of the golden number in the old Calendar could take its beginning from no other number than 3. — 339
- That among the Alexandrians the cycle of the golden number always began from the last day of their year, and from golden number 1. — 337
- Why the cycle of the golden number — or any other that does not fill all the places of the Calendar — cannot stand unchangeable in the Calendar. — 166
- That Aloysius Lilius [Luigi Lilio] alone laid out a perpetual cycle of the Moon in the Calendar, and at the same time assigned a fixed seat to the equinox. — 1
- That no cycle, whatever it may be, can avoid every drawback. — 352
- That no cycle, whatever it may be and by whatever method laid out in the Calendar, can escape sometimes displaying the 15th Moon in the second month, or in the last, which is nevertheless taken as the Paschal Moon. — 356
- That any nineteen-year cycle of epacts begins either from the first day of January or from the last day of December. — 336
- That before the correction, after the Council of Nicaea, the cycle of the golden number always began from golden number 3 and from the first day of January. — 336
- Why most people judged it impossible for a perpetual lunar cycle to be laid out in the Calendar and for a fixed seat to be assigned to the equinox. — 1
- That the nineteen-year cycle of the golden number begins either from the golden number written at the Kalends of January, or from the one that would be assigned to the last day of December, if the solar year began there. — 336
- Why it always seemed difficult to inscribe a perpetual cycle in the Calendar. — 167
- How it may be known that every nineteen-year cycle contains 7 embolismic years, and which they are. — 337
- That the cycle of epacts in the Calendar shows how many days have usually elapsed after the true conjunction. — 353

- That the cycle of epacts is so arranged that the Paschal 14th Moons do not precede the mean oppositions by more than one day, and why. — 347
- The interruption of the cycle of Dominical letters, devised by Aloysius Lilius from the method of equating the equinox. — 4
- That any 19-year cycle of epacts begins either from * or from j. — 335
- The nineteen-year cycle of epacts can perpetually show the Paschal 14th Moon, provided an equation is applied at certain times. — 4
- In what sense the cycle of epacts of the new Calendar is said to be adaptable to any length of the year. — 167
- What the cycle of the golden number is. — 133
- That the cycle of Dominical letters is the same as the solar cycle. — 361
- The cycle of epacts inscribed in the Calendar can be adapted to any length of the year. — 11
- Why every nineteen-year cycle has one of its 7 embolismic lunations of only 29 days. — 337
- Which cycle should be chosen out of them all. — 347
- Why every nineteen-year cycle has years 3, 6, 9, 11, 14, 17 and 19 as embolismic. — 337
- What the solar cycle is. — 361
- That the cycle of Dominical letters was devised so that there should be no disagreement about which Sunday to observe. — 62
- The 400-year cycle of Dominical letters after the correction. — 372
- Whence the 28-year cycle of Dominical letters arises. — 365
- Why no cycle, whatever it may be, can exactly correspond to the celestial motions. — 352
- The ancient perpetual 28-year solar cycle, or cycle of Dominical letters, with the table of equation of the same cycle. — 27
- Why the table of equation of epacts covering 300,000 years was set out in chapter 11, although it is fallacious. — 155

D.

- Meton of Athens [Meton], inventor of the nineteen-year cycle of the golden number. — 86
- The decree of the Council of Nicaea on the celebration of Easter is confirmed by the Councils of Antioch, Chalcedon, and others. — 55
- The decree of the Council of Nicaea, on celebrating Easter. — 3

- The decree of the Council of Caesarea in Palestine on celebrating Easter after the 14th Moon of the first month. — 55
- The decree of St Pius, Pope and martyr, on celebrating [Easter] on the Lord's Day. — 55
- The decree of St Victor, Pope and martyr, on celebrating Easter on the Sunday after the 14th Moon of the first month. — 55
- The deficiency of the golden number for tracking the new moons. — 99
- That God, through Moses, commanded the observance of the first month, and of the 10th day and the 14th, in a rustic or simple manner suited to the understanding of the whole Israelite people. — 68
- That a day is sometimes called the last of one month which should more truly be called the first of the following month. — 353
- That in the civil solar year a day is sometimes called the first which would more truly be the last. — 353
- In how many years the intercalary day would have to be omitted according to Ptolemy's year. — 71
- Why the 10 days were removed all at once from the year 1582, and not one by one from individual years or months. — 65
- In how many years the intercalary day would have to be omitted according to the Alphonsine year. — 71
- In how many years the intercalary day would have to be omitted according to al-Battānī's [Albategnius] year. — 71
- How one may know from memory, on the fingers, for any given year, from which day of the week any day of the month takes its name. — 580
- That the intercalation of one day every fourth year is greater than it should be, and why. — 70
- How to find the number of days removed from the year 1700 inclusive up to any hundredth year inclusive. — 145
- How the number of days removed on account of the solar equation is reckoned. — 145.575
- Why the days removed on account of the equinox-equation must be added to the calculation of the lunations. — 172
- That the 21st of March, assigned to the equinox, holds the mean position between the 23rd day and the 19th, out to which the equinox can run, since from there it returns of its own accord to the 21st day. — 83
- That the difference between the true and the mean equinox does not reach one and a half days. — 79

- How great the difference is between 19 solar years and 235 mean lunations. — 86
- How great the maximum discrepancy is between the true and the mean equinox. — 79
- That the Christian Easter is to be celebrated on the first Sunday after the 14th Moon of the first month. — 54
- Finding the Dominical letter for any given year after the year 1700. — 25
- Finding the Dominical letter by means of the solar cycle, from a table. — 366
- Finding the Dominical letter from the 400-year cycle after the correction. — 372
- An easier way of finding the Dominical letter, without the solar cycle, from a table. — 369

D (continued) — *Dominicalis*

- Finding the Dominical letter in the Ecclesiastical Computus, by means of the solar cycle, from its own table. — 586
- Whence the 28-year cycle of Dominical letters arises. — 365
- Finding the Dominical letter from the year of the correction up to the year 1700 exclusive. — 24
- Finding the Dominical letter in the Ecclesiastical Computus, without the help of the solar cycle, from its own table. — 586
- Finding the Dominical letter from the perpetual solar cycle, for any given year. — 27
- How one may know from memory the number of Sundays between Pentecost and Advent. — 580
- That the cycle of Dominical letters is interrupted, on account of the method of equating the equinox devised by Aloysius Lilius. — 4
- That the Dominical letters found for the first 4 years of Christ according to the prescription of the Calendar differ from those actually in use at that time. — 372
- Finding the Dominical letter on the fingers, from memory. — 571
- A perpetual table of Dominical letters from the year 1700 inclusive, if in every 400 years three bissextiles are omitted, together with the table of equation of the same table. — 25

E.

- Why the Church preferred Easter to be movable rather than fixed. — 54
- That the Church celebrates two kinds of feasts. — 1
- That the Church has more at heart the peace of the faithful in the celebration of Easter than an exact observation of the equinox and the course of the Moon. — 73
- That in adopting a lunar cycle the Church follows all antiquity. — 69
- That the Church does not contradict the decrees of the Fathers, even though it sometimes celebrates Easter in the last month or in the second, since this can in no way be avoided. — 72
- That the Church is not greatly anxious about the true or mean new and full moons, since in tracking them it has always used cycles. — 68
- That the Church freely observes the equinox and the Moon in the solemnity of Easter; and why it observes them. — 73
- That the Church considers only the mean motions, for many reasons. — 66
- What the Church does when in some year there is no Paschal full moon. — 356
- The old Ecclesiastical Calendar, which the Church used from the Council of Nicaea up to the correction of the year made by Gregory XIII. — 90
- The Ecclesiastical Calendar which the Church ought to use after the correction of the year made by Gregory XIII, up to the year 1700, if the golden numbers had been written in it in place of the epacts. — 94
- Why it is not absurd that the ecclesiastical equinox should sometimes differ from the true one. — 73
- How long the ecclesiastical year is according to the reckoning of Julius Caesar. — 65
- By how much the ecclesiastical year — the Roman, or Julian — is longer than the Alphonsine year. — 65
- When the embolismic year contains 384 days, and when. — 337
- What the embolismic lunar year and the common year are, both full and hollow. — 85
- That the embolisms and the leap of the Moon bring it about that sometimes two or three consecutive lunations are of 29 days, and two, three, or four of 30 days. — 341
- Which are the embolismic years containing only 383 days, and the common years of 353 days. — 341
- What an embolism is. — 337

- In praise of the new Calendar. — 167
- How the epact of any year is obtained from the expanded table and its equation. — 141
- By which table the epact is more correctly found after the year 8200. — 141
- That the epact of each year begins in January. — 142
- Why epact xxiiij is not used in the same cycle when epact xxv and a golden number not greater than 11 concur; likewise why epact xxvi is not in use in the same cycle when epact 25 and a golden number greater than 11 concur. — 102
- What the epacts are, and why they are 30. — 100
- How the epact of each year is formed from the epact of the preceding year. — 165
- Finding the epact for any year, from the perpetual cycle of epacts. — 142
- How the embolismic epacts are perpetually known from the table of new moons. — 344
- Why every epact must be less than 30. — 100
- That when epact xvij concurs with golden number 19 it is embolismic, otherwise not. — 338.339
- Why epact 19 is placed in the Calendar in a different colour or type, at the last day of December, opposite epact xx. — 103
- What the epacts of years and of months are, and how they are gathered and reduced to tables. — 168
- Why the epacts are arranged in the Calendar in retrograde order. — 101
- That epact 19, placed at the last day of December opposite epact xx, does not produce two new moons on the same day in the same nineteen-year cycle. — 104
- By what method Scaliger [Joseph Scaliger] investigates the epact of any year. — 612
- That epact 25, placed in a different colour or type opposite epact xxvi, does not disturb the lunations. — 102
- Why the epacts are so called. — 100
- Why two epacts are assigned to the same day in six places of the Calendar. — 101
- A more accurate way of finding the epact of any year than was given in No. 5 of chapter 12. — 154
- That epact 25, written in a different colour or type above epact xxv, does not cause two new moons in the same cycle to fall on the same day. — 01

- How the corrupted epacts are gathered for computing the new moons after the correction. — 530
- Finding the epact of any year in the Ecclesiastical Computus, from its own table. — 159
- That the epacts arranged in the Calendar do not keep the order of the Cycle. — 101
- Why the epact concurring with golden number 1 is formed from the epact concurring with golden number 19 by adding 12. — 165
- That the epact of the following year is usually shown by the days of December that remain after the last lunation of the year. — 104
- Finding the epact of any year on the fingers, from memory. — 564
- Why epact 25 must be written in a different type or colour above the other epact xxv in six places of the Calendar. — 101
- Finding the epact from the perpetual cycle. — 20
- Why the epacts in the Calendar were not moved up by one day, so that they might indicate the new moons earlier than they now do. — 347
- Why the epacts in the expanded table do not show, for the times of the Council of Nicaea, the golden numbers as they are arranged in the old Calendar. — 343
- That only 19 epacts out of all 30 are used in any one or more centuries for showing the new moons. — 105
- How the epacts are arranged in the Calendar. — 101
- Which are the embolismic epacts having a thirteenth lunation of 30 days and embolismic. — 339
- When the embolismic epacts having a 13th lunation of 30 days have the first lunation of the year of 29 days. — 339
- That epacts xviii and xix, concurring with golden number 19, have the 13th lunation embolismic and of 29 days. — 340

E (continued) — *Epacta / Epactarum*

- Which are the embolismic epacts having the first lunation of the year embolismic and of 29 days; and when the same epacts have the second lunation embolismic and of 30 days. — 340
- By what method Viète [François Viète] investigates the epact for any year. — 524
- When epacts one unit greater or less than those in use are to be taken. — 105

- By what method the epacts can perpetually indicate the new moons in the Calendar. — 104
- That some epacts, in the years of the same century, show their 14th Moons before the mean oppositions, others after them. — 358
- A perpetual table of the cycle of epacts, with the table of equation of the same cycle. — 20
- How the equation of the epacts was established by Aloysius Lilius according to the Alphonsine year. — 9
- Why the equation of epacts set out in the Calendar of the Compendium was rejected, and another established in the new Calendar. — 103
- The nineteen-year cycle of epacts can perpetually show the Paschal 14th Moon, provided an equation is applied at certain times. — 4
- That the cycle of epacts is so arranged that the Paschal 14th Moons do not precede the mean oppositions by more than one day, and why. — 347
- The cycle of epacts inscribed in the Calendar can be adapted to any length of the year. — 11
- In what sense the cycle of epacts of the new Calendar is said to be adaptable to any length of the year. — 167
- A table of the epacts corresponding to the golden numbers before the correction of the Calendar. — 18
- Some temporary tables of the epacts corresponding to the golden numbers after the correction of the Calendar. — 19
- Why the placement of the epacts and their equation in the Gregorian Calendar cannot justly be criticized. — 518
- By what method the equation of epacts should be established, following the opinion of Nicolaus Copernicus, according to the varying length of the year. — 12
- That the arrangement of the epacts in the Calendar cannot justly be criticized. — 351
- The expanded table of epacts, together with the table of equation according to Lilius's intention, and with the days removed on account of the equinox-equation. — 110
- Some temporary tables of epacts, according to Aloysius Lilius, and their use. — 11
- The expanded table of epacts of Aloysius Lilius, with the table of equation of the same epacts. — 9.& 10

- That the cycle of epacts in the Calendar shows how many days have usually elapsed after the true conjunction. — 353
- How the expanded table of epacts is constructed. — 195
- That the same epact now shows the 14th Moon anticipated, now delayed, now finally in agreement with the Canons. — 502
- How the table of equation of epacts is constructed. — 106
- Where the root of the equation of epacts is to be fixed. — 107
- Why letters of the alphabet, rather than years of the Lord, were assigned to the lines of the epacts in the expanded table. — 106
- Why the following epact is not always formed from the preceding one by adding 11 or 12. — 166
- That the epacts do not change their places in the Calendar, even if the table of equation must be renewed. — 166
- That the epacts were rightly substituted in the place of the golden numbers. — 100
- That the epacts of the new Calendar hold a middle course in the anticipation and postponement of the new moons. — 352
- That the epacts could not be better placed than they have been in the new Calendar. — 352
- That the epacts of the new Calendar rightly indicate the new moons after the mean conjunctions. — 353
- That the epacts are not to be investigated by the table of equation of chapter 11 after the year 8200. — 131
- That some epacts in any cycle do not show suitable 14th Moons. — 518
- How it may be known that the epacts are rightly placed and equated in the Calendar. — 358
- That the epacts rightly indicate the 14th Moons is shown by the temporary table of movable feasts from the year 1600 to the year 5000. — 502
- That the epacts rightly succeeded to the place of the golden numbers, and are suitably arranged in the Calendar in retrograde order. — 104 [?]
- That all 30 epacts could also be arranged in the Calendar in direct order. — 105
- That eleven epacts are always embolismic, and which they are. — 338
- How it may be known, from the expanded table and from the 35 tables of lunations of chapter 16, that eleven epacts alone are always embolismic. — 338

- A fragment of the letter of the Council of Nicaea on the celebration of Easter. — 55
- The error of certain people in defining the first month. — 61
- By whom the errors of the Calendar of the Council of Nicaea were chiefly detected, and who wrote about their emendation. — 2
- That four errors can be avoided in no Calendar, and what they are. — 360
- That many Supreme Pontiffs attempted to correct the error of the equinox and of the 14th Moon. — 33
- That the care of the cycle of the golden number was entrusted by the Nicene Council to Eusebius of Caesarea [Eusebius of Caesarea] and to the Alexandrians. — 56

F.

- The immovable feasts require only the use of solar months. — 1
- What the movable feasts are. — 375
- The movable feasts require both solar and lunar months. — 1
- Two kinds of feasts are celebrated by the Church. — 1
- Finding the movable feasts from a double perpetual table. — 29
- A very easy way of finding the movable feasts from the resolved table of 70 years. — 376
- Finding the movable feasts in the Ecclesiastical Computus, from a table. — 595
- Finding the movable feasts on the fingers, from memory. — 577
- What the roots of the movable feasts are. — 577
- A temporary table of the movable feasts from the year 1582 to the year 1631. — 32
- The old table of the movable feasts, reformed and made perpetual. — 33
- The new table of the movable feasts, reformed and made perpetual. — 34
- A fragment of the letter of the Council of Nicaea on the celebration of Easter. — 55

G.

- In what the perpetuity and perfection of the Gregorian Calendar consists. — 73
- Why the Gregorian Calendar is called perpetual. — 167
- In what respects the Gregorian Calendar is criticized by many. — 540

Index Alphabeticus (continued)

*Alphabetical index to the Explicatio Romani Calendarii**. The entries are translated but kept in their printed order under each letter-heading; the trailing figure is the page reference exactly as printed. Two columns per leaf, read left column then right.*

G (continued)

- Gregorian Calendar for the correction year 1582, comprising the last three months of that year. — 49
- The Gregorian Calendar, with the Epacts distributed through the days of the months. — 36
- That Gregory XIII's intention in correcting the Calendar was not what Viète [Vieta; François Viète] imagines it to have been. — 519
- Gregory XIII's Bull on the corrected Calendar. — 13
- Why Gregory XIII sent the *Compendium* of the new method of restoring the Calendar to the [Christian] Princes. — 3
- Gregory XIII resolved to follow the consensus of the whole Christian world in correcting the Calendar. — 12
- According to which opinion Gregory XIII restored the equinox. — 65

H.

- When the Hebrews used to celebrate Passover, by divine command. — 53
- Which was the first month of the Hebrews. — 54
- The troubles that would have beset history, chronology, and the chief festivals of the year had the Calendar not been corrected. — 63

I

- Finding the Ides, Nones, and Kalends from memory. — 581
- The immovable feasts require only the use of the solar months. — 1
- Finding the Indiction in the Ecclesiastical Computus, from its own table. — 594
- Finding the Indiction on the fingers, from memory. — 582
- Finding the Indiction from the year 1582. — 28
- Finding the Indiction for any given year by a table. — 28
- Finding the Indiction by arithmetic. — 29
- What method was adopted for keeping intercalation tied to the equinox near 21 March. — 69

- The two ways of keeping the equinox on 21 March by intercalation. — 71
- In how many years the intercalary day would have to be omitted according to al-Battānī's [Albategnij] year. — 71
- By what reckoning the omission of the intercalary day in the centennial years — every four-hundredth excepted — squares with the Alphonsine year. — 74
- In how many years the intercalary day would have to be omitted according to the Alphonsine year. — 71
- In how many years the intercalary day would have to be omitted according to Ptolemy's [Ptolemæi] year. — 71
- That the intercalation established for the mean year introduces no inconvenience of any moment. — 72
- By what device the scheme of intercalation established for the mean year corrects itself. — 71
- That the intercalation of one day every fourth year is greater than it ought to be, and why. — 70
- Who was the inventor of the nineteen-year Cycle of the golden number. — 86
- When the Jews used to celebrate Passover, by divine command. — 53
- Which was the first month of the Jews. — 54
- That the table of Jewish new moons proposed by Scaliger [Scaligero; Joseph Scaliger] does not sufficiently agree with the perpetual Cycle of Epacts. — 542
- How long the year of Julius Caesar and the Ecclesiastical year each are. — 65

K.

- The Κριτικὰ [Greek: Kritika, "critical objections"] of Viète against the Gregorian Calendar, and their solutions. — 515

L.

- Lilius's [Lilij; Aloysius Lilius] Calendar with the Cycle of Epacts. — 5
- Lilius's table of expanded Epacts, with the subsidiary table for the equation of those same Epacts. — 9 & 10
- That it is not strictly necessary to correct Lilius's table of the equation. — 150
- Why Lilius wished to propose his own equation, though over widely separated ages it is fallacious. — 150

- What Lilius and the correctors of the Calendar had in view in the equation of the Epacts. — 518
- Lilius the first author of the new Gregorian Calendar, in the Epistle to the Reader. —
- How Lilius established the equation of the Epacts according to the Alphonsine year. — 9
- What remedy Lilius devised for assigning a fixed seat to the equinox. — 3
- That Lilius alone described a perpetual Cycle of the Moon in the Calendar and at the same time assigned a fixed seat to the equinox. — 1
- By what method the letter of the expanded table — or of the perpetual Cycle of Epacts — is found by arithmetic, in order to investigate the Epact of any given year. — 145
- Finding the Dominical letter in the Ecclesiastical Computus, without the Solar Cycle, from its own table. — 593
- Finding the Dominical letter from the perpetual Solar Cycle, for any year proposed. — 27
- Finding the Dominical letter for any year proposed after the year 1700. — 25
- Finding the Dominical letter from the correction year up to the year 1700 exclusive. — 24
- Finding the Dominical letter from the 400-year Cycle, after the correction. — 372
- Finding the Dominical letter by the Solar Cycle, from a table. — 366
- An easier finding of the Dominical letter, without the Solar Cycle, from a table. — 369
- Finding the Dominical letter in the Ecclesiastical Computus, by aid of the Solar cycle, from its own table. — 586
- Finding the Dominical letter on the fingers, from memory. — 571
- Finding the letter of the Martyrology from memory. — 564
- Finding the letter of the Martyrology in the Ecclesiastical Computus, from a table. — 585
- A more accurate finding of the letter of the expanded table over widely separated ages. — 153
- That the letter of the expanded table is sought in vain beyond 100000 or 200000 years. — 154

- The table of Dominical letters, perpetual from the year 1700 inclusive provided that every 400 years three bissextiles are omitted, together with the table for the equation of that same table. — 23
- The 400-year Cycle of Dominical letters after the correction. — 372
- Whence the 28-year Cycle of Dominical letters arises. — 365
- That the figures for the equation of the Epacts in the table of chapter 11 progress, after 10000 years, in the same proportion as before, and why. — 132
- That the Dominical letters found for the first four years of Christ according to the prescription of the Calendar differ from those actually then in use, and why they then differed. — 372
- When the Moon is to be called "first" according to Bede [Bedam]. — 352
- When the Moon is to be called "first" according to Campanus [Campanum]. — 352
- What the fourteenth Moon is according to Theophilus and St. Cyril. — 353
- That the great period of 3400 years does not, as Viète supposes, accurately restore the synodic months of the Moon. — 528
- In which years between 1600 and 5000 the fourteenth Moons appear to run ahead of the mean oppositions more than is proper. — 502

(L continues on the next leaf.)

- That the fourteenth Moon was falsely indicated by the golden number before the correction. — 3
- That the error of the Paschal fourteenth Moon, when it anticipates the mean opposition by more than is proper, is often corrected by means of the Dominical letter. — 352
- That Aloysius Lilius alone described a perpetual Cycle of the Moon in the Calendar and at the same time assigned a fixed seat to the equinox. — 1
- How great the anticipation of the Moon is in 19 years, and in 76. — 4
- That the Paschal fourteenth Moon can be indicated in the Calendar by the Cycle of Epacts, if at certain times an equation is applied. — 4
- Why the Paschal fourteenth Moon cannot be indicated perpetually in the Calendar by the golden number. — 4
- By what device the postponement of the Moon in every centennial year is found. — 149
- By what method the place of the Moon in the Zodiac is found, more or less, from memory. — 584

- That the Paschal fourteenth Moon is not rightly understood by some. — 346
- What the Paschal fourteenth Moon is, according to the usage of the Church. — 346
- By what device it may be known from memory for how many hours the Moon shines at night. — 584
- What the astronomical lunar year is, and how long, both common and embolismic. — 86
- That the lunar and solar months are required for celebrating the movable feasts. — 1
- Why most have thought it impossible to describe a perpetual Lunar Cycle in the Calendar and to assign a fixed seat to the equinox. — 1
- That 235 civil lunar months are made in 19 solar years. — 86
- Why the lunar months in the Calendar are alternately of 30 and 29 days. — 86
- Why the lunar and solar year alike had to be corrected. — 1
- How great the half of a lunar month, and its quarter part, are. — 86
- How great the astronomical lunar month is according to the mean motion. — 86
- Why the equation of the lunar months was made rather by the Epacts xxv and xxiiij set together than by others. — 102
- What the lunar year, both common and embolismic, full and hollow, is. — 85
- How great the civil lunar month is. — 86
- What the civil lunar year is — of how many kinds and how long. — 85
- That 235 mean lunar months are made in 19 solar years. — 86
- That Scaliger's fourteenth Moons very often occur two, three, or even four days before the Gregorian fourteenth Moons. — 546
- That the first lunation of an embolismic year ends on some one of the first 11 days of January, and why. — 338
- That the thirteenth lunation ends, in an embolismic year, on some one of the last 11 days of December, and why. — 338
- That a lunation is assigned to the month in which it ends, and why. — 335
- That a lunation in bissextile years sometimes contains 31 days, and why this is not absurd. — 512
- The calculation of the lunations carried down to fourths (quartæ). — 552
- Which one of the 13 lunations of an embolismic year is to be called the embolismic lunation. — 339

- That the lunations anticipate one day in 312½ years, but not in 304 years, as some would have it. — 384
- Why the lunations in a bissextile year, after the intercalary day, are later than is proper. — 352
- That according to Viète some lunations contain only 28 days, indeed 27. — 511
- That two or more continuous lunations are sometimes of 29 or 30 days, which is neither novel nor absurd. — 341
- That 235 civil lunations are made in 19 solar years. — 87
- That the first lunation of the year following an embolismic year always begins from some embolismic Epact, except in that embolism in which the Epact xix does not concur with the golden number 19, and why. — 338

M.

- That 235 civil lunations contained within 19 years fill out, by their reckoning, the same span as the same number of mean lunations — even though in each of them there are omitted 4 minutes, 4 seconds, 3 thirds, and 11 fourths of one hour. — 87
- That 235 mean lunations are made in 19 solar years. — 86
- Which are the lunations Paschal by the Council of Nicaea, yet rejected before the correction of the Calendar as non-Paschal because of the error of the equinox. — 63
- That the lunations are made alternately of 30 and 29 days, on account of the assignment of two Epacts to the same day in six places of the Calendar. — 101
- Why the lunations in the Calendar are alternately of 30 and 29 days. — 86
- Why the Paschal lunations in the new Calendar are not all of 29 days, as in the old. — 103
- By what reckoning thirteen lunations can be contained within one year. — 337
- That from the first lunation of the year, on account of the equation of the Moon, one day is necessarily taken away or added. — 512
- How the letter of the Martyrology is found from memory. — 569
- Why the greatest year is not suited for the equation of the solar year. — 71
- That only the mean motions are considered by the Church, for many reasons. — 66

- That the mean motions are useful for judging which Cycle of several more correctly indicates the fourteenth Moon in the Calendar. — 69
- When the mean equinox precedes, and when it follows, the true. — 79
- That the mean equinox can be distant from the true by a whole four days — some have falsely supposed — and why. — 79
- When the mean equinox occurs. — 79
- That it is not the mean equinox when the line of the Sun's mean motion is joined with the point of the mean equinox. — 80
- That the mean year, that is the Alphonsine, is alone suited for equating to the solar year. — 71
- That the first month is rightly said to be that whose fourteenth Moon falls on the day of the equinox, or next follows it. — 61
- That 235 mean lunar months are made in 19 solar years. — 86
- Why the lunar months in the Calendar are alternately of 30 and 29 days. — 86
- That 235 civil lunar months are made in 19 solar years. — 87
- Which is the first month of the Jews. — 54
- How great the half of a lunar month, and its quarter part, are. — 86
- That both solar and lunar months are required for celebrating the movable feasts. — 1
- How great the astronomical lunar month is according to the mean motion. — 86
- How great the civil lunar month is. — 86
- That the first month is not rightly defined by some. — 61
- Why the equation of the lunar months was made rather by the Epacts xxv and xxiiij set together than by others. — 102
- That the use only of the solar months is required for celebrating the immovable feasts. — 1
- Meton of Athens [Atheniensis], inventor of the nineteen-year Cycle of the golden number. — 86
- The Metonic nineteen-year cycle. — 86
- Why the smallest year is not suited for equating to the solar year. — 71
- What the movable feasts are. — 375
- That the movable feasts require both solar and lunar months. — 1
- Finding the movable feasts in the Ecclesiastical Computus, from a table. — 595

- Finding the movable feasts from a double perpetual table. — 29

(M continues on the next leaf.)

- Finding the movable feasts on the fingers, from memory. — 576
- A very easy finding of the movable feasts from a resolved table of 70 years. — 376
- What the roots of the movable feasts are. — 577
- The temporary table of movable feasts from the year 1582 up to the year 1631. — 32
- The new reformed and perpetual table of movable feasts. — 34
- The old reformed and perpetual table of movable feasts. — 33
- That only the mean motions are considered by the Church, for many reasons. — 66
- That the mean motions are useful for judging which Cycle of several more correctly exhibits the fourteenth Moon in the Calendar. — 69
- That Moses [Moysen] commanded the observance of the first month, and of the 10th day, and of the 14th, in a rustic or simple fashion, adapted to the understanding of the whole people of Israel. — 68

N

- That the table of Jewish new moons [Neomeniæ] proposed by Scaliger does not sufficiently agree with the perpetual Cycle of Epacts. — 542
- By what method the successions of the new moons are gathered. — 537
- The succession of the new moons from century to century, according to Viète's opinion. — 529
- The truer succession of the new moons from century to century after the correction — how great it is. — 529
- The succession of the new moons from century to century before the correction — how great it is. — 529
- That the decree of the Nicene Council on the celebration of Easter is confirmed by the Councils of Antioch, Chalcedon, and others. — 55
- A fragment of the epistle of the Nicene Council on the celebration of Easter. — 55
- That the Nicene Council rather confirmed than instituted that Easter be celebrated on the Sunday after the fourteenth Moon of the first month. — 55

- That the Nicene Council entrusted the care of the Cycle of the golden number to Eusebius of Caesarea and to the Alexandrians. — 56
- That the Nicene Council fixed the seat of the equinox on 21 March. — 3
- How many and which new moons the Nicene Council determines to be Paschal. — 62
- When the Nicene Council decrees that Easter is to be celebrated. — 55
- That the Nicene Council assigned 21 March to the vernal equinox. — 62
- Nicolaus Copernicus's [Nicolai Copernici] observations on the inequality of the year. — 70
- Finding the Nones, Ides, and Kalends from memory. — 581
- Why the new moons in any year mostly fall 11 days earlier than in the immediately preceding year. — 86
- That new moons too much postponed cause Easter sometimes to be celebrated in the last month. — 351
- By what reckoning the new moons and full moons are sought from the tables of Epacts. — 171
- How the new moons are investigated, according to the usage of the Church, from the Epacts arranged in the Calendar. — 104
- By what reckoning the new moons can be indicated perpetually by the Epacts in the Calendar. — 104
- How much the new moons had anticipated from the time of the Nicene Council up to the correction year 1582. — 99
- That the new moons of the golden numbers around the time of the Nicene Council were nearly the same as those occurring in the heavens. — 107
- That the new moons of the golden numbers around the year of the Lord 130 fell later than in the heavens, and so more fittingly for the usage of the Church. — 107
- That if the conjunctions which occur in the heavens were not to follow, Easter would often be celebrated before the full moon. — 347
- That the new moons and the equinox, at the time when the Calendar was being corrected by Gregory XIII, did not fall on the same days as at the time of the Nicene Council. — 63
- That the new moons must, according to the usage of the Church, be indicated by the Cycle after the celestial new moons. — 107
- How the new moons are investigated from the golden numbers arranged in the Calendar. — 99

- How many and which the Paschal new moons are, by the decree of the Nicene Council. — 62
- Which are the new moons Paschal by the Council of Nicaea, yet rejected before the correction of the Calendar as non-Paschal because of the error of the equinox. — 63
- That the new moons were investigated by the golden numbers arranged in the Calendar before the correction of the year, so that all might celebrate the new moons on the same days. — 62
- That the new moons in the Calendar were, with mature counsel, postponed to the celestial new moons. — 20
- How the new and full moons in the centennial common years are found from the table of new moons. — 253
- Finding the new moon and full moon in any month from the year 1501 up to 1576, from the table of new moons. — 253
- Finding the new moon and full moon after the correction year 1582, from the table of new moons. — 253
- Finding the new moon and full moon in any month after the year 1576 up to the Gregorian correction, from the table of new moons. — 253
- What is to be done when the new moon or full moon sought falls beyond the month proposed. — 172
- Finding the new moons in the Computus, from its own table. — 590
- Finding the new moons from memory. — 565
- The perpetual table of new moons. — 344
- How the Paschal new moon and full moon are computed by the successions of the new moons. — 539
- How the Paschal new or full moon of any expanded year is elicited from the new or full moon of the nearest preceding centennial year. — 533
- How the new or full moon of any month is derived from the new or full moon of March or April. — 535
- How the Paschal new moon of any centennial year after the correction is computed by the corrected Epacts. — 533
- That the Paschal new moon of 5 April ceases to be Paschal when the transit is made from the upper line of the expanded table to the lower; and the non-Paschal new moon of 7 March begins to be Paschal. — 354
- That the Paschal new moon of 8 March ceases to be Paschal when the transit is made from the lower line of the expanded table to the upper; and the non-Paschal new moon of 6 April begins to be Paschal. — 354

O.

- Wherein the right ordering of the Cycle in the Calendar consists. — 519
- The order among the golden numbers in the Calendar. — 88
- The order which the author of this book follows. — 2

P.

- When, before the correction of the year, Easter was celebrated in the second month, because of the error of the equinox. — 63
- That after some years, unless the Calendar had been corrected, Easter would always have come to be celebrated in the second month, the third, the fourth, and so on, because of the rising of the equinox toward the beginnings of the months. — 63
- When, before the correction of the year, Easter was celebrated on the twenty-fifth Moon (Luna xxv)... (*entry continues on the next leaf*)

Each entry is given as the verbatim Latin index-phrase (*italic*), an English rendering, and the printed page reference. Section-letter divisions are marked as in the source. Reading order is left column top-to-bottom, then right column, on each leaf; this coincides with the alphabetical run. The index is unpaginated (leaves carry gathering signatures, not page numbers).

P (continued)

...xxv. ob Nouiluniorum per aureos numeros inuentorum errorem. — [continuation of the preceding entry] ...by 25 [days], on account of the error of the new moons found by means of the golden numbers. → 63

Pascha post aliquot annos, nisi correctum fuisset Calendarium, celebrari contigisset in Nouilunio, Luna ij. iij. &c. ob errorem Nouiluniorum, quæ per aureos numeros inquirebantur. — Easter, after some years, had the Calendar not been corrected, would have happened to be celebrated at the new moon, on Luna ij, iij, etc., because of the error of the new moons, which were sought through the golden numbers. → 63

Pascha ante emendationem anni, ob æquinotij errorem, & Lunæ xiiij. ex aureis numeris inuentæ, sæpe celebratum est cum errore 7. aut 28. aut etiam 35. dierum. — Before the correction of the year, Easter was often celebrated with an error of 7, or 28, or even 35 days, on account of the error of the equinox and of Luna xiiij as found from the golden numbers. → 63

Pascha post multos annos, nisi Calēdarium fuisset correctum, celebrari contigisset cum errore 42. dierum, & eo amplius. — After many years, had the Calendar not been corrected, Easter would have happened to be celebrated with an error of 42 days, and even more. → 63

Pascha interdum celebrari vel in vltimo mense, vel in secundo non repugnat Decretis Patrum, cū id nullo modo vitari possit: neque nouum est. — That Easter is sometimes celebrated either in the last month or in the second is not contrary to the Decrees of the Fathers, since it cannot in any way be avoided; nor is it anything new. → 72

Pascha ex decreto Concilij Nicæni quando celebrandum sit. — When Easter is to be celebrated according to the decree of the Council of Nicaea. → 3

Pascha non esse celebrandum Luna xv. falso nonnulli opinantur. — Some wrongly suppose that Easter is not to be celebrated on Luna xv. → 346

Pascha Christianorum ne cum Iudæis celebretur, quo modo prohibitum sit. — In what way it was forbidden that the Christians' Easter be celebrated together with the Jews. → 346

Pascha frequenter celebratum esse in Ecclesia Luna. xv. — That Easter has frequently been celebrated in the Church on Luna xv. → 346

Pascha interdum celebrari vel in secundo mense, vel in vltimo, nouum non est, propter annos communes, & bissextiles. — That Easter is sometimes celebrated either in the second month or in the last is nothing new, on account of common and bissextile years. → 72

Pascha necessario celebratum esse interdum & in secundo mense, & in vltimo, etiam ipsis Concilij Nicæni temporibus. — That Easter necessarily was celebrated at times both in the second month and in the last, even in the very times of the Council of Nicaea. → 72

Pascha cur ab Ecclesia statuatur mobile potius, quàm fixum. — Why Easter is fixed by the Church as movable rather than fixed. → 54

Pascha Christianum Dominica prima post Lunam xiiij primi mensis celebrandum esse. — That the Christian Easter is to be celebrated on the first Sunday after Luna xiiij of the first month. → 54

Pascha quando à Iudæis celebrabatur ex præcepto diuino. — When Easter was celebrated by the Jews by divine command. → 53

Pascha die Dominica post Lunam xiiij. primi mensis celebratum esse temporibus Apostolorum, esseque traditionem Apostolicam, ita esse celebrandum. — That Easter was celebrated on the Sunday after Luna xiiij of the first month in the times of the Apostles, and that it is an Apostolic tradition that it be so celebrated. → 56

Pascha semper celebratam esse, & celebrari debere Dominica prima post Lunam xiiij. etiamsi ea Dominica in Lunam xv. incidat, contra quosdam, qui id negant. — That Easter always has been, and ought to be, celebrated on the first Sunday after Luna xiiij, even if that Sunday falls on Luna xv — against certain persons who deny this. → 57

Pascha vt rite celebretur, tria obseruanda sunt ex decretis Pontificum, & Conciliorum. — For Easter to be duly celebrated, three things are to be observed from the decrees of the Popes and the Councils. → 62

Pascha quot diebus anni, & quibus celebrari possit, ex decreto Concilij Nicæni. — On how many days of the year, and which, Easter may be celebrated, according to the decree of the Council of Nicaea. → 62

Pascha circa tempora Concilij Nicæni frequenter incidisse quasi in Lunā xiiij. eo quod Nouilunia nimis cito ab aureis numeris monstrabantur. — That around the time of the Council of Nicaea Easter frequently fell almost on Luna xiiij, because the new moons were shown too early by the golden numbers. → 350

Paschæ celebratio cur post Concilium etiam Nicænum tot dissensiones inter Orientalem, & Occidentalem Ecclesiam excitauerit. — Why the celebration of Easter, even after the Council of Nicaea, stirred up so many disputes between the Eastern and Western Church. → 350

Pascha sæpius non recte celebraretur, si Epactæ citius Nouilunia indicarent, quam nunc indicant. — Easter would more often be wrongly celebrated if the epacts indicated the new moons earlier than they now do. → 351

Pascha anni 1598. ex die 22. Martij in 29. reijciendum fuisse, non recte à quibusdam affirmari. — That some wrongly assert that the Easter of the year 1598 should have been moved from the 22nd of March to the 29th. → 351

Pascha sæpe celebraretur ante Plenilunium, si Nouilunia Cycli non subsequerētur coniunctiones, quæ in cælo fiunt. — Easter would often be celebrated before the full moon, if the new moons of the Cycle did not follow the conjunctions that take place in the heavens. → 347

Pascha celebrandum esse die Dominica post Lunam xiiij. confirmatum fuisse potius à Concilio Nicæno, quàm institutum. — That the celebration of Easter on the Sunday after Luna xiiij was confirmed by the Council of Nicaea rather than instituted by it. → 55

Pascha sæpenumero non haberetur in anno aliquo, si motus medij, non autem Cycli, ab Ecclesia obseruarentur. — That very often there would be no Easter in some year, if the mean motions, and not the Cycle, were observed by the Church. → 356

Pascha in Calendario nouo raro celebrari ante mediam oppositionem fere, ita vt ipsam aliquo modo non attingat. — That in the new Calendar Easter is rarely celebrated before roughly the mean opposition, in such a way that it does not in some measure reach it. → 351

Pascha ab aureo numero eodem reijci aliquando ex Martio in Aprilem, & contra. — That under the same golden number Easter is sometimes moved from March into April, and the reverse. → 357

Pascha apud Vietam, secundum posteriorem tabulam æquationis, sæpius in mense vltimo celebrari. — That in Viète, according to the later table of equation, Easter is more often celebrated in the last month. → 525

Pascha vno eodemque die in omnibus mundi partibus esse celebrandum. — That Easter is to be celebrated on one and the same day in all parts of the world. → 505

Paschæ inuentio in Calendario per Epactam, & literam Dominicalem, vna cum alijs festis mobilibus. — The finding of Easter in the Calendar by means of the epact and the Dominical letter, together with the other movable feasts. → 29

Paschæ celebratio vbi, & quando præcipiatur in sacra Scriptura. — Where and when the celebration of Easter is commanded in Sacred Scripture. → 53

Pascha apud Vietam, secundum priorem tabulam æquationis, non raro in secundo mense celebrari. — That in Viète, according to the earlier table of equation, Easter is not rarely celebrated in the second month. → 524

Paschale Nouilunium aut Plenilunium cuiusuis anni expansi, quo pacto ex Nouilunio, plenilunioe centesimi anni proxime antecedentis eliciatur. — By what method the Paschal new moon or full moon of any expanded year is drawn out from the new or full moon of the immediately preceding centennial year. → 533

Paschale plenilunim [recte: plenilunium] quando in Martium, & quando in Aprilem cadat. — When the Paschal full moon falls in March, and when in April. → 533

Paschale Nouilunium diei 5. Aprilis desint [recte: desinit] esse Paschale, quando fit transitus de superiori linea tabulæ expansæ ad inferiorem; & Nouilunium non Paschale diei 7. Martij incipit esse Paschale. — The new moon of 5 April ceases to be Paschal when the passage is made from the upper line of the expanded table to the lower; and the non-Paschal new moon of 7 March begins to be Paschal. → 354

Paschale Nouilunium cuiusuis centesimi post correctionem, quo pacto per Epactas correctas supputetur. — By what method the Paschal new moon of any centennial year after the correction is reckoned by the corrected epacts. → 533

Paschale Nouilunium diei 8. Martij desinit esse Paschale, quando fit transitus de inferiori linea tabulæ expansæ ad superiorem, & Nouilunium non Paschale diei 6. Aprilis incipit esse Paschale. — The new moon of 8 March ceases to be Paschal when the passage is made from the lower line of the expanded table to the upper, and the non-Paschal new moon of 6 April begins to be Paschal. → 354

Pascha raro in vltimum, vel secundum mensem in nouo Calendario incurrere. — That in the new Calendar Easter rarely runs into the last or second month. → 83

Pascha celebrari nonnunquam in secundo mense, error dici non debet, cum id vitari nequeat, propter duos dies, quos æquinotium postulat, siue nouum Calendarium recipiatur, siue vetus retineatur. — That Easter being sometimes celebrated in the second month ought not to be called an error, since it cannot be avoided, on account of the two days that the equinox requires, whether the new Calendar be adopted or the old retained. → 83

Paschalia Nouilunia quot & quæ sint, ex decreto Concilij Nicæni. — How many the Paschal new moons are, and which, according to the decree of the Council of Nicaea. → 62

Paschale plenilunium medium nullum in quibusdam annis reperiri in veteri Calendario. — That in some years no mean Paschal full moon is found in the old Calendar. → 359

Paschalia Nouilunia quot, & quæ sint, ex decreto Concilij Nicæni. — How many the Paschal new moons are, and which, according to the decree of the Council of Nicaea. → 62

Paschale plenilunium ac Nouilunium, quo pacto per progressus Neomeniarum supputetur. — By what method the Paschal full moon and new moon is reckoned through the progressions of the new moons [Neomeniæ]. → 539

Paschale Plenilunium cuiusuis centesimi post correctionem quo pacto per Epactas correctas supputetur. — By what method the Paschal full moon of any centennial year after the correction is reckoned by the corrected epacts. → 553

Paschales Lunationes cur non omnes in nouo Calendario sint 29. dierum, vt in veteri. — Why not all the Paschal lunations in the new Calendar are of 29 days, as in the old. → 103

Paschales menses esse plenos, vt vult Vieta, non esse necessarium, immo Patribus Concilij Nicæni contrarium. — That the Paschal months be full, as Viète wishes, is not necessary — indeed it is contrary to the Fathers of the Council of Nicaea. → 515

Paschalis tabula, siue festorum mobilium antiqua reformata & perpetua. — The Paschal table, or the ancient, reformed, and perpetual table of movable feasts. → 33

Paschalis tabula, siue festorum mobilium noua reformata, & perpetua. — The Paschal table, or the new, reformed, and perpetual table of movable feasts. → 34

Paschata 125. ante Plenilunium medium, secundum priorem tabulam æquationis Vietæ. — 125 Easters before the mean full moon, according to Viète's earlier table of equation. → 521

Perfectio ac perpetuitas Calendarij Gregoriani in quo consistat. — In what the perfection and perpetuity of the Gregorian Calendar consists. → 73

Periodi anomalie æquinociorum Radix. — The radix of the period of the anomaly of the equinoxes. → 76

Periodum magnam Lunæ annorum 3400. non restituere accurate, vt putat Vieta, synodicos menses. — That the great period of the Moon of 3400 years does not, as Viète thinks, accurately restore the synodic months. → 528

Periodus anomalie æquinociorum quo anno Christi inceptura sit. — In what year of Christ the period of the anomaly of the equinoxes is to begin. → 76

Periodus Callippi annorum 76. — The period of Callippus, of 76 years. → 86

Perpetuitas, ac perfectio Calendarij Gregoriani in quo consistat. — In what the perpetuity and perfection of the Gregorian Calendar consists. → 73

Pij Papæ mart. decretum de Paschæ celebratione. — The decree of Pope Pius, martyr, concerning the celebration of Easter. → 55

Plenilunia ac Nouilunia in centesimis annis communibus, quo modo reperiantur ex tabula Nouiluniorum. — In what way the full moons and new moons in the common centennial years are found from the table of new moons. → 253

Plenilunia, Nouiluniaque qua ratione ex tabulis Epactarum inquirantur. — By what method the full moons and new moons are sought from the tables of epacts. → 171

Plenilunij ac Nouilunij inuentio post annum correctionis 1582. ex tabula Nouiluniorum. — The finding of the full moon and new moon after the year of the correction 1582, from the table of new moons. → 253

Plenilunij ac Nouilunij inuentio in quolibet mense ab anno 1501. vsque ad 1576. ex tabula Nouiluniorum. — The finding of the full moon and new moon in any month from the year 1501 up to 1576, from the table of new moons. → 253

Plenilunij ac Nouilunij inuentio in quolibet mense post annum 1576. vsque ad correctionem Gregorianam, ex tabula Nouiluniorum. — The finding of the full moon and new moon in any month after the year 1576 up to the Gregorian correction, from the table of new moons. → 253

Plenilunio, Nouilunioe quæsito ultra mensem propositum cadente, quid agendum. — What is to be done when the full moon or new moon sought falls beyond the month proposed. → 172

Plenilunium medium incidere in diem Paschæ ante Solis occasum, non censeri esse contra Canonem Concilij Nicæni. — That the mean full moon falling on the day of Easter before sunset is not judged to be against the Canon of the Council of Nicaea. → 502

Plenilunium aut Nouilunium cuiusuis mensis quo pacto ex Nouilunio plenilunioe Martij, vel Aprilis eruatur. — By what method the full moon or new moon of any month is drawn out from the new or full moon of March or April. → 535

Plenilunium cuiusuis centesimi Paschale post correctionem quo pacto per Epactas correctas supputetur. — By what method the Paschal full moon of any centennial year after the correction is reckoned by the corrected epacts. → 533

Plenilunium aut Nouilunium Paschale cuiusuis anni expansi quo pacto ex Nouilunio, plenilunioe centesimi anni proxime antecedentis eliciatur. — By what method the Paschal full moon or new moon of any expanded year is drawn out from the new or full moon of the immediately preceding centennial year. → 533

Plenilunium, ac Nouilunium Paschale quo pacto per progressus Neomeniarum supputetur. — By what method the Paschal full moon and new moon is reckoned through the progressions of the new moons. → 539

Plenilunium Paschale quando in Martium, & quando in Aprilem cadat. — When the Paschal full moon falls in March, and when in April. → 533

Plenus & cauus annus Lunaris tam communis, quam Embolismicus quid. — What the full and hollow lunar year is, both common and embolismic. → 85

Pontifices multi Romani, & Concilia non pauca correctionem calendarij desiderarunt. — Many Roman Popes, and not a few Councils, desired the correction of the calendar. → 1

Pontifices summi complures tentarunt errorem æquinotij & Lunæ xiiij. emendare. — Several supreme Pontiffs attempted to correct the error of the equinox and of Luna xiiij. → 3

Postpositio Lunæ quouis centesimo anno, quo pacta [recte: pacto] inueniatur. — By what method the postposition of the Moon in each centennial year is found. → 149

Primum mensem recte dici eum, cuius Luna xiiij. in diem æquinotij incidit, vel eum proxime sequitur. — That the first month is rightly said to be that whose Luna xiiij falls on the day of the equinox, or immediately follows it. → 61

Primus mensis non recte à nonnullis definitur. — The first month is not rightly defined by some. → 61

Primus mensis Iudæorum quis. — Which is the first month of the Jews. → 54

Progressus Neomeniarum à centuria ad centuriam, ex sententia Vietæ. — The progression of the new moons from century to century, according to Viète's opinion. → 529

Progressus verior Neomeniarum à centuria ad centuriam, post correctionem, quantus sit. — How great the truer progression of the new moons from century to century is, after the correction. → 529

Progressus Neomeniarum à centuria ad centuriam, ante correctionem, quantus sit. — How great the progression of the new moons from century to century is, before the correction. → 529

Progressus Nouiluniorum, ac pleniluniorum, quo pacto colligatur. — By what method the progression of the new moons and full moons is gathered. → 537

Prutenicæ tabulæ, quæ hodie ab omnibus vsurpantur, cur incertæ iudicari possint. — Why the Prutenic tables, which are today used by all, may be judged uncertain. → 67

Prutenicas tabulas ad Calendarium restituendum esse adhibitas. — That the Prutenic tables were employed for the restoration of the Calendar. → 81

Ptolemæi annus quot annos requirat, vt dies intercalaris omittatur. — How many years Ptolemy's year requires, that the intercalary day be omitted. → 71

Ptolemæo quantus sit annus. — How great the year is according to Ptolemy. → 70

R.

Radix æquationis Epactarum vbi statuenda. — Where the radix of the equation of the epacts is to be established. → 107

Radices festorum mobilium, quæ. — The radices of the movable feasts, which they are. → 577

Radix periodi anomalie æquinocriorum. — The radix of the period of the anomaly of the equinoxes. → 76

Regula tripartita continuandi tabulam æquationis Epactarum in infinitum, ex Lilijs sententia. — The threefold rule for continuing the table of the equation of the epacts to infinity, according to Lilius's opinion. → 131

Responsio generalis ad omnia argumenta, quæ contra æquationem æquinocitij afferri solent. — A general reply to all the arguments customarily brought against the equation of the equinox. → 84

Romani multi Pontifices, & Concilia non pauca Calendarij correctionem desiderarunt. — Many Roman Popes, and not a few Councils, desired the correction of the Calendar. → 1

S.

Saltus Lunæ, & Embolismi faciunt, vt nonnunquam duæ, vel tres Lunationes continuæ sint dierum 29. & duæ, tresue, vel quatuor, dierum 30. — The leap of the Moon and the embolisms bring it about that sometimes two or three continuous lunations are of 29 days, and two, three, or four of 30 days. → 341

Saltus Lunæ apud Computistas quid in annis Lunaribus communibus. — What the leap of the Moon is according to the computists in common lunar years. → 340

Saltum Lunæ quando dici possit fieri in anno Embolismico. — When the leap of the Moon may be said to occur in an embolismic year. → 340

Saltum Lunæ semper fieri, cum aureus numerus est j. alias nunquam, nisi in annis Embolismicis Epactarum xix. & xvij. — That the leap of the Moon always occurs when the golden number is j, and otherwise never, except in the embolismic years of epacts xix and xvij. → 341

Saltus Lunæ cur plerisque displiceat. — Why the leap of the Moon displeases most people. → 341

Scaligeri Lunas xiiij. aliquas nimis postponi. — That some of Scaliger's Lunæ xiiij are postponed too far. → 549

Scaligerum in æquatione Epactarum non habuisse semper rationem postpositionum Lunæ, ac dierum exemptorum. — That Scaliger, in the equation of the epacts, did not always take account of the postpositions of the Moon and of the days removed. → 544

Scaligerum sumpsisse Calendarium Compendij pro suo. — That Scaliger took the Calendar of the Compendium for his own. → 540

Scaliger quæ errata in suo Calendario commiserit. — What errors Scaliger committed in his Calendar. → 540

Sedem stabilem æquinotio posse in Calendario assignari, Lunaremque Cyclum perpetuum posse describi, cur plerique impossibile esse censuerint. — Why most people judged it impossible that a stable seat could be assigned to the equinox in the Calendar, and that a perpetual Lunar Cycle could be described. → 1

Sententiæ varicæ de æquinotij restitutione. — Various opinions concerning the restitution of the equinox. → 64

Similitudo inter intercalationem quadringentesimo quoque anno adhibendam, & intercalationem quarto quoque anno consuetam. — The likeness between the intercalation to be applied in every four-hundredth year, and the intercalation customary in every fourth year. → 74

Similitudo inter medias Luminarium coniunctiones, & æquationem ad annum medium institutam. — The likeness between the mean conjunctions of the Luminaries, and the equation established for the mean year. → 72

Solares, ac Lunares menses ad festa mobilia celebranda necessarij sunt. — Solar and lunar months are necessary for celebrating the movable feasts. → 1

Solares anni 19. quot dies contineant. — How many days 19 solar years contain. → 86

Solaris annus non est eiusdem semper magnitudinis. — The solar year is not always of the same magnitude. → 70

Solaris, atque Lunaris annus, cur corrigendus fuerit. — Why the solar and the lunar year had to be corrected. → 1

Solaris Cycli inuentio in Computo Ecclesiastico ex propria tabella. — The finding of the Solar Cycle in the Ecclesiastical Computus from its own little table. → 591

Solaris Cycli inuentio per Arithmetica. — The finding of the Solar Cycle by arithmetic. → 23

Solaris Cycli inuentio per tabulam, quocunque anno proposito. — The finding of the Solar Cycle by a table, for any year proposed. → 23

Solaris cycli inuentio in digitis memoriter. — The finding of the solar cycle on the fingers, from memory. → 570

Solaris cycli inuentio ex tabella, quæ incipit ab anno correctionis 1582. — The finding of the solar cycle from a little table that begins with the year of the correction 1582. → 22

Solaris Cyclus quid. — What the Solar Cycle is. → 361

Solaris Cyclus idem, qui literarum Dominicalium. — The Solar Cycle is the same as that of the Dominical letters. → 361

Solaris Cyclus, seu literarum Dominicalium antiquus annorum 28. perpetuus, cum tabula æquationis eiusdem Cycli. — The Solar Cycle, or the ancient perpetual [cycle] of the Dominical letters, of 28 years, with the table of equation of the same Cycle. → 27

Solarium tantum mensium vsus ad festa immobilia celebranda necessarius est. — The use of solar months alone is necessary for celebrating the immovable feasts. → 1

Solis locus in zodiaco, quo pacto memoriter inueniatur. — By what method the place of the Sun in the zodiac is found from memory. → 583

Supputatio Lunationum vsque ad Quartā. — The reckoning of the lunations up to the Quarta. → 552

Supputatio Nouiluniorum, ac Pleniluniorum mediorum. — The reckoning of the mean new moons and full moons. → 168

T.

Tabula Paschalis, siue festorum mobilium antiqua reformata, & perpetua. — The Paschal table, or the ancient, reformed, and perpetual table of movable feasts. → 33

Tabula Nouiluniorum pro 76. annis ab anno 1501. inclusiue vsque ad annum 1576. inclusiue, qui constituunt vnam periodum Callippi. — The table of new moons for the 76 years from the year 1501 inclusive up to the year 1576 inclusive, which make up one period of Callippus. → 176

Tabula æquationis Epactarum capituli 11. continetur Cyclo 300000. annorum. — The table of the equation of the epacts of chapter 11 is contained within a Cycle of 300,000 years. → 133

Tabula Epactarum expansa, vna cum tabula æquationis ex mente Liliij, nec non cum diebus propter æquinoclij æquationem exemptis. — The expanded table of epacts, together with the table of equation according to Lilius's intention, and also with the days removed on account of the equation of the equinox. → 110

Tabula ad supputanda Nouilunia, Pleniluniaque ad annum vsque 1000000000. — The table for reckoning the new moons and full moons up to the year 1,000,000,000. → 174

Tabula anticipationis Lunæ in annis per 76. progredientibus. — The table of the anticipation of the Moon in years advancing by 76. → 176

Tabula reuolutionum Nouiluniorum ad plurimos annos supputata. — The table of revolutions of the new moons, reckoned for very many years. → 173

Tabula festorum mobilium temporaria ab anno 1600. vsque ad annum 5000. — The temporary table of movable feasts from the year 1600 up to the year 5000. → 380

Tabula æquationis Epactarum qua ratione instauranda sit, si forte alia anni magnitudo à posteris deprehendatur. — By what method the table of the equation of the epacts is to be renewed, if perhaps another magnitude of the year should be discovered by posterity. → 166

Tabula æquationis Epactarum, qua ratione instauranda sit, si forte Luna aliter æquanda sit, quam supra declaratum est. — By what method the table of the

equation of the epacts is to be renewed, if perhaps the Moon should have to be equated otherwise than was declared above. → 166

Tabellæ temporariæ ad inuestigandas Epactas, quo pacto construantur. — By what method the temporary little tables for investigating the epacts are constructed. → 159

Tabellæ temporariæ Cycli Solaris. — The temporary little tables of the Solar Cycle. → 364

Tabula Nouiluniorum perpetua. — The perpetual table of new moons. → 344

Tabulæ Epactarum expansæ constructio. — The construction of the expanded table of epacts. → 105

Tabellæ temporariæ literarum Dominicalium constructio ad quodcunque seculum propositum. — The construction of the temporary little table of Dominical letters for any century proposed. → 26

Tabula æquationis Epactarum capituli 11. Compendium, vna cum eius vsu. — A compendium of the table of the equation of the epacts of chapter 11, together with its use. → 144

Tabula æquationis Epactarum accuratior constructio, quam cap. 11. factum est. — A more accurate construction of the table of the equation of the epacts than was done in chapter 11. → 154

Tabula Epactarum annorum, ac mensium. — The table of epacts of years and of months. → 169

Tabula æquationis Epactarum constructio. — The construction of the table of the equation of the epacts. → 106

Tabulæ 30. amplectentes omnes Lunationes triginta Cyclorum tabulæ expansæ. — The 30 tables embracing all the lunations of the thirty Cycles of the expanded table. → 304

Tabellæ temporariæ literarum Dominicalium. — The temporary little tables of the Dominical letters. → 369

Tabula Paschalis, siue festorum mobilium noua reformata, & perpetua. — The Paschal table, or the new, reformed, and perpetual table of movable feasts. → 34

Tabula Lunationum aureorum numerorum in veteri Calendario descriptorum. — The table of the lunations of the golden numbers described in the old Calendar. → 342

Tabulæ Prutenicæ, quæ hodie ab omnibus vsurpantur, cur incertæ iudicari possint. — Why the Prutenic tables, which are today used by all, may be judged uncertain. → 67

Tabularum Astronomicarū inconstantia vnde proueniat. — Whence the inconstancy of the Astronomical tables arises. → 67

Tabularum Astronomicarum inconstantiam non obesse perfectioni, ac perpetuitati Calendarij. — That the inconstancy of the Astronomical tables does not stand in the way of the perfection and perpetuity of the Calendar. → 81

Tabulas Astronomicas magni faciendas esse etiamsi longo tempore durare nequeant. — That the Astronomical tables are to be highly valued, even if they cannot last for a long time. → 67

Tabulas medij motus Lunæ vtilis esse ad examinandum Cyclum quemcunque propositum. — That the tables of the mean motion of the Moon are useful for examining any Cycle proposed. → 347

Tabulas Prutenicas ad Calendarium restituendum esse adhibitas. — That the Prutenic tables were employed for the restoration of the Calendar. → 81

Traditionem esse Apostolicam de celebrando Paschate die Dominica post Lunam xiiij. primi mensis. — That it is an Apostolic tradition to celebrate Easter on the Sunday after Luna xiiij of the first month. → 56

Tropicus annus quando sit maximus, quando minimus, & quando mediocris. — When the tropical year is greatest, when least, and when middling. → 76

V.

Verno æquinotio dies 21. Martij à Concilio Nicæno tributus est. — The 21st of March was assigned to the vernal equinox by the Council of Nicaea. → 62

Verum æquinotium prolapsurum ad diem 27. Martij, quare quidam Astronomus opinatus sit. — Why a certain Astronomer supposed that the true equinox would slip forward to the 27th of March. → 80

Victoris Papæ Mart. decretum de Paschate celebrando post Lunam xiiij. primi mensis. — The decree of Pope Victor, martyr, concerning the celebration of Easter after Luna xiiij of the first month. → 55

Vietæ propter quam causam cogatur toties constituere Lunarem mensem dierum 28. & interdum dierum duntaxat 27. — For what reason Viète is compelled so often to set up a lunar month of 28 days, and sometimes of only 27 days. → 512

Vietæ Calendarij inscriptio. — The title of Viète's Calendar. → 505

Vietam comminisci nouam Epactarum collocationem, nouumque anni principium. — That Viète contrives a new placement of the epacts, and a new beginning of the year. → 506

Vietæ κριτικὰ [Greek: kritika, "critical objections"] aduersus Calendarium Gregorianum, eorumque solutiones. — Viète's critical objections against the Gregorian Calendar, and their solutions. → 515

Vietæ audax facinus in Calendario suo seorsum excudendo, cum bulla Gregorij. — Viète's bold deed in printing his own Calendar separately, [set] with the bull of Gregory. → 510

Vietam secundum priorem tabulam æquationis celebrare Pascha non raro in secundo mense. — That Viète, following the earlier table of equation, not rarely celebrates Easter in the second month. → 524

Vietam, velit, nolit, facere interdum Lunationem dierum 31. in anno bissextili. — That Viète, willy-nilly, sometimes makes a lunation of 31 days in a bissextile year. → 512

Vietam infringere regulam vulgarem inuestigandi ætatem Lunæ per Epactas. — That Viète breaks the common rule for investigating the age of the Moon by the epacts. → 510

Vietæ Epactas vere non esse Epactas. — That Viète's epacts are truly not epacts. → 510

Vietæ Epactas non esse æquales diebus, qui in Decembri post vltimam Lunationem supersunt. — That Viète's epacts are not equal to the days that remain in December after the last lunation. → 511

Vietam duas tabulas æquationis Epactarum proponere inter se contrarias. — That Viète sets forth two tables of the equation of the epacts contrary to each other. → 519

Vietam secundum priorem tabulam æquationis exhibere Paschata ante Plenilunium medium. — That Viète, following the earlier table of equation, presents Easters before the mean full moon. → 521

Vietam secundum posteriorem tabulam æquationis sæpius in mense vltimo Pascha celebrare. — That Viète, following the later table of equation, more often celebrates Easter in the last month. → 525

Vietam sæpissime exhibere Lunas xv. ante tempus legitimum. — That Viète very often presents Lunæ xv before the lawful time. → 527

Vietam non paucas Lunas xiiij. plus æquo, postponere. — That Viète postpones not a few Lunæ xiiij more than is fair. → 528

Vietam nonnunquam vel constituere duo Nouilunia proxima, nullo intercedente die, vel nullum habere in vno anno Nouilunium Paschale, vniue Lunationi dies 31. tribuere. — That Viète sometimes either sets two new moons next to each other, with no day intervening, or has no Paschal new moon in one year, and assigns 31 days to a single lunation. → 513

Vietam interdum vel constituere Lunationem duorum tantum dierum, vel 32. nullumque habere in vno anno Nouilunium Paschale. — That Viète at times either sets up a lunation of only two days, or of 32, and has no Paschal new moon in one year. → 514

Vietam non semper addere 11. vt Epacta sequens formetur, etiamsi neque aureus numerus sit 19. neque alia litera æquationis accipienda sit: contra omnium Computistarum doctrinam. — That Viète does not always add 11 to form the following epact, even when the golden number is not 19 and no other letter of equation is to be taken: against the teaching of all the computists. → 514

Vietam temere sex dies anni Nouilunio priuare. — That Viète rashly deprives the year of six days of new moon. → 514

Vsus æquationis Epactarum secundum Aloysium Liliū instituta. — The use of the equation of the epacts as instituted by Aloysius Lilius. → 10

FINIS.

Apology for the New Roman Calendar (Novi Calendarii Romani Apologia)

NOVI CALENDARII ROMANI APOLOGIA, *Aduersus Michaelē
Mæstlinum Gæppingensem, in Tubingensi Academia Mathematicum,*
**DVOBVS LIBRIS EXPLICATA, AVCTORE CHRISTOPHORO CLAVIO
BAMBERGENSI E SOCIETATE IESV.**

[IHS device]

MOGVNTIÆ, Sumptibus ANTONII HIERAT, excudebat JOANNES
ALBINVS. *Cum Gratia & Priuilegio Sacræ Cæsar. Maiest.* ANNO M.DC.XII.

Translation:

A DEFENCE OF THE NEW ROMAN CALENDAR, against Michael Mästlin of
Göppingen, mathematician in the University of Tübingen, set out in two books, by
the author **Christoph Clavius of Bamberg, of the Society of Jesus**.

Mainz, at the expense of Antonius Hierat, printed by Joannes Albinus. With the
grace and privilege of His Sacred Imperial Majesty. In the year 1612.

Diagram. The Jesuit printer's device at the center of the title page: an oval
sunburst medallion enclosing the Christogram **IHS** surmounted by a cross, with
three nails below, flanked and crowned by cherub figures and foliate scrollwork.
The legend runs around the oval frame.

- Around the oval (upper half): **NOMEN DOMINI** ("the name of the Lord")
- Around the oval (lower half): **LAVDABILE** ("praiseworthy") — together
"Laudabile nomen Domini" ("Praiseworthy is the name of the Lord," Psalm
112/113:3)
- Center: **IHS** with a cross rising from the crossbar of the H, and three nails
beneath

[Printer to the Reader]

TYPOGRAPHVS LECTORI. (The Printer to the Reader.)

The man who had devoted the greatest toil and labor to composing the new
Roman Calendar was the very same one who labored, almost alone, in defending
it: Christoph Clavius [Christophorus Clavius]. And first of all, when Michael
Mästlin [Michael Mästlin] had rushed to attack it before nearly all others, Clavius
checked his assault with this very Apology. Then, when many others pressed on
to attack the manifest truth — some driven by the same religious hatred as
Maestlin, others thinking their own reputation for talent to be at risk if they
should admit that anything had been done well and successfully by others — he
judged that this defense must be furnished with a greater apparatus. And so he

brought out, in a second work, the *Exposition of the Roman Calendar restored by Gregory XIII* [*Romani Calendarii a Gregorio XIII. restituti Explicationem*], into which he transferred much from this Apology and added so much more that scarcely anything further could be desired, and we would seem to be doing nothing worthwhile were we to submit that earlier Apology to the press once again.

Yet, lest anything from the writings of so learned a man should perish, we made it a matter of conscience not to omit even the least thing. Only those thirty Calendars of the golden numbers — laid out in thirty lines of a table corresponding to the Epacts [Epactarum] — and an equal number of the Lunations of the Cycles [Cyclorum Lunationes], we did not think need be repeated, since they already appear in that fuller exposition of the Calendar and so could be absent here without any inconvenience. We have also separated the one book from the other, so that a reader may use whichever he wishes on its own: for either of them is fully sufficient to master the doctrine that concerns the Calendar. And of this matter we wished to advise the reader.

APOLOGY FOR THE NEW CALENDAR

AGAINST MICHAEL MAESTLIN [Michael Mästlin], mathematician of Tübingen.

BOOK ONE (LIBER PRIMVS).

PREFACE (PRÆFATIO).

What the Ecumenical Councils desired with their fullest prayers, and what all mathematicians and all good men have always longed for — that the Roman Calendar be recalled from the errors into which it had slipped, over the long course of time, on account of the unequal motions of the Sun and Moon — this, in recent years, was brought to completion and perfection, with God's help, by Gregory XIII [Gregory XIII], Supreme Pontiff, after he had consulted by letter the princes of the whole Christian world and had engaged the most expert mathematicians. And when this achievement had been approved and praised — by Rudolf II [Rudolf II], ever-august Emperor of the Romans, by the kings and Christian princes, by the commonwealths, and by the foremost universities — with a wonderful and almost incredible agreement of will and zeal, it was thereafter confirmed by laws, so that it might be observed devoutly by all.

In these very days there has come forward one Michael Mästlin, some fellow of Göppingen, a mathematician in the University of Tübingen, who, swollen with an

arrogance more than heretical, not only holds as nothing and despises this deed of the Pontiff — a deed worthy of remembrance — just as he does all the other precepts and laws of all the Pontiffs (which has always been the mark of every heretic), but also, in a treatise long and wordy enough, attempts to overturn the correction of the Calendar from its very foundations. And this he does with such headlong and reckless audacity that, like a second Ishmael [Ismael] whose hand is against all men, he rushes wantonly upon the Pontiff himself, Christ's Vicar, upon all mathematicians, and upon the consensus of all the faithful.

He had indeed earlier published, as he asserts, another treatise written in the German language, which has not yet come into my hands; but because he saw that it had not had strength enough to remove the Calendar from the scene — as he wished — inasmuch as not only all Catholics but also most heretics, drawn by its excellence and truth, had adopted it, he added this second one, by which he truly supposes that he has won a victory over the Calendar and has imposed silence upon all those who have hitherto approved it, and who, by their encouragement and counsel among princes and magistrates, have been its champions for having it received by all. But so that everyone may see how arrogantly and insolently, in this latter treatise, this hundredfold Briareus [Briareus] declares war not only on the new Calendar and on the heavens, but also challenges to battle all the mathematicians there are in every nation whatsoever — I have judged it not out of place to insert here, word for word, his inflated title, which runs as follows.

[Reproduced title of Maestlin's work, set as the display heading of the page:]

**A SECOND EXAMINATION OF THE NEW PONTIFICAL GREGORIAN
CALENDAR, IN WHICH IT IS DEMONSTRATED FROM THE VERY
SOURCES** that the new Calendar, in all those parts by which it either is,
or is thought to be, most correctly reformed, is in many ways faulty, and
defective in its very foundations.

[Margin: The insolent title of Maestlin's examination.]

By whose warrant does he so boldly challenge all the mathematicians — both those who first constructed that new Calendar and those who have defended it up to now — [demanding] that, unless they wish to be reckoned impostors and disturbers of the public peace within the Holy Roman Empire, they answer this examination; or, if they cannot answer, that they frankly admit, for the common welfare of our country, that they praised this Calendar with too rash an applause and premature counsel, and everywhere persuaded people to adopt it?

This is the boasting talk of that vaunted soldier, by which he has quite convinced himself that no one would dare to reply to his examination. For my own part, I judge that no one has so far been willing to answer that examination — whether because of the obscurity of its author or because of its patent slanders and follies (I make my guess from myself).

[Margin: Why no answer was made sooner to Maestlin's examination.]

For they supposed that no one would be so foolish, so silly, so blind, that with him the loquacity of a single man could prevail against the authority of the Supreme Pontiff, of the Roman Emperor, and of the Christian kings, and against the consensus of the Catholic world. And of what man are we speaking? Of one, forsooth, who has emerged out of a corner of Germany, Göppingen, out of the lurking-places of ignorance — unknown to all — and who seeks fame and celebrity of name from the overthrow of the Roman Calendar, just as that man of old sought it from the ruin of the Ephesian Diana. Indeed, though I was often urged by men of the greatest gravity to answer, this very consideration made me the slower both to undertake the task and to carry it through. But at last, when I had learned from friends' letters that this man was raging most insolently at the disdain of so ignoble a contest, as though it were a concession of victory, and that the minds of certain over-credulous people were beginning little by little to waver, I resolved not to shrink from this contest, whatever its nature.

I therefore — being one of those to whom the business of correcting the old Calendar was entrusted, small as I am — will engage with this Goliath for the honor of the Church, like a second David, relying on divine help rather than on my own strength. For who is this uncircumcised Philistine who has defied the army of the living God? And so, by this Apology, I will do what lies in me (since he challenges me along with the others) to make everyone understand that we are not impostors, nor disturbers of the peace, but that with prudent and necessary counsel we removed errors from the Calendar; whereas he has neither understood wherein the correction of the Calendar consists, nor rightly attacked it now that it is restored and amended, but has in many places wrested it, with a wicked and unjust mind, to an alien sense, so as the more easily to impose upon the world and to stir up the ignorant and unskilled against the new Calendar — as though it were crammed with countless faults and errors — and at the same time against the Supreme Pontiff, its author. I will pass over in silence the impious cries of this whirlwind of the church against the authority of the Roman Pontiff; for it has always been the mark of all heretics, ancient and recent alike, to withdraw themselves from obedience to the head of the Church — that the head

is the Roman Pontiff, an almost countless number of Doctors have demonstrated, more clearly than daylight, from the Councils and the Fathers. I will only examine, as best I can, this examination by the corrector of all the nations, so that its true character may at last be discerned.

For the rest, I beg and beseech those who are going to read this volume, that if at any time I answer that man in the manner he has provoked, they should not think me forgetful of modesty or of myself; but let them remember that so great an audacity in a heretic, insolently insulting the pontifical majesty, was not to be received gently and mildly. For as the ignorance of one who errs must be taught, so the audacity of one who rages must be broken. We see that St. Jerome and the other holy Fathers did just this very thing, when they beat back the impudence of heretics with sharp and vehement speech — lest, of course, the leniency of Catholics should feed and increase the insolence of heretics, if those most arrogant men should interpret restraint as fear. Therefore no one will be so unjust a judge of things as not to think that in the same cause the same is permitted to me as well: especially since this new Goliath cannot be conquered and laid low unless the outstretched and hardened brow of that most audacious man be repeatedly struck. Yet we shall do this with moderation, so that he too may understand that we wished to draw not so much blood as a blush.

Now, so that this reply of mine may be neither unprofitable to its readers nor difficult for all to grasp, there will need to be explained in it whatever shall seem serviceable to the business of correcting the Calendar — and among other things, why it needed to be amended, and wherein its restoration consists. For thus it will come about, I think, that not only will Maestlin's slanders be answered most fully, but silence will also be imposed on all others who are sometimes wont to disapprove of this new Calendar (for no other reason, I judge, than that the grounds of the correction have not been clearly seen and understood by them); while those who have long been eager to learn more diligently the reasoning of the new Calendar may at last have something from which to seek a fuller understanding of it. All the foundations of the restored Calendar are indeed most amply set out in the book on the new method of restoring the Roman Calendar; but since that book has not yet come to light — partly on account of the untimely death of Gregory XIII, of happy memory, partly on account of other impediments that have variously arisen — it has seemed good to set forth in this reply, with the greatest possible brevity, those things without which Maestlin's cavils cannot be fully answered.

[Margin: The division of this work into two books.]

The whole Apology we shall distribute into two books. In the first, everything that pertains to the Equinox will be explained. The second will contain the cycle of Epacts and of the Dominical Letters, and will most clearly demonstrate that the Epacts are rightly arranged in the Calendar for the celebration of Easter at its due time.

Chapter 1 — What Scripture prescribes concerning the celebration of Easter, and what has been sanctioned about it by the holy Fathers and by the Councils

[Margin: The precept concerning the celebration of Easter, from Sacred Scripture.]

At the outset, then, that we may begin from certain and agreed points: in Exodus, chapter xii, the Phase, or Passover, is prescribed to the Hebrews in these words. *"The Lord also said to Moses and Aaron in the land of Egypt: This month shall be to you the beginning of months; it shall be the first in the months of the year. Speak to the whole assembly of the children of Israel, and say to them: On the tenth day of this month let every one take a lamb by their families and houses."* And a little further on: *"And you shall keep it until the fourteenth day of this month; and the whole multitude of the children of Israel shall sacrifice it in the evening."* And after a few words: *"For it is the Phase (that is, the Passing) of the Lord."* And further on: *"And you shall have this day for a memorial, and you shall keep it a feast to the Lord in your generations with an everlasting observance."* And a little after: *"In the first month, on the fourteenth day of the month, in the evening, you shall eat unleavened bread until the one-and-twentieth day of the same month."* Next, in Leviticus, chapter XXIII: *"These, then, are the holy feasts of the Lord, which you must celebrate in their seasons. In the first month, on the fourteenth day of the month, in the evening, is the Phase of the Lord; and on the fifteenth day of this month is the solemnity of the unleavened bread of the Lord."* Likewise in Numbers, chapter IX: *"The Lord spoke to Moses in the desert of Sinai, in the second year after they had gone out of the land of Egypt, in the first month, saying: Let the children of Israel keep the Phase in its due time, on the fourteenth day of this month, in the evening, according to all its ceremonies and justifications."* And somewhat later: *"The Lord spoke to Moses, saying: Speak to the children of Israel: The man that shall be unclean by occasion of one that is dead, or shall be in a journey afar off in your nation, let him keep the Phase to the Lord in the second month, on the fourteenth day of the month, in the evening."* In Numbers, chapter XXVIII too, these words are found: *"But in the first month, on the fourteenth day of the month, shall*

be the Phase of the Lord, and on the fifteenth day the solemnity." From all these passages it is clear that it was prescribed by God to the Hebrews that they should celebrate the Phase, or Passover, on the fourteenth day of the first month, in the evening.

[Margin: When the Jews celebrated Passover by divine command. / Which is the first month.]

Now this month is a lunar one — for the Hebrews used lunar months — namely the one whose fourteenth day of the Moon (counting also the very day of the new moon, or neomenia) falls either on the day of the vernal equinox or first occurs after the equinox. This is gathered without obscurity from the older and more learned Hebrews, who always taught that Passover was to be celebrated, according to the lunar cycle, on the fourteenth Moon falling on the equinox or next following it. The most amply attested witness of this matter is Josephus the Jew, in Book III of the *Antiquities of the Jews*, chapter XIII, who writes thus: *"In the month called Xanthicus — which among us is named Nisan, and is the beginning of the year — on the fourteenth Moon, with the Sun opposite in Aries, in which month we were delivered from the servitude of the Egyptians, He commanded us to sacrifice year by year the offering which they made at that time when they went out of Egypt (this is called the Passover); and we do indeed celebrate it throughout our tribes, keeping nothing of what is sacrificed until the morrow."* By these words he plainly teaches that the fourteenth Moon of the first month, on which the Jews celebrated Passover, was the one that either falls on the day of the equinox or next follows the equinox — that is, when the Sun is either at the beginning of Aries or in some degree of Aries.

That Philo, the most learned of the Jews, and other more ancient Jews held the same view, Anatolius — bishop of Laodicea, a city of Syria, who flourished about the year of the Lord 280, some 45 years before the Council of Nicaea — teaches in the clearest words. After he had taught (as Eusebius reports, Book VII of the *Ecclesiastical History*, chapter XXIX) that the year, as far as concerns the celebration of Easter, ought to be begun from the vernal equinox, he adds this: *"And therefore we say that those men offend not a little who think that Passover is to be celebrated before the beginning of this new year (that is, before the vernal equinox). Nor does this reckoning first take its beginning from us, but it is shown to have been approved by the ancient Jews and observed before the coming of Christ — as Philo and Josephus clearly teach, and, older than they, Agathobulus, and, taught by him, Aristobulus of Paneas, who was one of those seventy elders sent by the high priests to Ptolemy, king of Egypt, to translate the books of the Hebrews into the*

Greek tongue; and who answered the King on many points from the traditions of Moses when he proposed and inquired of them. These men, therefore, when they were expounding the questions of Exodus, said that the Passover was not to be sacrificed before the vernal equinox had passed. But Aristobulus added this further: that on the day of Passover it must be observed not only that the Sun cross the vernal equinox, but the Moon also. For since there are two equinoxes, of Spring and of Autumn, separated by equal intervals, and since the solemnity of the fourteenth of the first month is appointed after the evening, when the Moon is found opposite the Sun on the far side — as one may also prove with the eyes — the Sun is found holding the part of the vernal equinox, and the Moon, on the contrary, that of the autumnal. I have read in their books, and in others, many things set forth on these most powerful assertions, which clearly show that the solemnity of Passover is in every way to be celebrated after the equinox." These things Eusebius reports from Anatolius.

From all this it is clear that the more ancient and skilled Hebrews took [from the tradition of Moses] that fourteenth Moon of the first month which either falls on the equinox or next follows it; whereas the fourteenth Moon preceding the equinox was always rejected as useless, and as belonging rather to the last month of the year than to the first. And these things were sanctioned in the sacred and divine Scripture, and by the Hebrew teachers, concerning the Mosaic Passover.

Now, in the time of grace, after the Mosaic Law, the Catholic Church — although it was not bound by those ceremonial precepts, since all the legal observances ceased through the death and resurrection of Jesus Christ, as the holy Doctors agree — nevertheless willed that the Christian Passover [Easter], of which the Jewish one was the figure and shadow, should likewise be variable and movable, not fixed and stationary; and that in celebrating it the Church should observe the same things as the Hebrews, that is, the vernal equinox and the fourteenth Moon

[Margin: Why the Church preferred Easter to be movable rather than fixed.]

of the first month — on account of the sacrament and the hidden mysteries that are contained in this manner of celebrating the Easter of the Lord's resurrection, as is amply written by St. Augustine in his book *To the Inquiries of Januarius*, book II, chapters I and II. Therefore those are not to be heeded who think that the Church ought to celebrate the solemnity of Easter always on a fixed day, after the manner of the other festivals that are called fixed, with no consideration had of the Moon of the first month — being led chiefly by this reasoning, that the Church might wholly free and disentangle herself from the difficulties and controversies that are wont to arise among writers over the Paschal new moons. They are not, I

say, to be heeded (although the Church, using her own right, could freely do this, and no one could reprehend her for it, since that precept of the Passover is ceremonial and has now ceased, as has been said), because the Catholic Church has never celebrated Passover by that rite, but has always, in celebrating it, observed the motion of the Moon and of the Sun; and so it was sanctioned by the most ancient and most holy Roman Pontiffs, confirmed too by the first Council of Nicaea and very many others, as we shall soon say. For this reason a custom so venerable seems in no way to be broken without some grave cause.

[Margin: That the Christian Easter is to be celebrated on the first Sunday after the fourteenth Moon of the first month, so that a fourteenth Moon falling on a Sunday is transferred to the following Sunday.]

In this, however, the Church departed from the manner of the Jews: that she ordered Passover to be celebrated not on the fourteenth Moon of the first month itself, as the Hebrews did, but on the Sunday which next follows the fourteenth Moon of the first month — because it was on the first Sunday after the Jews' Passover that the Lord rose from the dead. Hence, just as the Jews celebrate Passover on the fourteenth [Moon] on account of the sacrificing of the lamb, which prefigured the death of Christ, so we celebrate at Easter the memory of Christ's resurrection, which took place on the Lord's Day. Nevertheless, whenever the fourteenth day of the Moon of the first month falls on a Sunday, [the Church] commands that the solemnity of Easter be transferred to the following Sunday — which, of course, falls on the sixteenth Moon of the first month. Two chief reasons for this are given by the Fathers and writers. First, that the Lenten fast should not be broken on the fourteenth Moon; or (if it be not then broken, but on the fourteenth Moon, as the ancient Fathers wished) lest we be compelled to fast on the Lord's Day together with the Manichaeian heretics, and the Paschal feasts should begin on the following day. But that it was not permitted to break the fast before the fourteenth Moon of the first month is plainly established from Eusebius, Book V of the *Ecclesiastical History*, chapter XXIII, where he says thus:

"In the provinces of Asia no small question arose, descending, as it were, from an ancient observance of theirs, in that they thought Passover must by all means be celebrated on the fourteenth Moon — namely when the lamb is commanded to be sacrificed by the Jews — affirming, as though of necessity, that on whatever day of the week the fourteenth Moon should come, the fast ought to be broken, since such a custom had never at all been observed in any other churches whatsoever." The same is taught by Blessed Ambrose in his Epistle to the Bishops established throughout Aemilia, in these words: *"Hence if it should fall out, as it will shortly,*

that the fourteenth Moon of the first month is on a Sunday — since we ought neither to fast on the Lord's Day, nor to break the fast on the thirteenth Moon when it falls on a Saturday (which above all ought to be kept on the day of the Passion) — the celebration of Easter must be deferred to the following week." The venerable Bede too, in his book *On the Reckoning of Time*, chapter LVII, writes thus on the same matter: *"It is therefore fitting to observe carefully that, as often as the fourteenth Moon falls on a Sunday, we should rather defer the Paschal day to the following week, for a twofold reason. First, that we should not break the fast when the thirteenth Moon is found on a Saturday, which is not consistent, since the law itself does not command it. Next, that we should not be compelled to fast on the Sunday on which the fourteenth Moon is set, thereby doing an unseemly and unlawful thing; for this custom the sect of the Manichaeans has held. And so on. Then, that we should never celebrate Passover with the Jews, nor agree with the Quartodeciman heretics,"* who taught that the Mosaic Law was to be observed together with the Gospel.

That Passover, moreover, is to be celebrated on a Sunday — and that the first one after the fourteenth Moon of the first month, that is, after the Passover of the Jews — can be confirmed by many authorities of the holy Fathers and by the decrees of Councils. That it must first of all not be celebrated on the fourteenth Moon with the Jews, but on the Lord's Day, was established by St. Pius, Pope and martyr, tenth from Blessed Peter, about the year of the Lord CL, in a decretal Epistle, in these words, as it is found in *De Consecratione*, Distinction 3, chapter *Nosse*: *"We wish you to know that the Lord's Passover is to be celebrated on the Lord's Day at its yearly seasons."* And a little after: *"Whence we too by Apostolic authority have ordained that all should observe the same, since we ourselves observe it too; nor ought you in any way to depart from the head."*

[Margin: The decree of St. Pius the Pope on celebrating Easter on Sunday.]

And St. Victor, Pope likewise and martyr, fourteenth from Blessed Peter, about the year of the Lord CXC, in his Epistle to Theophilus, bishop of Caesarea — which is found in *De Consecratione*, Distinction III, chapter *Celebritatem* — decrees that Passover ought to be celebrated not on just any Sunday, but on the one that follows the fourteenth Moon of the first month, writing thus: *"That the celebration of the holy Passover ought to be held on a Sunday, our predecessors have already decreed, and we command that it be solemnly celebrated on the same day; for it is not fitting that the members should differ from the head, or act otherwise. And let the same festival be celebrated from the fourteenth Moon of the first month up to the twenty-first of the same month."*

[Margin: The decree of St. Victor the Pope on celebrating Easter on the Sunday after the fourteenth Moon of the first month.]

Besides this, the same has been confirmed and sanctioned by various Councils. For in the first Council after the Apostles — which was held at the exhortation of St. Victor, the Supreme Pontiff whom we have just mentioned, at Caesarea in Palestine, by several bishops, over whom presided Theophilus, bishop of that city, Narcissus, bishop of Jerusalem, and Cassius, bishop of the church of Tyre — we read, in Eusebius, Book V of the *Ecclesiastical History*, chapter XXII, that it was thus decreed: *"Assemblies of bishops and councils are convened throughout each several province, and by letters prolonged and sent to one another about each and every place, they all confirm one ecclesiastical doctrine: that it be not permitted at any time, save on the Lord's Day — on which the Lord rose from the dead — to celebrate the Lord's Paschal mystery, and that only on this day is the Paschal fast to be broken."* Concerning this decree, the same Theophilus, in a Synodal epistle where he explains more clearly that Passover is to be celebrated on the Sunday after the fourteenth Moon, writes thus: *"It was established in that Synod that Easter should be observed from the 11th day before the Kalends of April up to the 12th day before the Kalends of May, and that no one has the liberty to overstep these limits either before or after. Likewise let the divine precept concerning the Moon be kept: 'Let the command given through Moses be observed by you, from the fourteenth Moon up to the twenty-first.' It is agreed, therefore, that these seven Moons were consecrated for Easter by being kept in like manner. When, therefore, a Sunday falls within that limit — from the 11th before the Kalends of April up to the 12th before the Kalends of May — and a Moon from among those seven hallowed ones, it befits us to observe Easter, as is right, in Christ Jesus the Lord"*

[Margin: The decree of the Council of Caesarea in Palestine on celebrating Easter after the fourteenth Moon of the first month.]

our Lord. From this arrangement it is plain that in that period Easter was regularly celebrated from 22 March through to 20 April. Later, however, five further days were added to this span, because the first month necessarily required it, so that Easter could be celebrated as late as 25 April inclusive. For the first month is not the one in which the Sun runs through the whole of Aries — as the Fathers at the Council of Caesarea seem to have wished — but the one whose 14th Moon [Luna xiiii] falls on some day from 21 March inclusive, on which the equinox occurs, up to 18 April inclusive. From this it follows that Easter can be celebrated on 25 April, as we shall say shortly.

Next, at that most famous Council of Nicaea, of 318 bishops distinguished for their holiness and innocence of life — with the legates of the Apostolic See present, sent there by Pope St. Sylvester [Sylvester I], and with Constantine the Great, at whose expense it was held — the same thing was decreed by solemn rite, or rather confirmed and renewed by the common consent of all. On this matter these words survive in the letter sent by that same Council to the Church of Alexandria and to the brethren dwelling in Egypt, Libya, and the Pentapolis, as Socrates [Socrates Scholasticus] reports in Book 1 of his *Ecclesiastical History*, chapter 6, and Theodoret in Book 1 of his *Ecclesiastical History*, chapter 9: [Margin: The Council's letter on the celebration of Easter.] "As for the general agreement concerning the celebration of the most sacred feast of Easter, know that by your prayers the controversy raised on this matter has been prudently and suitably settled, so that all the brethren who dwell in the East, and who previously used to imitate the custom of the Jews in observing this feast, will now, with united minds, henceforth diligently follow the Romans, ourselves, and all of you who from the earliest times have kept the same practice as we do in observing it." The Emperor Constantine the Great himself also wrote an elegant letter on the same subject to the churches, which is likewise preserved by the same writers at the places cited.

Finally, the same was afterwards established and enjoined under pain of anathema at the Council of Antioch and at the Council of Chalcedon of 630 bishops — held under Leo the Great [Leo I] — and at most other councils. [Margin: The decree of the Council of Nicaea on the celebration of Easter confirmed by the Council of Antioch, the Council of Chalcedon, etc.]

Although those words of the Council of Nicaea do not expressly state on what day the most holy Easter is to be celebrated — they seem only to indicate that it is not to be observed together with the Jews — nonetheless it can be gathered from them, without obscurity, that the custom of the Roman Church, and the ruling of the Roman pontiffs Pius [Pius I] and Victor [Victor I], by which Easter is directed to be celebrated on a Sunday between the 14th and the 21st Moon, was confirmed and renewed. For they plainly signify that all the Easterners, who formerly celebrated Easter with the Jews on the 14th Moon, embraced with united minds the practice of the Romans, who had always observed it on the Sunday after the 14th Moon. [Margin: The Council of Nicaea confirmed rather than instituted.] And that this was the mind of that great Council concerning the celebration of Easter — indeed, that a ruling on the matter was issued in that very canon — almost countless writers on Church affairs have taught. Among them the Venerable Bede confirms the same in many places, and especially in explicit words in Book 3,

chapter 15, of his *Ecclesiastical History of the English People*, where, in a certain debate about the correct celebration of Easter, he brings in one Wilfrid, who, when ordered by the King to speak, began thus: [Margin: Easter to be celebrated on the Sunday after the 14th Moon. Bede's view that the Council of Nicaea renewed the ecclesiastical decree on celebrating Easter on the Sunday after the 14th Moon of the first month, on the Lord's Day.]

"The Easter that we keep" — he is speaking of celebrating Easter on the Lord's Day after the 14th Moon, as is clear from what follows — "we have seen kept by everyone at Rome, where the blessed Apostles Peter and Paul lived, taught, suffered, and were buried; and so too in Italy, in Gaul, and so on." Then a little later: "But Peter, when he preached at Rome, remembering that the Lord rose from the dead on the first day of the week and thereby gave the world the hope of resurrection, understood that Easter must be kept in this way: that, according to the custom and the precepts of the Law, he should — just as John did — always wait for the 14th Moon of the first month to rise at evening; and once it had risen, if the Lord's Day (which was then called the first day of the week) was to come in the morning, he would begin to celebrate the Lord's Easter on that very evening, in the way we all do today. But if the Lord's Day was to come not on the next morning after the 14th Moon, but on the 16th, or 17th, or any other Moon up to the 21st, he would wait for it and, on the preceding Saturday evening, begin the most holy solemnities of Easter. And so it came about that the Lord's Day of Easter was kept only from the 15th Moon to the 21st. Nor does this evangelical and apostolic tradition abolish the Law; rather it fulfils it, for in it the precept is that Easter be kept from the 14th Moon of the first month at evening, up to the 21st Moon of the same month at evening. To the keeping of this observance all the successors of St. John in Asia after his death, and the whole Church throughout the world, were converted; and that this is the true Easter, and this alone is to be celebrated by the faithful, was not newly enacted by the Council of Nicaea but confirmed, as ecclesiastical history teaches."

Blessed Ambrose too, in his 83rd letter to the bishops appointed throughout Aemilia, writes as follows about the same Easter solemnity: [Margin: St. Ambrose's view on the celebration of Easter, from the decree of the Council of Nicaea.] "That it takes no ordinary wisdom to fix the day of the Easter celebration, both divine Scripture instructs us and the learning of our forefathers, who, meeting at the Council of Nicaea, among those decrees of the Faith that are as true as they are admirable, and having gathered together the men most skilled in calculation, also worked out a reckoning of nineteen years concerning the celebration in question, and established, as it were, a kind of cycle from which a

pattern might be generated for the remaining years. This cycle they called the ἐννεα-δεκαετηρίδα [Greek: enneadekaetērida, "nineteen-year period"; the standard classical form is ἐννεακαιδεκαετηρίς — the printed word breaks across the line at ἐννεα- / δεκαετηρίδα], following the principle that we ought not to waver over such a celebration by some idle opinion, but, once the true reckoning has been ascertained, so to act that our devotion does not clash, so that on one and the same night the sacrifice for the Lord's resurrection may be offered everywhere." Then, expounding more clearly what was decreed at the Council of Nicaea, he writes thus: "Two things are to be observed in the solemnity of Easter: the fourteenth Moon and the first month, which is called the month of new things." And somewhat later, after teaching that Easter is to be celebrated on the Lord's Day, he adds: "The month begins, not according to common usage, but according to the practice of the learned, from the equinox, which day is the 12th of the Kalends of April [21 March]," and so on.

In this letter St. Ambrose makes two points chiefly. First, that by the decree of the Council of Nicaea Easter is to be celebrated on the Sunday after the 14th Moon of the first month, because it begins from the equinox. By these words he explains that the first month is the one whose 14th Moon falls on the equinox — that is, on 21 March — or next follows it. For when he says that the first month begins from the equinox, and not before, he does not mean that the new moon of the first month must be reckoned from the equinox, but the 14th Moon. Otherwise Easter could never have been celebrated before 4 April, since on this reasoning the earliest Paschal 14th Moon of all would fall on 3 April — whereas he plainly teaches in the same letter that in his own time, by the ruling of the Council of Nicaea, Easter was celebrated in the month of March. And it is clear that he meant the Sunday after the 14th Moon to be taken. For in the same letter he asserts that Easter must be deferred to the following week

when the Lord's Day falls on the 14th Moon, as we set out above from this same letter of Ambrose. Secondly, he teaches the same thing: that the Fathers of the Council of Nicaea decreed that the 14th Moon of the first month should be found by means of the nineteen-year cycle of the golden number, since they entrusted the arrangement of it in the calendar to those most skilled in the art of calculation — namely, to Eusebius, Bishop of Caesarea [Eusebius of Caesarea], and to the Alexandrian Egyptians.

Bede states the same thing more plainly in his work *On the Reckoning of Time*, chapter 47, where he writes in this way: [Margin: The care of the golden-number cycle given to Eusebius of Caesarea and the Alexandrians by the Nicene Council.]

"Eusebius, Bishop of Caesarea in Palestine, was the first to draw up the order of the nineteen-year cycle for finding the fourteenth Moons of the Easter festival and the day of Easter itself, because the Moon of any age returns, after so long an interval, to the same day of the solar year — not that the Church of Egypt, or the rest of Christ's Church throughout the East, did not until then know how properly to find the Moon's course or the day of Easter, but because the things that in those very times used yearly to be worked out with labour and sent around the world, and often came into dispute, could more easily be learned once a cyclical rule had been fixed, and could thereafter be observed forever without any scruple of doubt." To this may be added what the same Bede teaches in his book *On the Reckoning of Computus*, chapter 16, namely that Eusebius, Bishop of Caesarea in Palestine, was the first to compose the order of the nineteen-year cycle. He repeats the same in Book 5, chapter 22, of the *Ecclesiastical History of the English People*, from the letter of Abbot Ceolfrid to King Nechtan [Naitanum], where these words occur:

"And so, at the equinoctial rising of the Sun, after the fourteenth day of the first month has been completed — all of which we have received as things to be observed by the Law — we still wait, as the Gospel warns, for the time of the Lord's Day within that same third week, and only then do we celebrate the votive feasts of our Easter, to show that we do not, with the ancients, venerate the throwing-off of the yoke of Egyptian bondage, but rather honour, with devout faith and love, the redemption of the whole world — which was prefigured in the liberation of God's ancient people and completed in the resurrection of Christ — and to signify that we rejoice with most certain hope in our own resurrection also, which we believe will take place on that same Lord's Day. This computus of Easter, which we show you as the one to be followed, is contained in the nineteen-year cycle, which indeed long ago — that is, in the very times of the Apostles — already began to be observed in the Church, especially at Rome and in Egypt, as we said above; but through the diligence of Eusebius, who takes his surname from the blessed martyr Pamphilus, it was arranged in order more distinctly, so that what up to then used to be announced each year to all the churches by the Pontiff of Alexandria might thereafter, once the series of the fourteenth Moons had been gathered into order, most easily be known by all." From all these testimonies it is plainly established that, by the Church's precept, Easter is to be celebrated on no other day than the first Sunday after the 14th Moon of the first month.

Now that this was not some new decree of popes and councils, but that from the very beginning of the infant Church this custom continually flourished at Rome

and among most other churches — namely, that Easter was celebrated not with the Jews on the 14th Moon but on the Lord's Day, and indeed that it was so handed down by the Apostles — can, it seems, be gathered clearly enough from several of the authorities we have cited. [Margin: The custom of celebrating Easter on the Sunday after the 14th Moon of the first month began in the time of the Apostles and is an apostolic tradition.] For the letter of the Council of Nicaea states in explicit words that the Romans, Alexandrians, and Egyptians had held that manner of celebrating Easter from the earliest times. This is understood more clearly from the passages of Bede, when he says that blessed Peter, when he preached at Rome, understood that Easter must be kept in this way, and that this custom is the evangelical and apostolic tradition, and that it began to be so observed in the Church in the very times of the Apostles, especially at Rome and in Egypt. But Abbot Ceolfrid affirms the same most clearly, as reported by Bede in Book 5, chapter 22, of the *Ecclesiastical History of the English People*, where it reads thus: "If, then, it could come about that the Lord's Day always fell on the fifteenth day of the first month — that is, on the 15th Moon — we could always celebrate Easter at one and the same time with God's ancient people (though distinct in the kind of sacraments), just as with one and the same faith. But because the day of the week does not run on an equal course with the Moon, the apostolic tradition — which was preached at Rome by blessed Peter and confirmed at Alexandria by Mark the Evangelist, his interpreter — decreed that, when the first month has come, and the evening of the fourteenth day has come within it, the Lord's Day should further be awaited, from the fifteenth up to the twenty-first day of the same month."

Eusebius too, in Book 5, chapter 22, of his *Ecclesiastical History*, testifies that the other churches — the Asian ones excepted — scattered throughout the whole world, kept the custom, continued from the apostolic tradition down to that time, of ending their fasts on no other day than the one on which the Saviour rose from the dead. Moreover, St. Cyril, Patriarch of Alexandria [Cyril of Alexandria], in all his Festal (Heortistic) sermons — which are very many, and in which he yearly announced to the people the solemn Lenten fast, the feast day of Easter, and Pentecost — always declares that Easter is celebrated on such a day of the month, on a Sunday, according to the evangelical or apostolic traditions. Again, the same St. Cyril, in his letter to Pope Innocent I [Innocent I] — which Johannes Stöffler [Ioan. Stoflerinus; Johannes Stöffler] cites in his *Roman Calendar*, proposition 32, at the beginning, and Albert Pigge [Albertus Pighius] in his book *On the Method of the Paschal Celebration and the Restoration of the Calendar*, proposition 8 — says thus: "The holy mystery of Easter, and its sacred solemnity, as it was handed down by our Saviour and the Apostles, would have remained inviolate, had not

the perversity of certain foolish men defiled it, among the other sacraments of the Faith," and so on. And there is no doubt that he is speaking of celebrating Easter on the Sunday after the 14th Moon of the first month, since he always steadfastly asserted that it must be so celebrated — from the teaching of Theophilus [Theophilus of Alexandria], his uncle and predecessor in the see of Alexandria — as is clear from the Festal sermons, in which he always perpetually sets before the people that Easter is to be celebrated on the Lord's Day.

Finally, this is evidently confirmed by the letter of Proterius, Prelate of Alexandria [Proterius of Alexandria], to blessed Pope Leo I, who had arranged, through the Emperor Marcian [Per Martianum Imperatorem], that the Bishop of Alexandria should explain Theophilus's Paschal cycle more accurately. For it reads thus in that letter — as the venerable Bede reports in his book *On the Reckoning of Time*, chapter 42, and in the little treatise *On the Equinox to Wicthed* [ad Vuichenredum] near the beginning, and Johannes Stöffler [Ioan. Stophlerinus] and Albert Pigge in their books, at the places cited: "The letters of your love, which our brother and fellow bishop Victorius brought as a dutiful service, gladdened me. For it was fitting that such writings should be sent from the prelate of the Church of Alexandria to the Apostolic See — writings that would show that, by the teaching of the most blessed Apostle Peter, the Egyptians learned the reckoning of the Easter feast from the beginning through blessed Mark his disciple, as it is also agreed the Romans learned it," and so on. And it is perfectly clear that in this letter the words concern the celebration of Easter after the 14th Moon of the first month, since it was always so celebrated at Rome and Alexandria. Hence, when Proterius says that the Ro-

mans, indeed, learned it from St. Peter, and the Alexandrians from St. Mark, it is clear that he asserts Easter must be observed in this way by apostolic tradition.

These points being thus settled — that Easter is to be celebrated on the Sunday after the 14th Moon of the first month — it must now be explained a little more carefully that the first month is the one whose 14th Moon falls on the day of the equinox, or next follows it, as we asserted above. [Margin: The error of some in defining the first month.] For there are those who think the first month should be defined otherwise, calling the first month the one whose new moon is nearest to the equinoctial day. Our Maestlin, too, is glad to adopt this opinion, so as to find an occasion for attacking the new calendar, as we shall see in its place. But these men are much deceived. For since it can happen that two new moons are equally distant from the equinoctial day — one before it, the other after — it could reasonably be doubted which of them should be chosen for the celebration of

Easter. Suppose, for example, that the equinox is set on 21 March, and that the mean full moon, or mean opposition of the luminaries (for in this business we use mean motions rather than true ones, as we shall show in Chapter 4), falls at noon of 21 March. Then the mean new moon that precedes the equinoctial day will be as far distant from noon of the 21st as the mean new moon that follows the same equinoctial day — since each is distant from the mean full moon by 14 days, 18 hours, 22 minutes, 2 seconds nearly, as we shall explain in Book 2. Therefore one might, with the best right, be in doubt which of those two new moons belongs to the first month. This will be understood clearly from the nineteen-year cycle of the golden number, which the Catholic Church used from the Council of Nicaea down to this correction of the calendar. For in it the golden number 8 was set both against 6 March and against 5 April. Hence, since each day is removed by an equal interval from 21 March — because 14 days are interposed both between 6 and 21 March and between 5 April and 21 March — it will be ambiguous whether the new moon of 6 March is the Paschal one, or rather the one that occurs on 5 April.

The same also appears from the cycle of epacts of the new calendar, which we shall show in Book 11 to be correctly distributed in it. For since the epact 25 in red [Epacta xxv rubra] is likewise set both against 6 March and against 5 April, the same ambiguity will necessarily arise about choosing the first Paschal month. And a greater difficulty will arise when the epact 24 [xxiiii] is in use, because its new moon, falling on 7 March, is nearer to the equinox — that is, to 21 March — than the new moon of the same epact which occurs on 5 April: for only 13 days are interposed between 7 and 21 March, whereas 14 days lie between 5 April and 21 March. According to the opinion, then, of those who think the first month should be measured from the new moon, that new moon of 7 March would be the Paschal one, while the other, falling on 5 April, would have to be rejected as not Paschal. This is entirely false, and contrary to the most ancient practice of the Catholic Church, which rejects the new moon of 7 March and appoints as Paschal the following one, which occurs on 5 April — for no other reason than that the 14th day of the former falls on 20 March, before the equinox, and must therefore be assigned to the last month of the year.

More correctly, then, is the first month described by the 14th Moon, which either falls on the day of the equinox or next follows it — as we have done, and as before us was approved by very many ecclesiastical writers, especially by the venerable Bede, most practised in this matter, both in other places and in these few passages that we have judged fit to adduce in confirmation of our view. [Margin: That the first month is rightly said to be the one whose 14th Moon falls

on the equinox, or next follows it.] Thus in his work *On the Reckoning of Time*, chapter 49, against a certain Victorius [Victorius of Aquitaine], who reckoned the first month and the Paschal fourteenth Moons otherwise, he writes as follows: "We know that the Egyptian discipline of calculation — which appears truer both in your own judgement (he is addressing Victorius) and by the consensus of the universal Church — is to be followed by all: namely, that the beginning of the first month runs from the eighth of the Ides of March [8 March] up to the day of the Nones of April [5 April]; that the fourteenth Paschal Moons run from the twelfth of the Kalends of April [21 March] up to the fourteenth of the Kalends of May [18 April]; and, further, that the Lord's Day of Easter is to be sought from the eleventh of the Kalends of April [22 March] — and this on the 15th Moon up to the 21st." By these words Bede plainly places the first Paschal 14th Moon at the equinox, and the last on 18 April; and accordingly he holds the first, that is, the Paschal, month to be the one whose 14th Moon falls either on the day of the equinox or next follows it. He declares the same more openly in chapter 43 of the same book, in this manner: "Both kinds of year (namely, the common and the embolismic), as was said above, take their beginning from the opening of the first month — which the Hebrews call Nisan, that is, from the kindling of the Paschal Moon — and the opening of this month must be observed by this rule: that the Paschal 14th Moon never precede the vernal equinox, but proceed lawfully either on the equinox itself (that is, on the twelfth of the Kalends of April [21 March]) or after it has passed. Whence it comes about that the beginnings of the lunar year are to be sought from the eighth of the Ides of March [8 March] up to the day of the Nones of April [5 April]. And that 14th Moon itself, occurring at its earliest on the twelfth of the Kalends of April [21 March] and at its latest on the fourteenth of the Kalends of May [18 April], causes the day of the Easter festival to be sought from the eleventh of the Kalends of April [22 March] up to the seventh of the Kalends of May [25 April]." He repeats the same in chapter 57, in these words: "For the Lord's Day that occurs after the 14th Moon is itself the Paschal Lord's Day of the Resurrection; and this 14th Moon shows its progress over the earth at evening, at its earliest at the equinox — that is, on the twelfth of the Kalends of April [21 March] — and at its latest on the twenty-ninth day from that point — that is, on the fourteenth of the Kalends of May [18 April]." Finally, he speaks thus in chapter 60: "The rule for this first month, and for its seven days of unleavened bread, is now such that whichever 15th Moon occurs after the equinox is to be understood as belonging to the first month, and whichever of its seven days, up to the 21st, receives the Lord's Day, offers a day fit for the joys of the Easter feast."

Since, therefore, the Roman and Catholic Church observes three things — by the decrees of the holy Pontiffs and Councils, as we have said — in the correct

celebration of Easter, on which the other movable feasts depend: the vernal equinox, the 14th Moon of the first month, and the first Sunday after that 14th Moon; it must now be declared what method the Church follows, so that in every place the sacred solemnity of Easter may be carried out by the faithful at the same time — that is, so that those three things necessary for its celebration may be sought out by all in the same way, with no discrepancy whatever existing among them. [Margin: Three things to be observed in the celebration of Easter.]

(Continuation of Chapter I.)

So that no one should be granted free license to err in fixing the equinox, the fourteenth Moon [Luna XIII] of the first month, and the Sunday on which Easter is to be celebrated, the Fathers of the Nicene Council established that 21 March be assigned to the vernal equinox, since on that day, or thereabouts, the equinox then fell. [Margin: That the vernal equinox was assigned by the Nicene Council to 21 March.] From this it follows that a fourteenth Moon [Luna XIII] preceding 21 March is reckoned to belong to the last month of the year, not the first, and is therefore unfit for the celebration of Easter; whereas the fourteenth Moon that falls on 21 March itself — or, if none falls on that day, the one that occurs first after 21 March — is the legitimate one for celebrating Easter. [Margin: Which and how many new moons are Paschal by decree of the Nicene Council.] From this it is clear that all and only the new moons that occur from 8 March to 5 April inclusive are Paschal, 29 in number: namely 24 in the latter 24 days of March, and 5 in the first 5 days of April. For among these 29 lunar months, no fourteenth Moon [Luna XIII] precedes 21 March, on which the equinox is fixed; rather each one's fourteenth Moon follows the equinox — the day we have named — except for the first new moon, whose fourteenth Moon falls on the 21st itself.

[Margin: On which days of the year Easter may be celebrated, and how many, by decree of the Nicene Council.] Since this is so, it is plainly established that Easter can and must always be celebrated on one of the days from 22 March to 25 April, so that the earliest and first possible Easter is 22 March, and the latest and last is 25 April. The whole Paschal solemnity thus has a range of 35 days, of which the first 10 fall at the end of March and the remaining 25 at the beginning of April. For when 21 March is a Saturday, and the first Paschal fourteenth Moon [Luna XIII] falls on it, the Paschal solemnity will be on the following Sunday, that is, on 22 March; and Easter cannot lawfully be celebrated before this day, nor has it ever hitherto been celebrated before it since the Nicene Council. Likewise, when 18 April is a Sunday, and the last Paschal fourteenth Moon [Luna XIII] falls on it, Easter will be celebrated on the next following Sunday, namely 25 April, after

which day Easter cannot be celebrated without offense by decree of the Nicene Council. And we have received these Paschal limits as established by the authority of the Nicene Council; they follow necessarily from placing the equinox on 21 March, as we have said.

[Margin: That the new moons were investigated by means of the golden numbers arranged in the Calendar, from the time of the Nicene Council up to the correction of the Calendar, so that all should celebrate the new moons on the same days.] Next, so that no further disagreement should arise among Christians concerning the new moons — and hence concerning the fourteenth Moons [Luna XIII] — as had happened from the Nicene Council down to roughly the time of the Emperor Justinian [Justinian I], but that all should declare the first day of the Moon on the same days, the 19 golden numbers received from the Alexandrians were arranged by Dionysius the Abbot [Dionysius Exiguus] through the days of the Calendar by such a device that each was prefixed to the day of any month on which the new moon fell in the year when that golden number was in use. Thus, while golden number 1 was current, the new moon occurred throughout that whole year on that day of each month to which golden number 1 was prefixed; while golden number 2 was current, the new moon fell on the day that had golden number 2 prefixed; and so on for the rest — so that the new moons always fell on different days of any given month, just as all 19 golden numbers were assigned to different days of the months, until 19 years had passed, after which the golden number was again 1, and the new moons accordingly returned to the same days, and so forth. But you will find more on this matter explained in Book II [lib. II].

[Margin: That the Cycle of Dominical Letters was devised so that there should be no disagreement in celebrating the Lord's day.] Finally, so that it should be clear to all when the Lord's day fell, the Cycle of Dominical Letters was instituted, comprising 28 years, so that once the dominical letter of any year was known, there would be no divergence among Christians in the celebration of the Lord's day — and hence in the celebration of the Paschal solemnity.

WHY THE CALENDAR HAD TO BE CORRECTED, AND IN WHAT ITS CORRECTION CONSISTS. CHAPTER II.

(CVR CALENDARIVM CORRIGI DEbuerit, & in quo eius correctio consistat. CAPVT II.)

[Margin: That the equinox and new moons, before the correction of the Calendar, no longer fell on the same days as they did at the time of the Nicene Council.]

Everything that we have said must be observed in the celebration of Easter was rightly and wisely determined by the authority of the Nicene Council. But because in our own age the vernal equinox no longer fell on 21 March, but on about the 11th, and likewise the new moons were not correctly indicated by the golden numbers placed in the Calendar, but four days and more later than they should have been, it came about that Easter has very often, right up to the present time, been celebrated contrary to the ordinance of the Nicene Council. [Margin: Which lunations that were Paschal by the Nicene Council were rejected as non-Paschal before the correction of the Calendar, on account of the error of the equinox.] For since, as we said above, the first lunar — and hence Paschal — month is the one whose fourteenth Moon [Luna XIII] either falls on the day of the vernal equinox or immediately follows it; and since, before the correction of the Calendar, the vernal equinox fell around 11 March; it follows that all fourteenth Moons [Luna XIII] from 11 March to the 20th were, by the prescription of the Nicene Council, Paschal — that is, of the first month. Yet the Church always rejected these as belonging to the last month and as preceding the equinox, because, together with the Nicene Council, it had fixed the vernal equinox to 21 March. Hence it came about that whenever a fourteenth Moon [Luna XIII] followed the 11th [?] of March and preceded the 21st, Easter was celebrated in the second month. [Margin: When, before the emendation of the Calendar, Easter was celebrated in the second month, on account of the error of the equinox. Had the Calendar not been corrected, it would have come about after some years that Easter was always celebrated in the second month, then the third, fourth, and so on, because of the equinox's advance toward the beginning of the month.] And this error, creeping on obscurely day by day, would have advanced still further had no remedy been applied — so much so that, as time went on, all the Paschal fourteenth Moons [Luna XIII] would have been abandoned as useless, and Easter would always have been celebrated in the second month, indeed at length in the third, the fourth, and so on, and even in high summer: which would surely have been utterly absurd and altogether contrary to the decrees of the Fathers.

[Margin: Had the Calendar not been corrected, it would have come about that Easter was celebrated at the new moon itself, on the second Moon, third, and so on, on account of the error of the new moons, which were sought by means of the golden numbers.] Next, on account of those four days and more by which the new moons, as we said, were indicated in the Calendar by the golden numbers later than the case required, it often happened that Easter was celebrated on the 25th Moon [Luna xxv]. This occurred when the fourteenth Moon [Luna XIII] found by the golden number — which was in truth the eighteenth Moon [Luna XVIII] — fell on a Sunday, and Easter was consequently deferred to the following Sunday.

[Margin: On account of the error of the equinox, and of the fourteenth Moon [Luna XIII] found from the golden numbers, it often happened that Easter was celebrated with an error of 7, or 28, or 35 days before the emendation of the Calendar.] But this manifestly conflicts with the decrees of the Supreme Pontiffs and of the Nicene Council, which insist again and again that Easter is to be

celebrated from the fourteenth Moon [Luna XIII] of the first month exclusive up to the twenty-first inclusive. And an error of this kind, had it not been met by some remedy, would have grown greater still thereafter, so that the most holy Easter would have come to be celebrated on the thirtieth Moon [Luna XXX], and indeed at the very new moon — that is, on the first day and the second Moon [Luna II], the third [III], and so on. And how much trouble this would have brought with it, there is no one who does not see.

[Margin: On account of the error of the equinox and of the fourteenth Moon [Luna XIII], it often happened that Easter was celebrated with an error of 7, or 28, or 35 days.] From this error of the vernal equinox and of the fourteenth Moon [Luna XIII] it came about that Easter was very often celebrated 7, or 28, or 35 days later than the decrees of the Fathers prescribe — as happened, before the restoration of the Calendar, in the years 1565, 1568, 1576, and 1579. The same would have happened, had the Calendar not been emended, in the years 1595, 1598, 1603, 1606, 1609, and very many others, in all of which there would have been an error of 35 days in the celebration of Easter — to say nothing of the years in which an error of either twenty-eight or seven days was committed. This is sufficiently apparent from Paul of Middelburg [Paulus Middelburgensis], in Book II of his *Paulina*, where he computed the Paschal solemnities from the year 1500 to the year 3000, together with the errors that were being committed according to ecclesiastical usage. Out of all these, only 200 festal days of Easter are found to be legitimate, while 1301 others were celebrated contrary to the decrees of the Fathers, with an error sometimes even of 42 days — an error that would indeed have grown into still more days as time went on, had the Calendar not been corrected. [Margin: That after many years an error of 42 days and more would have arisen in the celebration of Easter, had the Calendar not been corrected.]

[Margin: The reason why the restoration of the Calendar was necessary.] Therefore, so that those inconveniences and absurdities we have recounted might be avoided, and so that posterity should not fall into greater ones — (I say nothing here, in this place, of the disturbance of history and of the seasons that would have followed from that continual anticipation of the vernal equinox toward the beginnings of the months: namely, that the Lord's Incarnation would

in the course of time have slipped into summer, the Nativity of CHRIST the Lord likewise into the spring, the Birth of St John the Baptist into autumn, and so on — as is set out clearly in the book of the new method of correcting the Roman Calendar) [Margin: The inconveniences to history, to the seasons, and to the chief celebrations of the year, had the Calendar not been emended.] — so that these inconveniences, I say, might be avoided by posterity, it was altogether necessary that the vernal equinox be restored to its former seat, the one assigned to it by the Fathers of the Nicene Council, that is, to 21 March, and that the new moons be shown by the numbers arranged in the Calendar in such a way that their full moons should not, so far as could be done, diverge from those that computation according to the mean motion exhibits. [Margin: In what the correction of the Calendar consists.] But since the equinox could not be restored to its seat except by the removal of some days, it came about that the Solar Cycle — that is, the Cycle of Dominical Letters — in use in the Church of GOD up to this time, had necessarily to be interrupted. It was necessary, then, to renew this Cycle also, so that by means of it the dominical letter might be found for any proposed year no differently after the correction of the Calendar than before it. And so, in these three things — the restoration of the equinox, the emendation of the new moons, and the renewal of the Solar Cycle — the whole business of the correction of the Calendar consists. By what method these were carried out, we shall make plain in what follows.

WHY THE VERNAL EQUINOX WAS RESTORED PREFERABLY TO 21 MARCH [ad diem XXI. Martii], AND BY WHAT METHOD IT WAS BROUGHT BACK. CHAPTER III.

(CVR AEQVINOCTIVM VERNVM AD DIEM XXI. Martii potissimum, & qua ratione reuocatum sit. CAPVT III.)

[Margin: Various opinions concerning the restoration of the equinox.] Among those who wrote on the correction of the Calendar, there were various opinions concerning the restoration of the equinox. For some judged that it should be left on the day where it was found at the time of the correction, namely on 11 March. Others asserted that it should be brought back to the 25th of the same month — that is, to the day of the Lord's Incarnation — because they held that the Incarnation of the eternal SON of GOD had taken place at the vernal equinox. But most, by a more prudent counsel, urged that it be restored to 21 March, where it was found to stand about the time of the Council. [Margin: Which opinion Gregory XIII followed in restoring the equinox.] And Gregory XIII rightly

embraced the opinion of these last, as being the one that involved the least novelty and change. For if the equinox had been left around 11 March, where it stood before the correction, or had been brought back to 25 March, or to any other day differing from the 21st, it would have been necessary to alter all the Paschal limits established by the authority of the Nicene Council, and to renew all the Breviaries and Missals — since all these have been so arranged and ordered as if the vernal equinox perpetually fell on 21 March. What great disturbance this would have brought upon the faithful, he certainly saw who had seen that Easter and the other movable feasts are now celebrated on days other than those on which they were celebrated of old by the ancient Fathers, as no one doubts. This is especially so since it would have brought no small loss upon churchmen, on account of the discarding of an almost countless number of ecclesiastical books, and the immense expense that would have been needed for buying new books pertaining to the worship of GOD. For most churches and monasteries have libraries of such books valued at many thousands of gold pieces, all of which would have been rendered useless had any day other than 21 March been adopted — the day on which the equinox was found at the time of the Nicene Council. For by this means the decree concerning the celebration of Easter, sanctioned by the Fathers in that Council, remained wholly intact and unimpaired. Finally, since the greater part of the Martyrs, Doctors, Confessors, and Virgins, whose solemnities the Church piously venerates in grateful memory, flourished about the times of the Nicene Council — the Martyrs indeed a little before, under Decius and Diocletian, the most cruel persecutors of the Church of GOD; the Confessors at the very time of the Council, or a little after, in the times of Basil, Gregory of Nazianzus [Gregory Nazianzen], John Chrysostom, John of Damascus [John Damascene], Ambrose, Augustine, Jerome, and Gregory the Great; and when the deserts of Egypt and Palestine were filled with a countless multitude of monks and anchorites under Paul, Antony, and Hilarion, those most holy Hermits — the equinox could not have been brought back to a more

fitting time than to the times of the Nicene Council, so that the festal days of the Saints might be celebrated at their proper seasons — that is, not far from those in which they lived on earth. For if it had been reduced to the time of the Lord's Incarnation, or retained in the place where it was found before the correction, the seasons of all those Saints would have been thrown into confusion and disorder.

[Margin: By what method the vernal equinox was restored to 21 March.] The equinox, then, was restored by Gregory XIII, Supreme Pontiff, to 21 March, ten days being removed from the month of October in the year 1582, in such a way

that after the fourth day of October — which is sacred to St Francis [B. Franciscus] — instead of the fifth day, the fifteenth was taken up at once, the ten days in between being that year wholly omitted. For by this means it came about that in the following year 1583, and in the others thereafter, the vernal equinox fell ten days later than before this correction. And so, whereas it had formerly occurred around 11 March, it is now seen to fall around the 21st, just as in the times of the Nicene Council.

[Margin: Why the 10 days were removed all at once from the year 1582, and not one from each of the several years or months.] This restoration was likewise made by the removal of ten days at once from a single month, and not by the omission of ten intercalary days over 40 years, nor by the subtraction of those same 10 days from 10 months, taking away one day from each single month — as some would have preferred. This was both because many things might have arisen in the course of 40 years to impede the correction, and also because the Cycle of Dominical Letters would then have had to be interrupted more often, whereas in this restoration of ours it has been interrupted only once.

[Margin: Why the equinox anticipated its seat by 10 days in the Calendar, from the time of the Nicene Council up to the correction of the Calendar.] If anyone should further wish to know how it came about that the equinox forsook its former seat — that is, 25 March — and reached the 11th, let him understand that the cause of this is that Julius Caesar, whom the Roman Catholic Church followed, assigned to the length of a single year more than was right. For he established the solar year at 365 days and 6 hours. And because in the civil year, which comprises only whole days, he left out those six hours, which in four years make up a whole day, he decreed that in every fourth year one day, made up of 24 hours, should be intercalated, and the year become one of 366 days, which they called bissextile. [Margin: The length of the year according to Julius Caesar and the Church.] But the true solar year, which they call the tropical year, is not so great, but is smaller by some minutes of an hour — so that, according to the tables of Alfonso, King of Spain [Alfonso X of Castile], it comprises 365 days and only 5 hours, 49 minutes, 16 seconds. [Margin: The length of the year according to the Alphonsine tables.] This length of the year is in a way midway between the greatest and the least length of the year. For, as we shall say more fully in Chapter VI of this book [Cap. vi. huius lib.], the more skilled astronomers have observed that the solar years are unequal: they affirm that the greatest year was about the times of Hipparchus and Ptolemy, the least in the age of al-Battānī [Albategnius], and a kind of mean around the times of King Alfonso, and that it has now again come near to its greatest magnitude. [Margin: By how much the Roman, or

ecclesiastical, year exceeds the Alphonsine year.] And so the Roman year, which is in use in the Church, exceeds the Alphonsine year — which we said is roughly midway between the greatest and the least — by 10 minutes and 44 seconds of one hour. From this it comes about that by that same number of minutes and seconds the equinoxes and solstices anticipate their seats in each Julian year; for when the Sun, by its own motion according to the Alphonsine tables, returns to the same point of the equinox or solstice from which it had departed, there are lacking, to complete the Julian year, those 10 minutes and 44 seconds of one hour which we mentioned. [Margin: In how many years the equinox anticipates one day, according to the Alphonsine years.] Wherefore, according to these same tables, the equinoxes and solstices run ahead of their seats by one whole day in about 134 years, and by about three days in 402 years. But if the length of the year that the Church uses agreed in every respect with the annual motion of the Sun, no anticipation of the equinoxes and solstices would be seen, but they would recur always on the same days of the year.

[Margin: Why the correction of the Calendar was instituted in the year 1582, and in October rather than in another year and month.] But if anyone should ask why that removal of ten days was made from the year 1582, in the month of October, and not rather from some centennial year, or from some other bissextile year — and not in October but in any other month whatever (for this in particular troubled Maestlin [Michael Mästlin]) — the answer is ready to hand. Those ten days could indeed have been removed from any year whatever, and even from any month; but the year 1582 was chosen because at that time all things necessary for the correction were first made ready and brought to completion. For the responses of all the Kings, Princes, and Commonwealths, and of the chief Universities, had been brought to the Supreme Pontiff, and had been examined as diligently as possible by the mathematicians convened for the emendation of the Calendar. Therefore, lest the restoration of the Calendar — which all Christian Princes and Commonwealths had wonderfully praised and approved — should be delayed any longer, it seemed good to the Supreme Pontiff to appoint the year 1582 for the correction so greatly desired.

[Margin: Why the correction was ordered to be made, in the year 1583, in more remote regions, in February.] As for why this was done in October rather than in another month, there was no other cause, nor is any other mystery to be sought in the matter, than that this month seemed the most fitting for the business, since it has more days free of the celebrations of the Saints. Hence it came about that the ten days removed from it produced less disturbance and confusion in the performance of the Divine Offices among churchmen. For although in February,

March, and April also a few festal days of the Saints are celebrated, nevertheless, because into those months fall Septuagesima, Lent, and the Paschal season, it was judged that these were not to be deprived of days, so that those seasons, which are celebrated by the Church with the utmost devotion, might run their course in continuous order without any interruption. This was especially so because if, for example, Septuagesima had then been celebrated according to the new Calendar on 14 February, with the ten preceding days omitted, there would have been only four Sundays after the Epiphany, and the remaining two could not have been inserted before Advent, since in that year there would have been only 24 Sundays after Pentecost. But because some provinces had not yet removed the ten days from October of the year 1582 — since copies of the new Calendar could not be conveyed to them so quickly — it was, by excellent counsel, arranged that in the following year 1583, without waiting for October, ten days should be removed from February, so that those peoples should not any longer differ from the Roman Church in the numbering of days. For although in that year those who had not yet emended the Calendar would celebrate Easter on the same day as we, nevertheless they would have differed from us in the number of the day, since we would keep Easter on the tenth day of April, but they on the last day of March. There is no reason, then, why Maestlin should torment himself so greatly in inquiring after the cause why, in the appointed year 1582, the Supreme Pontiff willed the restoration of the Calendar to be made in the month of October, and in the year 1583 in the month of February.

But, that the arrogance of Maestlin, and at the same time his ignorance in the business of the Calendar, may be made manifest to all, and more

(Page ends: "& lu-".)

and it appears clearer than daylight how craftily and maliciously he has conducted himself in his examination — driven more by a zeal to slander the new Calendar than to search out the truth. I should like, then, to examine here a little more closely the pretext he has invented for the correction's being carried out in October — a pretext he devised solely to impose upon people and to rail the more freely against the Roman Pontiff. He writes as follows:

But the beginning of this correction could not be made before the Easter of the year 1582. For had it been done, the whole work of this Calendar would have been imperiled; a great part of the Pontiff's authority, and of his calendar-makers', would have been endangered; all the expense scraped together and laid out for its sake would have been wasted; and — what is greatest — the Pontiff would once again have been cheated of

his hope. For in that very year the empty futility of this Gregorian Calendar's calculation would have been detected. For since the golden number, which that year was 6, gave an epact of 26 [xxvi] and set the Paschal terminus on 17 April — which was a Saturday — it followed, according to the numbers and rules of the new Calendar, that the next day, the 18th, should be Easter Sunday. But on that very Sunday fell at last the true opposition of the Moon and Sun, according to astronomical calculation; and so in that very year 1582 Easter would have had to be celebrated at the full moon. This would beyond doubt have been highly ominous for the new Calendar: for it could not have escaped anyone's notice, since in each and every almanac or perpetual calendar this full moon would have been found marked on Easter day. And it would have been the more conspicuous to unlettered and lettered alike (and there is scarcely anyone who does not always carry some such annual almanac about with him, or at least keep one fixed to the wall at home) because in that year the old Calendar's Easter kept its fitting place, namely the 25th of the new, or the 15th of the old Calendar. Who, then, will doubt that the Pontiff feared he and this work of his would be hissed off the stage, because he was dragging the feast of Easter out of its true place and casting it into an erroneous — or, as the author calls it, a heretical — one? But now that this danger has been cunningly, not to say deceitfully, avoided, both he and the author of the Calendar hope they are now quite safe; for they are confident that no one will have wit enough to draw the calculation back over the years already elapsed. And even if someone should attempt this, they trust the calculation will not carry as much weight as it would have had, if the falsehood had been shown in the present, plain case. But if this grossest error — which, on the author's own view, is heretical — with which this new Calendar of yours labored at the very outset of its inauguration, is not the true cause of the said postponement, then you mathematicians, point out another; and at the same time defend this very error of the present year. But I know that neither is possible for you to do.

[Margin: Maestlin's reasoning why the correction was made in October, and not before the Easter of the year 1582 — that is, in February.]

By these words Maestlin plainly betrays his rashness and ignorance, not only to the mathematicians whom he challenges, but to everyone else not unversed in these matters. For he confuses the 15th day of the Moon with the 14th, and calls "Quartodecimans" — heretics — those who celebrate Easter on the 15th Moon,

that is, at the opposition of the Moon with the Sun. Thus he is convicted of being utterly ignorant of what the Fathers and the Councils decreed concerning the right celebration of Easter, and of what the Church has observed in this matter down to the present time. For it was never forbidden that Easter be celebrated on the 15th Moon, or at the full moon (as he wrongly supposes), but only that the Paschal solemnity should not be kept on the 14th Moon, with the Quartodeciman heretics, without waiting for the Sunday after the 14th Moon of the first month. From this alone one may plainly infer Maestlin's ignorance and rashness, in that he dares so impudently to censure what the Church, by the prescription of the Fathers and Councils, has always most religiously observed. And so, if in the year of the correction, 1582, Easter had been celebrated according to the new Calendar, the Church would in no respect have departed from the Decrees of the Fathers and of the Council of Nicaea, but would have carried it out most correctly according to their judgment — as is obvious to anyone even moderately versed in the ecclesiastical computus. For since in that year (had the ten days been removed in February) the mean opposition of the luminaries — which in this business the Church employs, the true opposition being set aside — fell, according to the tables of Antonio Magini [Giovanni Antonio Magini], which are more recent, on 17 April at 7 hours 57 minutes after noon, or rather, according to the Prutenic Tables, at 3 hours and more before noon: who will doubt, save Maestlin alone, utterly ignorant of ecclesiastical matters, that on the following day, the 18th, which was a Sunday, Easter could have been lawfully celebrated by the prescription of the Fathers of the Council of Nicaea, since that Sunday immediately follows the 14th Moon of the first month? Indeed, the Church never keeps the Paschal solemnity more correctly than when, in the first month, the Sunday falls on the mean opposition of the Sun and Moon. For the remaining six days of the Moon that follow — namely the 16th, 17th, 18th, 19th, 20th, 21st — were taken up for the celebration of Easter for the sake of the Sunday, which does not always fall on the 15th Moon (as would be desirable), that is, on the mean opposition, before which it is not lawful to celebrate Easter, but sometimes on the 16th, or 17th Moon, and so on up to the 21st inclusive, beyond which it is not permitted to defer Easter. But this new mathematician of Tübingen was ignorant not only that Easter may lawfully be celebrated on the 15th Moon, but [maintained] that Easter of the year 1582, had it been celebrated according to the new Calendar, would have been wrongly kept on whatever day — as though the Church employed the true motions, and not rather the mean, or cycles, for this business, as we shall make plain in the next chapter. And in this too he wondrously deceives himself, since in that year the true opposition of the luminaries occurred on 17 April, at about 15 hours after noon; so that no one can

doubt that that Easter was legitimate even according to the true motion, since it would have been celebrated after the full moon, and thus much more after the true 14th Moon — though this is not necessary.

[Margin: Maestlin's ignorance of what the Catholic Church has always observed in the celebration of Easter.]

[Margin: The Decrees of the Fathers do not forbid celebrating Easter on the 15th Moon, but on the 14th Moon.]

[Margin: Easter of the year 1582, by the new Calendar — had the removal of the 10 days been made in February — would then not have been illegitimate, contrary to what Maestlin wrongly maintains.]

[Margin: Easter of the year 1582, by the new Calendar — had the 10 days been removed in February — would have been legitimate even according to the true motion, contrary to what Maestlin maintains.]

And lest Maestlin suppose that I speak rashly (as he himself is wont to do) and lay it down without any authority — that Easter may be celebrated on any Sunday after the 14th Moon up to the 21st, and that from the beginning of the primitive Church this was so ordained — let him weigh carefully the authorities and testimonies of the Fathers and Councils which we adduced in Chapter I to confirm that Easter must be celebrated on a Sunday, and that the first month is that whose 14th Moon falls on the equinox or immediately follows it. For in all of them it is expressly explained that Easter must be celebrated on the first Sunday after the 14th Moon of the first month — which of course falls on the 15th, 16th, and so on up to the 21st Moon inclusive. To these authorities may be added the following.

[Margin: That Easter may be celebrated on the 15th Moon, if that day be a Sunday, is proved by various testimonies and by the practice of the Church.]

Bede the Venerable [Bede], in his book *On the Reckoning of Time* [*De temporum ratione*], chapter 57, after teaching that the Sunday which occurs after the 14th Moon is the Paschal day of the Lord's resurrection, adds a little later:

And if it could happen that in every year the 14th Moon fell on a Saturday, our Paschal observance would differ in no point of time from the legal one. For we too, in accordance with the ordinances of the Law, always sacrificing on the evening of the 14th Moon of the first month, and eating the flesh of the spotless Lamb, and sprinkling His blood upon our doorposts to drive off the destroyer — that is, the water of Baptism —

— and celebrating the solemnities of the Paschal Masses, we should overcome the spiritual Egypt, and at the dawning of the morning on the 15th Moon of the same month we should enter upon the first day of unleavened bread, and complete the seven lawful days of that same festival — from the morning of the fifteenth day to the evening of the twenty-first of that month, that is, from Easter Sunday to the Sunday of the octave of Easter — with due reverence. But because the same day of the Moon rolls round onto different days of the week, it comes about that we, who because of our Redeemer's resurrection are taught to reserve the beginning of the Paschal feast for the Lord's Day, sometimes have the festival begin on the seventh day after the start of the legal unleavened bread.

Do you not see that here Bede teaches most plainly that Easter Sunday can fall on the 15th Moon, and that then indeed Easter is celebrated most correctly?

The same author teaches most clearly in chapter 59, where he says thus:

For whereas in the Old Testament the Paschal season is commanded to be observed by three marks of evidence — namely, that it be kept after the equinox, in the first month, and in its third week, that is, from the evening of the 14th Moon (which is the beginning of the 15th) to the evening, that is, to the term of the 21st — a fourth rule in its observance has been laid upon us from the time of the Lord's resurrection: that when, the equinox being passed, we have seen the 14th Moon of the first month rise in the evening, we should not at once leap forward to keep the Pasch, but, awaiting the Lord's Day — on which He deigned by rising again to accomplish the Pasch itself, that is, the passage from death to life, from corruption to incorruption, from punishment to glory — we may at last on that day celebrate the fitting solemnities of Easter.

And a little later:

Whenever, then, we have the Lord's Day fall at once, as the 14th Moon comes on, our Paschal season is in no way discordant with the legal one, although we keep the solemnities of that same Pasch with other kinds of sacraments. But whenever the same Lord's Day occurs on the second, or third, or fourth, or fifth, or sixth, or seventh day thereafter, not even so do we dissolve the Law or the Prophets, but rather fulfill them with the sacraments of evangelical grace.

This custom of the Church he confirms also from Theophilus, Bishop of Alexandria [Theophilus of Alexandria]; and he repeats the same rather often in chapters 60 and 61 and elsewhere.

This very thing all the computists, as many as have written on the celebration of Easter, constantly affirm by common consent. For, to pass over others, Paul of Middelburg [Paul of Middelburg], Bishop of Fossombrone, writes thus not far from the beginning of Book XII:

We therefore, in reckoning the Paschal Moon, shall call the day of the opposition of the luminaries the 15th Moon; and if it falls on a Sunday, we shall note that Easter is to be celebrated on that same day, according to the Canon established by the holy Fathers in the Council of Nicaea, by which Easter is commanded to be celebrated on the Sunday from the 14th Moon to the 21st — that is, on the first Sunday after the 14th Moon.

From all this it is established that Easter can be rightly and lawfully celebrated — indeed, that by the Decrees of the Fathers it must altogether be celebrated — on the 15th Moon, that is, at the opposition of the luminaries, if the Lord's Day then falls. And we see that this custom has always been preserved in the Church, both Eastern and Western. For down to our own age Easter has always been celebrated on the first Sunday after the 14th Moon.

Let Maestlin, then, be ashamed — if he is capable of shame — of his arrogance and rashness: that he styles himself a mathematician, and yet is utterly ignorant of a thing most familiar not only to mathematicians but to all Christians, namely that Easter can be celebrated on the 15th Moon; seeing that he does not scruple to call it a most gross — indeed a heretical — error, if Easter be celebrated at the mean full moon. But what wonder that a heretic should be ignorant of the custom observed by the Church in the celebration of Easter, when he so rashly and impudently spurns and despises all her laws, so that, driven by a spirit of vertigo, he can freely believe whatever comes into his head? See there, Maestlin, the true cause of the postponement into October of the year 1582, which you so earnestly demand be pointed out to you. You have at the same time one who defends the Easter of that same year — had it been celebrated according to the new Calendar — and proves that it would have been legitimate, from the Decrees of the Fathers, and of the Nicene Council, and of the Councils, and from the practice of the Church. Yet in this very matter, committing the grossest error yourself, you falsely accuse others of committing it — while you were rashly persuading yourself that neither was possible for us to do.

[Margin: Easter of the year 1582, by the old Calendar, was celebrated — against the Decrees of the Fathers — in the fourth week, that is, on the 14th [?] Moon.]

The Supreme Pontiff, then, if he had determined to remove ten days from February, could not have feared — as you falsely boast — that he and this work of his would be hissed off the stage. For he would not, as you insinuate, then have dragged the feast of Easter out of its true place and cast it into an erroneous or heretical one; on the contrary, he would rather have restored it from an erroneous place back to its true one. For in that year Easter was celebrated on the 23rd Moon [Luna xxiii], that is, in the fourth week, against the sanctions of the Fathers and Councils; whereas, according to the new [Calendar], it would have been carried out on the 15th Moon, that is, at the beginning of the third week, in which alone Easter can lawfully be celebrated. Now put forth the powers of your intellect, and with that marvelous prudence of yours (with which you would have anyone endowed who draws the calculation back over past times) — or rather, as I interpret it, with your notable impudence — defend this erroneous Easter of yours which the [old] Calendar exhibited, and prove, as best you can, that the one the new Calendar would have shown would have been false. *Hic Rhodus, hic saltus* — here is Rhodes, here make your leap. For I am glad to turn back against you the very saying which you are wont rashly to hurl, more than once, at the supporters of the Gregorian Calendar, as though you had already won the victory.

[Margin: That the Church sometimes celebrates Easter on the 14th Moon must be ascribed to a defect of the cycle, which cannot be altogether perfect; but that she does not on that account fall into the heresy of the Quartodecimans.]

For when you falsely suppose that the error which, on the view of the Calendar's author, is heretical is committed by celebrating Easter at the full moon, and so call it heretical (as you do also in other places), you plainly play the sycophant. For in the Calendar the reference is to the Quartodeciman heretics, who, against the decrees of the Councils and the usage of the universal Church, contended that Easter should be celebrated with the Jews on the 14th Moon. From this error, however, the Church is far removed, even if sometimes, on account of the imperfect reckoning of the lunar cycle (for no cycle, however perfect, can indicate the new and full moons — as we shall show hereafter — in such a way that they always answer exactly to the celestial motions), she celebrates Easter on the 14th Moon. This can indeed sometimes happen in the new Calendar, yet far more rarely than in the old, which followed the cycle of the golden number issued at the Council of Nicaea — and especially so near the times of that Council, as we shall show hereafter in its place. The Church, I say, is far from the error of

the heretics, if she sometimes, on account of the imperfect nature of the cycle, celebrates Easter on the 14th Moon; for she does not affirm that Easter is to be celebrated on the 14th Moon, but by chance and (to speak with the philosophers) accidentally celebrates it so on occasion, and applies all diligence so to arrange the cycle in the Calendar that, as far as possible, Easter is never celebrated on the 14th Moon, as we shall explain more fully below. But you and your like, who have all entered into an ancient covenant against the Catholic Church of God, cannot escape the mark of heresy, since, despising all the laws

and ordinances of the Catholic Church, and driven by a spirit of pride, you preach a new faith and a new Gospel, and so stubbornly defend the collapsed old Calendar, out of hatred for the new one issued by the Roman Pontiff.

And yet you have dared, O man of dead-and-buried shame, to charge greed and sordidness upon Gregory XIII, Supreme Pontiff, whose lavish generosity — or rather munificence — has overflowed into the whole world, and above all into Germany, so as to have quenched the slander of all the heretics but you. As if that Pontiff, as great in greatness of soul as in his priesthood, while he poured out vast treasures for the salvation of all nations, were aiming — by issuing the new Calendar (as you allege) — to collect a few paltry coins from the common folk! Indeed I would confirm on oath (for I was present in these affairs) that not so much as a farthing came from this into the Pontiff's treasury — did I not fear that my testimony would do injury to the well-attested bounty of so great a Pontiff: especially since your accusation of its own accord rebounds from him and falls back upon yourself, who had no reason to publish these "examinations" except to scrape together a little money from the ignorant. For the bit of glory you snatched at the same time by your calumny has turned, as you see, into disgrace. But enough of this. For I will not allow myself to seem to imitate the slanderer's slander. These things have been said not to slander, but to repel slander, and at the same time so that all might take the measure of this splendid "examination," seeing almost with their own eyes with how fair and sincere a mind, with how keen a wit, and with how firm reasons this little manikin, molded of clay and mud, has striven to assail the Gregorian Calendar, and to tear down the consensus of the whole Christian world and the Pontifical authority — whose impudence, wrapped in such great ignorance, the very title of the "examination," as we have shown, has proclaimed to be so great that nothing else could in any way excuse it, unless he were willing to confess (what the thing itself proclaims) that, when he wrote the "examination," he was not sufficiently sober.

Why the Church, Setting Aside the True or Apparent Motions, Employs Only the Mean — or Equable — Motions, or Rather Cycles, in the Celebration of the Movable Feasts. Chapter IV.

The equinox having been restored to its former seat, in which it was placed by the Council of Nicaea, a method also had to be prescribed by which that same equinox might be kept in its place. To make this clearer, it must first be explained a little more carefully what motions the Church considers and employs in the celebration of the movable feasts. For once this has been set out, it will also be plainly established how rashly and without cause the new Calendar is attacked by Maestlin. Behold, then: setting aside the true motions of the Moon and Sun — as belonging rather to the astronomers — she considers the mean and equable motions alone.

[Margin: That the Church considers only the mean motions, for many reasons.]

First, because the true motions are unequal — now swifter, now slower — whereas the mean motions are always equal and uniform; and so the latter can be reduced to a cycle without difficulty, but not the former. Since, then, for investigating the equinox, the new moon, and the Paschal full moon, easy rules had to be handed down — rules that could be grasped and retained without great labor by anyone, even one wholly untrained in and ignorant of astronomy, and without knowledge of the astronomical tables, so that the whole people should not be forced to learn astronomy thoroughly (which is a novel and unheard-of thing, and utterly impossible to accomplish) — the mean motions had to be adopted rather than the true, especially because error can more easily creep into the true and apparent motions than into the mean. Nor does it much matter that the true motions really exist in the celestial bodies, while the mean were devised by the astronomers only in thought and by art, namely so as to investigate the true by means of the mean. For the Church is not bound, nor ever was, to the exact laws and motions of the stars; it is enough if she attains the motions of the Sun and Moon with a certain rough-and-ready skill (as they say, "by a coarse Minerva"), provided she does not depart far from the truth. And this the most ancient practice — continued and carried on from the primitive Church down to our own age — plainly demonstrates.

[Margin: First reason. Because the mean motions are equal and uniform, and therefore suited to the grasp of the common people; whereas the true motions are unequal and irregular.]

Next, because if the Church used the true motions, there would stand a perpetual seed-bed of discords and quarrels among the faithful of Christ in the celebration of the most holy Easter, on account of the variety and discrepancy of the astronomical tables and the different hypotheses of the motions — since some would contend that these tables should be followed, others those: just as today we see some employ the Alphonsine Tables, others the Prutenic, in ascertaining the motions of the stars. From this it would follow that different people would observe different equinoxes and new moons, and thus would celebrate Easter at different times — which would be very discordant and absurd.

[Margin: Second reason. Lest a perpetual seed-bed of quarrels and discords be stirred up in the Church, if the true motions were observed, on account of the variety of the astronomical tables.]

Thirdly, because down to this day no tables have been drawn up by the astronomers by which the true motions of the stars can be inquired into and known for all time, certainly and without any error; but each has always made tables agreeing with the observations of his own time, which afterward, when a long time had elapsed, were found to have fallen away from the truth — because not even the period of a single celestial motion has yet been exactly and thoroughly known. For Ptolemy [Ptolemy], the prince of astronomers and most skillful investigator of the celestial motions, drew up — some 1450 years ago — tables agreeing with his observations, by which at that time the motions of the heavens were reckoned most certainly and beyond all doubt. To these, since experience had taught that they no longer exhibited the celestial motions accurately, there succeeded other tables called the Alphonsine, which were drawn up by astronomers at the expense and by the diligence of Alphonso, king of Spain [Alfonso X], about 340 years ago, and by which at that time the motions were found more certainly than by Ptolemy's tables. In their place, finally, there have been substituted in our own time the tables of Copernicus [Copernicus], commonly called the Prutenic, because by the nearly universal consent of astronomers they agree far more exactly with the celestial phenomena than the Alphonsine. And so perhaps, after many ages, our descendants will observe other periods of the celestial motions, and will therefore frame new hypotheses, and even substitute other new tables for the Prutenic. For who can [say] for certain

[Margin: Third reason. Because up to this day no tables have been constructed that would exhibit the true motions without error, for many years.] ...[for who] would dare to affirm with certainty that the Prutenic Tables [tabulæ Prutenicæ] will forever agree with the motions of the heavens, when he sees that the tables

of Ptolemy [Ptolemæus] — that most excellent astronomer, deservedly ranked ahead of all others — are now defective and imperfect, though in his own day they were as accurate as could be? All the more so, since the Prutenic Tables rest on hypotheses that are uncertain, indeed absurd, at odds with the common opinion of mankind, and contradicted by all the natural philosophers. Add to this that not even one complete period of the anomaly of the precession of the equinoxes — on which Copernicus [Copernicus] founds the whole inequality of the solar year — has yet run its full course. One may therefore reasonably doubt the reliability of tables built up from that anomaly, and question whether, once one period is complete, the next will correspond to the previous one in every respect.

[Margin: The Prutenic tables, which today are used by everyone, why they may be judged uncertain.]

Since this is so, who will be so brazen and bold as to bind God's Church to astronomical rules and tables so uncertain and deceptive? No one, I think — unless perhaps you mean to say that the Church ought to embrace now these tables, now those, according as it observes them to fit the motions of the heavens at one time or another. But that would be nothing other than to throw everything into doubt, since the astronomers themselves scarcely agree on which tables are more to be trusted. We see this even in our own age: there are most excellent mathematicians who hold that, for the motion of the Sun and Moon, the Alphonsine Tables [tabulæ Alphonsinæ] are more to be believed than the Prutenic.

[Margin: On the astronomical grounds on which some hold that, for the motion of the Sun and Moon, the Alphonsine tables are more to be trusted than the Prutenic.]

Tycho Brahe [Tycho Brahe], a certain Danish nobleman and distinguished mathematician, who now examines the motions of the stars by his own observations and is wholly devoted to presenting them to us as accurately as possible, found — with careful diligence, in the year 1586, as I learned from that learned man, most skilled in mathematics, Bartholomäus Scultetus [Bartholomäus Scultetus] — that the vernal equinox, that is, the Sun's entry into Aries, occurred on 10 March, at 9 hours 2 minutes after noon, according to the old Calendar. The Alphonsine Tables put it very nearly six hours earlier, the Prutenic almost thirteen hours later. Here it plainly appears that the Alphonsine reckoning comes closer to the observation just cited than does the Prutenic (or Copernican). By the new Calendar, that same observed equinox falls on 20 March, at 9 hours 2

minutes after noon, and so was rightly assigned to the following day, the 21st. From this too it is clear, and evident, that in this correction of the Calendar it was excellently done to remove ten days from the year 1582, so that the equinox might be restored to 21 March.

[Margin: That ten days were rightly removed in order to restore the equinox to the 21st day of March is confirmed by the observations of a certain noble Dane.]

Therefore, in order that this discord and disagreement among the astronomers might be removed from the midst, the Church, with the most prudent counsel, has always refused tables of the true motions — leaving them to the curiosity of the astronomers — and has judged that the mean motions, which are equal and uniform, or rather cycles that best agree with the mean motions, should be employed for the solemn observance of the movable feasts.

Yet I have not brought these things forward with the idea that astronomical tables should be rejected altogether as false and worthless. On the contrary, I have always held the astronomers worthy of every praise — men who at various times, with the greatest labor and study, observed the motions of the stars, and, in order to compute those same motions readily (though not with perfect exactness, yet so as to depart little from the truth), worked out various tables with admirable industry and handed them down to posterity. My sole contention is that the Church ought not to be bound to the fastidious subtleties of the astronomers, since the same tables cannot last long, but different ones must be adopted from time to time as circumstances change, as I have said. Nor does this detract at all from the dignity and excellence of astronomy, that most noble science; rather, it wonderfully commends it, that it has set before our eyes so great a variety of motions so accurately that we come as near as possible to the truth itself. And what wonder that the astronomers cannot grasp perfectly, by their understanding, the motions of the heavens, which lie at so great a distance from us — when the philosophers have not yet been able to attain complete knowledge of even a single substance, however small, here in this lower world?

[Margin: That great astronomical tables ought to be made, even if they cannot last a long time.]

[Margin: Whence the inconstancy of astronomical tables arises.]

And indeed it seems to me that God, Best and Greatest, the most wise architect of the heavens and the stars, deliberately willed to wrap the motions of the planets and stars in such great difficulties that no mortal could unravel and explain them by his own wit. For who, from the founding of the world down to our own times,

has been found so excellent in astronomy as to define the periods of the celestial motions so exactly that, after some centuries of years, they would depart nothing from the truth — given the minute quantities, some in excess and some in deficit, in the period of each planet, which over a great interval of time introduce no slight error? And this is so, no doubt, that we may always find something to admire in the workmanship of these most noble bodies, so wonderful, and in the harmony and concord of their motions, so constant, and may celebrate their Creator and Mover with perpetual praise. Above all, it may be supposed to have been written of the immense mass of the heavens, their order, and their motions — in which there always seems to remain something for the most diligent searchers into celestial things to investigate — what Ecclesiastes says at chapter 3: *And he has delivered the world to their disputation.* This, doubtless, so that men might not at some time — had they perfectly understood the number, order, and motion of the heavens — cease to inquire into and admire the works of God, and so that their minds, deprived of any occasion for exercise, might not grow torpid, as it were, from inactivity.

Fourth, the Church disregards the true motions and takes up the mean ones, or rather cycles, because even if astronomical tables existed that were perfectly accurate and cleansed of every error, so as to be free of all fault, it would nonetheless be pointless, and without any necessity, to employ that exact and painstaking computation of hours and minutes according to the true motions in celebrating the movable feasts. For however accurately the vernal equinox and the Paschal full moons might be computed from the true motions, the variety of regions and meridians would still render that labor useless and vain. When, for example, the vernal equinox falls at Rome at noon on 21 March, it falls for certain more easterly peoples on the same 21st at sunset, and for others at the following midnight of that day, so that it will have to be assigned to the next day, the 22nd — and so on. Likewise, if the true full moon then occurs at Rome around noon on 21 March, the same will happen among the more easterly peoples at sunset, and among those still farther east around midnight, and so forth. Hence, if in that year 22 March were a Sunday, Easter would indeed be celebrated at Rome according to the ordinances of the Fathers and the Council; but among the more easterly peoples it could not be celebrated, because — being more remote — they must look to the true motion, since for them the equinox falls on the 22nd and the time of the full moon has not yet come. Now it is established from the decrees of the Fathers that Easter cannot lawfully be celebrated on the very day of the equinox, but that it is necessary that the

[Margin: **Fourth reason.** Because even if the astronomical tables that existed were perfectly accurate, the true motions would still be adopted in vain by the Church, on account of the variety of meridians.]

CAPUT QUARTUM

day of the equinox precede it, and that it be celebrated neither before the full moon, nor on the 14th of the Moon [Luna XIII], nor before the 14th. And since it was decreed in the Council of Nicaea that all should celebrate Easter in the same month and on the same day as the Roman Church observes it — a decree afterward confirmed in the Council of Arles [Concilium Atelatense] and the fourth Council of Carthage, and most clearly asserted by St. Ambrose [S. Ambrosius] in many words in his letter to the bishops appointed throughout Aemilia — it is plainly gathered that the Church cannot take account of the true motion of the luminaries in the celebration of Easter.

Fifth, on account of that most ancient custom by which the mean motions, or rather the cycles, have always been in use in the Church, the true motions being set aside — a custom that ought not to be changed without some pressing necessity. For that the Church has not observed the vernal equinox according to the true motion is clearly shown by the decree of the holy Fathers issued in the Council of Nicaea, whereby they ordained, for the whole world, that the equinox was to be observed on 21 March. But it is plain that the equinox can be tied and fixed neither to the true motion nor to a single mean day. For if, in the year immediately preceding a leap year, it falls on the 21st, it necessarily falls on the 20th in the following leap year, on account of the intercalary day added to February. Likewise, if in one leap year the equinox is about noon of some day, the same will necessarily fall, in the year immediately following the leap year, at sunset of that day; in the second year after the leap year, about midnight; and finally in the third year after the leap year, at sunrise of the next day — on account of those six hours which are omitted in each common year, since in those years only 365 whole days are counted, though nearly six hours are left over in each year. From this it is plainly concluded that the said decree can be referred neither to the true nor to the mean motion, but only to 21 March, the time at which the equinox used to occur — even if by astronomical calculation it was sometimes found to happen a little before or a little after that day. This was so that the equinox should not be observed by some on the 21st, and by others on another day if they chose to consult astronomical tables, and Easter thus be celebrated at different times — which would be absurd.

[Margin: **Fifth reason.** Because it is the most ancient custom of the Church to observe the mean motions, not the true ones — a custom that ought not to be changed without pressing cause.]

Nor does it greatly matter, as regards the solemnity of Easter, whether the equinox falls on the very 21st of March, or precedes it, or follows it, provided it is not far from it. For the Church was never bound to such precise and subtle rules of the astronomers — since not even the Hebrews themselves, for whom everything was ceremonial, were commanded to observe the true or the mean equinox in the solemnity of the Passover, but only the time at which the days, by the judgment of the senses, become equal to the nights — a period of three or four days, which the equinox is wont to span without any great difference.

[Margin: That it makes little difference, as regards the feast of Easter, whether the equinox does not always fall on the very 21st day of March, but sometimes precedes or follows it by some amount.]

This is gathered clearly enough from Sacred Scripture. For God commands the celebration of the Passover through Moses [Moyses] in Exodus 12, in these words: *This month shall be to you the beginning of months; it shall be the first among the months of the year*, etc. And a little later: *And you shall keep it* (the lamb, that is) *until the fourteenth day of this month*, etc. Here these words, *this* and *of this*, are repeatedly stressed, by which it seems to be signified that God did not wish to change the accustomed form and numbering of the year and months of the Hebrews, but only to change the seventh month into the first — as if it were said: This month, which hitherto in your Egypt, according to the common usage of the year (and not according to astronomical calculation), has been held and named the seventh, shall henceforth be to you the first of the whole year, and in it you shall celebrate the Passover. Nor can it be said that the true magnitude of both years — the solar as well as the lunar — was then unknown to Moses, instructed by God, for that would be absurd. Rather it must be said that Moses spoke to the understanding of the common people, who were ignorant of astronomy, since he was addressing the whole assembly of the children of Israel. And that he named the first month not in the astronomical manner — namely, when the Sun enters the first point of Aries — but in a wholly common and rustic fashion, that is, *Abib* in Hebrew, and ἀβίβ [Greek: abíb] in Greek, which in Latin means "the month of new things," or of the new crops, since in springtime the new crops are gathered in Egypt.

[Margin: That God, through Moses, commanded the observance of the first month, and of the 10th day, and of the 14th, in a rustic manner, accommodated to the understanding of the whole people of Israel.]

Now, that the Church labors little over the true or the mean motion even in investigating the new moons and full moons can be established from this: that in searching them out it has, from the very beginning, always used lunar cycles, that is, nineteen-year cycles, which can in no way agree in every respect with the true or the mean motions. For according to the cycles, the lunations comprise whole days, whereas both by the true and by the mean motion they contain, beyond the whole days, some hours and fractions of hours. I add that in leap years the lunations come one day later in the cycle after the intercalary day, an adjustment that cannot be taken into account until many years have elapsed, as will appear in Book 2, when we expound the reckoning of the golden number. And indeed, as regards the lunar cycle, the Church in this matter imitates not only the Hebrews, Alexandrians, and Romans, but also the Chaldeans, Arabs, Athenians, and the peoples of nearly every age — all of whom, both long before the coming of Christ and afterward, used lunar cycles to search out the new moons — all of whom Paul of Middelburg [Paulus Middelburgensis] expounds in Book 2 of his *Paulina*.

[Margin: That the Church is not greatly concerned about the true or mean new and full moons, since in investigating them it has always used cycles.]

[Margin: That the Church, in employing the lunar cycle, imitates all antiquity.]

Sixth, finally, the same is confirmed by the authority of many astronomers, and of all who have written on matters pertaining to the Roman Calendar according to the custom of the Church. Chief among them is Campanus [Campanus], at the beginning of his greater *Computus*, where he asserts that the *Computus* is the science of the numbering and division of times (I use his own words) according to common observances, etc.; at chapter 15 he teaches that the computists, having left the true lunations to the astronomers on account of their difficult variability, have concerned themselves only with the mean ones, on account of their uniformity.

[Margin: **Sixth reason.** Because various writers and computists testify that it ought to be done thus.]

Johannes Stöffler [Ioannes Stoflerinus] too, in his *Roman Calendar*, proposition 34, at the capital letter Z, teaches that the universal Church, from the Council of Nicaea down to the present day, has employed for the celebration of Easter the cycle of the golden number received from the Alexandrians, who had used it

earlier. And a little further on he affirms that the golden numbers inscribed in the Calendar indicate the days of the mean conjunctions of the luminaries, etc. And somewhat later he writes that the Orthodox Church, especially the Latin, before the Nicene Synod, in seeking out Easter by the 14th of the Moon, used the customary lunar cycle instituted by Julius Caesar [Iulius Cæsar]. He repeats the same in many other places.

Paul of Middelburg likewise, Bishop of Fossombrone [Episcopus Forosempronienensis], in his *Paulina*, Book 10, about the middle, a little before the table of equinoxes, after a long disputation on the varying and unequal magnitude of the year, writes in these words: *Nevertheless, this varying quantity of the solar year does not hinder our work, undertaken as a norm for the Paschal solemnity, because the Roman Church in its Paschal computation does not observe the varying or extreme motions, on account of their variability, but only the mean and uniform ones. Now the mean quantity of the year, between the greatest and the least, is 365 days, 5 hours, 49 minutes, 16 seconds, &c. [S. &c. 16.]* And he adds at once: *Wherefore, setting aside this scruple of the equation of the solar year, which is necessary for astronomers, we here set down the vernal equinoxes for the first month and Paschal norm, computed according to the reckoning derived from the Alphonsine Tables, etc.*

[Margin: That the mean motions are useful for judging which cycle, out of several, more correctly displays the 14th of the Moon in the Calendar.]

From all this I believe it is sufficiently confirmed that neither the day of the vernal equinox nor the Paschal 14ths of the Moon should be examined by ephemerides and astronomical [tables] of the true or mean motion — as some vainly contend — but that it is enough if they are sought by the popular rules, easy to grasp and still in use in the Church, of which sort are the cycles. I would not, however, deny that the mean motions drawn from astronomical tables — not the true ones (since the latter are unequal, the former equal) — are of the greatest use for judging which cycle among all those arranged in the Calendar most correctly displays the Paschal 14ths of the Moon.

What method of intercalation has been employed, so that the equinox may be kept near 21 March, to which it has been recalled.

CAPUT V

Lest the vernal equinox, with the progress of time, again desert 21 March, to which it has been recalled, and move back toward the beginning of the month, this method of intercalation was established before the correction of the Calendar: that, while the customary rule of intercalating one day every fourth year is indeed retained, not all the hundredth years shall henceforth be leap years (although by the customary rule of leap years they all ought to be leap years); but the first three hundredth years after the year 1600 shall be made common, that is, of only 365 days — such as the years 1700, 1800, 1900 — while the fourth following hundredth year, that is, 2000, shall be a leap year, of 366 days. Likewise the next three hundredth years, 2100, 2200, 2300, shall be made common in the same way, and the next hundredth year, 2400, shall be a leap year. And so on thereafter, the same order being always kept. Since the reasoning of this intercalation is sharply attacked by Maestlin [Michael Mästlin], it must be explained here somewhat more fully, so that all may understand that no other, more convenient method of intercalation could have been devised, and that this one is impugned by Maestlin cunningly and maliciously. And that this may be made plainer, a few things must first be said about the varying magnitude of the year found by the astronomers at different times. And to take our beginning from this: the solar year is twofold — astronomical and civil.

[Margin: What method of intercalation has been employed, so that the equinox may be kept near the 21st day of March.]

[Margin: What the astronomical year is.]

The **astronomical year** is the space of time in which the Sun by its proper motion traverses the whole Zodiac from west to east, beginning from some fixed point — as from the beginning of Aries — until it returns to the same point. This span of time comprises, beyond 365 whole days, 5 hours, and in addition some minutes of an hour, as sufficiently appears from the observations of the astronomers.

[Margin: That the astronomical year consists of days and hours, and fractions of hours.]

The **civil year** consists only of whole days: sometimes of 365, and it is called Common; sometimes of 366, and it is called Bissextile, or Intercalary. Nor can the civil year be reckoned otherwise than by whole days, the hours and fractions of hours being neglected, since it must be arranged for the use of the people and the common folk — who reckon not by a numbering of days together with hours, but only by whole days, without the small fractions of hours. Such a reckoning of the year could not be laid out in a Calendar, nor would it be suitable or accommodated to carrying on trade and commerce and other civil affairs, nor to keeping the feast days and duly performing the sacred ceremonies of the Church — because a year counted in that way begins its start-point now from noon, now from sunset, now from midnight, now from sunrise, and now finally from some other moment of the day; whereas in a Calendar only whole days, not the small fractions of hours, are set down. For example, the year 1588, if account be taken of hours and minutes, begins, according to the Ephemerides of Giovanni Antonio Magini [Ioannes Antonius Maginus], on 20 March, at about 9 hours 49 minutes after noon. The next year, 1589, on 20 March, at about 15 hours 36 minutes after noon. The year 1590, on 20 March, at 21 hours 31 minutes after noon. The year 1591, on 21 March, at about 3 hours 28 minutes after noon. And finally the year 1592 takes its beginning again from 20 March, at about 9 hours 23 minutes after noon. Here you see that the year never begins at the same moment of time — a thing that can in no way be suitable for the use of the people, unless we should wish all to be instructed in astronomy, which is both ridiculous and altogether impossible.

[Margin: What the civil year is.]

[Margin: That the civil year necessarily consists of whole days.]

[Margin: That the astronomical year does not always begin from the same moment of the same day.]

And although this reckoning by days, hours, and fractions of hours cannot, as we have said, be applied to common use, knowledge of it is nonetheless necessary, so that the civil year, consisting of whole days, may from time to time be equalized — now by the addition, now by the subtraction, of one day (which is made up from the omitted hours and their fractions) — so that it may agree, as far as possible, with the astronomical year, and the Sun may bring about the equinoxes and solstices at nearly the same times of the year.

[Margin: That knowledge of the astronomical year is necessary.]

For this reason the Church, every fourth year, by the institution of Julius Caesar, intercalates one day...

is added to the year, so that it becomes one of 366 days, while the other three preceding years comprise only 365. For since the Church, following the reckoning of Julius Caesar [Iulius Caesar] that is most widely received, sets the astronomical year at 365 days and 6 hours, whereas the civil year contains only 365 days, it follows that in the first civil year 6 hours are wanting to complete the astronomical year, in the second 12, in the third 18, and in the fourth 24 — which make up one full natural day. It is therefore necessary, so that those 24 hours are not lost, to make the fourth year one of 366 days. Otherwise the equinoxes and solstices would then fall one day earlier than they are marked in the calendar; after another four years, two days earlier; and so on, so that within 120 years they would slip back by a whole month — that is, by a full 30 days — toward the end of the year, and so forth, and would not return to their former places until after 1460 years. In that span of time the vernal equinox would run through every month, and indeed every day, in a complete cycle. Who does not see what confusion of the seasons this would bring?

[Margin: Why every fourth year is bissextile.]

[Margin: If all years were common, the equinox would traverse every day of the whole year in 1460 years.]

But since astronomers have observed the solar year to be somewhat shorter than 365 days and 6 hours, the result is that more is intercalated every fourth year than ought to be, because the hours and fractions by which the astronomical year exceeds the civil do not grow, in four years, into one whole day. Therefore, unless account is taken of those fractions which in each four-year period fall short of completing a whole day — so that, once they have grown into a whole day, one day is removed from the year (that is, the intercalation is omitted once) — the equinoxes and solstices will gradually advance toward the beginnings of the months, as happened before the correction of the calendar. To prevent this from happening in the future, this remedy has been devised: that some year which ought to be bissextile is instead made a common year of 365 days, and not an intercalary one of 366, as will be explained more fully below. But so that we may determine over how many years the fractions of hours — those wanting to complete the six hours in each astronomical year — make up one whole day, and thus one intercalary day ought to be omitted, we must consider carefully and diligently what has been handed down to memory concerning the length of the year through the observations of the more celebrated astronomers.

[Margin: Why the intercalation of one day every fourth year is greater than it ought to be.]

Setting aside, then, the more ancient astronomers: Ptolemy [Ptolemaeus], about the year 130 after the birth of Christ, found from his observations that the length of the year was 365 days and 6 hours less a three-hundredth part of one day — that is, beyond the whole days, 5 hours, 55 minutes, 12 seconds.

[Margin: The length of the year according to Ptolemy.]

Al-Battānī [Albategnius], about the year of the Lord 880 — that is, roughly 750 years after Ptolemy — found the year to contain 365 days, 5 hours, 46 minutes, 24 seconds.

[Margin: The length of the year according to al-Battānī.]

The Alphonsine Tables [Alphonsinae tabulae], drawn up about the year of the Lord 1250, establish that the year consists of 365 days, 5 hours, 49 minutes, 16 seconds.

[Margin: The length of the year according to the Alphonsine tables.]

These are the more celebrated opinions concerning the length of the solar year. From them it is clear that the solar year is now greater, now smaller, since it has been observed by the most skilled astronomers to be different and variable at different times. The ancient astronomers indeed were led by quite probable conjecture to suspect that the solar year cannot always be of the same length — both on account of the apparent unequal and irregular motion of the Sun, and on account of the irregular motion of the eighth sphere [sphaera octava]. But since this matter cannot be fully known except after many centuries have elapsed, they have left us nothing certain about the inequality of the solar years.

[Margin: That the solar year is not always of the same length.]

One man alone within human memory, Nicolaus Copernicus [Copernicus], the outstanding mathematician of our age, comparing his own observations most diligently with those of Hipparchus [Hipparchus], Ptolemy, al-Battānī, and Alphonso [Alphonsus], ventured — with truly incredible skill, and employing new hypotheses — to demonstrate this increase and decrease of the solar year, and to reduce the year's inequality to a certain and definite standard. By a calculation drawn from his hypotheses he found that the solar year, when it has grown to its greatest length, is a little greater than the one Ptolemy determined — namely 365 days, 5 hours, 55 minutes, 37 seconds, 40 thirds; and when it has most decreased,

a little smaller than the one al-Battānī found — that is, 365 days, 5 hours, 42 minutes, 55 seconds, 7 thirds — so that the length of the Alphonsine year is very nearly midway between the greatest and the least length of the year. Concerning this inequality of the years we shall write more in the following chapter.

[Margin: Copernicus's observations on the inequality of the year.]

Since this is so, it was truly difficult for Gregory XIII [Gregorius XIII], that most prudent Pontiff, to determine what method of intercalation he should prescribe so that the vernal equinox might be kept on the 21st of March. For the length of the Ptolemaic year required that about every three-hundredth year one intercalary day be omitted, because that year is smaller by a three-hundredth part of one day than the Julian or ecclesiastical year of 365 days and 6 hours, and therefore in the space of three hundred years the equinox would be advanced by one day toward the beginning of the month from the seat assigned to it in the calendar. But according to al-Battānī's year one intercalary day would have to be omitted about every hundredth year, since in so great a span of years the equinox of that year anticipates its own seat in the calendar by nearly one day. Finally, if the Alphonsine year were adopted, the intercalation of one day would have to be suspended once in the space of about 134 years. And this variety of intercalation would keep increasing in proportion as the length of the year turned out variously between the greatest and the least year. Which way, then, was the Pontiff to turn, or what path should he set himself to follow?

[Margin: The difficulty of intercalating so as to keep the equinox on the 21st of March.]

[Margin: In how many years one intercalary day would have to be omitted once, if the Ptolemaic year were reckoned.]

[Margin: In how many years, according to al-Battānī's year, the intercalation would have to be suspended once.]

[Margin: In how many years the Alphonsine year requires the removal of one intercalary day.]

Two methods above all were proposed to him by the eminent astronomers in charge of this business. The first was that, in keeping with the inequality of the solar year, one intercalary day should be removed now at a greater interval of years, now at a smaller, according as the year turned out greater or smaller by Copernicus's calculation. The second was that, setting aside the year's inequality, the method of intercalation should be fitted to the Alphonsine year, which is in a

manner intermediate between the greatest and the least. Both methods were sent, in a compendium of the new scheme for restoring the calendar, to the Christian princes, the commonwealths, and the more famous universities, so that, after the matter had been carefully, long, and thoroughly considered, they might deliberate which of the two seemed the more suitable and fitting, in order that the Supreme Pontiff might approve it by his authority as, so to speak, the consensus of the whole Christian world. But when all of them, with at most one or two exceptions, had left the whole matter to his...

judgment, this latter method was at length chosen, on the advice of the astronomers, chiefly for the following reasons.

[Margin: By what method the intercalation was chosen, and for what reasons.]

First, since in the celebration of Easter the Church ought to follow something regular and uniform — something fixed and not far from the truth — rather than the exact computation of the astronomers (because the measures of years, months, and other periods of time ought to be adapted to the understanding of ordinary people), the first method of intercalating seems in no way to be adopted, because it is uncertain, irregular, and unequal, being one in which at one time the intercalary day would have to be omitted after more years, at another after fewer. And what would this be but to cast the whole Christian people into inextricable snares, since they would be perpetually doubtful and uncertain as to when the intercalary day was to be omitted?

[Margin: First reason.]

[Margin: Why in the correction of the calendar the mean magnitude was adopted.]

Nor can it be said that the Church ought to set before the people a table of intercalation in which are listed the years in which the intercalation is not to be used: for among the astronomers a blaze of discord and of intolerable disturbances would be kindled, since each would force his own calculation upon this business, seeing that (as we said in the previous chapter) one contends that these tables are to be adopted, another those.

[Margin: That an unequal year is not suitable for establishing the intercalation.]

For, I ask, for what other reason did so many dissensions and disputes over the celebration of Easter arise between Greeks and Latins, from the Council of Nicaea down to the time of the Emperor Justinian [Iustinianus], except that in that Council those most holy Fathers did not propose any fixed cycle for the whole

Church to observe, but entrusted the care of it to Eusebius, Bishop of Caesarea [Eusebius Caesariensis], and to the Alexandrians?

[Margin: Whence arose the disputes over the celebration of Easter from the Council of Nicaea to the Emperor Justinian.]

Hence it came about that the Latins contended Easter should be celebrated according to one cycle, and the Greeks according to another, until, in the time of Justinian the Elder, Dionysius the Abbot [Dionysius Exiguus] inscribed the cycle of the Alexandrians in the Roman calendar, which all the churches thereafter followed with concordant minds — as indeed was done both by the Eastern Church and by the Western, down to this Gregorian correction. Therefore, had Gregory XIII, that most prudent Pontiff, not prescribed some equable and regular formula of intercalation, but left the care of it to the astronomers, to draw up from the true motion tables listing the years in which the intercalation was to be suspended, who does not see that there would have been perpetual quarrels and dissensions among the astronomers, each forcing his own calculation upon the Church? One single, definite length of the year therefore had to be chosen, so that the scheme might be established in accordance with it, by which the intercalation would be suspended at a certain fixed interval of years. For in this way both the common and unlearned people are better served, and all material for discord among the astronomers is utterly removed.

Since, then, the year is unequal — greatest, least, and mean — the greatest cannot be adopted for this purpose, because the intercalation would be omitted too rarely, that is, only once every three-hundredth year. And although this method, at the time when the year had grown to its greatest length, would answer exactly to the motion of the Sun, it would nonetheless differ most from the truth when that same year had its least length.

[Margin: Why the greatest year is not suitable for the equation of the solar year.]

For the same reason neither can the least year be suitable for this purpose, because it demands too frequent an omission of the intercalary day, and would answer to the motion of the Sun only at the time when the least year was being completed.

[Margin: Why the least year is not suitable for the equation of the solar year.]

Therefore only the year midway between greatest and least — such as the Alphonsine is — will be fit for this office. For whether the year is found to be greater at some time, or smaller than the mean, we shall be able to depart but

little from the truth, if we set the omission of the intercalary day according to the magnitude of that mean year, since the intercalary day is then removed from the reckoning neither too rarely nor too frequently, but a certain mean rule is always preserved — so much so that this method of intercalation corrects and amends itself. For when the intercalary day is omitted more frequently than is fair at one time, this error is compensated at another time, when the intercalary day is removed more rarely; and vice versa.

[Margin: Why the mean year, that is, the Alphonsine, is alone suitable for equating the solar year.]

[Margin: How the method of intercalation established for the mean year corrects itself.]

This will be evident from the calculations of several years at the end of Chapter VI, where it will appear clearer than daylight that an equable equation can be established only for the mean year, and not for the least or the greatest: for the equations of these [extreme] years drive the equinox far from its proper place after some years, whereas the equation of the former — that is, of the mean year — keeps it about the same 21st day, which is its proper seat, so that it cannot stray far from it, even over many thousands of years.

Nor can any other inconvenience (if it can be called an inconvenience) follow from this omission of the intercalation, established according to the mean length of the year, than that in the greatest year we remove the intercalary day sooner than is needful — and so the equinox recedes a little from the 21st of March toward the end of the month, and the ecclesiastical equinox, fixed to the 21st, falls before the true one; while in the least year we omit the intercalary day later than is fair, and accordingly the equinox leaves [deserat] the 21st of March and advances toward the beginning of the month, so that the ecclesiastical equinox falls after the celestial, or true, one. That this is not absurd, but rather most consonant with the custom of the Church, will be understood from what follows.

[Margin: That no inconvenience of any moment follows from the intercalation established for the mean year.]

Secondly, this latter method has been the more approved because — as we shall prove by many arguments in the next chapter — the Church has always used the mean motions in investigating the new moons and the fourteenth moons [Lunas XIII] for the correct determination of Easter, leaving the true motions to the more exact scrutiny of the astronomers; for the mean motions are always equal and uniform, whereas the true ones are unequal and irregular, now greater than

the mean, now smaller. It seems fitting and consistent, therefore, that for keeping the equinox in its seat the Church should also employ the length of the year that is mean between the greatest and the least. For just as the mean conjunctions of the luminaries now precede the true conjunctions and now follow them, so too the equinox which the year midway between greatest and least exhibits will at one time precede [the true equinox], the true one following; and at another time fall after the true one, as we said a little earlier.

[Margin: Second reason.]

[Margin: Why in the correction of the calendar the mean magnitude of the year was adopted.]

[Margin: The likeness between the mean conjunctions of the luminaries and the equation established for the mean year.]

But if someone should object that, from the fact that the true equinox does not always fall on the 21st of March (where the Church has placed it) but sometimes before and sometimes after, it necessarily follows that some fourteenth moons belong to the first month and are Paschal by the decrees and ordinances of the Fathers and of the Council of Nicaea, and...

and yet that these are rejected as non-Paschal and as belonging to the last month, because they occur before the 21st of March, on which the Church supposes the equinox to fall — even though those fourteenth moons occur before the actual day of the equinox (which then perhaps precedes the 21st), or even follow it; and again that some fourteenth moons are not Paschal by the same decrees and ordinances of the Fathers and of the Council of Nicaea, but belong to the last month, and yet are reckoned by the Church as legitimate for celebrating Easter and as belonging to the first month, because they fall on the 21st of March, appointed to the equinox, or follow it, even though they precede the true equinox (which then perhaps occurs after the 21st) — both of which seem absurd, since the former fourteenth moons throw Easter into the second month, while the latter present it for celebration in the twelfth and last month:

[Margin: An objection — that Easter is sometimes thrown into the second month, and sometimes anticipates the first month, because the equinox does not always stay on the 21st of March if the equation is set for the mean year.]

If anyone, I say, should object in this way, the answer is that this is neither absurd nor new in the Church of God.

[Margin: Resolution of the objection.]

For the equinox cannot be contained within a single day, but demands two days for itself. For if in some bissextile year it falls, say, on the 20th of March about noon, in the following year it will occur six hours later — namely on the 20th about sunset — on account of those six hours which in every year after the bissextile are dropped; then in the next year on the 20th about midnight, and in another following year on the 21st about sunrise; and finally in the next year, which is again bissextile, it returns to the earlier 20th day about noon, on account of the intercalary day added to the year.

[Margin: That it is nothing new for Easter to be celebrated sometimes in the second month, sometimes in the last, on account of the common and bissextile years.]

Since, then, the equinox requires two days, but the Church has always assigned a single day to the equinox — namely the 21st of March — so that all the faithful of Christ may everywhere celebrate Easter on the same day, that is, on the first Sunday after the fourteenth moon which falls either on the day of the equinox (the 21st of March) or next after it, but does not precede it (as we taught above), it could not be avoided at any time — not even in the days of the Council of Nicaea, when the Paschal Canon was first confirmed and issued by a general Council — that Easter should sometimes be celebrated in the last month, or in the second. This I shall make plain as follows.

Suppose that the equinox, around the time of the Council of Nicaea (which the Fathers fixed on the 21st of March), truly fell on the 21st and 22nd of March, as the tables of Copernicus, or the Prutenic Tables [Prutenicae], show us — in which we find that the equinox in the year of the Lord 324, a bissextile year, fell on the 21st of March about noon, and therefore in the third year after the bissextile on the 22nd about sunrise. This being granted, whenever, in that third year after the bissextile, the fourteenth moon fell on the 21st of March (which, while the golden number XVI was running, always happened before the correction of the calendar), Easter was celebrated in the last month, since that fourteenth moon preceded the equinox — and Easter fell on the equinox itself, if the 22nd then happened to be a Sunday.

[Margin: That Easter would necessarily have been celebrated sometimes both in the second month and in the last, even in the very days of the Council of Nicaea.]

Suppose next that the equinox, around the same time of the Council, occupied the 20th and the 21st of March, which agrees better with the Alphonsine Tables, since these place the equinox in the year 324, a bissextile, on the 20th of March about

22 hours before noon. If, I say, we accept this, then whenever at that time the fourteenth moon in a bissextile year fell on the 20th of March, Easter was thrown into the second month, although that fourteenth moon was truly Paschal — because it fell either on the equinox or after it — and yet the Church rejected it as belonging to the last month, for no other reason than that it preceded the 21st assigned to the equinox. The same must now, after the correction, necessarily happen whenever the epacts XXIII and XXIII are in use. For when the equinox falls on the 20th of March and the epact XXIII is running, the fourteenth moon of this epact — falling on the 20th of March — would be Paschal by the decrees of the Fathers and of the Council of Nicaea; yet it is rejected, and another, of the second month, is accepted. But when the equinox falls on the 22nd and the epact XXIII is running, the fourteenth moon of this epact, falling on the 21st, is taken as Paschal, although by the decrees of the Fathers it belongs to the last month, because it occurs before the equinox.

[Margin: That the Church does not conflict with the decrees of the Fathers and of the Council of Nicaea, even if Easter is sometimes celebrated in the last month or in the second, since this can in no way be avoided.]

From these things it plainly appears that it is nothing new in the Church for Easter to be celebrated either in the last month or in the second, on account of the equinox being fixed to a single day, which demands two days. Nor is the Church herein to be thought to depart from the decrees of the Fathers and of the Council of Nicaea; for those decrees are not to be taken so strictly as to require the Church to determine the equinox from astronomical tables, but are to be understood only as directing the Church, in the celebration of Easter, to observe the day ascribed to the equinox — even though the equinox may sometimes precede or follow that day, provided it does not recede far from it.

[Margin: That the equinox is twofold: astronomical, or true; and ecclesiastical, or political/conventional.]

Therefore it can rightly be said that the equinox can be taken in two ways: in one, as it truly exists in the nature of things and is considered by the astronomers; in the other, as it is fixed in the calendar to some certain day and is used by the Church for the due celebration of Easter. And although this ecclesiastical equinox ought to be referred, as far as can be done, to that astronomical and true one, yet for just reasons the one may differ somewhat from the other. The most just reason why the ecclesiastical equinox sometimes differs from the natural and true one is the concord and consensus of the faithful — for the sake of which the Church has ascribed the equinox to a single day, so that throughout the Christian

world all might, with united minds, keep the most holy day of Easter on one and the same day. This concord could scarcely, or only with difficulty, be preserved if the equinox, with account taken of the true motion, were bound to two or even more days, as is clear from what has been said. And so, although in the celebration of Easter the Church freely and of its own accord (for it is bound by no laws to do this) proposes to itself the observation of the equinox and of the course of the Moon — namely for the fuller unfolding of the mysteries contained in the most holy Passion and Resurrection of the Lord — nevertheless the peace and concord of the faithful is dearer to its heart; so much so that, if by any chance the concord of the faithful should suffer harm, it would rather have Easter celebrated by all on the same day, even if the equinox and the course of the Moon were not perfectly kept, than that the least agreement of the faithful in celebrating it should be broken or disturbed. For who would with justice reprehend the Church, or charge it with error, if it should deviate a little from the perfect observation of the equinox and of the fourteenth moon, so that tranquility and peace among the faithful might be preserved in the celebration of Easter, the most solemn of all feasts? For it considers the equinox and the fourteenth moon freely, and only on account of a certain congruence and likeness with the Passover of the Hebrews in this matter (as we taught in Chapter I); but the peace and concord of believers it is bound, by divine command, to protect and preserve.

[Margin: That the Church is free in observing the equinox and the course of the Moon for the celebration of Easter, but observes them for the sake of the mystery; that the peace of the faithful in the celebration of Easter is dearer to the Church than an exact observation of the equinox and of the course of the Moon.]

[Margin: Third reason. Why in the correction of the calendar the mean magnitude of the year was adopted. If after some years the equinox should abandon March 21, by what means it could be recalled to it.]

Finally, in this matter the Church has followed above all the *mean* year. For even though — on account of the omission of the intercalary day set up in proportion to the mean magnitude of the year — it might come about, after the passage of several centuries, that the equinox would not remain on March 21, but be found by new observations to have either slipped toward the end of the month or advanced toward its beginning (something we do not deny can happen, owing to the inconstancy and mutability of the astronomical tables): just as the tables of Ptolemy and of King Alfonso [Alphonsine tables] have by now been found to have deviated somewhat from the true motions — although in their own day, when

they were composed, they represented those motions most accurately — so likewise we cannot promise perpetuity and permanence for the Prutenic tables [tabulae Prutenicae] drawn from the doctrine of Copernicus. Even if, I say, the equinox were found to have moved from its seat, it can nonetheless be recalled to the 21st without any difficulty: by decree of the Roman Pontiff, one or another day — or even several, if need be — may be intercalated out of the ordinary course in some year, should it be found to have slipped toward the end of the month; or taken away from some year, should it have advanced toward the beginning — according, that is, to the number of days by which the equinox is observed to have receded from the 21st. For in this way it will be restored to the 21st, and on that account nothing in the epacts of the calendar will have to be altered: only the equations of the expanded table of epacts will have to be arranged a little differently. In what manner this ought to be done, we shall set out in Book 2, Chapter 4.

[Margin: In what the perpetuity and perfection of the Gregorian calendar consists.]

And it is in this that the excellence and perpetuity of the Gregorian calendar consists: that it can be fitted to any form of intercalation whatever — that is, to any magnitude of the year — with no change made in the calendar's Cycle of Epacts. This is something that can be made to square with no other Lunar Cycle; for once the manner of intercalation is changed, the disposition of the Cycle in the calendar must of necessity be changed as well, as we shall explain fully in Chapter 4 of the second book, when we treat of the expanded table of epacts. This Maestlin, sharp-witted man though he is, did not see; otherwise he would not have been so bold in finding fault with this calendar.

[Margin: That Maestlin failed to grasp in what the perfection and perpetuity of the calendar consists.]

For it is not the case that the Gregorian calendar has been called perpetual and liable to no alteration whatever because — as Maestlin falsely interprets it — such a formula of intercalation has been prescribed in it that by means of it the equinox is held fixed on March 21 in such a way that it can never at any time recede from it. This, in fact, can by no means be brought about, so long as a *civil* year composed of whole days, together with an easy and regular manner of intercalation (as is fitting) — and not an *astronomical* year made up of days, hours, and fractions of hours, with an irregular form of intercalation — is to be set before an untrained populace. For who is so stupid and dull, provided he has any tincture of astronomy, as to persuade himself of this, when daily experience

teaches us that not even within a span of four years, because of the six hours omitted each year, can the equinox stand on the same day?

[Margin: That it cannot be brought about that the equinox stay fixed on the same day, on account of the six hours omitted each year.]

[Margin: That the new calendar will remain untouched even if another method of intercalation be instituted, should posterity perhaps discover a different magnitude of the year.]

Rather, the calendar is said to be perpetual and liable to no alteration for this reason: that even if posterity should discover a different magnitude of the year — and therefore have to institute a different rule of intercalation in accordance with it (which we frankly admit can happen, on account of the year's uncertain and unequal magnitude; and it was for this very reason that, in the compendium of the restoration of the calendar, two formulae of intercalation were proposed to the Christian princes and to the mathematicians) — the calendar itself, as regards the disposition of the epacts, will nevertheless remain entirely untouched. This would not be the case had the golden number been left in the calendar, as many wished.

[Margin: That, had the golden number been left in the calendar, thirty calendars would have had to be composed.]

For then, not only if one form of intercalation after another were instituted for different magnitudes of the year, but even keeping always the same form of intercalation — namely, the one we have expounded according to the Alphonsine year — it would have been necessary to change the golden number in the calendar thirty times over, and therefore thirty different calendars (which would be intolerable) would have had to be composed, as will appear below.

[Margin: For what reason the intercalary day, being omitted in the centesimal years — every four-hundredth excepted — squares with the Alphonsine year.]

Therefore, since in this business of the correction the magnitude was chosen from the Alphonsine year — according to which a form of intercalation is instituted for keeping the equinox on the same day, as being more uniform and better suited to the common understanding — let us now explain in what way the omission of the intercalary day in every hundredth year after the year 1600 (every four-hundredth excepted), as was stated at the beginning of this chapter, squares with this magnitude of the year. For since, as we showed in Chapter 3, the equinox in about 134 years anticipates one whole day — so that, if it now

clings to March 21, after 134 years it will have advanced to the 20th — it follows that if the intercalary day were omitted in any given 134th year, by making the year now 132, now 136 (since the 134th year is not a leap year) a common year, that is, one of 365 days, and not a leap year (as it would have to be, were the Julian or ecclesiastical year neither greater nor less than 365 days and 6 hours), the equinox would be brought back to the 21st — just as, by the omission of ten days made in the year 1582 (the days by which it had departed from the 21st toward the beginning of the month), it was restored to that same 21st day. But since this variety, whereby the intercalation would have to be omitted now in some 132nd year, now in some 136th, could easily be forgotten — those years being marked by no conspicuous sign — the *centesimal* years were chosen for this purpose instead, since these are more prominent, and negligence or forgetfulness cannot so easily creep in with regard to them, especially because all the centesimal years are dedicated to Jubilees, and hence are exceedingly well known to and eagerly awaited by the sons of the Catholic Church. For since, as has been said, the equinox in 134 years anticipates one day, it will forestall its own seat in the calendar by three days in the space of 402 years.

Therefore, if in every space of four hundred years three intercalary days are omitted, this order being kept — that the first three centesimals after 1600 (for the year 1600 needs no equation, since in it, owing to the nearness of the year 1582 in which the calendar was corrected, the equinox could not yet have anticipated a whole day) be common years and not leap years, while every four-hundredth is made a leap year — the equinox will be preserved near March 21, exactly as if the intercalary day were omitted in every one-hundred-and-thirty-fourth year.

And so, although in future every fourth year is still, by custom, a leap year, nevertheless the years 1700, 1800, 1900 will not be reckoned leap years (although they are contained within the number of the leap years), but common years; while the year 2000 will be a leap year. In the same way the years 2100, 2200, 2300 will become common, and the year 2400 a leap year — and so on thereafter, always keeping the same order, until it has been ascertained that

the equinox has so departed from March 21 that it cannot return to it, save by a decree of the Supreme Pontiff for an extraordinary intercalation, or for the omission of one or several days in some year, as we showed above. As for the fact that we have neglected those two years which remain over and above 400, no one should wonder at it: for in many thousands of years they can scarcely produce an error of a single day, even if no account is taken of them; and this error, if it

should grow to a whole day, will easily be corrected by an extraordinary intercalation of a single day in some common year — that day then being restored to the year from which it was removed without necessity.

[Margin: A likeness between the intercalation to be applied every four-hundredth year and that applied every fourth year.]

You see, then, that this scheme of intercalation, instituted in the centesimal years, is very similar to the customary form of intercalation every fourth year, and can easily be kept in memory by the people. For just as every fourth year after the birth of Christ always was, and will be, a leap year, while all the other years are common, so after the year 1600 every four-hundredth year will be a leap year, while all the other centesimal years will be common. Likewise, just as among the non-centesimal years only those are leap years that four divides evenly — such as the years 20, 84, 1588, 3416, and so on — so too, after the correction, of the centesimal years only those will be leap years the number of whose hundreds four divides evenly, such as the years 1600, 2000, 2400, 3600, 9600, and so on. For four measures all these numbers of hundreds — 16, 20, 24, 36, 96 — as is plain.

[Margin: An objection: that the equation seems not rightly applied in the centesimal years, since it ought to be made in every 134th year.]

But someone will say: this omission of the intercalary day in the centesimal years is indeed exceedingly well suited to the grasp of the common people and to memory, yet it seems less fit for keeping the equinox on March 21. For since, in order to hold the equinox on the same day, one intercalary day must be omitted for each 134th year, in accordance with the magnitude of the Alphonsine year (as was shown above), it follows that in the equation, which proceeds by centesimal years, in the first centesimal the just and legitimate equation is anticipated, through the omission of the intercalary day, by 34 years; in the second centesimal, by 68 years; and in the third centesimal, by 102 years. And this does not seem to keep the equinox in its seat, but rather to drive it from it.

[Margin: A resolution of the objection: that the equation applied in the centesimal years does not obstruct the intercalation which ought to be made in every 134th year, but rather perfects it.]

Nevertheless, if we are willing to consider the matter a little more attentively, we shall understand that by this our equation — supposing the magnitude of the year were indeed exactly what the Alphonsine tables give us — the equinox is kept more correctly in its seat than if the equation were made in every 134th year. And this is plain as follows.

[Margin: That the equation applied in the centesimal years preserves the equinox on the same day in the very same way as it is preserved by the intercalation every fourth year.]

Let us suppose, for example, that the equinox falls in some year on March 21, six hours before sunrise — that is, at the midnight preceding. This posited, after $33\frac{1}{2}$ years it will forestall that midnight by six hours, and will fall about sunset of the 20th, since in 134 years it anticipates one day, and therefore in $33\frac{1}{2}$ years a quarter of a day, that is, six hours. And after 67 years, for the same reason, it will be found at midday of the same 20th. And after 100 years, at sunrise of the same 20th. Thus, after a span of 100 years, the equinox has receded from the seat first assigned to it, toward the beginning of the month, by three-quarters of a day, that is, by 18 hours. Now if in this hundredth year the intercalary day be not removed, but the 134th year be awaited, this recession toward the beginning of the month will grow to 24 hours, and the equinox will fall before the 20th, at midnight, before the day is removed in the 134th year; and this will always happen in every span of 134 years. But if in the first hundredth year the intercalary day be subtracted — even though the anticipation of the equinox has not yet grown to a whole day, but only to 18 hours — the equinox will be carried from sunrise of the 20th to sunrise of the 21st, and will stand six hours toward the end of the month from the point first assigned, and not 18 hours toward the beginning of the month. Then, in the second centesimal, when the equinox has first reached midday of the 20th, it is restored, by the subtraction of the intercalary day, to midday of the 21st, and stands 12 hours from its first seat. And in the third centesimal, when the equinox has now reached sunset of the 20th, it is recalled, by the removal of another day, to sunset of the 21st, and stands 18 hours from its first seat. Thereafter this distance is gradually diminished, until in the fourth centesimal it has been reduced by 18 hours (since in every hundredth year the equinox forestalls its seat by 18 hours), and therefore comes to rest once more at its former place, that is, at midnight before the 21st — in which case, at that hundredth year, the intercalary day is not omitted, but intercalated in the usual manner.

You see, then, that if one day were removed in every 134th year — which perhaps might seem to not a few to be expedient — the equinox would always be receding toward the beginning of the month from the seat assigned to it, so that this recession, near the 134th year, would grow to almost a whole day; whereas by our equation, instituted in the centesimal years, the distance of the equinox from its first seat cannot come to be 24 hours, but at most 18 hours. And therefore the

equinox is more correctly kept at the 21st if the equation is made in the centesimal years, than if the 134th year be awaited.

[Margin: That the equation applied in the centesimal years preserves the equinox on the same day in the same manner as the intercalation every fourth year.]

Add to this that our equation, applied in the centesimal years, not only conforms — as was said before — to the customary quadrennial method of intercalation, but the ratio in both is exactly the same, as regards the preservation of the equinox in the same seat. For just as in the first year after the leap year the equinox slips toward the end of the month by six hours; in the second, by 12 hours; and in the third, by 18 hours, on account of the six hours omitted in each of the common years; and finally in the fourth, by the intercalation of one day near the beginning of the year — without waiting for the full 24 hours to be completed — it is restored to the same seat: so too, in every space of four hundred years it comes about, if the first three centesimals be made common and the fourth be a leap year, exactly as is clearly established from what has just been said.

[Margin: That the Arabs, in the equation of the lunar year, follow almost the same method of intercalation.]

And what of the fact that the Arabs follow almost the same method of intercalation in the equation of the lunar year? For they never wait until a whole day is made up from the omitted hours; but whenever, from those hours, a number greater than 12 is composed, they institute an intercalary year, adding one day to the lunar year of 354 days — which they call an embolism — so that, namely, the lunar year may be equalized. On this matter one should read Campanus [Campanus of Novara] in the *Greater Computus* [*Computus maior*], and Paul of Middelburg [Paulus Middelburgensis], Book 2 of his *Paulina*. But that it may be more clearly perceived that no more convenient way of equalization, and none truer to fact, could be entered upon than the one we have explained in this chapter, we shall bring forward the arguments — or rather the cavils — of Maestlin against this method of equalizing the solar year. But first, in the following chapter, a few things must be explained somewhat more

carefully; namely, the whole period of the anomaly of the equinoxes and of the inequality of the years, according to the hypotheses of Nicolaus Copernicus. For from this it will most clearly appear both that the formula of equation we have prescribed is most apt, and that Maestlin, in attacking it, was thoroughly crafty and malicious.

ON THE PERIOD OF THE ANOMALY OF THE EQUINOXES, AND OF THE INEQUALITY OF THE YEARS, FROM THE DOCTRINE OF NICOLAUS COPERNICUS.

CAPVT VI.

Since, in order to overturn from the foundations the formula for equalizing the solar year explained in the immediately preceding chapter, Maestlin rashly asserts that the vernal equinox, if that formula be applied, will — not so very many thousands of years hence — slip from March 21 all the way to the 27th, and will return no more to the 21st; and adds, moreover, that the mean equinox at this time falls on March 23, and that the true equinox can depart from the mean, both by advancing and by receding, through a whole four-day span: I judge it worthwhile, in order to expose the madness of this prophet, and in keeping with the purpose of the *Apologia*, to set briefly before the eyes in this chapter both the true and the mean equinoxes throughout the whole period of the anomaly of the equinoxes and of the inequality of the solar years — drawn from the Prutenic tables, which among nearly everyone are now almost the only ones held in esteem, and out of which Maestlin fashioned and drew forth all his arguments. For thus the slanders which he here employs against the equation of the equinoxes prescribed in the new calendar will all be made manifest, and it will be made plain that the vernal equinox, with our formula of intercalation applied, does not recede from March 21 by so great a span as he — falsely, and out of a mere spirit of contradiction — prophesies that it will depart.

[Margin: When the period of the anomaly of the equinoxes began before the birth of Christ.]

And since Nicolaus Copernicus — from whose doctrine the Prutenic tables are constructed — laid it down that the period of the anomaly of the precession of the equinoxes is completed in a span of 1717 Egyptian years, which make up 1715 Julian years (those we now use) and 302 days, we shall divide this whole circuit and revolution into 8 chief parts: first indeed into four quadrants, and then each quadrant into two equal parts, so that the time of each of these eight equal parts embraces 214 years, 174 days, and 15 hours.

[Margin: In what year of Christ the period of the anomaly of the equinoxes is to begin again.]

Now this revolution of the anomaly had its beginning 63 completed years, 227 days, 20 hours, and 42 minutes before the birth of Christ; because in so great an interval of time the equal, or mean, motion of that anomaly completes the arc assigned by Copernicus for its Radix at the beginning of the years of the Lord — which Radix contains 0 signs, 6 degrees, 40 minutes, 27 seconds, 28 thirds, 6 fourths. If, then, to the 63 years, 227 days, 20 hours, and 42 minutes elapsed before the Nativity of Christ [CHRITI: for CHRISTI] there be added the 1715 years and 302 days of the whole circuit and revolution, we shall find that the same anomaly begins its revolution anew in the year of the Lord 1653, on the 25th of March according to the new calendar — whereas the beginning of the prior revolution had fallen on the 18th day of May, had the Julian year then been in use. Hence, by the continual addition of 214 years, 174 days, 15 hours, there will be gathered the years in which the same revolution occupies those eight parts of the whole period — as has been done in the appended scheme, in which two complete revolutions are set out.

[The lower half of printed page 24 is blank; the "appended scheme" (formula) referred to falls on the following leaf.]

Apologia against Maestlin — Book One, Chapter Six (continued)

On the period of the anomaly of the equinoxes [De periodo anomalix æquinociorum]

The following table gives, for each of the eight parts of the revolution, the years of the Lord in which the anomaly of the equinoxes stands there, together with the day and month of the equinox.

| When the anomaly of the equinoxes stands in each of the eight parts | Years of the Lord elapsing [Anni Domini Labentes] | Days [Dies] | Months [Menses] |
|---|---|-------------|-----------------|
| At the beginning of the revolution, or of the first quadrant. | 63. ante Christum natum expleto. & 1653. | 18. / 25. | Maij. / Martij. |

| When the anomaly of
the equinoxes stands
in each of the eight
parts | Years of the Lord
elapsing [Anni Domini
Labentes] | Days
[Dies] | Months [Menses] |
|--|---|----------------|------------------------|
| At the middle of the
first quadrant. | 151. & 1867. | 8. / 18. | Nouemb. /
Septemb. |
| At the end of the first
quadrant, and the
beginning of the
second. | 366. & 2082. | 2. / 13. | Maij. / Martij. |

[Margin: When the true and the mean equinox occur in various ways [multifariam], and when they differ most from one another, and when their difference is intermediate.]

The true and the mean equinox, therefore, do not differ from one another but occur together, whenever the anomaly stands both at the beginning of its revolution and at the end of the second quadrant — that is, at the beginning of both the first and the third quadrant — because at those points the equation of

the precession is nil. The difference between the two equinoxes is greatest, however, when the anomaly, in the course of its revolution, occupies the end of the first quadrant and of the third, because then the equation of the precession is greatest. Finally, the difference between the two equinoxes is intermediate at the middle of each quadrant, because then the equation of the precession is in an intermediate state. And so, over the whole period of the anomaly, the two equinoxes coincide twice, twice the one differs from the other to the maximum, and four times their difference stands at a certain intermediate value.

[Margin: The tropical year, when it is longest, when shortest, and when it stands intermediate and at the mean.]

Again, the tropical or turning year is longest when the anomaly stands both at the beginning of its revolution and at its end — namely at the start of the first quadrant and at the end of the fourth. It is shortest when the same anomaly is set at the middle of its revolution, that is, at the end of the second quadrant or at the beginning of the third. At all the other positions of the anomaly it is intermediate. The cause of this variation is this: the precession of the equinoxes for a single year — which must always be subtracted from the equal sidereal year (which contains 365 days, 6 hours, 9 minutes, 39 seconds, according to the view of Thebit [Thābit ibn Qurra] and Copernicus [Nicolaus Copernicus]), so that the magnitude of the tropical year may be left — is slowest both at the beginning and at the end of its revolution, and fastest at the middle. At all the other positions it stands in an intermediate state between the slowest and the fastest of its motion. And so, over the whole period of the anomaly of the precession of the equinoxes, the year is once longest, once shortest, and more often intermediate — yet in such a way that the magnitudes of any two years equally distant on either side from the shortest year are always equal to one another. All of this is contained in the following table, where the time of the true and the mean equinox — when the anomaly stands near those eight positions of the whole revolution begun in the year 1653 — is computed together with the magnitude of the turning year.

The computation, moreover, has been made for the leap years nearest to the years in which the anomaly stands at those eight positions (except for the year 1653, which is the beginning of the revolution and to which the reckoning has been reduced, although it is not a leap year), because in leap years a smaller variation is observed in the Sun's entry into the first degree of Aries. The reckoning has also been fitted to the equation of the restored Calendar, which advances over 400 years. We have, however, neglected the hours in the equinoxes, since it seemed sufficient if the day of the spring equinox were

recorded with the time before or after noon, or midnight, the hours being omitted.

In the year 1653, when the revolution of the anomaly of the precession of the equinoxes begins:

The equinox — {true / mean} — will occur: {20 March after midnight [post med. noc.] / 20 March after midnight [post med. noc.]}

The tropical year will contain 365 days, 5 hours, 55 minutes, 37 seconds, 40 thirds [tertia]. This was also the magnitude of the year in the year 63 before the birth of Christ our Lord; and according to it the equinox anticipates one day in nearly 329 years.

In the year 1868, when the anomaly will be near the middle of the first quadrant of its revolution:

The equinox — {true / mean} — will occur: {21 March after midnight / 20 March about sunrise [circa ortum Solis]}.

The tropical year will contain 365 days, 5 hours, 53 minutes, 52 seconds. This magnitude of the year also suits the time around the year of the Lord 151; and according to it the equinox anticipates one day in nearly 231 years.

In the year 2080, the anomaly holding nearly the end of the first quadrant and the beginning of the second of its revolution:

The equinox — {true / mean} — will occur: {21 March about sunset [circa occasum Solis] / 20 March after noon [post mer.]}

The tropical year will be 365 days, 5 hours, 49 minutes, 16 seconds, 29 thirds. This magnitude of the year squares also with the time around the year of the Lord 366; and according to it the anticipation of the equinox by one day requires about 134 years.

In the year 2296, when the anomaly will be engaged around the middle of the second quadrant of its revolution:

The equinox — {true / mean} — will occur: {21 March after noon [post merid.] / 20 March toward sunset [sub occasum Solis]}.

The tropical year will be 365 days, 5 hours, 44 minutes, 46 seconds, 59 thirds. This magnitude of the year existed also around the year of the Lord 580; and according to it the equinox anticipates one day in about 94 years.

In the year 2512, when the anomaly will be near the end of the second quadrant and at the beginning of nearly the third — that is, at the middle of the whole revolution:

The equinox — {true / mean} — will occur: {21 March before noon [ante mer.] / 21 March before noon [ante mer.]}.

The tropical year will be 365 days, 5 hours, 42 minutes, 55 seconds, 7 thirds. This magnitude of the year existed also around the year of the Lord 795; and according to it, for the equinox to anticipate one day, about 84 years are required.

In the year 2724, the anomaly occupying nearly the middle of the third quadrant of its revolution:

The equinox — {true / mean} — will occur: {20 March after midnight [post med. noc.] / 21 March about sunset [circa occasum Solis]}.

The tropical year will be 365 days, 5 hours, 44 minutes, 46 seconds, 59 thirds. This magnitude of the year existed also around the year of the Lord 1009; and for the anticipation of the equinox by one day it demands about 94 years.

In the year 2940, the anomaly being engaged near the end of the third quadrant of its revolution and at the beginning of nearly the fourth:

The equinox — {true / mean} — will occur: {19 March after midnight [post med. noc.] / 21 March about sunrise [circa ortum Solis]}.

The tropical year will be 365 days, 5 hours, 49 minutes, 16 seconds, 29 thirds. This magnitude of the year squares also with the time around the year of the Lord 1224, and it demands about 134 years for the equinox to be able to anticipate one day.

In the year 3156, when the anomaly will be nearly at the middle of the fourth quadrant of its revolution:

The equinox — {true / mean} — will occur: {20 March about sunset [circa occasum Solis] / 21 March about noon [circa merid.]}.

The tropical year will be 365 days, 5 hours, 53 minutes, 52 seconds. This magnitude of the year existed also around the times of the year of the Lord 1438; and according to it, for the equinox to anticipate one day, about 231 years are required.

In the year 3368, when the anomaly will hold nearly the end of the whole revolution — that is, will be engaged at nearly the end of the fourth quadrant:

The equinox — {true / mean} — will occur: {21 March about noon [circa mer.] / 21 March about noon [circa mer.]}

The tropical year will be 365 days, 5 hours, 55 minutes, 37 seconds, 40 thirds. This magnitude of the year agrees also with the times around the year of the Lord 1653 and around the year 63 before the rising of Christ; and it requires about 329 years for the equinox to anticipate one day. And if the year always had this magnitude, the customary bissextile intercalation would have to be omitted every 329 years.

[Margin: Confusion among Christians, if the equation of the equinox were established according to the true motion.]

From all this it can readily be gathered how great a confusion would arise throughout the whole Christian world if the equation of the equinox were to be established according to the true motion — since it would very often have to be changed within the space of 1715 years, on account of the varying magnitude of the year, which in that span continually grows and shrinks in a remarkable way. This matter would throw all the Churches into great anxiety, since they would perpetually be in doubt whether in this or that leap year the intercalary day ought to be omitted, and would be compelled to canvass the opinions of astronomers on the question year after year — which would be utterly absurd, and, down to the present time, unheard of.

At the same time it is established that no equation of the solar year which prescribes that the intercalary day be omitted at fixed and settled times (such as ours is, laying down that in every four-hundredth year three intercalary days be removed) can in every respect square with the true motion of the Sun, so as to keep and preserve the equinox forever on 21 March. And this for the following reason: according to the true motion, now more years, now fewer, are required for the equinox to advance by one day in the Calendar toward the beginning of the month.

[Margin: That the equinox, according to the equation of the new Calendar, does not recede far from 21 March, and that therefore it was rightly instituted with reference to the Alphonsine year, which is intermediate.]

It is established, besides, that the spring equinox, throughout the whole period next to come, which will begin from the year 1653, will diverge from its seat no farther than the space of one day on either side, even though the equation of intercalation of the new Calendar be applied — since the magnitude of the Alphonsine year, which is in a way intermediate between the greatest and the least, has rightly been assumed as that from which the formula of intercalation is prescribed. For that formula is both consistent and uniform, and most accommodated to the common understanding, and it so holds the equinox around 21 March — on which its seat has been fixed — that it cannot recede far from it, but now precedes it, now follows it, and now finally falls upon the 21st day itself.

[Margin: That the difference between the true and the mean equinox does not reach one day and a half [diem vnum cum semisse].]

Lastly, from what we have said it is gathered that, over one whole period of the anomaly of the equinoxes, the discrepancy between the true and the mean equinox never grows to two full days — indeed, not even to a day and a half — a thing which nevertheless Maestlin [Michael Mästlin], by calumny, asserts can amount to a whole four-day span. And in this he manifestly conflicts with the doctrine of Copernicus, which he himself so greatly parades. This too will become plain as follows: the true and the mean equinox occur together, at the same moment of time, whenever the equation of the precession is nil — the anomaly of the precession holding the beginning, or the middle, or the end of its circuit and revolution; but the one is most distant from the other when that same equation is greatest, which indeed happens whenever the anomaly is engaged at the beginning of the second and of the fourth quadrant of its revolution.

[Margin: The true and the mean equinox: when they occur together, and when they are most distant from one another.]

[Margin: When the mean equinox precedes, or follows, the true.]

Further, when these two equinoxes differ from one another, the mean precedes and the true follows — that is, the mean equinox falls before the true — whenever the equation of the precession of the equinoxes is subtracted from the mean precession, so that the true precession may be gathered; which indeed happens whenever the doubled anomaly is less than a semicircle, that is, when the anomaly of the equinoxes has not yet [completed] the second quadrant...

[Continuation of the *Apologia adversus Maestlinum*, Liber Primus, Caput VI. The opening words complete a sentence carried over from the previous leaf.]

it will have completed the [second] quarter of the whole period. The mean equinox, by contrast, comes later and precedes the true one; that is, the true equinox falls before the mean whenever the equation of the precession of the equinoxes [aequatio praecessionis Aequinoctiorum] is added to the mean precession in order to make up the true precession. This happens whenever the doubled anomaly is greater than a semicircle — that is, when the anomaly has already passed the second quarter of the whole period.

[Margin: How great the maximum difference is between the true and the mean equinox.]

The one equinox precedes or follows the other by just so much time as suffices for the Sun to traverse, by its true motion, the arc of the equation of the precession of the equinoxes. Now the greatest equation of the equinoxes never exceeds $1^{\circ} 11' 22'' 30'''$, and the Sun's daily motion is at no time less than $0^{\circ} 56' 46''$. It follows that the interval between the true and the mean equinox never exceeds 1 day and 6 hours, or a little more — even when the Sun's motion is slowest and the equation of the equinoxes is greatest. I am therefore utterly amazed at what came into Maestlin's head when, as if dreaming, he said that the difference between the two equinoxes could swell to a whole four days, and that the mean equinox in this present age falls on 23 March — whereas in fact, from the year of Christ our Lord 1653 all the way to the year 3368, through one entire revolution of the anomaly, it never passes beyond the 21st, as is plain from the calculation given above.

[Margin: What deceived Maestlin, so that he thought the mean equinox could stand a whole four days away from the true one.]

But I think I can see the source of this Tübingen mathematician's error. He reasoned about the mean and true equinox just as we are accustomed to reason about the mean and true conjunction or opposition of the luminaries. For he supposed that the equinox becomes "mean" only when the line of the mean [motion reaches the] mean equinox — just as the mean conjunction or opposition of the Sun and Moon occurs when the lines of the mean motions of the Sun and Moon are conjoined or opposed. [He imagined that,] when the Sun stands at the point of the mean equinox, then between the point of the true equinox and the Sun's body the true equinox would be distant from the mean by a greater interval than the prostaphaeresis [prostaphaeresis], or equation of the precession of the equinoxes, allows — although even so this distance could not reach a whole four days, since the Sun's equation never amounts to two degrees.

[Margin: When the mean equinox occurs.]

But this lynx-eyed mathematician has deceived himself. For the case of the mean equinox is one thing, and that of the mean conjunction or opposition of the luminaries is another. The mean equinox occurs as soon as the Sun first reaches the point of the mean equinox, as the astronomers teach. Erasmus Reinhold [Erasmus Reinholdus], that most skilled astronomer, writes thus in the Prutenic Tables [tabulae Prutenicae], Precept 22: *There is no doubt that the Sun completes the vernal equinox when it still precedes the first star of Aries by just so great an interval as lies between the very true intersection of the two circles — the equinoctial and the oblique — and that same star.* That this is to be understood of the mean vernal section as much as of the true one is gathered from Precept 10, where he calls the difference between the mean and the apparent equinox the prostaphaeresis, or equation of the equinoxes, whose maximum is 7 first-minutes and 22 seconds together with the half of one second [7' 22½"].

Josephus Moletius [Giuseppe Moletti], a celebrated astronomer, teaches the same thing far more clearly in the Gregorian Tables [tabulae Gregorianae], Canon 13, where he says: *The apparent equinox occurs when the Sun enters the point of intersection of the apparent Ecliptic and Equator; the mean equinox, however, when the Sun enters the point of intersection of the mean Equator and the Ecliptic. And so the true equinox occurs when the Sun precedes the first star of Aries by as great a space as is the true precession of the equinoxes for the given time; the mean equinox, however, when the Sun precedes the first star of Aries by as great an interval as is the arc of the mean precession. The difference between these two equinoxes is the time corresponding to the prostaphaeresis of the equinoxes.*

Therefore the mean equinox does not occur when the line of the Sun's mean motion occupies the point of the mean equinox — as Maestlin wrongly maintains — but when the Sun itself holds that point, as we have set forth. For if the mean equinox came about when the Sun by its mean motion held the mean vernal section, the true and the mean equinox would not always occur together at the moment when the prostaphaeresis of the equinoxes is nil — something that would happen only very rarely, namely only then, when the true motion of the Sun does not differ from the mean. But this conflicts with all the astronomers, since they all teach that the mean equinox occurs together with the true one whenever the prostaphaeresis of the precession of the equinoxes is nil.

But let us carry the calculation forward to some further years, so that it may appear how rash and thoughtless Maestlin has been in this too, when he asserted that, if the method of equating the solar year prescribed in the new Calendar were kept, the equinox would slip back before the year of our Lord 15000 to 27

March. He asserted this not from any calculation, but from the false opinion by which he judged that the mean equinox falls on 23 March, and that the true equinox can stand a whole four days away from the mean. For it is from this, and from nothing else, that it is inferred that the true equinox will at some time slip back to 27 March, and will advance as far as the 19th. But that this is false, the calculation of the following years [demonstrates] clearly [and evidently].

[Margin: Why Maestlin thought the true equinox would slip back to 27 March.]

The vernal equinox, then, will occur [as follows]:

| Years of the Lord | Days of March | Time before or after noon, or midnight |
|-------------------|---------------|--|
| 4709 | 21 | after midnight |
| 5084 | 21. | before midnight |
| 5209. | 23. | about midnight |
| 6004 | 23. | about sunset |
| 10020. | 23. | after midnight |
| 15002. | 21. | after midnight |
| 15004. | 20. | about midnight |
| 15102 | 21. | after midnight |
| 15202. | 21. | after midnight |
| 15604. | 22. | after midnight |
| 15804. | 23. | about midnight |
| 20004. | 20. | after noon |
| 20005. | 20. | after midnight |

Where, I ask, in these 13 years down to the year 20005, is there an equinox on 27 March? I certainly find that it does not stand more than two or three days, and a little more, away from the 21st — even when the true equinox is computed from the Prutenic Tables with the formula of the Gregorian Calendar's equation always applied. But evidently Maestlin, simple fellow, supposed that none of us would go so far as to sift his prophecy about the equinox slipping to the 27th by reckoning it out into future ages — the same objection he earlier made to us about the feast of Easter of the year 1582 on the basis of earlier ages.

[Margin: That the new Calendar is perfect, even if the Prutenic Tables should still agree with the true motions after 10000 years.]

And if, after so great a span of years, it should be established that the Prutenic Tables still agree with the celestial motions (supposing the world is to last so long — lest our adversary rashly cry out, as he does more than once and most tiresomely, that we do not believe in a Last Day, just as one who extends a calculation to some future years is not thereby asserting for certain that the world will last through all those years) — who does not see that our method of intercalation, the mean method, fitted to run its course through 400 years, is the most suitable, if in the ecclesiastical computus something regular and even is to be set before the untrained people for determining the moveable feasts from the motions of the heavens (which we have shown at length to be altogether necessary in Chapter iiii and in other places)? For with this formula of intercalation applied, the equinox of its own accord returns to 21 March, even though, on account of the unequal magnitude of the solar year, or the unequal precession of the equinoxes, it is wont sometimes to stray a little to and fro from the 21st. And so with the fullest right this equation of ours may be said to keep the equinox about 21 March.

[Margin: Why the equinox, by the equation of the new Calendar, more frequently falls in the heavens after 21 March than before.]

Yet it must not be passed over here that the equinox, if the equation established for the Alphonsine or mean year be applied, more frequently follows 21 March than anticipates it, and recedes by a greater interval from that same 21st toward the end of the month than toward the beginning of the month. For since, as has been said, the shortest year requires 84 years for the anticipation of the equinox by one day, whereas the Alphonsine or mean year demands 134 years, and the longest 329 years, it comes about that the speed with which we forestall the equation owed to the longest year is greater than the slowness with which we prolong the equation answering to the shortest year. Hence, when the year is nearly at its longest, the equinox will indeed be rolled forward to the later days of the month, because more intercalary days are omitted by our equation of the mean year than the situation requires; and when the year is nearly at its shortest, the equinox has slipped back to the earlier days of the month, because not so many intercalary days have been retained by our equation of the Alphonsine year (days that ought to have been retained on account of the shortest year) as were previously omitted, which the longest year prescribed should be retained.

[Margin: That any equation other than the one established for the mean year drives the equinox further from its proper place than it should.]

But so that it may appear yet more evidently that the mean year had necessarily to be assumed in order that a fixed and determinate equation might be prescribed — not the shortest or the longest year, as we set forth in Chapter v — we have computed the equinox of the year 5084, applying the equation now with the span of 84 years (which the shortest year requires for the anticipation of the equinox by one day), now with the span of 329 years (which we said the longest year demands for the equinox to anticipate by one day). And so, if the former equation be used, there will be removed from the year 5084 (counting in those ten days that were taken away in the year of the correction) altogether 51 days, and the equinox will fall on about 7 April — that is, 17 days after 21 March. But if the latter equation be applied, there will be removed altogether only 21 days, and the equinox will fall on about 7 March — that is, nearly 14 days before 21 March. Yet with our equation applied, the days removed up to that year will be 36, and the equinox on 21 March will fall about before midnight, as is plain from the recent calculation of the 13 years above. You see, therefore, that by the equation of the shortest year the equinox recedes from 21 March toward the later part of the month by too great an interval, while by the equation of the longest year it slips back too far toward the beginning of the month from that same 21st,

back. This, however, the equation of the mean year keeps and guards about that same 21st day. In the same way, the calculation will show that an equation set up for any year other than the mean drives the equinox from its proper seat — the seat we fixed for it on 21 March — further than it should.

[Margin: That the equation established for the mean year cannot [?] be faulted.]

This is clear from the magnitude of the year of 365 days 5 hours 53 minutes 2 seconds 37 thirds, which requires about 207 years for the anticipation of one day, and which might therefore seem apt for an equation to be prescribed to it, since 207 years hold almost the middle place between 84 and 329, which we said were the shortest and the longest year required for the equinox to anticipate by one day in the Calendar. Let us see, then, whether this equation keeps the equinox at 21 March as well as ours does. The calculation shows that in the year 2940, when 18 days will have been removed in all by this equation, the equinox occurs on 18 March about sunrise — that is, before 21 March; and in the year 10020, when by the same equation 51 days in all will have been taken away, the equinox occurs on 1 March, also about sunrise — 20 days and more, that is, before 21 March. Let us now compare these equinoxes with the equinoxes of the same years derived from our equation, and we shall find that ours (even though the 134 years by which the equinox anticipates one day according to it do not hold the middle

place between the 84 and 329 years that the shortest and longest year require for the anticipation of one day) drives the equinox from its proper seat by so much smaller an interval: since in the year 2940 it does **not** exhibit the equinox on 19 March after midnight, while in the year 10020 the same equation throws it back to 23 March after midnight. From which it follows that our equation can be justly faulted by no one, since no more suitable one can be brought forward — unless someone should say that an uneven and irregular equation, varying with the varying magnitude of the year, ought to be applied at various times: which we long ago excluded from the usage and custom of the Church.

MAESTLIN'S ARGUMENTS AGAINST THE METHOD of equating the solar year, to be applied in each set of four hundred years, and their solutions.

CHAPTER VII.

[Margin: Maestlin's malice and fraud in attacking the equinox of the new Calendar.]

Although, from what we have written in the two preceding chapters, everything that can be brought against the Gregorian correction of the year (so far as concerns the restoration of the equinox to 21 March and its preservation there) can be refuted with little trouble, nonetheless — so that the truth may appear more fully — we shall in this chapter dissolve all the arguments of our adversary, the many arguments he has fabricated to overthrow the new Calendar from its foundations and has gathered together into a book of his own. And first, it must not be concealed that in this matter he acts most maliciously: for in certain years he ascribes to the following day, before noon, an equinox that the Prutenic Tables place on 22 March after noon; and, on the other hand, an equinox that the same tables set on 21 March before noon he throws back into the preceding day, after noon — so that by this device he may falsely persuade those ignorant of astronomy that the equinox recedes from 21 March, by our equation, more than is right. And he shows himself no less a trickster when, to make it appear that the equinox falls not on the 21st of March but on the 20th, he adapts his calculation to bissextile [leap] years, in which necessarily, on account of the added intercalary day, the equinox occurs earlier than in common years. This appears in the years 1584 and 1596 (to pass over others), in the former of which he asserts that the equinox falls on 20 March at the 10th hour after noon, and in the latter at the 9th hour after noon of the same 20th day. But this does not conflict with our equation. For since these years are bissextile, it is no wonder that in them the

equinox occurs on the 20th and not the 21st. Indeed (when it presses so), we may rightly say, in the ecclesiastical manner, that in both cases the equinox is to be assigned to the 21st, since it occurs in the night preceding the 21st — that is, after sunset of the 20th. But setting these matters aside (from which, however, one may gather how solid his arguments are, resting as they do on so tricky a reasoning), let us come to the thing itself.

[Margin: Maestlin's first argument, from the inconstancy of the astronomical tables.]

First, then, Maestlin inquires, with anxious and worried mind, which astronomical tables this Gregorian emendation of the Calendar follows — the Alphonsine or the Prutenic. And after concluding from certain conjectures that the Prutenic have been used, he cries out and clamors that the very foundations of the new Calendar are shaky, on the ground that the calculation of no tables published down to this day agrees exactly with the heavens, since they are uncertain and call for some vigorous restorer; and he affirms that this is the common complaint of all mathematicians. From this he concludes that the new Calendar is in no way perfect or perpetual, and therefore will not endure through all ages without some change, since its foundation is by no means firm.

[Margin: Maestlin's second argument, from the equinoxes of the present years.]

Next (for it pleases me to set out all this trickster's arguments together, so that all his sleights of hand may alike vanish), he attempts to overturn our equation from its foundations by various examples, pertaining now to the present years, now to future and past ones. For concerning the present years he writes thus:

But why say much? Why does the author of the Calendar, the Pontiff, and their follower boast of the perfection of this Calendar, when the experience of the present years, in which we now live, convicts it of falsehood? For the omission of the 10 days has not brought back

[it] brought the equinox back completely to 21 March. For in our own time it falls, in every intercalary year, not on the 21st but on the 20th of March. Thus in the year 1584 it fell on 20 March at the tenth hour of the night; in 1596 it will be at the ninth hour of the night of the same day; in 1612 at the eighth hour, and in 1624 at the seventh hour after noon of the same 20th day of March, and so on in succession. Indeed, after the year 1640 the equinox will climb — even in those years that are the first after the intercalary ones — to the same 20th day of March. And so from that year on, the equinoxes of all the bissextile years, and of all the years next following them, will fall on 20 March, right up to the year 1700.

And although by the omission of the intercalary day of the year 1700 some of this will be restored, that restoration is merely the settling of a shifted balance [versurae solutio]. For the equinoxes of the bissextile years, and of the years first after them, will indeed be brought back, by the deletion of the intercalary day of the year 1700, to 21 March; but in this very way the equinoxes of the second and third years after the bissextiles will be shifted to 22 March. And this permutation and alternation cannot be removed, until at last — not so very many years afterward — the equinoxes of all the bissextile years, and of the three years following them, abandon the 21st of March altogether. So far is it [from being possible] that any remedy can be devised for this difficulty by the new Calendar, even if everyone were to heap all their learning into a single pile.

And in this way Maestlin [Michael Mästlin] tries to show that the correction of the Calendar does not suit the present years.

[Margin: 3. Maestlin's third argument, from the equinoxes of future years.]

That our equation [aequatio] by no means corresponds to future years, he thinks he can conclude as follows. In the year 1600 the equinox falls on 10 March, at half past the eighth hour after noon; in 1900, on 9 March at half past the eighth hour after noon — according to the day-numbers of the old Calendar. The true anticipation, therefore, is only one day. But the new Calendar, over these 300 years, passes over a whole three-day span — namely those three days, the intercalary days of the years 1700, 1800, and 1900. Therefore, according to its numbers, this equinox will fall (with the 10 remaining days also removed) in the year 1600 on 20 March, but in the year 1900 on 22 March. Moreover, in the years following after 1900 this same divergence has greater increments: as in the year 1905, which is the first after some bissextile year, the equinox falls on 23 March, at the 2nd hour of the morning. In 1906, which is likewise the second after some intercalary year, the equinox will occur on the 23rd, at the 8th hour before noon. And in 1907, the third after a bissextile, the equinox will be on 23 March, at the 2nd hour after noon. You see, then — you who exalt this Calendar to the stars with such praises, and celebrate a fixed seat in it for the equinox — that this equinox is too slippery for you to be able to hold it fixed on the 21st of March.

Then, after nearly a page and a half, he closes this second argument in this fashion: "You mathematicians, then, defenders of the new Calendar — do you still say, along with the Pontiff, that the day of the equinox is fixed? Are 19 and 23 March the same as the 21st?"

[Margin: 4. Maestlin's fourth argument, from the equinoxes of past years.]

Finally, he strives to persuade us that the correction of the Calendar does not even agree with past years, in these words: "Astronomical calculation (of which the computus of the Calendar is a part) has this property, that it can be extended to preceding times as well as to following ones, reckoned from the epoch of its founding. For this reason, from the calculation of the celestial motions built up out of the observations of these last 2000 years only, we compute the motions of the heavenly bodies backward, right up to the first creation of things, no otherwise than if the calculation of the motions had already then been so constructed." And he adds shortly after: "In just the same way, the use of this Calendar can be accommodated to past as well as to coming years. For this is its intention, and it can be nothing else, than that — just as it now performs what has to be performed — so it would already long ago have performed the very same thing, had it only begun to be used earlier. But how the matter stands, even this one example shows. In the year 1200 the true vernal equinox was on 12 March at 6 p.m.; but the day that in the old Calendar was the 12th would then, in the new, have been the 19th. For of the 10 days omitted in the year 1582, the three later ones fall to those 400 years between the years 1200 and 1600. Therefore the day of the equinox there was by no means the 21st, but the 19th of March."

[Margin: 5. Maestlin's fifth argument, against the removal of the ten days that was carried out.]

Our adversary goes on, and strives to confirm in these words that the removal of the ten days in the year 1582 does not agree with the times of the Council of Nicaea: "In particular, here is singularly to be noted the gross and ridiculous — not to say shameful — aberration of the new Calendar. The foundation and origin of the correction is the authority, or the decree, of the Council of Nicaea. Who here will not say that the calculation of the new Calendar ought to agree in the highest degree with the time of that Council? For if it has any perfection, that perfection must surely be of such a kind that, had it been known to the Fathers of that Council and received by them, it would from that time on, gradually, at the appropriate places and times, have removed those 10 days. And had this been done, there would now be no need for those 10 days to be collected into a single heap and eliminated all at once over this whole span of time; rather the Calendar itself, of its own accord, would have offered all these things just as they are now displayed. And in this way one and the same state — namely the one that obtained at the time of the Nicene Council — would have remained unchanged in a continuous series. But behold what its constancy is! The 10 days have been thrown out all at once, precisely because they were not removed one by one,

from the Council of Nicaea onward, at the appropriate times. But what are those places and times at which this elimination was neglected? Surely one must hold that this [omission] failed to be carried out on ten separate occasions, seeing that it grew to 10 days. One must also be able to note those very places in the new Calendar most exactly. Yet if this new calculation (mark this, you mathematicians!) is drawn back to the said years in the same proportion in which it is handed down to be continued into future years, by no means 10, but only 9 days are shown to have needed eliminating up to now — namely the intercalary days of the years 1500, 1400, 1300, 1100, 1000, 900, 700, 600, and 500. For the remaining centennial years, namely 1200, 800, and 400, remain bissextile. You see that plainly no place is left over for exterminating a 10th day. Therefore the equinox there must have been not on the 21st, but on the 20th of March — against which, however, both experience and your own so-often-repeated testimony cry out. Behold what the perfection of your work is, how elegant its concord with experience and with the observations!"

These are the chief arguments by which Maestlin — that new mathematician fallen from the sky, who despises and counts as nothing all mathematicians whatsoever, past, present, and to come — supposes he has utterly overthrown the equinox of the new Calendar, both because it has not been rightly restored to 21 March and because it cannot stay constantly on the same day. Since these attacks assail the equinox of the new Calendar on many heads, we shall answer them one by one, and shall also refute several other cavils of his against the same equinox, which he has scattered here and there throughout his examination.

To begin, then: all these arguments of his sin in many ways, and have no force whatever against

[Margin: That Maestlin's arguments err, in that they assume the true equinox.]

the new Calendar. For in them the true motion is always assumed, and the true equinox — whereas it has been abundantly and sufficiently shown above that, in the business of correcting the Calendar, only the mean and uniform motions are to be considered; indeed, that even the mean motions being set aside, something regular and even should rather be employed, something fitted, like a kind of cycle, to the grasp of the common people, provided only it does not stray far from the truth. This our adversary himself, compelled by the truth, admits, when — after examining the equinox of several years from the true motions — he writes thus:

[Margin: Maestlin's testimony that in the ecclesiastical year the subtleties of the astronomers are not to be observed.]

"Should anyone wonder why I dispute about these astronomical subtleties in the civil or ecclesiastical year, let him know that I — and with me all sound and prudent mathematicians — freely confess that these astronomical subtleties in truth contribute nothing to the civil year; and therefore we hold that none of the civil authorities or of the common people should be burdened with them. Just as Julius Caesar, that most prudent emperor, was unwilling in his reform of the year to stir up any disturbances with subtleties; nor did the Fathers of the Council of Nicaea — who furnished the occasion for this new Calendar (though beyond their own intention, as I have shown in my *Dialexis*, chapter 6) — give any admonition about these subtleties. Indeed, we ourselves know that whenever the Church has lapsed into subtleties of this kind — such as once existed between the Roman and the Alexandrian Church concerning the term of Easter, before the nineteen-year cycle was restored by Dionysius [Dionysius Exiguus], a Roman abbot, around the year of CHRIST 532 — it has been horribly disturbed, with the greatest offense to the weak. On the other hand, it is unknown to no one that in the meantime, from the year 532 up to this new Calendar, because these subtleties were set aside, uniformity and a never-sufficiently-praised concord (as regards the present use of the Calendar, together with the celebration of Easter) were preserved throughout the whole Christian world. It is therefore not pleasing to me to raise here any question about these subtleties; I would rather leave them to the school of astronomy. But the author of the Calendar, in his Canons, and the Pontiff, in the Bull, and the other collaborators of theirs whom the Pontiff summoned to the city in great number (as he himself testifies in the Bull), do occupy themselves with these subtleties, and are not ashamed to boast on their account about this new Calendar of theirs — that it is so perfect that it will never be subject to any change: which surely they understand of the astronomical subtleties observed by them with unwavering rigor. For if anything were found wanting in these, it is certain that such splendid praise, destined to endure forever, could by no means belong to this Calendar of theirs. Hence Pope Gregory XIII does not shrink from subjecting the whole Christian world, by the subtleties of those canons, under threat of the wrath of Almighty God himself and of his blessed apostles Peter and Paul, exactly as if a great part of eternal salvation were reposed in these subtleties. For this reason these very subtleties must here be examined by me, so that it may be shown how foolish — indeed how impossible — it is to wish to bind the civil year to subtleties of this kind: because not a correction, but a confusion of the Calendar must necessarily follow from it. Whence it becomes manifest how unhappily this very thing has been attempted in the new Calendar."

[Margin: How true the statements are in Maestlin's immediately preceding testimony.]

In these words he has said much that is true (lest we seem to disapprove even if he has for once said something good), and much very aptly for the use of the new Calendar; but much also that is false, by calumny, as is his habit, he has pronounced. Most truly indeed he said that in the civil and ecclesiastical year astronomical subtleties are not to be pursued, and that none of the civil authorities or of the common people should be burdened with them — which we too freely admit. For throughout the whole Calendar, setting aside the true motions, we have consistently employed only the mean motions, or rather cycles, most easily grasped by the civil and common folk. This is clear both from the [reckoning] of the year, since it is established to the magnitude of the mean year, and from the Cycle of Epacts [Cyclus Epactarum], which is inscribed in the Calendar for indicating the new and full moons — since it always assumes equal (mean) motions of the Moon and its conjunctions and oppositions with the Sun. So that from this alone it may be inferred that Maestlin is rashly and inconsiderately inveighing, with such force and such ferocity, against the new Calendar, when he attacks it with astronomical subtleties which he himself, together with us, judged should be rejected in the business of the Calendar.

[Margin: Maestlin's rashness in attacking the Calendar.]

He also truly affirmed that neither did Julius Caesar follow them [these subtleties] in his reform of the year (just as neither did we follow them in this restoration of the Calendar), nor did the Fathers of the Council of Nicaea give any admonition about them. From which it follows that he is rash, and impudent in his *Examen*, who — in order to parade the subtlety of his own wit — for that reason alone disapproves the Calendar, because it does not in every respect answer to the subtleties of the astronomers, that is, to the true motions.

Finally, it is true, what he says: that from the time when the abbot Dionysius restored the nineteen-year cycle of the golden number — or, to speak more truly, inscribed in the Roman Calendar the cycle framed by Eusebius of Caesarea [Eusebius] in the times of the Council of Nicaea and expounded by Theophilus of Alexandria [Theophilus], making no change in it except so far as the method of computation required, on account of the differing starting-points of the calendars — from that time, I say, because the subtleties of the true motions were set aside, the greatest concord in the celebration of Easter was preserved.

[Margin: How often Easter was celebrated contrary to the mind of the Council of Nicaea, in the few years before the restoration of the Calendar.]

And would that this same peace and concord those who have departed from the [Catholic] Church might resolve to enter upon and to preserve together with us — namely, that, leaving aside that exact calculation of the true motions, they should follow, along with the Catholic Church, the mean, or (so to speak) cyclic, motions: just as those early Christians most gladly, out of zeal for peace and unity, accepted the cycle inscribed in the Calendar by Dionysius, even though very often, by that cycle, Easter was celebrated otherwise than the Fathers and Councils had decreed (which could not be otherwise, on account of the imperfect condition and nature of the cycle); seeing that in this our age — to pass over the illegitimate Easter feast-days of earlier times — before the correction of the Calendar, in any nineteen-year span, six times Easter, on account of the anticipation of the equinox alone, was not rightly celebrated by that cycle. This happens whenever these six golden numbers — 3, 6, 8, 11, 14, 19 — occur. For the 14th moons of all these, by the institution of the Fathers of the Nicene Council, were Paschal and fell in March. For the golden number 6 placed its 14th moon on 11 March, on which the equinox occurred; while the other five golden numbers had their 14th moons set after 11 March and before 21 March, on which the Church had placed the equinox, and therefore were suitable for the celebration of Easter — yet the Church rejected them all as useless, because they showed the 14th moons before the time of its equinox, that is, before 21 March.

I pass over in silence the errors that were committed in celebrating this same Easter, because the golden numbers were showing the new moons a whole four days, and more, later than they ought — from their right course

[Margin: Unless the Calendar had been corrected, Easter after the year 2624 would always have had to be celebrated against the decree of the Council of Nicaea. The necessity of the correction of the Calendar, against Maestlin.]

deviating [from their right course]. So much so that from the year 1500 to the year 1582 — that is, in the span of 83 years, up to the point at which the Calendar was corrected — 54 Easter feast-days were not rightly celebrated, and only 29 rightly. And had the Calendar not been restored, in the remaining 17 years up to the year 1600 Easter would have been wrongly celebrated twelve times, and rightly only five times. From the year 2624 onward, moreover, no Easter would any longer have been legitimate, but all would have had to be celebrated against the sanctions of the Pontiffs and of the Council of Nicaea. All of which has been most carefully collected by Paul of Middelburg [Paulus de Middelburg], in book

12 of the *Paulina*. So that here too the necessity appears of this correction, instituted by Gregory XIII — lest, that is, the Church slip into such foul errors and disturb, or utterly dissolve, that concord and confession of the faithful.

[Margin: That Maestlin, out of hatred for the Roman Pontiff, urges that the old Calendar be retained. In what respects this same immediately preceding testimony of Maestlin is false.]

Who, then, can doubt that Maestlin is trying to persuade the Christian people — out of hatred for the Roman Pontiff rather than out of zeal for peace and concord — to explode the new Calendar and retain the old? For far greater concord and agreement in celebrating Easter would be preserved under the new Calendar than under the old, if only Maestlin, that seditious peacemaker, and the other heretics were willing to lay aside their inveterate anger against the Supreme Pontiff and accept it. For, as will clearly appear from what follows, so many and such shameful errors cannot be committed in the celebration of Easter under the new Calendar.

I have set out what Maestlin said truly, though not with a sincere mind; now let us see what he said falsely (the things he spoke from the heart). First, then, it is false, what he denies — that it is pleasing to him to raise here any question about the subtleties of the astronomers — since he does nothing else in his whole examination but harass the new Calendar, on this ground alone: that it does not entirely agree with those subtleties. Next, lest he seem more a malicious dissembler of his own design than an accuser of another's, he falsely charges the author of the Calendar, the Pontiff, and the other astronomers summoned by the Pontiff for the emendation of the Calendar, with occupying themselves with these subtleties. For had we wished to pursue subtleties of this kind, we would neither have established the equation of the solar year according to the mean magnitude of the year, nor have inscribed the Lunar Cycle in the Calendar, but would have prescribed that all these things be observed from the astronomical tables.

[Margin: That Maestlin falsely asserts that in the new Calendar the astronomical subtleties are observed. What the Pontiff intends in the excommunication against those who do not accept the new Calendar.]

Finally, it is false, and far removed from the truth — indeed a most impudent lie — that Gregory XIII, in the Bull of the Calendar, subjects the whole Christian world, under threat of the wrath of Almighty God, to the subtleties of the astronomers, exactly as if a great part of eternal salvation were reposed in these subtleties. For in that whole Bull you will find not a word making mention of

these subtleties; and the Pontiff strikes with anathema only those who are disturbers of peace and concord, and contumacious against his edict — whose standard-bearer and leader Maestlin professes himself to be. And in the preserving of this peace a great part of eternal salvation is reposed — not in the subtleties of the astronomers — since, without the obedience owed to the Roman Pontiff as the Vicar of Christ and universal shepherd of the whole Church, and which alone safeguards peace among the faithful, eternal salvation is to be hoped for by no one. But this argument — that the Roman Pontiff could by right, under pain of excommunication, command that the new Calendar be observed — has been most learnedly treated by Johann Busaeus [Johannes Busaeus] in his Apologetic disputation for the Gregorian Calendar against Jakob Heerbrand [Iacobus Heerbrandus], Maestlin's associate in the same disease of impiety and slander; to whom we refer the reader.

[Margin: Maestlin, unwilling, favors the new Calendar.]

Since these things are so, there is no reason, Maestlin, for you to undertake to examine these very subtleties, in order to demonstrate how foolish, and even impossible, it is to wish to bind the civil year to subtleties of this kind, because not a correction but a confusion of the Calendar must necessarily follow from it. For of our own accord and with a willing mind we grant and concede to you that it cannot be that the civil year should be bound to the subtleties of the astronomers, and that the greatest disturbance would arise in the whole Christian world if these were applied to the Calendar. It was for this very reason that we neglected them, and were content rather with the mean motions, or cycles. In this matter no one can rightly reprehend us — not even you yourself as judge, if you are willing to abide by your own judgment. Meanwhile we give and render you huge thanks, that you have so vigorously favored our cause with these words of yours, so that you appear to have been one of those who took part in the restoration of the Calendar. But now let us come to the solutions of the arguments.

[Margin: Solution of Maestlin's first argument. That the Prutenic Tables were employed in restoring the Calendar. That the inconstancy of the astronomical tables does not stand in the way of the perfection and perpetuity of the new Calendar.]

As for what concerns Maestlin's first argument: I admit that in this business of correction the Prutenic Tables [tabulae Prutenicae] were employed, as being in this age more celebrated and more probable. Hence it came about that — since they teach that sometimes more years than 134 are required for the equinox to anticipate by one day in the Calendar, and sometimes fewer — the equation of

the solar year was established according to the mean magnitude of the year, exactly as if in each span of 134 years the equinox advanced by one day toward the beginning of the month; so that by this mean [rate] that excessive slowness and swiftness might in some way be compensated.

Nor indeed does the inconstancy or variety of the tables stand in the way of this. For, as we said in Chapter 5, the perfection and perpetuity of the Calendar does not consist in this: that the equinox be so fixed and stabilized on 21 March that it can never be moved from it, by our own or by any other equation whatever — since this can in no way come about, both on account of the mutability of the tables (whichever we might in the end choose to follow), and also because a certain middle, even and regular way, fitted to the grasp of the common people, has to be chosen, as reason requires, and has been observed in the emended Calendar. Rather, the perpetuity of the Calendar consists in this (as was said above): that in it the Cycle of Epacts is arranged with such artifice that nothing in it need ever be changed in future ages, but the Calendar will remain wholly untouched — even if, by the intercalation or omission of one day or of several, by decree of the Supreme Pontiff, the equinox will have to be recalled to 21 March, should it happen to have slipped too far from it, so that it cannot return of its own accord, without this remedy. Of this perpetuity of the Calendar we shall treat more fully in Book 2, Chapter 4; where we shall also show by what method the new moons too, and the full moons, can, if need be, be corrected, with no change at all made in the Cycle of Epacts that is inscribed in the Calendar.

There is this further point: as was said in the previous Chapter, the equinox, according to our equation and the Prutenic Tables [tabulae Prutenicae], returns to the 21st day even after 20000 years, though in the interval it wanders now to the 23rd, now to the 19th. And this is no absurdity, since no equation of the solar year, being even and uniform, can keep and retain the equinox on the 21st day itself, as we showed in the same Chapter.

[Margin: Solution of Maestlin's second argument.]

There is therefore no need (as he claims) for the author of the Calendar to bend all his strength to this task, nor for us its defenders to join our forces together, and to reconcile this Elogium of the Pontiff — which boasts that the reformed Calendar answers to every magnitude of the year — with this even anticipation of ours over 400 years, lest the true vernal equinox slip out of our hands like an eel. For it is with such words that Maestlin [Michael Mästlin] boldly challenges us all, and, like a braggart soldier, empty-headedly boasts that he has led a triumph over us, reproaching us more than once that, whatever we contrive, we cannot hold

fast the equinox which we fixed with great labour on 21 March. There is no need, I say, for such straining of the mind, because with no trouble the equinox will either stay in its seat, or at least, if it should ever depart from it, will be restored to it — provided that the remedy of which we have spoken is applied at fitting times, by the authority of the Roman Pontiff; and this will very rarely happen. All of which is easily apparent from what we have said.

[Margin: The restoration of the equinox to 21 March, by omitting the intercalary day in the year 1700, is not the settlement of a *versura* [a paying of one debt with another loan], as Maestlin falsely alleges.]

WRONGLY, next, does he try to prove by Maestlin's argument that the equinox, through the removal of 10 days, and our equation, do not agree in the present years. For the years 1584, 1596, 1612, 1624, which he sets down as examples, are all bissextile [leap] years. It is no wonder, then, that in them the equinox, on account of the added intercalary day, advances from the 21st toward the 20th of March; although with full right it can still be assigned to the 21st day, since in all those years it falls after sunset, namely at 10, 9, 8, and 7 hours after noon — as we also maintained above at the beginning of this Chapter. And indeed it is known to all astronomers that at least two days must be allotted to the equinox, on account of the common and bissextile years, even if the intercalation applied every fourth year answered most exactly to the solar year. So that from this too it is plainly evident that Maestlin, in his examination, is a sycophant, and is (as the proverb says) looking for a knot in a bulrush [seeking difficulty where there is none]. Most rightly, therefore, as regards the present years, was the equinox recalled to 21 March. That after the year 1640 the equinox will move ever more and more toward the beginning of the year (for in the year 1645, which is not bissextile but the first after a bissextile, it will fall on 20 March at 12 hours 24 minutes after noon; and in the year 1697, which is the first after a bissextile, it will likewise fall on 20 March at 9 hours after noon) — this wonderfully confirms the omission of the intercalary day to be made in the year 1700, so that in this way, in the years after the bissextile, the equinox may be drawn back to the 21st day.

[Margin: The equinox, on account of the inequality of the year, departs from the 21st day in both directions.]

NOR indeed is this restoration (as Maestlin slanderously claims) merely the settlement of a *versura*. For although in future years after 1700, on account of this same removal of a day, the equinox of the years that are second and third after the bissextiles will be shifted to the 22nd and even to the 23rd day (which Maestlin also raises in his third argument), this cannot be blamed on our

equation, but on the inequality of the solar year. For since, as was shown above, the equation of the year must be even and regular, so that it can be grasped by everyone, whereas the magnitude of the year is unequal, now greater, now lesser — it comes about that, if an equation is applied answering to the mean magnitude of the year (which alone is even, as the use of the Church requires), the equinox cannot perpetually be kept on 21 March, but from the 21st day rolls down now to the 22nd and 23rd, now climbs up to the 20th and 19th.

[Margin: When the equinox rolls down from the 21st day to the 22nd and 23rd, and when it returns to the 21st.]

It will roll down to the 22nd and 23rd day when the magnitude of the year is greatest, and therefore more years than 134 are required for the anticipation of one day — as happens in our own century, and will continue to happen right up to the year 2080, because throughout all this time the turning year [annus vertens] is greater than the Alphonsine [Alphonsine year], as is clear from the preceding Chapter. But from there it will return to the 21st day when the turning year becomes smaller than the Alphonsine, since then the equinox will require fewer than 134 years for the anticipation of one day. But from the 21st day it will advance to the 20th and 19th of March when, on account of the least magnitude of the year, it has returned to the 21st day, and the year is found to be still smaller than the Alphonsine year. And as soon as the year becomes greater, the equinox will draw back from the 19th and 20th to the 21st.

[Margin: When the same recedes from the 21st day to the 20th and 19th, and when it returns from there to the 21st.]

The 21st of March, then, is assigned to the equinox, holding as it were the middle place between the 23rd day and the 19th [Margin small type; day-number worn but the body reads 19], out to which the equinox runs, so that it can scarcely run further, not even in the space of very many centuries, but from there of its own accord returns to the 21st day, as was shown in the previous Chapter. And so this, Maestlin, either is not a *versura* at all, or, if it can in any way be called a *versura*, must be reckoned not the *versura* of a bankrupt spendthrift for ruining the family estate, but the *versura* of a prudent head of household for establishing the family estate — a device undertaken to gain time.

[Margin: The 21st of March, assigned to the equinox, holds the middle place between the 23rd day and the 10th [recte: 19th], out to which the equinox can run, since from there it returns of its own accord to the 21st day.]

BUT if someone should object that from this excursion of the equinox to the 23rd of March and to the 19th it comes about that Easter can be celebrated both in the last month and in the second — which seems absurd: I answer, first, that this can happen only very rarely. For even if the equinox rolls down to the 22nd or 23rd, Easter will never on that account be celebrated in the last month, unless Epact [epacta] xxi or xxii is in use — which rarely happens, since Epacts xxiii and xxii do not come into use in every nineteen-year cycle, but out of all 30 cycles of the Epacts in only eight. For among the remaining 22 cycles, Epact xxiii is found alone in ii cycles, and Epact xxii in another ii, as will afterward be evident from the expanded table of Epacts. There is this further point: that this error, whenever it occurs, is very often removed by the Dominical letter [littera Dominicalis], so that Easter is celebrated after the equinox, even though those Epacts are in use and cast their 14th Moons into the twelfth month. By the same reasoning, although the equinox may advance to the 20th or 19th of March, Easter will never on that account be thrown back into the second month, unless Epact xxiiii or xxv is running — which too will happen rarely.

[Margin: Rarely does Easter fall into the last or the second month under the new Calendar.]

NEXT, suppose both do happen: even so, this is not new or unusual in the Church of GOD, since this very thing must necessarily have occurred in the times of the Council of Nicaea itself, when the Decree concerning the right celebration of Easter was established — or rather confirmed — as we demonstrated above in Chapter 5. Indeed, even if the solar year needed no equation, but the equinox were always fixed on the 21st and 20th of March,

[Margin: It is nothing new that Easter should sometimes fall into the last or the second month.]

CAPVT SEPTIMVM [Chapter Seven, continued]

and the old Calendar were retained, Easter would still necessarily be thrown back into the second month whenever, the equinox falling on 20 March (which in bissextile years can necessarily happen, as we showed above), the 14th Moon fell on 20 March. Nor indeed will anyone justly blame the Catholic Church for this — that it sometimes celebrates Easter in the first or second month, when the reckoning of the cycle, or the day fixed for the equinox, so requires — since she has been freed from the yoke of the Mosaic Law. For did not Easter, before the correction of the Calendar, very frequently get thrown back into the second month, and into the fourth week of the first month, and yet no one dared on this

account to condemn the Church? It is enough that the Church celebrate Easter according to the decrees of the Fathers and the Councils, keeping to a certain fixed day of the equinox (even if it does not always fall on that day), and applying the Lunar cycle to find the 14th Moons — although these 14th Moons sometimes differ from the true motion.

[Margin: Easter is necessarily celebrated sometimes in the second month, on account of the two days that the equinox requires, whether the old Calendar be retained or the new one adopted.]

I, indeed, together with very many other most learned men, was always of this opinion: that the equinox ought not to have been corrected by the Church, even though it had run out as far as 11 March, if it had checked its course there, and had begun of its own accord — with no equation applied — to return to the 21st day. How much more, then, ought we now to be content with this equation, to be applied every four-hundredth year according to the mean magnitude of the year — the easiest of all — which lets the equinox be moved from its established seat, that is, from 21 March, by no more than an interval of two or at most three days?

[Margin: There would have been no need to desire a correction of the Calendar, if the equinox, having advanced to 11 March, had begun of its own accord to return to the 21st, with no remedy applied.]

NOW if it should happen that the equinox altogether leaves 21 March — whether by advancing toward the end of the month or toward the beginning, so that it cannot return to its appointed seat — it has been said often enough by what method, through an extraordinary intercalation or omission of a few days, by the edict of the Supreme Pontiff, it is to be restored to 21 March. And this is not repugnant to the perpetuity of the Calendar, as we have said.

HERE, moreover, this advance and retreat of the equinox has place only in the Prutenic Tables, and was foreseen beforehand by those who amended the Calendar by order of the Supreme Pontiff — as can be understood from the compendium of the new method of restoring the Calendar sent to the Christian Princes, in which both the even and regular equation, accommodated to the mean magnitude of the year, and the uneven, irregular one drawn from the doctrine of Copernicus [Copernicus], were described: the former [placed] first, as easier and better suited to the use of the Church, as was said above. But if perhaps the Prutenic Tables are not so certain as most astronomers hold, but the Alphonsine Tables answer the Sun's motion more correctly [as most astronomers affirm], then this advance and retreat of the equinox will have no place, but

through a long series of ages it will remain in its assigned seat. And then again it will have to be restored to that seat, if it should ever depart from it, just as we said above.

[Margin: The recession of the equinox from the 21st day has its place in the Prutenic Tables.]

You see, therefore, Maestlin, how easily, by an extraordinary intercalation or omission of an intercalation, a remedy can be provided under this new Calendar for this difficulty about the advance and retreat of the equinox, if need be — even without all men (as you demanded) heaping all their learning into one pile. Would that a remedy could as easily be provided for your mind! Then you would surely understand that our Calendar needs no other remedy.

FROM what has just been said, an easy answer can be given to the third argument — that is, to the examples of future years, by which the adversary tries to prove that the equinox slips forward from 21 March to the 22nd and 23rd. For it must be said that this necessarily has to happen, on account of the unequal magnitude of the solar year, to which no uniform and regular equation can answer in every part, as we showed in the preceding Chapter. For since at this time we are nearly at the greatest magnitude of the year, what wonder is it that the equinox in the years 1800 and 1900 rolls down toward the end of the month, since our regular and uniform equation removes more intercalary days than the greatest magnitude of the year requires? And although in these years the true equinox, on account of our equation, falls after 21 March, this is nevertheless not absurd, since — following the Prutenic Tables, which in the centennial years roll the equinox down toward the end of the month — it returns afterward to the same 21st day. For in the years 2080, 2296, 2512, and others, the equinox will again be found on or about the 21st day, as is clear from the preceding Chapter (which we have also indicated more than once above).

[Margin: Solution of Maestlin's third argument. Why the equinox in the coming centennial years slips down from the 21st day toward the end of the month.]

MOREOVER, the reader, I think, must be warned at this point (as I have often noted above) that my adversary, in all those years, is employing the true equinox from the Prutenic Tables — which does not bear on the matter we are treating; for we in our equation are speaking of the mean equinox according to the Alphonsine calculation. And it has been shown above that this mean equinox in general nearly always stays midway in the advance and retreat of the true equinox (from the doctrine of Copernicus) from the 21st of March toward the

beginning of the month and toward the end. That we are speaking of this [mean equinox] is plainly clear from the equation to be applied every four-hundredth year, which suits only the Alphonsine year, and which through many ages will so keep the true Copernican equinox near the 21st day that it cannot wander far from it — which is quite enough for the use of the Church, that the feast of Easter may be celebrated at the same time throughout the whole Christian world.

[Margin: The equinox, reckoned by the mean year, uniformly anticipates by one day in 134 years, on Maestlin's own testimony.]

NOR indeed did Maestlin fail to recognize this — so much so that, if he had wished to judge the Calendar with a calm and tranquil mind, he could not but have thought the same and persuaded everyone of it (had not his hatred of the Roman Pontiff drawn him away from this counsel), namely, that with the old one exploded they should adopt the new Calendar. For not far from the beginning of Chapter 1 he writes as follows:

A tropical year [annus tropicus] is indeed 365 days, 5 hours, 49 minutes [Scrup.], 16 seconds — that is, it falls short of a quarter of a day, or of six hours, by about 10 minutes and 44 seconds. Hence in 134 years the anticipation amounts to nearly one whole day, and in 402 years to nearly a full three days [triduum].

See how Maestlin, compelled by the force of truth, asserts the very thing we do — namely, that the equinox, according to the mean magnitude of the year (which is even), always advances evenly toward the beginning of the month, so that in any span of 402 years its advance takes in a full three days.

FOR the rest, driven on by his perversity, he returns to his old bent, and knowingly and willingly rushes headlong, when he at once adds that we ought, setting aside the mean, to consider the true [equinox] this year — which can by no means be granted in ecclesiastical and political matters. For he himself laid down above that no one among the politicians and common folk should be burdened with astronomical subtleties; and we have shown fully enough in Chapter 4 that the Church ought to employ mean rather than true motions in the celebration of the movable feasts.

[Margin: The Church does not sin against God because its equinox sometimes stands one or two days off from the true one, since it returns beyond, to the 21st day — just as the same Church did not sin before the correction in placing on the 21st day what fell on the 11th. When it is a sin not to celebrate Easter at the proper time, and when it is not.]

NEXT, after nearly one page, he speaks thus as well:

But if someone should object that the celestial motions are bound by such equations that whatever is taken away in one place is restored in another, so that by a mutual compensation it will come about that the true vernal equinox returns to 21 March: I answer that, although equations must be added in one place which are subtracted in another, their restitution is nevertheless not completed except after some hundreds, or even thousands, of years, as will be said shortly; and in the meantime, throughout all that time, the Church would be polluted with sins — and indeed most absurd ones (for so are errors of this kind named by the author of the Calendar, in Canon 2) — since, persuaded by Pope Gregory XIII, she would falsely believe that the vernal equinox — not the mean, but the true — always keeps its fixed seat on 21 March. Hence it will come about that Easter (as will be shown below), even though it be observed according to the prescription of the Calendar, will nevertheless not be celebrated at the fitting time. Here, then, once again behold the certitude of your Calendar.

By these words Maestlin again clearly testifies that our uniform and even equation compensates the slowness and the swiftness of the anticipation of the true equinox according to the unequal and irregular year. So that it now appears he has waged so fierce a war against the Calendar in vain. For even if this compensation is not made except after some hundreds, or even thousands, of years, yet in the intervening time the Church will not recede far from the true equinox, so that she cannot on that account be said to pollute herself with most absurd sins (with which indeed Maestlin himself is polluted, when he casts these charges at the Church) merely because she departs a little from the true equinox.

[Margin: The Church does not sin against God because its equinox is sometimes one or two days distant from the true, since it returns beyond, to the 21st day: just as the same Church did not sin, before the correction, in establishing on the 21st day what fell on the 11th.]

For never did Pope GREGORY XIII, in the Bull of the Calendar, try to persuade the Christian people that the true equinox, according to the restitution of the Calendar, always keeps a fixed seat on 21 March; he spoke only of the mean, or rather of the equinox of the mean and even year, which cannot be far from the true if the equation of 400 years is applied — since the difference is not great, and scarcely grows beyond two or three days; so that even after 20000 years and more the true equinox will still be found on or about 21 March, as in the Prutenic Tables, provided that equation of 400 years is not interrupted. And indeed, if

before the correction of the Calendar the ecclesiastical equinox, which was thought to be 21 March, was 10 days distant from the true, and yet no one, unless impious, ever said that the Church had sinned against God: who will be so shameless and bold — save Maestlin alone — as to make the Church guilty of sin, if after the restitution of the Calendar the ecclesiastical equinox should sometimes differ from the true by one, or at most two, days, especially since of itself, with no other remedy applied, it returns to its seat?

[Margin: When it is a sin not to celebrate Easter at the due time, and when it is not.]

AS FOR celebrating Easter at an unfitting time, if the Church follows the mean and not the true equinox: I answer that it would indeed be a most absurd sin if someone were deliberately to prescribe the Paschal termini [termini Paschales] in such a way that Easter should be celebrated not at the lawful time, and contrary to the decrees of the Fathers and Councils, when he could arrange them otherwise, and indeed more aptly. But when, from the nature of the Cycles — which ought to agree with the mean motions rather than the true — it sometimes happens that Easter is celebrated not at the lawful time, so that this error cannot be avoided unless the true motions are adopted (which we have shown, in Chapter 4, ought not to be done), then it ought not to be reckoned a sin. For no Cycle can be so perfect and complete in all its numbers as to be able to avoid every error, as we have said above and will explain more clearly in Book 2, Chapter 5. See therefore, Maestlin, the certitude of our Calendar — which you would rather not see — a certitude as great as it can be through the Cycles to which it is necessarily bound; nor will you ever overthrow it, though you bring all your engines to bear.

BUT let us look at yet one passage of our adversary, where he again concedes that the mean equinox, if the equation of 400 years be applied, can keep a fixed seat on some certain day for many centuries. This passage is at the end of the first Chapter, where he inveighs against the new Calendar thus, a man full of laughter:

It is no less ridiculous that the authors of this Calendar, who ought to be mathematicians, compute the motion — or anticipation — of the true equinox no otherwise than as a mean motion. But what, I ask, can be said more absurd in astronomy? Since all astronomical science consists chiefly in this: that it teaches how unequal the true or apparent motions are, and how much they differ from the mean. Wherefore, although the mean equinoxes, hitherto, by this omission of three days [triduum] within 400 years, could perhaps for many ages (yet not for all, as appears in my

Dialexis, Chapter xi, Observation iv, on the second astronomical defect) keep a seat almost fixed on one certain day: yet this affair does not concern the mean vernal equinox, which falls not on the 21st, but on the 23rd of March. Since, then, the authors of the Calendar did not weigh this, they set themselves up splendidly to be laughed at, in that they hallucinate in matters that ought to be known to the beginners of any astronomy. But just as the true equinox can recede from the mean by a whole four days [quatriduum] into the preceding signs (as was said above concerning the year 1200 — for in that year the true equinox was earlier than the mean by four days, namely by as much as the 19th is distant from the 23rd; which is wont to happen whenever both the prosthaphaeresis [prosthaphaeresis] of the equinoxes and the annual anomaly of the Sun are at their maximum, and additive): so, when both will be at their maximum and subtractive (if the world should last so long — although the new Calendar knows nothing of any last day, otherwise it would not continue its Canons to 40000 years after the birth of CHRIST), there again the same true equinox will follow the mean, likewise by four days, and will fall on the 27th day of March. Where here is the 21st of March? By your own praises, you Mathematicians, you seem to have raised your Calendar too high above the stars, so that its equinox, seized by vertigo, nodding this way and that, has at last fallen from its seat — which you fixed as firm for it on 21 March — and slipped down into those other days. Come to the aid, then, of your client, lest by too much erring it utterly delude and shame you, as follows presently. For I add this too, which I would have you consider. In this our century, while the apogee [apogaeum] of the Sun still lingers near the summer solstice, so that the prosthaphaeresis of the annual anomaly — which is owed to its motion on the day of the vernal equinox — is not only additive but nearly maximal: therefore the true equinox itself, on account of the prosthaphaeresis of the equinoxes (now to be added, now to be subtracted), nods from the 21st day and swings back to the 19th and to the 23rd of March. But because of the descent of the apogee toward Libra, it comes about that this additive prosthaphaeresis is gradually diminished, until at length it is wholly annihilated. But when the apogee of the Sun shall have passed the earlier parts of Libra, the same prosthaphaeresis...

(The chapter, Caput VII of Liber Secundus, continues from the previous leaf; these pages carry on within Maestlin's quoted objection and Clavius's reply. The passage opens mid-sentence — catchword from the prior leaf: "-sthaphaeresis.")

...the prosthaphaeresis, which yields to the day of the true vernal equinox, will be increased once again — but under the heading of *subtraction*, and so forth. From this it necessarily follows that the reciprocal shift of the equinoctial day no longer depends on 21 March, but passes over to the 22nd, 23rd, 24th, and up to the 25th of the same month, oscillating from each of these likewise by two days before and two days after. And so it will come about — I speak once more according to the reasoning of the new Calendar, which has no last day — that the true vernal equinox will at last desert 21 March entirely, so that not even by any oscillation will it be able to reach that day again. This will happen around the year of Christ 4700. For although this same equinox will meanwhile spend the greater part of that period outside 21 March, wandering through the 20th, 22nd, 23rd, 24th, and 25th, it will nonetheless still occasionally swing back to the 21st. But once the year 4700 has been reached, its return to 21 March is never again to be expected, until 15000 years after Christ have been completed. Consider once more, you mathematicians, how PERPETUAL and FIXED is the seat of your equinox on 21 March! You see here that for ten thousand years and more it will be found not on the 21st, but on the 22nd, 23rd, 24th, 25th, 26th, or even the 27th of March. And this is still to be so during the very time for which this new Calendar promises itself the most perfect certainty; for I have not yet carried my reckoning so far, but that the Calendar's own author has extended his calculation to far more remote years. So then, you defenders of the new Calendar, you see what an exquisite Calendar you possess — one that, like a stubborn and untamable horse, will neither go forward nor back; nay, one that is caught out as false at the very threshold, since it will neither return, nor is able to return, to its first station as to its native place; in which, moreover, for the 21st day all the rest from the 19th to the 27th are thrust upon you together; and in which the true vernal equinox for the most part falls on those other days, more rarely — indeed, if you examine the whole revolutions of the said anomalies, most rarely of all — on the 21st. What confusion all this brings into the Paschal feast will appear from what follows. You can therefore no longer doubt that you have not only been wretchedly deceived yourselves, but also — that you might not be wretched alone — have by your Counsels and approvals led others, too, to accept this faulty Calendar. But what, meanwhile, of your conscience? Answer, if you can.

Here indeed this Tübingen Thraso, somewhat more cheerful, as though he had won a victory, rages against the Calendar. Yet in this wordy display — if you set aside the few words in which he affirms that the mean equinoxes, by the omission of three days within 400 years, could perhaps for many ages hold a nearly fixed seat on one certain day — good God, how many falsehoods, how many empty and absurd things does it contain! [Margin: It is not ridiculous, but necessary, that the *mean* equinox, and not the *true*, be considered in the Calendar. Maestlin rashly wishes to bind the Church to the true motions.] First: how can it be ridiculous that the authors of this Calendar reckon the anticipation of the equinox after the manner of a mean motion? And, by the same token, how can it be true that in this business of the Calendar the concern is not with the *mean* vernal equinox, when it has been shown by many arguments in Chapter 4 that the Church, in celebrating the solemnity of Easter, employs only the mean motions and sets the true ones aside? Since the authors of the Calendar weighed this, let the adversary see to it that he does not (as he charges *them* with doing) make himself thoroughly ridiculous, in that he blunders over what ought to be plain to any beginner in ecclesiastical computation — namely, that the Church adopts the mean motions, or rather the Cycles, and sets the true motions after them. Let him beware, too, lest he show himself ridiculous and rash, when a man of no worth or judgment presumes to impose laws on the Church, and rashly to cast out from her long-standing custom and possession the Cycles, or the mean motions, and to bind her to the true motions — especially since he himself asserts, as we showed above, that astronomical subtleties in truth contribute nothing to the civil year, and that the Fathers of the Council of Nicaea gave no instruction about these niceties. In which matter, indeed, if he had set his mind on lying, he ought (as the proverb has it) to have kept a better memory.

[Margin: Maestlin falsely asserts that the mean equinox falls on 23 March, and that it can differ from the true by four days.] Next, I do not see from what astronomy this Tübingen Ptolemy has learned that the mean equinox falls on 23 March, and that the true can sometimes be distant from it by a whole four days. [Margin: How far the mean equinox can differ from the true.] For if the difference between the true and the mean equinox is the interval answering to the equation of the precession of the equinoxes [aequatio praecessionis Aequinoctiorum], and this equation, by the Prutenic Tables, never exceeds $1^{\circ} 11' 22\frac{1}{2}''$ [the fraction on $22''$ is small type — reading probable], then the one cannot possibly be distant from the other by $1\frac{1}{2}$ [?] days, as we set forth at length in the preceding Chapter. Therefore, since at this time the true equinox falls on 21 March — indeed, on Maestlin's own testimony, rises to the 20th — the mean equinox cannot fall on 23 March, but necessarily occurs before that day.

Moreover, in the year 1653, which is not very far from the present time, when the anomaly of the precession of the equinoxes begins its period anew, the equation of the precession of the equinoxes will be nil, and therefore both equinoxes will fall together on 20 March after midnight, as we said in the preceding chapter. Where here lies the 23rd for the mean equinox? Are the 20th and the 21st the same as the 23rd? For my part, from the arithmetic I had to learn (for so you jest at us), I cannot recognize one and the same day among these three. But if you have a new arithmetic, please share it with others too, that you may not be the only one to seem wise.

[Margin: Maestlin rashly contends that the equinox can be carried forward to 27 March.] Now, that the true equinox will at some time slip forward as far as 27 March — as you jibe — because, once the Sun's apogee is set in Libra, the equation of the precession of the equinoxes must be subtracted: this I have not yet been able to discover, not even from the calculation of many thousands of years, as is clear from the next Chapter. For what of it? Will not the Sun's apogee stand, in the year 6004, in the 20th degree of Libra, and yet the equinox not pass beyond the limits of the 23rd? Surely the 23rd and the 27th differ greatly. Will not the equinox fall a little after the 23rd, when the Sun's apogee resides in the 10th degree of Sagittarius? [Margin: Why it is not absurd that the Church should sometimes stray from the true equinox after the correction.] But grant that after 4700, down to the year 15000, the equinox altogether deserts 21 March and slides to the end of the month, as you contend: will it not, after that year 15000 — even on your own showing — return to 21 March? And if it seems harsh to you that the Church should stray from the true equinox throughout the whole period that lies between the years 4700 and 15000, remember that before the new Calendar it was a full 10 days — and that around the time of men's offense — away from the equinox; so that it is no wonder if, sometimes after the correction of the Calendar, it differs from it by two, or at most three, days; which indeed happens on account of the unequal progression of the equinox, if the Prutenic Tables tell the truth — although

from this error, too, the Church can easily free itself, should it seem good, if she prescribe that some days be intercalated, out of the ordinary course, into a single year, as we advised above — though this is not necessary, since of its own nature the equinox, after some interval of time, returns to 21 March; which did not happen before the correction.

[Margin: Maestlin's buffoonish mockery concerning the "last day" in our Calendar.] For as to what Maestlin, with more than scurrilous garrulity, has here

rashly blurted out — and elsewhere, too, harps on to the point of nausea — that the new Calendar knows nothing of any last day, because in it the reckoning is extended to 40 thousand years after the birth of Christ: who does not see that these are mere trifles, and that this was put forward by him not so much to overthrow the Calendar as to have something to say? For the new Calendar takes many years and ages into examination, not on account of a last day, but for the sake of the Calendar's perpetuity. Certainly all astronomers teach that their tables are accommodated to many thousands of years, and yet no one has ever on that account said that they believe nothing about the last day of the world. But if Maestlin thinks that the author of the new Calendar acknowledges no last day, because he extends his reckoning over many years, then, by his logic, it will not be permitted to anyone to extend any calculation over 1000 years — indeed, not even over 100, or fewer — since no one would dare to affirm for certain that so many years remain before the last day. Yet let this religious and timid man — whose ears, like those of blessed Jerome of old, the dreadful trumpet of the Last Judgment resounds about — take care not to seem too impudently jesting in so grave a matter; a man who, I rather think, would not have tried to burden the ears of the faithful with so many and so absurd falsehoods, and to disturb the peace of the Church, if he believed that on that last day an account must be rendered to GOD even for idle words. [Margin: Matthew 11.]

Nor, Maestlin — as you insinuate — do we lift the Calendar to the stars, so that there is danger lest its equinox, seized by a vertigo (as you yourself jest, perhaps not without some giddiness of the head), by oscillating this way and that, should at last slip from its seat, which we have fixed firm for it on 21 March. Rather, we adorn it with modest and truthful praises, since in it the equinox is so fixed to 21 March that, at this time and for very many ages to come, it oscillates reciprocally about it (to use your own testimony) as far as the 19th and the 23rd of March — so that, by this observation, 21 March is the middle term between the 19th and the 23rd of March, and is therefore rightly to be retained as fixed in ecclesiastical computation, in which not unequal, but chiefly equal, motions ought to be considered, as is clear from what precedes. See, then, whether it is not you who need people to relieve your vertigo, rather than the Calendar's.

We defenders of the new Calendar, for our part, are not sorry how exquisite a Calendar we have — one such that, like a tamed and gentle horse, it both goes on and advances with no trouble, however the case demands. For it so keeps and guards the equinox, according to the mean magnitude of the year, in the seat we have assigned it on 21 March, that for many ages of years it holds steady, while the true equinox, by the Prutenic Tables, wanders freely to and fro about the

mean equinox. What more could be desired in ecclesiastical computation? For that this conservation of the mean equinox in no way disturbs the Paschal feast, we shall show hereafter. Wherefore — I address you in your own words — there can no longer be any doubt for you (if any soundness remains in you) but that you see you have not only been wretchedly deceived in attacking this praiseworthy work of the Calendar, but also (that you might not be wretched alone) have, by your perverse Counsels and censures, wrongly and unjustly dissuaded others, too, from receiving this amended Calendar. But what, meanwhile, of your conscience? Lay aside, I beg, that inveterate hatred against the Roman Pontiff, and embrace the new Calendar together with the whole Catholic world. For you will find, if you are willing to judge the matter without love, without hatred, and without envy, that the Pontiff's Calendar is not so faulty as you persuade yourself, but that it nonetheless brings its praisers more credit than it brings its disparagers discredit.

[Margin: Solution to Maestlin's 4th argument.] To the fourth argument as well — by which Maestlin tries to show that our equation does not agree with past years — an answer can easily be made from what has been said. [Margin: That the equation of the new Calendar does not correspond exactly in certain past and future years.] For although an astronomical calculation duly established can be extended even to earlier times, our equation, to be applied at every four-hundredth year, cannot on that account square exactly with all past years — just as it cannot with future ones, as we said in the solution of the previous argument. For since our equation is uniform and equal, whereas the progression and regression of the equinox is unequal, owing to the unequal magnitude of the solar year, it can be perfectly in accord with the celestial motions neither when drawn back to past years nor when extended to future ones, as we declared in the preceding Chapter. It is enough that our equation should present the true equinox, whether it is fitted to past years or to future ones — yet in such a way that it presents the equinox not far from the truth. This the equation of the new Calendar entirely accomplishes. For it answers wonderfully to the times of Ptolemy, who flourished around the year of the Lord 130, since it then presents the vernal equinox on 22 March, on account of the 11 days that would have been removed down to the correction — in the years 200, 300, 500, 600, 700, 900, 1000, 1100, 1300, 1400, 1500 (for the remaining centennial years, 400, 800, 1200, would have stayed bissextile) — had our equation then been in use: on which day Ptolemy observed it to occur, very nearly. Again, the same equation most exactly keeps the equinox on 21 March in several future years, namely around the years of the Lord 1655, 2080, 2296, 2512, 2724, 3156, 3368, 15004; at which times we made plain, in the preceding Chapter, that the equinox falls around 21 March.

Rightly, then, is our equation to be said to agree with both past and future years, since its equinox stands, as it were, in the middle of the progression and regression of the true equinox — that is, it falls now before, now after, and now together with it — just as the mean New Moons compared with the true New Moons. Since this is so, it is no wonder that the equinox of the year 1200, which the adversary sets as his example, does not, if our equation is applied, agree in every respect with the true equinox. For it cannot be that a uniform and equable equation, whatever it may be, should exactly answer to the true motion, as was explained in the preceding Chapter. And yet, if we are willing to consider the matter a little more attentively, we shall find that in that year our equinox is little distant from the true one. For the true vernal equinox then falls —

as the Prutenic Tables show, on 12 March at 6 hours after noon, so that it may not undeservedly be ascribed to the 13th. Therefore, if the use of the amended Calendar had been in force at that time, the 13th day would have been the 20th, because, of those 10 days omitted in the year 1582, the three later ones fall to the three centennial years between the year 1200 and 1600. And it is no wonder, nor anything new among astronomers, that the equinox in a bissextile year — such as the year 1200 was — falls on 20 March, if in a common year it falls on the 21st; since the equinox, on account of bissextile and common years, requires two days, as we said above.

[Margin: Solution to Maestlin's 5th argument.] In nearly the same way is Maestlin's fifth and last argument refuted, by which he shows — as he claims — that our equation does not agree with the times of the Council of Nicaea, on the ground that, drawn back to past years, it indicates that the equinox in the times of the Council of Nicaea fell on 20 March, not the 21st, as we assert; inasmuch as only 9 days would have had to be removed up to that time, in the years 1500, 1400, 1300, 1100, 1000, 900, 700, 600, 500, the remaining centennial years 1200, 800, 400 staying bissextile. For we reply, as we replied above, that our equation, being equable and regular, cannot agree to a hair with any and every year, whether past or future, on account of the irregular motion of the equinox; but that it is enough for it to answer to some, and in others to present the equinox little distant from the true one, as we explained a little before.

[Margin: Why the equation of the new Calendar, in certain past and future years, offers fewer days for removal than the case requires, and in others more.] As for the fact that our equation sometimes offers fewer days for elimination than it ought, if it is applied to years drawn back, this should seem no wonder, since at about the midpoint between the birth of Christ and the year of the correction,

1582 — that is, about the year 880, when al-Battānī [Albategnius] lived — the magnitude of the year was the least of all, and consequently the anticipation of the equinox the swiftest. For hence it comes about that in fewer years than 134 — that is, more frequently than our equable and uniform equation requires — the intercalary day would have had to be omitted then, on account of that least magnitude of the year; just as, in the years nearest to come, since the year is nearly the greatest, it would have to be omitted more rarely, if the equation were to answer exactly to the true motion. Since this is not done, on account of our equation, which we have established as always equal and uniform, it follows of necessity that, because the removal of the intercalary day would have to be made too frequently in the years 1700, 1800, 1900, the equinox slips somewhat forward from 21 March toward the end of the month, as we showed above.

[Margin: How the equation of the new Calendar, retracted to the times of the Council of Nicaea, presents 10 days for removal.] Further, it is not altogether true, as Maestlin says, that the equinox, if our equation is accommodated to past years, falls on 20 March at the time of the Council of Nicaea. For if our equation is recalled to earlier years, we shall find that 10 days are offered for removal down to the times of the Council of Nicaea. For in the year 300, from which the year of that Council was little distant, one day too would have had to be removed, had this equation then been in use; and consequently the equinox would be presented, around that time, on 21 March — so that our equation agrees not only with the years in which Ptolemy lived, but also with the times of the Council of Nicaea, which was celebrated not long after Ptolemy's times. Maliciously, then — or at any rate, what he least wishes to seem, ignorantly — did Maestlin act, when he drew our equation back only to the year 500, whereas he ought to have drawn it back to the year 300, which was nearer to that Council than the year 500.

[Margin: That the removal of 10 days was necessary, so that the equinox might be restored from the 11th to the 21st, whether or not the equation yields 10 days for removal down to the Council of Nicaea.] But if the adversary presses that, although the equation, drawn back to past times, removes 10 days down to the year 300 inclusive — which was near the Council of Nicaea — nevertheless, if the same equation had begun from the time of the Council and been extended down to our own times, it would remove only 9 days, as he himself assumed in his argument: it must be answered that this is not absurd, for the reason lately alleged — namely, because in the intervening time the year was at its least. It can also be said that the intercalary day was to be omitted in the year 400, because it was far from the Council — about 80 years distant — so that the equinox might be held in its seat; and therefore that, down to the year 1600 inclusive, 10 days had

to be removed in these centennial years — 400, 500, 600, 800, 900, 1000, 1200, 1300, 1400, 1600 — every fourth centennial (700, 1100, 1500), such as they would have been, remaining bissextile.

But however it may be — whether our equation answers exactly to the year of the Council of Nicaea, or not — it is certain and settled with us that 10 days had absolutely to be removed, so that the equinox might be recalled from 11 March, to which it had advanced, back to the 21st; just as, if it had had to be recalled to the 25th, the day of the Lord's Incarnation (which few desired), 14 days would have had to be removed — even though, from the Incarnation of the Lord down to our own times, the equinox has not anticipated its seat by so many days, since from Ptolemy's observations it is clearly established that at the time of the Incarnation of the WORD of GOD the equinox fell on 23 March.

And let these things have been said against the arguments of Maestlin, which he devised so maliciously and craftily against the equation of the solar year prescribed in the new Calendar. [Margin: A general reply to all the arguments that can be brought against the equation of the new Calendar.] Yet to these, and to all the other objections that can be brought forward, it will be possible to reply, if we say that all his arguments are taken from the true motion, drawn from the Prutenic Tables — which is very unequal and irregular, and cannot be accommodated to any Cycle; whereas our equation rests on the mean motion, which is equal, and on the magnitude of the mean year, which is likewise regular and equable. And so, by its stability and equality, it beautifully and neatly compensates for the unequal and irregular progression and regression of the true equinox, over many thousands of years, so that the equinox of this equation never recedes from the truth by more than two days at most, or a little more — now anticipating it, now following after. And this is enough for the due celebration of Easter, by the Decree of the Church, which, in the reckoning of time, employs and considers, from most ancient custom, motions not unequal but regular — or rather Cycles — the true and non-uniform motions being set aside.

But if perchance, over a long interval of time, it should happen (which we frankly confess can occur, on account of the inconstancy of the astronomical tables) that the equinox of the new Calendar has departed from the truth more than is fair, the true equinox will have to be restored — as has often been said — to 21 March, by an intercalation, or by an omission of intercalation, applied out of the ordinary course; and thereafter either the same formula of equation as before is to be retained, or else another more suited to that time is to be prescribed, according to the judgment of the astronomers — yet in such a way that in the Cal-

[Margin: Why the new Calendar is called perpetual by the Pontiff.]

the Calendar, so far as concerns the arrangement of the Epacts, no change is made. On this account, even though the equinox may at some time need to be restored, or the method of the equation to be altered, the Calendar itself is nonetheless called perpetual in the Pontiff's Bull, and of such a kind that it can be adapted to any magnitude of the year whatever, by means of an interrupted or a varied equation, while the Calendar itself, together with the Epacts, remains meanwhile untouched, stable, and wholly unchangeable — as will be more plainly explained in the eleventh book, in the equation of the Moon.

[Margin: That no Calendar can be constructed in any other way than that in which the Gregorian was constructed, so as to be perfect and perpetual, or long-lasting.]

[Margin: What is required for any Calendar to be called complete and long-lasting.]

Therefore, what argument, in the end, can be devised that would have any force against the Calendar as being perpetual in the sense stated? For although the equation of the solar year may, over a long time, fail to keep the equinox so fixed on the 21st day that it needs no correction, the Calendar ought not on that account to be judged faulty or imperfect; since, with nothing in it changed, the equinox can be corrected without any trouble, by an equation varied in some way, if that should seem good. And certainly no Calendar can be constructed in any other way than the one described, such as to be either perpetual or long-lasting — seeing that everything the astronomers have handed down, subtly and acutely, concerning the magnitude and inequality of the solar year, is uncertain and doubtful, so that concerning no equation of it, whether framed with reference to the mean motion or to the true, can we promise ourselves a constant, perpetual, or lasting truth.

[Margin: That Maestlin, had he wished, could have understood its perfection from the Compendium of the Calendar's restitution.]

But if some equation of the solar year is instituted — together with the lunar cycle laid out through the days of the Calendar — by such an artifice that nothing ever need be renewed in the Calendar, even should some error be detected in the equinox as it is kept in its fixed seat, so that the equation of the solar year must be altered by the method we set forth above: then at last the Calendar itself may rightly and deservedly be reckoned perfect and complete. Of this kind is the new Calendar published by Gregory XIII, Supreme Pontiff, in the year 1582 — as is

partly clear from what has been said, and will appear partly, and indeed much more evidently, from what will be said. Had Maestlin weighed these things with a sincere and untroubled mind, he would assuredly not have poured out so many words and revilings against the new Calendar so rashly. And indeed, had he not been hindered by the utmost malevolence and envy against the Roman Pontiff, he could have understood all this without any trouble from the Compendium of the Calendar's restitution, sent to the Christian Princes, where it is most openly declared that the cycle of the Epacts can be adapted to any magnitude of the year whatever. So much so that, once it is described in the Calendar, and once the method of intercalation is applied in every four-hundredth year, as we have said, together with the equation of that cycle too, of which we shall treat below, the years and months will thereafter so agree with the reckoning of the Sun and Moon that no further variation or disagreement of any moment can arise. And should it ever happen that some discrepancy does arise, the same Compendium plainly testifies that everything can be restored to its own state by the easiest method. For this very reason a double table of the equation of the Epacts was constructed in it: one agreeing with the Alphonsine year, which is mean and uniform, the other answering to Copernicus's year, which is unequal and irregular — so that no one can justly object against us that we did not foresee what might be urged against the Calendar, or did not understand in what sense it can be called perpetual and never liable to any change.

But concerning the defence of the Calendar so far as it pertains to the equinox, enough. It remains for us to defend the Epacts as well, the Dominical letters, and the movable feasts of the same Calendar, against the same Tübingen Mathematician.

Tübingen — Book Two]

QVO PACTO CYCLVS DECENNOVENNALIS annos 19. Solares exæquet.

[In what manner the Nineteen-Year Cycle equalizes 19 solar years]

CAPVT I.

Having dispatched, in the previous book, the matters pertaining to the equinox, it remains for us in this second book to treat of the new moons and full moons, according to the use and custom of the Church, and to dissolve all the adversary's arguments by which he assails the new moons, the fourteenth days of the Paschal moon, and the cycle of the Dominical letters. First, then, let us set out by what reasoning the nineteen-year cycle of the golden number agrees with 19 solar years.

The lunar year, just as we said of the solar year in Chapter V of the preceding book, is twofold: the one civil or political, the other astronomical.

[Margin: The civil lunar year: what it is, of how many kinds, and how great.]

The civil year consists of whole days and is itself twofold: the common and the embolismic. The common year contains now 354 days, now (which rarely happens) 353; the former of these is usually called full, the latter hollow or deficient, and each comprises 12 lunations. The embolismic year, however, contains for the most part 384 days, but sometimes (though more rarely) 383. The former of these too is called full, the latter hollow in the same way, and each is comprised in 13 lunations. Nor can the civil lunar year be arranged or reckoned in the Calendar otherwise than by whole days, any more than the solar year can; the reason for which we have set forth abundantly in Chapter V of the preceding book. For the same reasoning of the solar year applies to the lunar.

[Margin: The astronomical lunar year: what it is and how great.]

The mean or equalized astronomical lunar year — for concerning the true one, since it is quite unequal and variable and belongs to the astronomers' province, nothing need be said here — comprises, beyond whole days, some hours and fractions of hours.

[Margin: The magnitude of the lunar month according to the mean motion.]

Thus the common year of 12 lunations contains 354 days, 8 hours, 48 minutes, 38 seconds, 12 thirds, nearly; while the embolismic year of 13 lunations contains about 383 days, 21 hours, 32 minutes, 41 seconds, 23 thirds. For a single lunation,

that is, a lunar month, reckoned by the mean course — the interval of time from one mean new moon to another — comprises 29 days, 12 hours, 44 minutes, 3 seconds, 11 thirds, nearly, according to the Prutenic Tables, which today are held to be more reliable.

[Margin: The magnitude of the lunar month according to the computists, greater than is right.]

This magnitude of the lunar month differs little from that which Ptolemy and Nicolaus Copernicus have handed down to us, and which is described in the Alphonsine Tables — so that I greatly wonder where the computists can have found the magnitude of a single lunar month to be 29 days, 12 hours, 44 minutes, 3 seconds, 3 thirds, when all astronomers make it greater. From the magnitude of the lunar month that we have established, it follows that half a lunar month comprises 14 days, 18 hours, 22 minutes, 1 second, 36 thirds; and a quarter of the same lunar month, 7 days, 9 hours, 11 minutes, 0 seconds, 48 thirds.

[Margin: The magnitude of the civil lunar month.]

And although this reckoning of the lunar month by days, hours, and fractions of hours cannot be written in the Calendar, which contains only whole days, knowledge of it is nonetheless quite necessary, so that the civil or political lunar months may be so instituted as to be able to agree with the solar year. And in what manner this is done by means of the nineteen-year cycle must here be explained.

[Margin: Why the lunations in the Calendar are alternately of 30 and 29 days.]

Accordingly, in the nineteen-year cycle the civil lunar month is fixed at 29 days and 12 hours only, the fractions of hours being omitted. And since hours cannot be written in the Calendar, the numbers of the nineteen-year cycle are laid out for finding the new moons by this device: that the lunations contain alternately 30 and 29 days. For thus it comes about that the 12 hours assigned in excess to the preceding lunation are taken away by the following one, and two lunations together comprise 59 days, while twelve lunations comprise 354 days, which make up the civil lunar year.

[Margin: Why the new moons in any year usually occur 11 days earlier than in the immediately preceding year.]

And therefore the common civil lunar year differs by 11 days from the common solar year of 365 days. From which it follows that the new moons of the following year usually occur 11 days earlier than the new moons of the preceding year; so

that if, for example, some new moon falls on the 29th of some month in this year, the same will fall on the 18th of the same month in the following year, and on the 7th in the third year, and so on, until 19 years are completed, after which that new moon falls once more on the 29th day [connective word illegible: [?]]. This is because all the lunar months contained in 19 solar years comprise nearly as many days and hours as the 19 solar years are made up of. For the 19 solar years (if you assign to each

[Margin: How many days the 19 solar years contain.]

each, from the institution of Julius Caesar, 365 days and 6 hours) contain 6939 days and 18 hours, in which are completed 235 lunations and something more, according to the mean course of the Moon; and just as many lunations are included in those same 19 solar years.

[Margin: In 19 solar years there occur 235 mean lunations.]

For the 235 mean lunations require 6939 days and, over and above, 16 hours only, 32 minutes, 28 seconds, 5 thirds; so that the 19 solar years exceed the 235 lunations by 1 hour, 27 minutes, 31 seconds, 55 thirds.

[Margin: How great is the difference between the days of the 19 solar years and the days of the 235 mean lunations.]

Hence it comes about that the mean new moons, when 19 solar years have passed, indeed fall on the same days of the months on which they fell 19 years before, yet not at exactly the same hours, but somewhat earlier — by that ratio of excess, of course, which we have mentioned. So very small is the interval of time by which the Moon, over 19 years, runs ahead of the seats fixed for it in the Calendar.

[Margin: How great is the anticipation of the mean lunations in 19 years, and how great in 76.]

From which it follows that in 76 years — that is, in 4 nineteen-year cycles — the Moon anticipates the same seats by 5 hours, 50 minutes, 7 seconds, 40 thirds; and at length, in $312\frac{1}{2}$ years, by nearly a whole day.

[Margin: The mean lunations anticipate one day in $312\frac{1}{2}$ years.]

Hence it has come about that the new moons, from the Council of Nicaea down to our own age, have advanced toward the beginnings of the months by four days and more.

[Margin: In 19 solar years are contained 235 civil lunations.]

That 235 civil lunations are contained in 19 solar years we shall make plain thus. Since in any single year there are 12 lunations of 30 and 29 days alternately, which make up 354 days, there will be in 19 years 228 lunations, and in addition 209 days, made up of the 11 days by which the solar year exceeds the lunar, as we said above. From these 209 days are constituted 7 extraordinary lunations, called embolismic — six of them of 30 days each, and one of 29 days, as we shall say below. And these seven extraordinary lunations, added to those 228, make up the number of 235 lunations. Rightly, therefore, is the lunar cycle said to comprise 19 solar years, since in this space of time are completed 235 lunations — precisely as many as can occur in the same interval according to the mean course of the Moon — except that there remains that difference we mentioned, of 1 hour, 27 minutes, 31 seconds, 55 thirds.

[Margin: In what way the 235 civil lunations contained in 19 solar years fill out the time of just as many mean lunations, even though in each one 44 minutes, 3 seconds, 11 thirds are omitted.]

But let us show a little more precisely in what manner the 235 civil lunations comprised in 19 solar years fill out the time of just as many astronomical lunations, according to the mean motion. For since in the civil lunations the fractions of an hour — namely 44 minutes, 3 seconds, 11 thirds of one hour in each lunation — are dropped, the civil lunations do not seem able to be equated with the astronomical ones. Nevertheless, you will learn from this that those dropped fractions are very neatly compensated by the bissextile days and the seven extraordinary lunations.

If the 235 civil lunations are each assigned $29\frac{1}{2}$ days — that is, if we make them alternately of 30 and 29 days, which we said the cycle requires — they make up 6932 days and 12 hours.

[Margin: In what way the 235 civil lunations contained in 19 solar years fill out the time of just as many mean lunations.]

But just as many mean astronomical lunations comprise 6939 days, 16 hours, 32 minutes, 28 seconds, 5 thirds. To fill out this time, then, the 235 civil lunations fall short by 7 days and $4\frac{1}{2}$ hours and a little more; and this deficiency is supplied as follows.

[Margin: Whence in 19 years are supplied the 44 minutes, 3 seconds, 11 thirds which are omitted in each civil lunation, together with the 12 hours taken away from the last extraordinary lunation.]

In the whole nineteen-year cycle, beyond the whole days of the solar years, there remain 114 hours, gathered from the 6 hours dropped in each year, which make up 4 intercalary days and 18 hours. The 4 days, then, in the 4 bissextile years, are assigned to the four lunations of February of 29 days, so that only 18 hours are wanting — those which, over the 19 years, besides the 4 intercalary days, we said were left over — and there will remain that same difference of 1 hour, 27 minutes, 31 seconds, 55 thirds, by which the 19 solar years exceed the 235 mean lunations. Fittingly and neatly, therefore, does the nineteen-year lunar cycle agree with the 19 solar years, since the 235 civil lunations comprised in them fill out almost exactly the time of just as many mean astronomical lunations, as we have set forth.

[Margin: Whence in 19 years are supplied...]

This will perhaps be perceived more clearly thus. The 228 civil lunations comprised in 19 solar years — if we assign to each year 12 lunations alternately of 30 and 29 days — make up 6726 days. If to these are added the 209 days gathered from the 11 days which, beyond the 12 lunations, are left over in each solar year, the sum will be 6935 days. If again there are added the 4 intercalary days and the 18 hours contained in the 19 solar years, there will result 6939 days and 18 hours, as many as are contained in 19 solar years. Thus, even though the 235 lunations — reckoning each at $29\frac{1}{2}$ days, except the last, which has only 29 days — make up only 6932 days, there are nonetheless inserted and added, out of the ordinary course, throughout the whole compass of the nineteen-year cycle, the remaining $7\frac{3}{4}$ days. These are gathered partly from the 4 intercalary days and 18 hours, partly from the 3 days which we assigned in excess to the six extraordinary lunations, so that the number of 6939 days and 18 hours is produced — as many as are needed, or nearly so, to complete the 235 mean astronomical lunations. For this time of the 235 lunations differs from that of the 19 solar years by only 1 hour, 27 minutes, 31 seconds, 55 thirds, as was said above.

[Margin: Meton of Athens, the inventor of the golden number, around the 86th Olympiad.]

And these $7\frac{3}{4}$ days inserted out of the ordinary course supply, approximately, those 44 minutes, 3 seconds, 11 thirds which are dropped in each civil lunation,

and the other 12 hours which we subtracted from the last extraordinary lunation — since we made it of only 29 days, whereas all the others contain $29\frac{1}{2}$ days, except the six earlier extraordinary ones, which each consist of 30 days. For 44 minutes, 3 seconds, 11 thirds, multiplied into 235 lunations, produce 7 days, 4 hours, 32 minutes, 28 seconds, 5 thirds; and if to these are joined those 12 hours dropped in the last extraordinary lunation, the number becomes 7 days, 16 hours, 32 minutes, 28 seconds, 5 thirds — which differs from the number of 7 days, 18 hours only by 1 hour, 27 minutes, 31 seconds, 55 thirds, the very difference which we said above exists between the 235 astronomical lunations, according to the mean course of the Moon, and the 19 solar years. This, then, is the reckoning of the nineteen-year lunar cycle, or golden number, which Meton of Athens is reported to have devised, by a truly marvelous artifice, around the 86th Olympiad — so that it was deservedly adopted among almost all nations for the investigation of the new moons.

Chapter II [Caput II]

In what way the golden numbers are arranged in the Calendar, and why, once they have been removed, epacts are substituted in their place.

Since the ancients had recognized that the new moons return to the same days once nineteen years have elapsed, they wrote into the Calendar a like number of numerals, from 1 up to 19, which they called "golden," beside those days on which, within each span of nineteen years, the new moons fell. Thus they set 1 before the day on which a new moon occurred while golden number 1 was current; 2 before the day on which the new moon fell while golden number 2 was current; and so on for the rest. In doing this they carefully saw to it that the lunations should be alternately of 30 and 29 days, and that the new moons of any one year should anticipate those of the preceding year usually by 11 days — on account of those 11 days by which the common solar year of 365 days exceeds the common lunar year of 354 days.

From this arrangement of the golden numbers there arose among them an order and sequence of such a kind that in the Calendar they do not keep the natural order of the numbers; rather, the larger number generally precedes the next smaller by 11 days, on account of those 11 days by which the solar year exceeds the lunar. So, for example, if golden number 1 is placed near some day of any given month, the next larger golden number, 2, runs ahead of it toward the beginning of the month by eleven days, ten days being interposed between them — because in the following year the new moon of that same month falls eleven

days earlier than the new moon of the previous year. In the same way, golden number 1 precedes golden number 19 in the Calendar toward the beginning of the month by eleven days — number 1 being the one that immediately follows 19 in the natural sequence of the numbers. And the same reckoning holds for the remaining golden numbers. Only very rarely does the larger precede the next smaller by only ten days, and much more rarely by twelve; yet this too happens from time to time, the nature of the nineteen-year cycle so requiring.

[Margin: In what order the golden numbers were placed in the Calendar by the ancients.]

Hence it comes about that in the Calendar each following golden number is constituted by adding eight to the preceding golden number — casting out 19, however, if the sum turns out greater than 19 — or (what amounts to the same thing) by subtracting 11 from the preceding golden number, first adding 19 if the preceding golden number was not greater than 11, so that the subtraction can be carried out. Conversely, it turns out that each preceding golden number is formed in turn by adding 11 to the following one — casting out 19, however, if the sum is greater than 19 — or (and this comes back to the same thing) by subtracting 8 from the following golden number, first adding 19 if the following number was not greater than 8.

[Margin: In the Calendar every golden number is generated from the one immediately preceding, by adding 8 or subtracting 11; and from the one immediately following, by adding 11 or subtracting 8.]

From this same arrangement of the golden numbers in the Calendar there follows a mutual linkage of the following sort: the following number, if it is smaller than the preceding one, follows immediately after it; but if it is larger, it follows not immediately but in the third place, one further day being left empty in between. This, however, is not observed in certain places of the Calendar; but occasionally, though rarely, the larger number does follow immediately after the smaller, the nineteen-year cycle necessarily demanding it — namely, so that the lunations may be constituted alternately of roughly 30 and 29 days. And so, once the golden number written at the beginning of January is known — whether it be set on the first day or the second (at the time of the Council of Nicaea, golden number 3 was placed at the first day of January; but now, after the correction of the Calendar, if the golden numbers were to be written into the Calendar, golden number 9 would have to be prefixed to the second day) — all the other golden numbers that follow will be formed from it by adding 8 or subtracting 11, as has been said, keeping this order: that a smaller number follows the larger immediately, but a

larger follows a smaller not immediately — a few places in the Calendar excepted, about which we shall say a little presently.

[Margin: In the Calendar the smaller golden number usually follows the larger immediately; but the larger follows the smaller not immediately, one empty day being left in between.]

Likewise, once the golden number that stands last in December is known — whether it occupies the final day or the next-to-last — all the other preceding golden numbers will be formed from it by adding 11 or subtracting 8, and so on. But since no single rule can be given for those places in which a larger number follows a smaller immediately — because it is not always the same golden number that is set at the beginning of January, or the same one at the end of December, but one succeeds another until all the golden numbers have in turn occupied the leading position, the equation of the Moon so requiring, as we shall explain below — we shall more easily set out these same golden numbers in the Calendar by means of the epacts written into the Calendar, whose disposition is both very easy and unchanging, as we shall show a little later.

[Margin: By what method, from the first golden number of the Calendar, or from the last, all the others are inscribed in the Calendar.]

Nevertheless, the arrangement of the golden numbers should not be passed over — the arrangement that the Church used in the Calendar before the Gregorian correction, and that it would now use after the correction, if golden numbers, and not epacts, were to be set out in it — so that it may be understood in how many places the larger golden number follows the smaller immediately. So then, placing number 3 at the first day of the year, as was done at the time of the Nicene Council, all the rest are formed by continually adding 8, always casting out 19 whenever the sum turns out greater than 19, and placing the smaller immediately below the larger, but the larger not immediately below the smaller — these few places excepted — so that the lunations come out alternately of 30 and 29 days. On 3 February let number 19 be written immediately below the smaller number 11. And on 6 April, 4 June, and 1 August, number 16 immediately below the smaller number 3. Likewise on 3 October and 1 December, number 13 immediately below the smaller number 5. Finally, once all the golden numbers have been arranged in this order, in July and in all the other five months following, up to the end of the year, let golden number 19 be moved up to the day above, so that it is placed immediately below the smaller number 11; and in those same months let the smaller number 8 be written not immediately below 19, but with one empty day left in between.

I am well aware that Campanus [Campanus of Novara] and some others place number 13 in December not on the first day but on the second, together with golden number 2. But since other considerations prevail in this matter — namely, that it would be absurd for two new moons to fall on the same day within a single nineteen-year cycle, such as those indicated by golden numbers 13 and 2, since on Campanus's arrangement these fall on 2 December — we have preferred, with the other computists, to write number 13 at 1 December, immediately after the smaller number 5 that is affixed to the last day of November. In this way, then, the golden numbers, according to the mind of the Council of Nicaea, were placed in the Calendar before the correction. But at the present time, after the correction, they would have to be placed as follows. Golden number 9 having been written at 2 January, all the rest would be formed by continually adding 8, as before, with these places excepted on account of the lunations alternating 30 and 29 days: on 5 February, 5 April, 3 June, 1 Augu-

[Margin: In which places the larger golden number follows the smaller immediately, in the old Calendar, and in the new one of the present time, if golden numbers were to be written in it.]

-st, 29 September, and 27 November, golden number 14 would have to be written immediately after the smaller golden number 6. Likewise, on the last day of December, golden number 19 would have to be set immediately below the smaller number 11. But come, so that this difference may become apparent, let us set before our eyes both Calendars, with the golden numbers arranged through the days of the year in the manner we have described.

There follows [SEQVITVR]:

THE ECCLESIASTICAL CALENDAR, which the Church used from the Council of Nicaea up to the correction of the year made by Gregory XIII.

*[The four columns of each month-panel are, as printed: **Aurei num.** (golden number) · **Literae Dñic.** (Dominical letter) · the source's unlabeled Roman-reckoning day column (Kalends / Nones / Ides + countdown numerals) · **Dies mensis** (day of the month). A blank golden-number cell means no golden number is printed for that day.]*

(Continuation of the ecclesiastical golden-number month-tables — the second half of the year, July through December — followed by the prose note on how the golden numbers are laid out, and then the opening of a second calendar table (January–March) showing what the reformed calendar would look like if golden numbers were entered in place of epacts.)

[Printed p. 46 — July, August, September]

Each month-panel has four columns: **Aurei num.** (golden number), **Literæ Dñic.** (Dominical / Sunday letter), the (unlabelled) **Roman day-reckoning**, and **Dies mensis** (day of the month). A blank golden-number cell means no golden number falls on that day.

[Numerical note: in December the golden numbers on days 12, 13 and 31 are set with i-terminal sorts — **xii** (12), **i** (golden number 1), and **xiii** (13) — whereas the norm elsewhere is j-terminal. Value 13 is doubled, printed **xiiĵ** (j-terminal) on day 1 and **xiii** (i-terminal) on day 31. Transcribed as printed.]

Prose note following the December table

In this calendar you can see plainly that each golden number is set down twelve times — as many times, that is, as there are lunations in a common lunar year — with the exception of the seven numbers which, after the 20th [?] of December, are repeated in a thirteenth position, and which of course also occupy the earlier days of January. I want you to be aware of this, so that you do not suppose the golden numbers to be arranged in the calendar after the fashion of a cycle, that is, as though the golden number of the first day of January were formed from the last golden number of the year by adding 8, like the rest. For this way of generating the successive golden numbers by adding 8 to the preceding ones ceases entirely at the end of the year, and begins afresh at the start of the year from the very same golden number with which it began before, without any regard to the golden number that stands last in December. Exactly the same thing is seen in the calendar that follows, where the golden numbers are so arranged that they indicate the new moons from the restored year up to the year 1700 — no otherwise than the way the same new moons are shown by the epacts in the new calendar.

SEQVITVR.

CALENDARIVM ECCLESIASTICVM QVO post anni
Correctionem à Gregorio XIII. factam Ecclesia vti deberet
vsque ad annum 1700. si aurei numeri pro Epactis in eo
descripti essent.

[The Ecclesiastical Calendar which, after the correction of the year made by
Gregory XIII [Gregory XIII], the Church would have had to use up to the year
1700, if golden numbers had been entered in it in place of epacts.]

[Printed p. 48 — the following calendar begins: January,
February, March]

In this second table the month-names are set in mixed case (Ianuarius,
Februarius, Martius) and the Dominical-letter column is headed **Litere Dñic.**
(with an e-caudata). The four columns are the same as before: golden number,
Dominical letter, Roman day-reckoning, day of the month.

Apologia adversus Maestlinum, Liber Secundus, Caput II (continued)

The Second Calendar — golden numbers set in place of epacts (valid to 1700), continued

These three leaves carry only the perpetual month-tables of the second calendar. Each month is set as four columns: the golden number (**Aurei num.** = *Aurei numeri*), the Dominical letter (**Literę Dñic.** = *Literę Dominicales*), the Roman-calendar reckoning of the day (unlabelled), and the day of the month (**Dies**

mensis). The tables continue directly from March on the preceding leaf and run April through December.

Typographic conventions preserved as printed: the golden-number column uses the j-terminal computistical sorts (j, ij, iij, iiij, vj, vij, viij, xj, xij, xiij, xiiij, xvj, xvij, xvij, xix); the Roman-reckoning column uses i-terminal forms (iii, iiij, vii, viii, xi, xii, xiii, xiiii, xvi, xvii, xviii, xix). Blank golden-number cells are left empty, as in the source.

[Margin: Why the following golden number is formed from the preceding one by adding 8 or subtracting 11, while the preceding is formed from the following by adding 11 or subtracting 8; and why the golden numbers are not written in the calendar in an unbroken sequence.]

The reason why the following golden number is formed from the preceding one by adding 8 or subtracting 11, and again the preceding from the following by

adding 11 or subtracting 8; and why the golden numbers are not written in the calendar in continuous order, but for the most part single days are left empty between each pair — is this. Eight solar years, allotting to each 365 days and 6 hours, comprise 2922 days, in which fall very nearly 99 lunations; from the last lunation alone there is wanting 1 day, 12 hours, 41 minutes, 15 seconds, 9 thirds. For 99 lunations, according to the mean course of the Moon, require 2923 days, 12 hours, 41 minutes, 15 seconds, 9 thirds. Therefore the lunations after 8 elapsed years do not begin on the same days on which the new moons occurred 8 years before, but nearly a day and a half later. For this reason, after any golden number there is written in the calendar a golden number greater than it by eight units, to signify that after eight years the new moons fall not on the days to which the preceding golden number was assigned, but on those to which the following golden number — formed from the preceding by adding 8 — is prefixed. And since, if the following golden number were to come immediately after the preceding one, the lunation of the following golden number would be brought forward by 12 hours, the next golden number must be written down, but with one empty day left between, lest its lunation be anticipated by a whole day. Thus this golden number, the third from the first (from which it is formed by adding 16), is written in the third place after it, just as its lunation likewise begins three days later than that of the first. This is the reason why the following golden number is composed by adding 8 to the preceding one, and why they are set down two together, with single days left empty between each pair — except for a few golden numbers which interrupt this order on account of the equation of the Moon that is required.

[Margin: How, from the golden numbers arranged in the calendar, the new moons are to be investigated.]

Now although the greater golden number could equally well have been placed next below the smaller — rather than the smaller next below the greater — this seems due to some chance circumstance rather than to any fixed reason that would compel the smaller to be written next below the greater rather than the greater next below the smaller, since by either arrangement the reckoning of the lunations would hold good. And let this be said concerning the reason why the golden numbers do not preserve a continuous order.

Let us now also explain the reason why the preceding golden number is formed from the following by adding 11 or subtracting 8, and why the golden numbers do not preserve a continuous order. Eleven solar years contain 4017 days and 18 hours, in which are completed 136 lunations, with 1 day left over — 1 day, 14

hours, 8 minutes, 47 seconds, 4 thirds. For 136 lunations require 4016 days, 3 hours, 51 minutes, 12 seconds, 56 thirds. Therefore the new moons after 11 elapsed years do not fall on the same days on which they occurred 11 years before, but begin earlier, namely by that day and by nearly a half. Since therefore any golden number is greater by eleven units than that which precedes it in the same calendar by 11 years, and since it is plain that the following golden number can be formed from the preceding, and the preceding from the following, either by adding 8 or 11 or by subtracting 11 or 8 — hence it came about that the ancient writers distinguished the nineteen-year cycle, which they called the ἐννεαδεκαετηρίδα [Greek: enneadekaeterida, "the nineteen-year period"], into an ὀγδόαδα [Greek: ogdoada, "ogdoad," a group of eight] and an ἐνδέκαδα [Greek: hendekada, "hendekad," a group of eleven]; since indeed its whole progression and its order in the calendar is constituted from the addition or subtraction of 8 or 11, as we have explained. And the ὀγδοάς [Greek: ogdoas, "the ogdoad"] indeed, with the 11 days by which the solar year exceeds the lunar, makes up the whole nineteen-year cycle; while the ἐνδεκάς [Greek: hendekas, "the hendekad"], together with the nineteen-year cycle, completes a full lunation of 30 days.

[Margin: The inadequacy of the golden number for investigating the new moons.]

Once the 19 golden numbers had been arranged in the calendar in the manner we have described, it was not difficult to find the time of the new moon of any month. For on that day the Moon was declared to be new — that is, the new moon — to which the golden number running in the year proposed was prefixed; and from this new moon Easter, together with the other movable feasts, was investigated.

[Margin: By how much the new moons had run ahead of their times from the age of the Council of Nicaea down to the year of the correction.]

And yet all these things which we have handed down concerning the arrangement and use of the golden number, though devised by the ancients with great ingenuity, the observation of astronomers finds not in every respect true. For the new moons, after 19 years have passed, do not return to precisely the same seats; but they run ahead a little before the 19 completed years, so that in any given span of 19 years they anticipate their places by 1 hour, 27 minutes, 31 seconds, 55 thirds; over the span of four nineteen-year cycles — that is, 76 years — by 5 hours, 50 minutes, 7 seconds, 40 thirds; and at last, in 312½ years, by nearly a whole day. As was shown in the preceding chapter, and thus indeed from the times of the Council of Nicaea down to our own age they have advanced by four days and more.

[Margin: In what way the golden numbers ought to have been moved forward in the old calendar so that they might indicate the new moons, both before the correction and after.]

From this it came about that, in order to find the new moons by the golden numbers of the Council of Nicaea (that is, supposing the golden number 3 to stand at the beginning of January), before the correction of the calendar one had to ascend from the place of the golden number proposed for the current year up to the fifth day inclusive — a thing which some were accustomed to do by these five syllables, IN COELIS EST HIC, or by these, HIC NOVA LVNA, or by these, IN COELO LVNA. And therefore, in order that the golden numbers before the correction might rightly indicate the new moons, they would all have had to be moved forward by five days, three empty days being left between the old and the new places, so that the golden number 19, which before the correction occupied the fifth day of January, would have to be assigned to the first day — the same rule being nevertheless preserved, that the lunations be constituted alternately of 30 and 29 days, as was done, before the emendation of the calendar, in the Breviaries and Missals corrected by Pius V [Pope Pius V]. And in this manner indeed the golden numbers, once arranged,

would have rightly indicated the new moons for those years which most nearly preceded the restitution of the year. But once the golden numbers had by this means been advanced toward the beginnings of the months, if they had had to be retained in the calendar after the correction — that is, after the removal of 10 days — they would have had to be moved back again toward the ends of the months by ten days, so that 9 days would lie between the golden numbers advanced before the correction of the year and those same numbers set back after the correction, the same alternating lunations of 30 and 29 days being preserved. For in this way, after the restitution of the year, the golden numbers would rightly show the new moons according to the mean course of the Moon.

But for all that, the golden numbers thus corrected and restored to their proper places, although for some while they would indicate the new moons rightly, could not do so perpetually, or for a long time. For whenever the intercalary day is taken away from some hundredth year — that is, whenever some hundredth year is made a common year, lest the equinox recede from March 21, as was said above — all the new moons would fall one day later than they would be indicated by the golden numbers. Therefore, as often as a hundredth year, which by its own nature is bissextile, is made a common year, so often would all the golden numbers have to be moved down by one day, that they might rightly show the

new moons. Again, since (as we showed in the preceding chapter) the new moons anticipate their seats in the calendar by one day in $312\frac{1}{2}$ years, it follows that after any $312\frac{1}{2}$ years the golden numbers would have to be moved toward the beginnings of the months by one day, that they might indicate the new moons — provided, however, that the intercalary day were not then to be omitted. And in this way 30 calendars would have to be made, so that the arrangement of the golden number would have 30 variations, each being moved up and down through 30 days — as many, that is, as are contained in one lunation of 30 days — as will be evident from what follows.

[Margin: That the golden numbers, once corrected in the calendar, cannot indicate the new moons perpetually or for a long time; and why. — That if the golden number had to be retained in the calendar, 30 calendars would have to be made. — That the 30 epacts were rightly substituted in place of the golden numbers.]

But because this would be exceedingly inconvenient and troublesome, it was by the best of counsel arranged that, the golden numbers being removed from the calendar, other numbers should succeed in their place, which in a single calendar might perpetually show the new moons — whether they advance toward the beginnings of the months or roll back toward the ends — with no change made in the calendar, as we shall say in the next chapter.

[Margin: Why every epact must be less than 30. — What the epacts are, and why they are 30.]

Now these numbers are 30: the epacts, from 1 up to xxx, or to *. For the last epact, 30, is marked by this sign *, rather than by the number xxx, because, if we wish to speak properly, no epact can be xxx, since every epact must be less than the time of a whole lunation. For the epact is nothing other than the number of days which, in the month of December, remain over after the last lunation of the year. Thus, if the last lunation ends on the very last day of December, so that no day remains over, the epact of the following year will be 0; if it closes on the second-to-last day, the epact will be 1, on account of the one day that remains; if it ends on the day before that — that is, on the 29th — the epact will be ij; and so on with the rest, until we come to a lunation that has its end on the Calends of December [December 1], so that 30 days remain over. For then that lunation is not the last but the second-to-last, since those 30 superfluous days constitute the last lunation, and consequently the epact will then be 0, or xxx, which we denote by the sign *. And this is the reason why there can be 30 epacts in all, from 1 up to xxx, or 0, or *, on account of the 1, 2, 3, and so on up to 30, or 0, days which can

remain over after a lunation ending in the month of December. And although, when some lunation ends on the first day of December, or on the last, the epact of the following year will be xxx, or 0, that epact xxx or 0 must nevertheless be marked with some sign, namely this *, so that by it the new moons of the following year may be investigated, and it may be understood that in December two lunations were then ended — one on the last day, so that no day remained over, the other on the first day, so that after it 30 days remained. But it happens sometimes that the epact of some year is greater by one unit than the number of days which remain over after the last lunation of the preceding year; and when this occurs will be told when we treat of the finding of the epact of each year.

This same number, 30, of the epacts, is gathered from the 11 days by which we said the lunar year is exceeded by the solar. For if in the first year 11 days remain over, there will remain 22 in the second, and 33 in the third; and, casting out the 30 that make up one lunation, the remainder will yield epact iij; and so on in turn, always adding 11 and casting out 30 whenever the sum is greater than 30. Thus all 30 epacts will be composed, so that the first is xj and the last xxx, or 0, or *, after which epact xj is again produced, as here appears:

xj. xxij. iij. xiiij. xxv. vj. xvij. xxviiij. ix. xx. j. xij. xxiiij. iiij. xv. xxvj. vij. xviiij. xxix. x. xxj. ij. xiiij. v. xvj. xxvij. viij. xix. xxx. — or 0, or *.

It happens now and then that 12, not 11, must be added to the preceding epact for the following epact to be formed; and when this happens will be told below, when we treat of the finding of the epact of each year.

[Margin: Why the epacts are so called.]

These 30 numbers are called Epacts, by a Greek word which in Latin means the same as "added," "adventitious," "inserted," or "interposed" days. For they are attached at the end of the last lunar month to fill out the number of days of the solar year, and to begin the first lunation of the following year. But in what way epacts of this kind, placed in the calendar, can perpetually indicate the new moons with no change made in the calendar, will be made plain from what follows; and first let us set forth by what art and skill they are to be arranged through the days of the calendar.

[Margin: Why the epacts are arranged in the calendar in retrograde order.]

BY WHAT DEVICE THE EPACTS ARE DESCRIBED IN THE CALENDAR.

CHAPTER III.

Although the epacts could be described in the calendar according to the natural series of the numbers, from 1 up to xxx or to *, it has nevertheless seemed more expedient that they be described in retrograde order, proceeding from xxx or * through xxix, xxviii, xxvii, and so on, down to 1 — so that they may be distinguished from the day-number of the same calendar, and so that they may indicate the new moons more naturally, as will be manifest from what follows. Beginning, then, from epact * at the start of January, epact xxix is written at the second day; xxviii

[Margin: In what way the epacts are to be arranged in the calendar.]

at the third, and so on in turn, in retrograde order, until 1 is reached, which epact is prefixed to January 30; after which all thirty epacts are repeated in the same order down to the end of the calendar. So that all of them are inscribed in the calendar only twelve times, except these eleven — *, xxix, xxviii, xxvii, xxvi, xxv, xxiiii, xxiii, xxii, xxi, xx — which are repeated a thirteenth time in the last eleven days of December. There is also an exception in epact 19, marked with a different character or colour; for this too is appended to the last day, next to epact xx, as we shall say below.

[Note on the load-bearing forms: the doubled epact of the nineteen-year cycle is set here in Arabic figures — "19" — and, throughout the argument below, "25", distinct from the Roman-numeral epacts "xxv", "xxiiij", "xxvj". This Roman-versus-Arabic contrast is the substance of the passage and is preserved as printed.]

In order that the epacts may rightly indicate the new moons, this caution must be used in describing them. In the second placing of the thirty epacts, and likewise in the fourth, sixth, eighth, tenth, and twelfth of the same — namely on February 5, April 5, June 3, August 1, September 29, and November 27 (the days on which epact xxv falls by the arrangement given above) — these two epacts, xxv and xxiiij, are to be inscribed together. From this it comes about that, after the twelfth inscription of the epacts, 11 days remain over in December, to which again these epacts are prefixed — *, xxix, xxviii, xxvii, xxvi, xxv, xxiiii, xxiii, xxii, xxi, xx — which, namely, were assigned to the first eleven days of January. All 30 epacts, inscribed twelve times, occupy exactly 354 days — as many as we said are

contained in the common lunar year — [so that they] cannot preserve the reckoning of the cycle, in such a way that the epact of the first day of January is the one next smaller than that which is written next to the last day of December, which precedes the first day of January; but their retrograde order breaks off at the end of the year, and begins again at the start of the year from epact *, as before.

Now if these two epacts were not appended to the same day in the six places of the calendar, but each followed the other singly in retrograde order, all 12 lunations of each epact would be of 30 days, and all the epacts, repeated twelve times, would occupy 360 days — a number which exceeds the common lunar year by six days, which is absurd. Therefore, that the lunations may exist alternately of 30 and 29 days, it is necessary to place two epacts together in six places. For in this way it will come about that the lunations are constituted alternately of 30 and 29 days. For when epact xxiiij, together with the others following it, has ascended into February — for example, on account of the two epacts xxv and xxiiij [placed together] toward the beginning of the month — it comes about that the lunations beginning from the preceding epacts, as from epacts xxiiij, xxiiij, xxij and the rest of January, contain only 29 days. And the same we mean to be understood of the lunations of the epacts which in the other five places of the calendar precede [that day].

Next, since it happens now and then that in one and the same nineteen-year cycle both epact xxv and epact xxiiij are in use, as will appear below, epact 25 must be written with a different character or colour, opposite epact xxvj, in those six places in which epacts xxv and xxiiij are set together. But in the other places, where on the same day epact xxiiij is to be written, this same epact 25 must be written with yet a different character or colour. For unless this be done, it will happen [that two new moons fall on one day] through epact xxv / 25 [being written] twice in the six places [?].

This inconvenience is entirely avoided by inscribing epact xxv / 25 twice in the six places of the calendar, in different characters or colours. For whenever, in some cycle, xxv runs together with a golden number greater than 11 — such as are these later eight golden numbers, 12, 13, 14, 15, 16, 17, 18, 19 — epact xxiiij will indeed also be in use in that same cycle: but if epact 25 be then taken, marked with a different character or colour, which in those six places is set opposite epact xxvj, two golden numbers, or two new moons, will not be able to fall on the same day with epact xxiiij; for epact 25, of a different [character], falls upon separate [days] in the several months. When, however, in some nineteen-

year cycle epact xxv runs with a golden number not greater than 11 — of which kind are these first eleven golden numbers, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 — epact xxiiij will never be in use in that same cycle; and epact xxv must then be taken, which is set opposite epact xxvj. So that, although in the same nineteen-year cycle epact 25 be placed twice, marked with a different character on the same day, two new moons do not on that account fall on one and the same day; because, while epact xxv is running — that one, 25, of a different colour or character — [it runs together] with epact xxvj for the finding of the new moons, of which we shall treat a little further on.

And all this will be made clear from the expanded table of the epacts (of which we shall speak a little below), in which the capital letters N, E, B and the small letters r, n, k, e, b perennially display [the individual nineteen-year cycles]. For there, in the eight lines to which [the capital letters are affixed] — each line of that table representing the several nineteen-year cycles — you will find epact 25 marked with a different [character], under these eight greater golden numbers, 12, 13, 14, 15, 16, 17, 18, 19; but epact xxiiij under the 11 lesser ones, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 — and never epact xxvj. In the other 22 lines, however, in which epact xxv is written [in the same character as the] golden numbers, you will indeed sometimes find [epact xxv], though they never occur together at the same time; you will [also] observe epact xxvj. For which reason, if now epact xxv be taken, now epact 25 of another character or colour — the one, namely, that is placed opposite epact xxvj — account being had, of course, of the lesser or greater golden number with which it runs together, as we said a little above: it is in no way possible that within the same nineteen-year cycle two new moons should fall together upon one and the same day, even though in the six places enumerated above epacts xxv and xxiiij are set opposite the same day, and epact 25, of another colour or character, is written next to that same day together with epact xxvj.

But that epact xxiv cannot be in use when epact xxv coincides with some golden number smaller than 12 — that is, not greater than 11 — and likewise that epact xxvi is not employed when epact 25 runs together with a golden number greater than 11, is also gathered very clearly from the arrangement of the golden numbers and the epacts in the Calendar.

For, as we said above, a smaller golden number is followed in the Calendar by a larger one not immediately, but with one day left between them. Hence, if in January, for example, opposite the 6th day — where epact xxv is placed — any golden number smaller than 12 is written, with which epact xxv is supposed to

run, then the next golden number must be written at January 8th, leaving the 7th empty; so that in that nineteen-year cycle no new moon can fall on the 7th. Therefore in the same cycle epact xxiv, which is placed immediately below xxv, cannot possibly be of use; otherwise a new moon would fall on January 7th. Again, since a larger golden number is immediately followed in the Calendar by a smaller one, as was said above, it follows that if opposite that same January 6th — to which epact xxv is prefixed — any golden number greater than 11 is written, with which epact 25 is supposed to run, then the following golden number must be written at January 7th, immediately after that larger one, so that in that cycle a new moon can fall on the 7th. Consequently, in the same cycle epact xxiv, placed immediately below 25, will mark the new moon, and will therefore be of use. But since a larger golden number is preceded by a smaller one not immediately, but with one day left empty, it follows that the golden number preceding that larger one — with which epact 25 is supposed to run — must be placed at the 4th day, so that on the 5th no new moon then occurs. Therefore epact xxvi, written against the 5th day, can in no way be of use then, lest a new moon fall in that cycle on January 5th.

[Margin: Why in the same cycle epact xxiv is not used, when epact xxv and a golden number not greater than 11 coincide; and likewise why epact xxvi is not in use in the same cycle, when epact 25 and a golden number greater than 11 coincide.]

This anticipation, moreover, of epact 25 — set in a different colour or character — is so far from disturbing the lunations in the Calendar that it rather brings them into correct order. For each lunation ends on one of the earlier 30 days of January [and] is the first of the whole [set]. With that epact 25, the first lunation of the year, ending on January 5th, is made 30 days long; the second, ending on February 3rd, only 29 days (though it too would be 30 days if epact xxv were taken below epact xxvi); the third is then again made 30 days, the fourth 29 days, and so on, as the order of alternating lunations of 30 and 29 days requires. The thirteenth, extraordinary lunation of that year — for whenever epact 25 is in use, the lunar year is embolismic, as will be said later — is likewise made 30 days; whereas, if epact xxv (assigned to the same day as [epact] xxiii) were running, it would be only 29 days. In short, there are just as many 30-day lunations while epact 25 (of a different colour or character) is running as are required when the other epact xxv is in use: for there are seven in the one case as in the other, although they proceed differently in the one and in the other. To this is added that the paschal lunation, when traced by epact 25 of a different colour or character, corresponds more exactly to the mean motion of the Moon. This will

become clear if the lunations marked by golden numbers greater than 11 are carefully compared with the calculation of the Moon's mean motion; for we shall generally find them shown by those golden numbers greater than 11 a little later than the Moon's mean motion requires. Therefore, since the paschal lunation beginning on April 4th — which is shown as marked by epact 25 with a character or colour different from the others, and which, as we said above, always runs with some golden number greater than 11 — begins one day earlier than it would if it were indicated by epact xxv assigned to April 5th, it plainly follows that the paschal lunation which that earlier epact 25 begins is more in accord with the Moon's mean motion than the one indicated by epact xxv placed at April 5th (running with the same golden number as the former runs with), because this latter begins one day later.

[Margin: That epact 25, of a different colour or character, placed opposite epact xxvi, does not disturb the lunations.]

But someone may ask why, in the equation of the lunar months — that is, in the placing of two epacts at one and the same day in six positions of the Calendar, so that the lunations may be constituted on alternate days of 30 and 29 — these two, xxv and xxiv, were adopted, set opposite February 5th, April 5th, June 5th, August 5th, September 29th, and November 27th, rather than two others; since it could equally well have been done with any two epacts, and especially with epacts * and xxix, which are set at the end of January and the beginning of February — so that this equation, of course, might be established after the first lunar month of 30 days had elapsed, as we read was done by Julius Caesar in the golden-number cycle, as Paul of Middelburg [Paulus Middelburgensis] testifies (book 2), where he sets out the Roman Calendar together with Julius Caesar's lunar cycle, in which we see the equation applied at the end of January and of March in the golden numbers 1 and 9. And the same was done by the author of the new Calendar, as appears in the *Compendium of the New Method of Restoring the Calendar* [Compendium novae rationis restituendi Calendarii], sent in 1577 to the Christian Princes by Gregory XIII [Gregorio XIII]. For there the equation of the Moon was made on the last day of January, the last of March, on May 29th, and so on, on which days these two epacts, ω [Greek: ω (ōmega), used here as the symbol for epact 30] and xxix, are jointly written — of which ω signifies epact 30, or o [the round nought]. Just as in the new Calendar there is epact *: above the same days, opposite epact 1, epact * is placed, which in that Compendium signifies the same as ω , and has only a different figure. In the same way, in the new Calendar epact 25, formed in a different character or colour, is written above epacts xxv and xxiv, which are placed at the same day; and the upper epact 25 differs from the

lower xxv only in figure or colour. If, I say, anyone should so ask, let him know that these two epacts, xxv and xxiv, were chosen above all for the equation of the Moon because in this way the lunations according to the cycle of 30 epacts — and especially the 30 paschal lunations — are made to agree better with the lunations of the golden numbers of the Council of Nicaea, whose decrees and ordinances we have retained in all things, so far as it could be done and as was fitting. For we see that the equation of the Moon was made at almost the same places by the golden numbers of the old Calendar as it is made in the new Calendar by epacts xxv and xxiv.

[Margin: Why the equation of the lunar months was made rather by epacts xxv and xxiv placed together than by others.]

Next, just as in that golden-number cycle all 19 paschal lunations contain only 29 days — the first beginning on March 8th, the last on April 5th — so too in this new cycle of epacts all 30 paschal lunations are bounded by the same extreme days, that is, March 8th and April 5th, and each contains 29 days, except the two lunations of epacts 25 and xxiv, when 25 (which rarely happens) [runs] with some golden number from the latter eight, which are greater than

[Margin: Why not all the paschal lunations in the new Calendar are of 29 days, as in the old.]

11. For these two alone are of 30 days — which ought not to seem surprising. For since the Fathers of the Council of Nicaea assigned 29 days to the paschal new moons, because they are counted from March 8th to April 5th, the 19 golden numbers could easily be arranged within those days, on the rule that each should make up a lunation of 29 days. But since there are 30 epacts, they cannot in any way all be arranged within those same 29 days, unless on some one and the same day two are placed together, as was done on April 5th. From this it comes about that the lunation of epact xxiv — and therefore also of epact 25, placed above xxiv — is constituted of 30 days; which would not have happened if the equation of the Moon had been applied after April 5th. But in that case, for the individual epacts to assign 30 days to the individual paschal lunations, it would have been necessary to give the paschal new moons 30 days, so that the last would begin after April 5th — which is as yet unheard-of in the Church.

But if the equation of the Moon were established at the end of March, as was indicated in the *Compendium of the New Method of Restoring the Calendar*, seven paschal lunations of 30 days would result, as plainly appears in that Calendar.

Therefore, in order that the paschal new moons of the new Calendar might be confined within the same limits by which they were bounded from the Council of Nicaea down to the new Calendar, and that only two paschal lunations should comprise 30 days — and so that we might depart less from the ancient custom of the Church — we rejected that equation described in the Compendium and chose the one we have set out; since according to it all the new moons, and especially the paschal ones, are found to have fallen at the time of the Council of Nicaea on exactly the same days on which the golden numbers of the old Calendar show them to have occurred — which by no means happens under the other equation of the Compendium. And this will be evident to anyone if he resolves into golden numbers the epacts both of the new Calendar and of the one described in the Compendium — by what method this ought to be done, we shall teach a little further on.

[Margin: Why epact 19, in a different colour or character, is placed at the last day of December opposite epact 20 [numeral foxed — form uncertain].]

In addition, at the end of December, next to epact 20, epact 19 must also be placed — in a character or colour different from the others — to show the new moon on the last day of December, when epact xix and golden number 19 coincide: which happens only once in many thousands of years, namely once in the thirty nineteen-year cycles of the expanded table, when its eighth line, prefixed with the capital letter D, is in use, as happens at the present time. For in that line alone is epact xix written under golden number 19. That epact 19, fixed to the last day of December, must necessarily mark the new moon at that time will become plain as follows. To the epact running with golden number 19 — whatever it may be — 12 must be added (whereas to the others only 11 are added) in order to form the following year's epact — just as, before the correction of the Calendar, to the last epact xxix running with golden number 19 there were likewise added 12, so that the first epact xi might again be composed, since the lunar cycle necessarily requires this, as we shall show below. It comes about, then, that while epact xix is running, since adding 12 to 19 makes 31, and casting out 30 leaves 1 as the epact of the following year. Therefore, since the use of epact 1 begins in January, where it is assigned to the 30th day, unless epact 19 were repeated at the end of December — so that from it a new moon might begin again before January — the lunation beginning on December 2nd, where epact xix is written, would embrace 59 days, namely as many as are counted from December 2nd to January 29th; because in December there is no other epact xix besides that one, from which a new moon can begin, nor in January any other epact 1 before the 30th day that would present the start of a new moon.

The reckoning of the lunations investigated by the nineteen-year cycle therefore necessarily requires either that epact 19 be repeated on the last day of December — so that the lunation begun on December 2nd by epact xix should contain only 29 days, while another, beginning on the last day [of December] from the same [epact 19], comprises 30 days, namely as many as are counted from the last of December to [January] 29th, opposite epact * — [and] that the lunation beginning on the first day of January from epact * be made 30 days, while another beginning on the first day of January from epact 1 embraces only 29 days; or else that epact 1 be placed at the last day of December in place of epact 19 [?], so that the lunation beginning there should contain [the requisite] days, [the lunation] which, assigned to epact xix at December 2nd, was begun as one of [29] days. But because we began the distribution of the epacts in the Calendar from the first day of January, it does not seem fitting that this equation should be made right at the beginning of the lunations by two [epacts] fixed to it; and so that equation was rejected onto the preceding day, that is, to the end of December, where by the natural order epact 1 ought to be placed if the year did not begin from January — just as in the other months epact 1 is placed above *. But since it did not seem right to repeat it so soon at the end of December, especially since it does not immediately follow, in retrograde order, epact 20 set at the end of December, we therefore judged that epact 19 should be written next to that 20, since these two epacts, 20 and 19, follow each other in correct order.

[Margin: Because epact 19, of a different colour or character, is placed at the last day of December, two new moons cannot fall on the same day in the same nineteen-year cycle.]

Nor indeed does it follow, from this placing of epact 19 next to epact 20, that two new moons fall on that same day within the span of 19 years. For in the cycle in which epact xix runs with golden number 19, epact xx is not in use, as appears in the line of the expanded table prefixed with the capital letter D. For in that line, under golden number 19, epact xix is indeed written, but epact xx is not found among the nineteen epacts of that cycle.

And this is the natural arrangement of the cycle of thirty epacts through the days of the months in the Calendar — and indeed the only one — showing the new moons, the full moons, and the age of the Moon each day at any time; although the new moons are sometimes forced to move up or down in the Calendar, on account of the equation of the Moon that must necessarily be applied, or on account of the intercalary day to be omitted in each span of four hundred years. For this cycle of epacts, thus arranged in the Calendar, can be adapted

perpetually and to any length of the year, provided the due equation is applied at its proper times, as will be explained in the next chapter.

But here is the new Calendar, with the epacts arranged through the days of the months by the method we have explained; to which we have joined the Calendar of the Compendium, so that all may understand that in our Calendar only two

paschal lunations are of 30 days — namely those shown by epact 25 (of a different character or colour) and by epact xxiv; whereas in the Calendar of the Compendium, seven paschal lunations contain 30 days, namely those indicated by epacts *, xxix, xxviii, xxvii, xxvi, xxv, and xxiv.

THERE FOLLOWS

THE GREGORIAN CALENDAR, with the epacts arranged in place of the golden numbers through the days of the months.

The Gregorian Calendar — January, February, March.

Each month presents four columns: **Epact** (*Epactae*, Roman numerals; * = the epact-30 asterisk of the new Calendar); **Dom.** (*Litterae Dominicales*, the dominical letters); **Roman day** (the Roman Kalends/Nones/Ides reckoning; CAL. = Kalends, NON = Nones, IDIB. = Ides, Prid. = *pridie*); and **Day** (*Dies Mensis*, the civil day of the month). The **[Eq.]** column records the marginal doubled-epact marks printed in the left margin (the different-colour/-character epacts of the lunar-month equation): Arabic 25 and Roman xxv, transcribed exactly as the two distinct sorts.

The epact month-tables continue (*Apologia adversus Maestlinum, Liber Secundus, Caput III*). Each panel gives, day by day, the epact whose new moon falls on that day, alongside the dominical letter, the Roman-calendar reckoning, and the civil day of the month. The four columns are headed **Epactæ** (epacts), **Literæ Dñic.** (dominical letters), an unlabeled column for the Roman-calendar day (Kalends / Nones / Ides countdown), and **Dies Mēf.** (day of the month). The doubled epact 25 is set in two sorts — Arabic **25** and Roman **xxv** — which fall on

different rows by the lunar equation; where one form stands in the epact column, the other is set as a small marginal marker to its left. The epact-30 slot is the asterisk *.

Aprilis (April)

[Margin: a marginal Arabic **25** stands to the left of the epact column near days 25–26 (the Roman **xxv** occupies the epact column at day 26). A second marginal marker, Arabic **19**, is set lower in the same margin, near day 31 — the doubled epact 19 (Roman **xix** stands in the epact column at day 2); the exact row of the marginal **19** is uncertain [?].]

SEQVITVR — Here follows

THE CALENDAR OF THE COMPENDIUM of the new method for restoring the Calendar, sent to the Christian Princes by Gregory XIII.

(Sequitur Calendarium Compendii novæ rationis restituendi Calendarij ad Principes Christianos à Gregorio XIII. transmissi.)

These leaves continue the *Calendarium Compendii* (the perpetual calendar in the form the 1577 Compendium transmitted to Gregory XIII), presenting the month-tables for January through September. Each month occupies one panel with four columns: the **Epact** [Epactæ], the **dominical letter** [Literæ Dominicales], the **Roman-calendar day** (the reckoning by Kalends, Nones, and Ides — this column is left unheaded in the source), and the **civil day of the month** [Dies Mensis].

Legend for the transcription below:

- **Mk.** = the thin leftmost margin sub-column, which carries the printed marks: * (asterisk sort) and ☉ (the small circular sort). Blank where the source margin is blank.
- In the **Epactæ** column, the epact value 30 is printed with the circular sort and is rendered ☉ (this is the *Compendium*'s epact-30 glyph — the circular sort, **not** the new-Calendar asterisk). All epact numerals are Roman (e.g. xxv, xxix); no Arabic epact figures occur on these leaves.
- The civil-day column [Dies] is Arabic (1–31); the Roman-day column keeps the printed abbreviations verbatim (CAL. = Kalendæ, NON. = Nonæ, IDIB. = Idibus, Prid. = Pridie).

Calendar of the Compendium — Epact Tables (continued): October, November, December

The three panels are set side by side across the leaf. Each panel gives, left to right: the epact (Epactæ), the dominical letter (Literæ Dñic.), the Roman-calendar day, and the civil day of the month (Dies Mensis). The leftmost Mk. column carries the margin sorts (* asterisk and ○ circular epact-30), read panel by panel from the leaf. Roman xxv/xix vs Arabic figures and the ○/* distinction are preserved as printed; the hooked dominical ç (= c) is kept as set.

Once the 30 epacts have been set out in the calendar in the order we have described, the first day of the Moon — that is, the new moon by the usage of the Church — will be declared to fall, in any given year, on those days to which the epact of that year is attached, just as, before the correction, the new moon was said by the Church to occur, in any year, on those days against which the golden number of that year was placed.

[Margin: How the new moons may be investigated, according to the usage of the Church, from the epacts arranged in the calendar.]

These 30 epacts, moreover, will indicate the new moons forever, with no change at all made to them in the calendar — even though, because of the omission of the intercalary day in the centennial years, the new moons drift downward, that is, toward the ends of the months, or over any span of 312½ years move upward, that is, toward the beginnings of the months. The golden numbers cannot achieve this unless they are rearranged in the calendar in various ways — that is, shifted now downward, now upward, as we said above. For whenever the new moons

descend one day toward the ends of the months, they will be indicated by the lower epact, the one next smaller than the one above. For example, if in some year the new moons are indicated by epact xx, and it then happens that an intercalary day is omitted, the same new moons will be indicated by epact xix, which is placed one day below epact xx in the calendar. But if the new moons ascend one day, they will be found by the higher epact, the one next greater than the lower. For example, if in some year the new moons are to be found by that same epact xx, and it happens that they have then moved up one day because of the $312\frac{1}{2}$ years elapsed, the same must be sought by epact xxj, which is written one day above epact xx in the calendar. But when the smaller or the larger epact is to be taken for finding the new moons, we shall explain fully below, when we teach how the epact of any given year is to be sought.

[Margin: By what principle the epacts can indicate the new moons in perpetuity.]

It was, moreover, an excellent plan to have substituted the 30 epacts in the calendar in place of the golden numbers, and to have distributed them in retrograde order through the days of the whole year. For from this anyone can easily recognize that, if one carefully counts all the days of December that remain after the end of the lunation ending in that same month in any year, that number of days not only gives the epact of the following year — that is, the days by which the solar year exceeds the preceding lunar year, as was said above — but also the lunations of the whole following year begin on the days beside which that epact of just so many units has been placed as there were days left over in December after the end of the lunation ending in that month; so that those surplus days give the epact that marks the new moons of the following year. For example, if the end of some lunation in any year falls on the 26th day of December — which happens while epact xxiiij is in force (since a new moon takes its start from the 27th, to which epact xxiiij is attached) — five days of December will be left over, and these give epact v of the following year, which, according to the earlier arrangement of the epacts, is placed beside the 26th of January, on which the new moon will fall that year; because the 25 days of January, together with epact v preceding them and with those five days that were left over in December, make up a complete lunation of 30 days, the number a lunation ending in the month of January usually contains. Likewise, when a lunation ends on the eighth of December — which happens when epact xij is in use — 23 days of December are left over, and for the following year these give epact xxiiij, attached to the eighth of January, on which the new moon will fall that year. And the reckoning is the same for the rest.

[Margin: That the epacts have rightly succeeded in place of the golden numbers, and are aptly arranged in the calendar in retrograde order.]

Nevertheless, when the golden number of a given year is 19, a unit must be added to the days that remain after the lunation ending in December, in order to obtain the epact of the following year — provided that epact xviiij or xix is not then in use. For while epact xviiij is in force together with golden number 19, the last lunation of the year ends on the final day of December, and no day is left over, because that lunation is one of 29 days, whereas it ought to be one of 30 days and to end on the first day of January, as happens when epact xviiij coincides not with golden number 19 but with the others. Therefore, since the following lunation then begins from epact *, which is set against the first of January, the epact of the following year will be * or ☉; so that no unit is to be added to the ☉ of December, which was left over after the last lunation. Likewise, when epact xix and golden number 19 coincide, the last lunation of the year ends on the second-to-last day of December, and one day is left over, since the next following lunation begins on the last day from epact 19 written in the margin, as we said above; and that one surplus day will give epact 1 of the following year without the addition of a unit, because that lunation then contains only 29 days — whereas in other years, when epact xix and golden number 19 do not coincide, it comprises 30 days and closes on the last day of December. Why these two lunations then come to have only 29 days will be explained below, in Chapter v, on the embolisms; and for what reason, in other cases, a unit is added to the days remaining after any lunation ending in December while golden number 19 is in force, we shall set forth in the next chapter.

[Margin: The days of December that remain after the last lunation of the year usually exhibit the epact of the following year.]

DE CONSTRUCTIONE TABVLÆ EXPANSÆ Epactarum, eiusque æquatione, & de inuentione Epactæ quolibet anno proposito. — CAPVT IV.

[On the construction of the Expanded Table of Epacts, its equation, and the finding of the epact for any given year. — Chapter 4.]

Since the new moons, after 19 solar years have elapsed, return to the same days of the months — though not to exactly the same hours, as was said in Chapter 1 of this book — it comes about that, out of the 30 epacts inscribed in the calendar, only 19 are to be taken, in one or in several centuries of years, corresponding to

the 19 golden numbers, each to each, by which the new moons of those years are investigated. For these epacts will indicate the new moons — just as the 19 [golden] numbers once did — for as long as, after 19 complete years, the conjunctions of the luminaries are found always to return to the same days. But as soon as the new moons have rolled forward by one day, whether toward the beginning of the month or toward its end — which will necessarily happen, both on account of the common centennial years and on account of the $312\frac{1}{2}$ years in which the lunations anticipate by one day in the calendar — other 19 epacts, corresponding to the same 19 golden numbers, will have to be brought in; of which some [are not found among the preceding 19 epacts...]

[Margin: Of the 30 epacts only 19 are used, in one or more spans of a hundred years, for showing the new moons.]

are not found among the preceding 19 epacts, while others are already in use among them as well. And so, when the new moons have risen one day toward the beginnings of the months, one must take the 19 epacts that each exceed by one unit the other 19 that were in use up to that time; but if the new moons have descended one day, one must choose the 19 epacts that are each one unit smaller than the immediately preceding 19 epacts, each to each. For in this way it comes about that those 19 epacts show, in the calendar, that the new moons occur one day earlier than the earlier ones, while these others show them one day later. An account must therefore now be given of which 19 epacts, out of all 30, correspond to the 19 golden numbers at any given time, and when the other 19 are to be summoned, and finally by what art, for any proposed year, the epact by which the new moons are shown may be drawn out from the known golden number of that same year. For this purpose a table of epacts must be constructed, which we call the Expanded [table] because it contains 30 lines, each of which embraces 19 epacts corresponding to the 19 golden numbers, so that all the variety may be laid out that can be found among the various 19 epacts and the same 19 golden numbers. Then another table, the equation of the epacts, must be drawn up, by which we may know which of those 30 lines of epacts is to be taken at this or that time. The construction, then, of the expanded table of epacts is as follows.

[Margin: When the 19 epacts one unit greater than the preceding 19 are to be assumed, and when the lesser ones.]

At the head of the table let all 19 golden numbers be written, beginning with golden number 3, which in the time of the Council of Nicaea was prefixed to the first of January — that is, to the first day of the year — in the calendar. Then, in the lowest line, out of all 30 let the 19 epacts be placed below the golden numbers,

beginning from 1 and each exceeding the next by eleven units, 30 being always cast out whenever the eleven units added to the preceding epact make a sum greater than 30 — yet in such a way that the epact following epact xxvij, placed under golden number 6, exceeds it not by eleven but by twelve units, so that under golden number 1 the epact is ix, not viij; because 12 added to 27 makes 39, and, 30 being cast out, ix remains. Now if from each epact of this lowest line one ascends upward through the natural series of numbers — writing this sign * for 30 [xxx], above which j is again written, then ij, iij, iiij, and so on — the whole expanded table of epacts will be composed, in which the epacts of any line exceed one another by eleven units, except for the epacts written under golden number 1. For these exceed the ones preceding, placed under golden number 19, by twelve units, just as in the lowest line. Epact 25, under these eight golden numbers greater [than the rest] — 12, 13, 14, 15, 16, 17, 18, 19 — is to be written in a color or a figure different from the others. Finally, along the left side of the table are to be set the small letters of the alphabet in their natural order, placing the letter a opposite the lowest line, b opposite the second, and so on up to u, the letter o being omitted lest, on account of its resemblance to the numeral character o, it breed confusion. After u, the capital letters of the alphabet are then likewise to be written, the letters I, K, L, O being omitted for the same reason. For I, L, O are letters used for numbers, since I signifies one, L fifty, and O nothing; while capital K differs little from small k, and so one could easily be taken for the other. These letters indicate which line of epacts is to be received into use at any proposed time, as will be clear from the equation table of the epacts. The same letters are also used in the Martyrology for declaring the age of the Moon on any given day, as is evident from the Martyrology restored to the new plan of the calendar.

[Margin: Why letters of the alphabet, rather than years of the Lord, are attached to the lines of the epacts in the expanded table.]

To these thirty lines of the epacts in the expanded table we have attached letters of the alphabet, rather than the years of the Lord to which the individual lines correspond, because we want this expanded table to be permanent and adaptable to any magnitude of the solar year. If, instead, the years of the Lord were set against them, this could not be done — both because not all years can be contained in so small a space, and, above all, because, since the magnitude of the solar year is still uncertain and not yet sufficiently explored, it is likewise uncertain whether the years of the Lord will always answer to those lines of epacts to which they have been prefixed. Therefore, so that I might point out to posterity how to set up another method of equating the solar year, should this

equating method of ours perhaps be found by astronomers after some years to depart from the truth, we have set down letters of the alphabet, so that any one of them may correspond to any year of the Lord. For in this way it comes about that this table of epacts is both permanent and adaptable to any magnitude of the year, provided one learns carefully, from the equation table that we shall presently construct, which letter of the alphabet corresponds to this or that year of the Lord. Only the equation table will need to be changed, if, as we said, some defect is detected in our equation, as we shall explain a little below.

The composition, however, of the equation table of the epacts, which advances by hundred-year steps, will be set up as follows. In the time of the Council of Nicaea, golden number 3 was prefixed to the first day of the year, as is clear from the old calendar; because at that time, whenever the golden number was 3, the new moon fell on the first day of the year, that is, on the first of January, and on those days of the other months against which the same golden number 3 was set. Since, therefore, in the new calendar this epact * has likewise been placed against the first of January, it follows that the first letter of the expanded epact table — the one in which epact * is placed under golden number 3 — corresponds to the years reckoned from those numbers at the time of the Council of Nicaea, and to the other following years as well, until the Moon requires an equation, that is, until the new moons fall on other days. For wherever epact * stands in the new calendar, there golden number 3 stood at the time of the Council of Nicaea; and where epact xj, which follows epact * in the first line of the expanded table, is placed, there golden number 4 was set — the one that follows golden number 3 at the head of the table. And where epact xxij is written, following epact xj, in that place golden number 5 stood. In the same way the remaining epacts, all placed in the first line of the expanded table, have their seats in those places of the calendar opposite which, in the old calendar, the golden numbers answering to them at the head of the same expanded table were placed. This will become clear if we carefully compare the days of the months of the new calendar, set opposite all 19 golden numbers, with the days of the months of the old calendar, set opposite all 19 golden numbers. A few places in the calendar are excepted, in which some difference is found — which is no wonder, because in February and in certain other months of the old calendar the equation of the lunations was made on exactly the same days, so that they were alternately of 30 and 29 days, just as it was made by us through the epacts xxiiij and xxv attached to the same day in six months, as we said a little earlier. Nor can it therefore be said that the cycle of the golden number is not rightly arranged in the old calendar, or the cycle of the epacts in the new; since each has its lunations alternately of 30 and 29 days, as reason requires. For although this happens not on the same [days...]

[Margin: How the expanded table of epacts is to be constructed.]

in exactly the same places. Yet this matters little, since no cycle can correspond in every respect to the celestial lunations, as we shall explain below. The Paschal lunations of March and April, however — which is more to the point — differ in nothing between the old calendar and the new. Therefore, since the Council of Nicaea was held around the year 325, the capital letter P, which is set at the head of the first line of epacts in the expanded table, must be placed to the left of the year 320 in the equation table. We preferred to take this year rather than 325, because it lies close to the time of the Nicene Council and is more conspicuous than 325, being a leap year [bissextilis] — as are the centennial years through which the equation table advances.

Next: since more than 300 years elapsed from the birth of Christ to the Council of Nicaea, the new moons must necessarily have fallen one day later in Christ's time than at the time of the Nicene Council. For over a span of 300 years the new moons anticipate their places by very nearly a whole day in the calendar, as we said above. It follows that in Christ's time the same 19 golden numbers would have answered to 19 different epacts — had this cycle of epacts and the new calendar then been in use — namely to those contained in the second line of the expanded table, each of which is one unit less than the epacts of the first line, one for one. For all the epacts of the second line are placed in the new calendar below the epacts contained in the first line; and so the new moons are indicated one day later by the epacts of the second line than by the epacts written in the first line, which we said were in use at the time of the Nicene Council. And if, in place of the epacts of the second line, the golden numbers were set in the calendar as they answer to those second-line epacts at the head of the expanded table, all the golden numbers would be seen to be one day lower than the golden numbers at the time of the Council of Nicaea. For this reason, in the equation table, next to the year of the Lord 1, the capital letter N must be written — the letter prefixed to the second line of epacts in the expanded table.

[Margin: The new moons of the [golden-number] cycle ought, in the Church's use, for the most part to follow the conjunctions found from the tables.]

[Margin: The new moons of the golden number around the time of the Council of Nicaea were nearly the same as those that occurred in the heavens.]

Further: so that the order of the lunar equation — by which, we said, the new moons anticipate their places by one day over a span of 312½ years — may be rightly established for the years after the Council of Nicaea, we must first fix the

root from which such an equation takes its start. For although, as we said, the first line of epacts in the expanded table agrees with the cycle of the golden number as issued at the time of the Nicene Council, nevertheless the root of the equation is not to be referred to that time, but to many years after that Council — as we shall make plain in the following way. The Church of God, in order duly to celebrate the movable feasts, is not greatly concerned that the new moons found by the cycle should agree exactly with the new moons drawn out from the tables of mean motions. On the contrary, of set purpose it so arranges the cycle in the calendar that its new moons follow very nearly those which are elicited from the tables — lest it should ever happen that the Paschal fourteenth Moon [Luna XIII] which the cycle offers should run ahead of the mean full moon by so great an interval that Easter would be celebrated before it, against the decrees of the Fathers and of the Councils, as we shall teach more fully a little below. Now the cycle of the golden number, as arranged by the Fathers of the Nicene Council, shows that around the year of the Lord 325 the new moons for the most part fell on the same days on which they are known, from the tables of mean motions, to have occurred in the heavens. Therefore that arrangement of the golden number, made at the time of the Nicene Council, cannot be reckoned suited to the Church's use, since it shows the conjunctions of the luminaries to have occurred earlier than the Church's practice requires, and so would not seldom have set Easter to be celebrated before the mean full moon — about which we shall write more below. Rather, it must have begun to serve the purpose (so far as concerns the due celebration of the movable feasts) some years after the Nicene Council had passed — namely, as many as are needed for so great an anticipation of the new moons in the calendar that the golden numbers should now exhibit the same new moons so long a time after the astronomical mean new moons that there is no danger of Easter being celebrated before the mean full moon, except very rarely indeed. This came about in the year of the Lord 550 — that is, 200 years and more after the Council of Nicaea — at the time when Justinian I held the Roman Empire.

[Margin: The new moons of the golden number around the year of the Lord 550 fell later than those in the heavens, and were therefore better suited to the use of the Church.]

For at that time the golden numbers indicated the new moons about sixteen hours later than at the time of the Nicene Council, as is established from the astronomical tables. At that same time, too, all the disputes between the Greeks and the Latins were laid to rest, and the cycle of the golden number was received into use, as it had been arranged in the calendar by Dionysius the Abbot

[Dionysius Exiguus] around the year of the Lord 532, in the reign of that same Justinian I.

[Margin: The root of the equation of the epacts must be referred to the year of the Lord 550; and why.]

Accordingly, the root of the equation is fixed by us at the year 550, because at that time the cycle of the golden number showed the new moons more correctly and more suitably for celebrating the movable feasts, as will be clear from what we are about to say. Nor is it an objection that in this way the Paschal fourteenth Moon [Luna XIII] is sometimes indicated by the cycle later than it should be. For less fault is committed in celebrating Easter if the fifteenth Moon [Luna XV] is taken for the fourteenth [Luna XIII], as Theophilus, Bishop of Alexandria, rightly advises in his letter to the elder Emperor Theodosius; because the greater number contains the lesser, but the lesser does not likewise contain the greater. But since in the equation table we set down only the centennial years, as the more celebrated and better known, we shall lay it down that the Moon anticipates its places by one day over a span of 300 years — although in fact its equation requires $312\frac{1}{2}$ years — so that we forestall the true equation by $12\frac{1}{2}$ years, of which nevertheless account must be taken once the sum collected from them amounts to 100 years.

[Margin: The lunar equation is anticipated every three-hundredth year by $12\frac{1}{2}$ years, of which account must nevertheless be taken when they have completed the sum of 100 years.]

For just as, above, in the equation of the solar year we determined that the intercalary day is to be omitted every hundredth year — forestalling the true equation, according to the Alphonsine tables, by 34 years, of which nevertheless account is likewise taken every fourth centennial year (for when they have grown to the sum of 136 years, unless the customary intercalation of one day were made every fourth centennial year, the equinoxes would slip forward by a whole day toward the ends of the months) — so too, in the equation of the Moon, account must be taken of those $12\frac{1}{2}$ years omitted every three-hundredth year. Thus, when the sum collected from them reaches 100 years, the lunar equation is not to be applied in the three-hundredth year after the last equation, but should anticipate in the calendar only in the four-hundredth year. For since in 300 years we suppose the Moon to anticipate its places by one day $12\frac{1}{2}$ years earlier than it should, it follows that in 600 years we suppose it to anticipate its places 25 years earlier than the matter requires, and in 1,200 years 50 years earlier, and in 2,400 years 100 years earlier than the matter demands. Therefore, since in the span of

100 years the Moon anticipates its places by about eight hours — so that in 300 years we reckon it to anticipate its places by a whole day, that is, by 24 hours — it follows that, if the equation is applied 100 years earlier than it should be, the Moon will have climbed upward in the calendar toward the beginnings of the months by only 16 hours. The equation is therefore not to be applied then; rather, a further 100 years must be waited for, in which the Moon will climb upward by another 8 hours, which together with the previous 16 make 24 — that is, a full...

TABVLA EPACTARVM EXPANSA. AVREI NVMERI. (Table of the Expanded Epacts. The Golden Numbers.)

The single expanded epact table is printed across the two facing pages of the opening. The left leaf (printed p. 68, headed TABVLA EPACTA- / AVREI NVMERI.) carries the golden-number columns **iiij–xj**; the right leaf (printed p. 69, headed RVM EXPANSA. / AVREI NVMERI.) carries the golden-number columns **xij–xix**, then **j** and **ij**. The two half-titles read together as TABVLA EPACTARVM EXPANSA. Both leaves share the same 30 index-letter rows in the left-hand Literæ column. On each leaf the six columns beneath the spanning decorative sub-header spell out the letters **E · P · A · C · T · Æ** (EPACTÆ) across the golden-number heads.

[Margin (left leaf, p. 68): Index letters of the epacts, for the variety of the times, corresponding to the same letters in the table of the equation of the epacts.]

Left leaf (printed p. 68) — golden numbers iiij–xj

Table of the Equation of the Expanded Epact Table

[TABVLA ÆQVATIONIS TABVLÆ EPACTARVM EXPANSÆ]

(Caput IV, continued.)

The table runs across this opening in three panels per page, read left to right and top to bottom, continuing from panel to panel and page to page. For each year of the Lord (given by centuries, with the reform anchor 1582 and its cyclic recurrences at 17582 and 32582), it lists four things: the **index letter** with which one enters the Expanded Epact Table; the **year AD** (*Anni Domini*); whether the year is **bissextile** (Biff. = *bissextilis*, i.e. a leap year); and the **equation mark** in the last column — a single crescent ☾ (one equation), a double crescent ☾☾ (the coincident equation that recurs every 2500 years). A marginal dagger † marks each boundary of the ten-thousand-year index-letter cycle (years 1700, 11700, 21700, 31700, 41700). The crescent-column values are transcribed exactly as read from the leaf; the fixed periodicity of the marks was used only as a cross-check, never to supply a value.

a whole natural day — on account of which the Moon then necessarily requires an equation — so that the new moons are not shown in the Calendar a whole day later than they should be. At which centennial years the sum of the omitted 12½-year periods accumulates up to 100, so that the equation of the Moon must consequently be deferred into the following century, will become plain from what we shall shortly set out below.

[Margin: Continuation of the table of the equation of the Epacts through the centennial years, up to the year of the correction.]

Having laid this down: since the table of the equation proceeds, as we have said, by centennial years, we shall prefix to the year 500 the same capital letter P, to indicate that the same first line of Epacts is then to be taken up which had been in use in the time of the Council of Nicaea — seeing that around the year of the Lord 500 the Cycle of the golden number had become better suited to the use of the Church than it had been at the very time of the Council of Nicaea, as we explained above. And although in this way we anticipate by 50 years the root of the equation, which we fixed at the year 550, we shall nevertheless take account of those years in their proper place. Then, because after 300 years the Moon anticipates one day in the Calendar, the last line of Epacts must then be taken up — the line containing those Epacts each of which, in the Calendar, precedes by

one day (toward the beginning of the months) each corresponding Epact of the first line. (And each Epact of that first line is greater by one unit than each Epact of this last line, since the former are composed from the latter by the addition of a unit, casting out 30 nonetheless when the sum is greater than 30, and writing the sign * when the sum is 30 — just as the Epacts of any upper line are formed from the Epacts of the line next below it. Of this kind is the lowest line of the expanded table compared with the topmost; for the lowest is the higher of the two. For the expanded table must be understood as a kind of circle containing 30 rows that return upon themselves, so that these letters — capital P and small a, and hence the first line and the lowest — are contiguous.) Since this is so, the small letter a must be assigned to the year 800 in the table of the equation, since this year is the three-hundredth after the year 500. By the same reasoning, since after a further 300 years the Moon anticipates a second day, the small letter b must be assigned to the year 1100 in the table of the equation. And in the same way the small letter b [?] must be prefixed to the year 1400.

[Margin: In what way the equation of the Epacts is established in the year of the correction, 1582.]

[Margin: The letter of the equation of the year of the correction, 1582, which.]

MOREOVER, since in the year 1582 ten days were taken away from the month of October, so that the vernal equinox might be restored to the 21st of March, it follows that after this subtraction all the new moons fell ten days later than the Epact of that year — which before the correction was vj — had indicated in the Calendar. Therefore the line of Epacts had then to be taken up in the expanded table beside which the capital letter D is placed — the line which, of course, holds the tenth place from the line of the small letter c exclusive, descending toward the small letters b and a, and from there toward the capital letters P, N, M, and so on. For all the Epacts of that line which has the capital letter D attached are ten units less than the Epacts of the other line, to which the small letter c is prefixed; since these are composed from those by the addition of 10 units, casting out 30 when the sum is greater than 30, and writing the sign * when the sum is 30. Likewise the Epacts of that line to which the capital letter D is attached are written in the Calendar 10 days below the Epacts of the line to which the small letter c is attached, exclusive. And so in the table of the equation, at the year 1582, after the removal of the 10 days from the month of October, the capital letter D is to be prefixed.

[Margin: In what way the table of the equation of the Epacts is established after the correction, account being taken also of the equation of the solar year.]

BUT since, after the removal of the 10 days, the solar year too must be equated — by omitting three intercalary days in every 400 years, namely one in each of the three earlier centuries, while retaining the intercalary day in the fourth century, as we explained in the previous book — all the centennial years must henceforth be written in the table of the equation, beginning from the year 1600, which is bissextile, and with the word "Bissextile," in this form "Biff.," attached to every fourth year from it, such as are 2000, 2400, 2800, 3200, and so on. For in this way the table of the equation — which after the correction of the year depends on both the year, the lunar and the solar — will be set up more easily. And since from the year 1400, where the lunar equation was last applied in the table of the equation, up to the year 1600 the 300 years have not elapsed, the Moon will not need an equation. Since therefore the solar year too does not then require an equation — the year 1600 being in the usual way bissextile — the same capital letter D must be prefixed to the year 1600 in the table of the equation which was prefixed to the year 1582.

[Margin: The letter of the equation of the year 1600, which.]

But since from the year 1400 up to the year 1700 there have elapsed 300 years, the Moon would then need an equation, if it were true that it anticipates one whole day in 300 years. But since more truly it anticipates one day in $312\frac{1}{2}$ years, and those $12\frac{1}{2}$ years, omitted four times from the year 500 up to the year 1700, make 50 years, and we thereby forestall the lunar equation by that many years (for we ought to have equated the Moon in the year 850, not in the year 800, because from the year 550 — where the root of the equation was placed by us — up to the year 850 there fall 300 years) — years which, together with the earlier 50 years, make up 100 years — the lunar equation is not to be applied in the year 1700, but is to be deferred to the following century, 1800, as was said above. But because in the year 1700 the intercalary day is omitted, on account of the equation of the solar year — namely so that the vernal equinox does not stray further from the 21st of March — the result is that the new moons then fall one day later. For this reason the line of Epacts must then be taken up which has the capital letter C at its head, and whose Epacts are one unit less than the Epacts near the capital letter D, and which for that reason show the new moons one day later in the Calendar. Hence it comes about that in the year 1700 the capital letter C is to be prefixed in the table of the equation.

[Margin: The letter of the equation of the years 1700, which.]

AGAIN, since in the year 1800 the intercalary day is once more omitted, the new moons ought again to fall one day later; but since then, as we have said, the Moon

needs an equation (for into this century the lunar equation was deferred from the year 1700), the result is that the new moons neither ascend nor descend, but remain on the same days. For the day on which the new moons are forced to descend toward the ends of the months, on account of the equation of the solar year, is restored toward the beginnings of the months by the equation of the Moon. On that account the same capital letter C is to be set before the year 1800 in the table of the equation.

[Margin: The letter of the equation of the year 1800, which.]

But in the year 1900, in which again the intercalary day is omitted, the new moons will descend by one day, and therefore to that year the capital letter B is prefixed in the table of the equation. And the same letter is set before the year 2000, because then neither is the intercalary day omitted, nor have 300 years elapsed from the last lunar equation made in the year 1800, so that neither year requires an equation. Likewise, because in the year 2100 both the intercalary day is omitted and the Moon needs an equation — since 300 years have elapsed from the year 1800, in which the last lunar equation was made, up to the year 2100 — the result is that the new moons then neither descend nor ascend in the Calendar, but remain on the same days...

[Margin: The letters of the equation of the years 1900, 2000, 2100, which.]

(as we said above concerning the year 1800). For this reason the same capital letter B is affixed to the year 2100 in the table of the equation. Furthermore, since in the year 2200 the intercalary day is omitted, while the Moon does not need an equation, the new moons will descend by one day, and therefore in the table of the equation the capital letter A is to be assigned to the year 2200; and by the same reasoning the small letter u is to be prefixed to the year 2300.

[Margin: The letter of the equation of the years 2200, 2300, which.]

But because in the following year 2400 — which is the third centennial year after the year 2100, in which the Moon was equated — the Moon requires an equation, while the solar year does not demand one (since that centennial year is bissextile), the new moons will necessarily ascend upward by one day in the Calendar. Therefore the line of Epacts must then again be taken up, to which the capital letter A is prefixed, and accordingly the same capital letter A is to be attached to the year 2400 in the table of the equation. But in the year 2500, on account of the equation of the solar year which then occurs, the new moons are again forced to descend by one day, and therefore to that same year the small letter u must again be affixed, just as in the year 2300.

[Margin: The letter of the equation of the years 2400, 2500, which.]

AND in this way the table of the equation will be continued to infinity, provided account is taken both of the intercalary day — whether omitted or retained — and of the lunar equation which is owed every 300 years; so long as those $12\frac{1}{2}$ years, omitted in each span of 300 years, are not neglected, but as soon as a sum of 100 years has been collected from them, the lunar equation is deferred to the next centennial year, as was done by us in the year 1700, from which we threw the equation forward into the year 1800. This same thing must again be done in the year 4200 — namely 2400 years after the year 1800, into which the lunar equation was deferred on account of those 100 years which had grown out of the omission of the $12\frac{1}{2}$ years. For the lunar equation which ought to be made in the year 4200, on account of the 300 years elapsed from the last equation, must be made in the following centennial year, 4300. And in the same way, after another 2400 years, the lunar equation must be thrown forward into the next centennial year, and so on.

[Margin: Continuation of the table of the equation of the Epacts after the correction, through the centennial years, to infinity.]

FROM all these things a threefold rule can be drawn for extending the table of the equation to any number of years, which is as follows.

[Margin: A threefold rule for continuing the table of the equation of the Epacts to infinity.]

1. WHEN in some centennial year the intercalary day is omitted and the Moon does not need an equation — that is, when the solar year alone needs an equation — one must descend in the expanded table to the next lower line of Epacts, and its letter must be attached to that centennial year.
2. WHEN, however, in some centennial year the intercalary day is not omitted, but the Moon needs an equation — that is, when the lunar year alone needs an equation — one must ascend in the expanded table to the next higher line of Epacts, and its letter must be assigned to that centennial year.
3. WHEN, finally, in some centennial year the intercalary day is omitted and the Moon needs an equation; or when neither is the intercalary day omitted nor does the Moon need an equation — that is, when both years, or neither, are to be equated — one must remain on the same line of Epacts of

the expanded table, and the same letter must be prefixed to that centennial year which was attached to the preceding centennial year.

ALL these things you see observed in the table of the equation. For to every centennial year that letter is always prefixed which represents the line of Epacts in the expanded table that must then be taken up — according as one must descend, or ascend, or remain on the same line, as these very rules teach. Furthermore, to make the reckoning of the equation easier, we have added this sign,), to those centennial years in which the Moon calls for an equation: single indeed for every third centennial year, but double for every fourth centennial year, into which the equation is deferred from the preceding three-hundredth year; which happens, as we have said, 2400 years after the year 1800, in which such a deferral of the equation was first made. For then the equation is deferred into the year 4300 from the year 4200, although the year 4200 is the third centennial year from the last lunar equation made in the year 3900. The same thing must be done 2400 years after the year 4300 — that is, from the year 6700, from which the equation is deferred into the year 6800. Likewise 2400 years after the year 6800, that is, in the year 9200. For then the equation must be applied not in the year 9200, but in 9300; and so with the rest.

[Margin: By what device the perpetual table of the cycle of the Epacts in the Gregorian Calendar has been constructed, together with the table of the equation.]

BY exactly the same artifice has the table of the equation of the perpetual Cycle of Epacts in the Gregorian Calendar been constructed, since it does not differ from this one. The perpetual table of the Cycle of Epacts in the same Calendar takes its beginning from the Epact *, and proceeds through all 30 Epacts, each of which is composed by the addition of 11 to the immediately preceding Epact, casting out 30 from the sum when they can be discarded. Then, above each Epact of that same table, is written the letter of the alphabet which in the expanded table is set down near that same Epact beneath the golden number 3. Finally, the Epact xxv. 25. is doubled beneath the capital letter F, and marked with different characters or colours — the one in red, the other in black — for the reason set out above. All of which will be clear to anyone who diligently compares that perpetual table of the Cycle of Epacts, which we have here repeated, with the expanded table of Epacts.

TABELLA CYCLI EPACTARVM PERPETVA

Perpetual Table of the Cycle of Epacts.

The table pairs each index letter (upper cell) with its Epact (lower cell), set in three horizontal bands across the page. The index letters run through the 30-letter cycle, turning from the small letters back to capital P; the Epacts advance by 11 (casting out 30). Epact 30 is shown as the asterisk *; Epact 25 is doubled as xxv. 25. (Roman and Arabic) beneath F. Terminal-sort forms (i- vs j-terminal) are transcribed as printed.

Band 1:

| Index letter | P | l | C | c | p | F | f | f | M | i | A |
|--------------|---|---|------|------|--------|----------|---|------|---------|---|---|
| Epact | * | x | xxij | iiij | xiiiij | xxv. 25. | v | xvii | xxviiij | i | x |
| | | j | | | | | j | | | x | x |

Band 2:

| Index letter | a | m | D | d | q | G | g | t | N | k | B |
|--------------|---|-----|-----------|-------|---|------|-----|--------|------|---|----|
| Epact | j | xij | xiiij [?] | iiiij | x | xxvj | vij | xviiij | xxix | x | xx |
| | | | | | v | | | | | | j |

Band 3:

| Index letter | b | n | E | e | r | H | h | u |
|--------------|----|-------|---------|---|-----|-------|------|-----|
| Epact | ij | xiiij | xxiiiij | v | xvj | xxvii | viii | xix |

We preferred, however, to write the index letters of the expanded table in this table above those Epacts which in the expanded table are placed near the same Epacts beneath the golden number 3, rather than above those which correspond to the same letters beneath the golden number 1 — so that it might be more easily understood that this table has been drawn from the expanded table. Nor was there any other reason for this arrangement.

Although the letters of the alphabet in the table of the equation seem to preserve no order, they nevertheless return upon themselves in the manner of a cycle over a span of 300000 years, so that the table of the equation of the Epacts, extended through 300000 years — beginning from the year 1700, where for the first time the capital letter C is used in place of the capital letter D — will be perpetual, if the world were to endure forever and the method of equating both years, solar and lunar, prescribed by us, should never need correction. This we shall make clear as follows. After 10000 years — that is, after 100 centennial years elapsed from the year 1700 — namely in the year 11700, exactly the same variety of letters returns, though not the same Epacts. For just as after the year 1600 the

same letter C is attached to the two years 1700 and 1800; the same letter B to the three years 1900, 2000, 2100; the letter A to the year 2200; the letter u to the year 2300; while in the year 2400 the letter A is repeated, and in the year 2500 the letter u; and the same letter t is assigned to the three years 2600, 2700, 2800, and so on — so exactly it comes about after 10000 years have elapsed. For after the year 11600, to the two years 11700 and 11800 the same letter i is assigned; to the three years 11900, 12000, 12100 the same letter h; to the year 12200 the letter g; to the year 12300 the letter f; in the year 12400 the letter g is repeated; in the year 12500 the letter f; and to the three years 12600, 12700, 12800 the same letter e is prefixed, and so on. Exactly the same is observed after 10000 years elapsed from the year 11700; for in the year 21700 the same variety returns. Likewise in the year 31700 — that is, 10000 years after the year 21700 elapsed. Likewise in the year 41700 — that is, after 10000 years likewise elapsed from the year 31700. And the reckoning is the same for the rest. This appears in the years set out below, excerpted from the equation table above; although the same holds true also in every span of 10000 years, from whatever centennial year one begins. Moreover, in the table of the equation, to the years at which the orders of 10000 years begin, we have prefixed this sign, +.

Table of the equation of the expanded table of Epacts (excerpt, showing the year-orders 1700, 11700, 21700, 31700, 41700). Each panel pairs an index letter with its year (Anni Domini). The rightmost panel additionally carries the bissextile marks and the lunar-equation sign (crescent). **The only header text actually printed on the page is Anni Dñi, over the year column of each panel; the header cell above every index-letter column, and above the bissextile and equation columns, is blank.** The bracketed [Litera], [Biff.] and [Equation] heads below are therefore editorial labels supplied for legibility, not transcription.

The reason for this is that in 10000 years there are contained 25 centuries, into which the lunar equation owed to the preceding centennial year is thrown forward, four times exactly; and therefore the lunar equations proceed in one span of 10000 years just as in any other. Since therefore the bissextile centennial years too behave in the same way in all spans of this kind — which is evident in the table set beside [the text], in which we have added the marks both of the lunar equation and of the bissextile years, excerpted from the same equation table above — it is necessary that the letters of the equation proceed in the same proportion in every span of 10000 years.

[Margin: The letter of the equation of the Epacts, after the year 10000, proceeds in altogether the same proportion; and why.]

THEREFORE the whole labour lies in constructing the table of the equation in the first span of 10000 years. For if, from the year 11700 — that is, after 10000 years elapsed from the year 1700 — the same order of letters is kept (the beginning, however, being made from the letter i), together with the marks of the lunar equation and of the bissextile centennial years which was kept from the year 1700 up to the year 11600 inclusive, and if the same is done after further and further intervals of 10000 years, until 300000 years after the year 1700 are

completed, then the whole table of the equation will have been constructed, embracing all the varieties.

[Margin: The whole labour of constructing the table of the equation of the Epacts is contained in the cycle of 10000 years; and why.]

BUT that after 300000 years not only is the same variety of the letters of the equation preserved, but the very same letters, in number, altogether return in a cycle, will become plain from this: that after 10000 years elapsed from the year 1700...

there occurs a mutation of 43 letters — that is (once the entire cycle of 30 letters of the expanded table has been cast out) of 13 letters — beginning from the letter C (majuscule) prefixed to the year 1700 and running up to and including the letter k (minuscule) set against the year 11600. In the second span of 10000 years there will occur a mutation of 26 letters, from the same letter C (majuscule) — that is, of another 13 letters, counting from the letter i. In the third span [the mutation is] 39, that is (casting out 30) 9; in the fourth, 22; in the fifth, 35, that is (casting out 30) 5; in the sixth, 18; in the seventh, 31, that is (casting out 30) 1; in the eighth, 14; in the ninth, 27; in the tenth, 40, that is (casting out 30) 10; in the eleventh, 23; in the twelfth, 36, or 6; in the thirteenth, 19; in the fourteenth, 32, or 2; in the fifteenth, 15; in the sixteenth, 28; in the seventeenth, 41, or 11; in the eighteenth, 24; in the nineteenth, 37, or 7; in the twentieth, 20; in the twenty-first, 33, or 3; in the twenty-second, 16; in the twenty-third, 29; in the twenty-fourth, 42, or 12; in the twenty-fifth, 25; in the twenty-sixth, 38, or 8; in the twenty-seventh, 21; in the twenty-eighth, 34, or 4; in the twenty-ninth, 17; and in the thirtieth, 30. For — I say — in each span of 10000 [years] there is a mutation of the letters, so that in the thirtieth span there is effected a mutation of all 30 letters of the expanded table — that is, once 300000 years have elapsed, the very same letters return in exactly the same order. The equation table of the epacts is therefore contained within a cycle of 300000 years: something that may well seem downright incredible to not a few.

[Margin: The use of the expanded table and of the equation of the epacts.]

The use of both tables — the expanded one and the equation — consists in this: that we may learn which of the 19 epacts correspond to the 19 golden numbers at any given time, and thus, once the golden number of any year is known, which epact answering to it in the expanded table is to be taken for tracing the new moons in the Calendar. This is done as follows. The proposed year is sought in the equation table, if it is one of the centennial years; but if it is not one of the

centennials, take the centennial year next below the proposed year, or else the year 1582 if the given year falls after the correction and before the year 1600. Then carefully note the letter prefixed to that centennial. For the line of epacts that has this same letter prefixed to it in the expanded table is to be used not only for the proposed year but for all the other years from that centennial up to the centennial year that has a different letter affixed to it. Therefore, if you take the epact that in that line answers to the golden number of the year in question, set at the head of the table, it will indicate all the new moons of that year in the Calendar.

For example. Given the year 1593, one must take in the equation table the year 1582, since it is the next below, together with the letter D (majuscule). Then in the expanded table one must take the line of epacts to which the same letter D (majuscule) is prefixed. For this line will be in use from the year 1582 after the correction up to (but excluding) the year 1700, which already has a different letter prefixed. And since in the year 1593 the golden number is 17, to which, in the assumed line of epacts of the letter D (majuscule), the epact xxvii answers, this epact will be employed in that very year 1593; and the new moons will fall in that year on the days to which the epact xxvii is prefixed in the Calendar.

Again, given the year 1916, one must take in the equation table the year 1900, together with the letter B (majuscule); and in the expanded table the line of epacts is to be taken that has the same letter B prefixed. For this line will be in use from the year 1900 up to (but excluding) the year 2200, to which a different letter is prefixed. And since the golden number of the year 1916 is 17, to which, in the adopted line of epacts of the letter B (majuscule), the epact 25 answers — marked with a different character from the others — this epact will indicate the new moons of that whole year in the Calendar.

[Margin: The use of the little table of the perpetual cycle of epacts, which is set forth in the Calendar.]

Finally — to give an example from before the correction of the year as well — if the year 415 is proposed, one must take in the equation table the year 320, as the one next below it, together with the letter P (majuscule); and in the expanded table the line of epacts to which this same letter P (majuscule) is assigned. This is the line then to be used. Since, then, in the year 415 the golden number was 17, to which in that line of epacts the epact iiij answers, all the new moons fell in that year on the days to which the epact iiij is assigned. And the same procedure holds in all other cases.

In the same way the epact may be found from the little table of the perpetual cycle of epacts, as explained in the Gregorian Calendar. For if from the equation table one takes the letter matching the proposed date, and finds the like letter in the perpetual table, the epact of that letter will answer to golden number 3, the next epact to golden number 4, and so on up to golden number 19, going back from the last epact, xix, to the first (*), if need be. For this little table is like a kind of circle, as we said of the expanded table. The epact preceding the letter taken in the perpetual table will answer to golden number 2, and the one before that to golden number 1, as was set forth in the Calendar, Canon 2, where you will find many examples of this matter. For example. In the year 3239 the letter r (minuscule) answers in the equation table, and the golden number is 10. So if to the letter r (minuscule) in the little table of the perpetual cycle you assign golden number 3, to the next 4, to the one next after that 5, and so on, returning to the beginning of the table, the golden number 10 of the proposed year will fall into the fourth cell of the letter c (minuscule), where the epact iiij is placed — the epact due to the proposed year. In the year 3211, however, to which the same letter r (minuscule) answers, the golden number is 1. So by assigning golden number 3 to the cell of that same letter r (minuscule), golden number 2 to the preceding cell, and 1 (printed j) to the cell of the letter E (majuscule), you will find there the epact xxiiij, which is to be used in the year 3211 for investigating the new moons. And so with the rest.

Now the reason why the epact of the following year is formed by adding 12 — rather than 11 — to the epact of that year in which the golden number is 19 is this. Out of the 209 days that are made up in 19 solar years, from the 11 days by which each solar year exceeds each lunar year, seven embolismic lunations are constituted, six indeed of 30 days but one of 29, as we said in Chapter 1 of this book. Hence one ought not always to cast out 30 from the sum gathered by adding 11 to the preceding epact when that sum is greater than 30; and accordingly, when the year in question is a lunar embolismic year containing 13 lunations — as will be understood from the next chapter — but in the seventh and last embolism, whose lunation embraces only 29 days, only 29 ought to be subtracted. Since, then, the customary rule always casts out 30, so that all the embolisms may be alike, it is necessary after the last embolism to add 12 to the epact in order to produce the epact of the following year: namely, so that the one unit taken from the preceding epact may be restored to the following one.

[Margin: Why 12 is added to the epact concurrent with golden number 19, in order to make the epact of the following year.]

For if only 29 had been taken from the earlier epact, as would be fitting, it would be enough to add 11 to obtain the epact of the following year, as is done in the other cases. For in that way there would be produced the very same epact, by number, that was in use 19 years earlier, and the new moons would return to the same days, as the reckoning of the nineteen-year cycle requires — just as happens when 12 is added to the last epact once 30 have been taken away in the last embolism. Now although the year in which the golden number is 19 was not, before the correction of the Calendar, the seventh or last embolismic year, but the penultimate, or sixth, as we showed in the preceding chapter — nevertheless, because that year was always embolismic, and the number 19 is the greatest and last of all the golden numbers, it pleased the computists to make the addition of the number 12 at the time when golden number 19 is in use. For no notable error in the lunations can arise from this. For the same reason we too have chosen to make that addition when the golden number is 19, whatever epact then answers to it, so that we may follow the footsteps of the ancients as far as can be done — even though that year is not always the last embolismic year, nor indeed always embolismic. But these matters will be perceived more plainly and clearly in the next chapter.

[Margin: Why, when golden number 9 is running, a unit must be added to the days that remain over in December after the last lunation, so that the epact of the following year may be established.]

Hence is clear the reason why, when golden number 19 is in use, a unit is added to the days that remain over after the last lunation of December, in order to form the epact of the following year — as was stated at the end of the preceding chapter. It is because 12 must be applied to the epact running with golden number 19, whereas only 11 is added to the others, to produce the epact of the following year, as we have just shown. For if a unit were not then added, those surplus days would present an epact one unit smaller — namely the one that would be produced by adding 11 to the earlier epact, as is done in the other cases — and not the one that is generated by adding 12; which is absurd. Yet these two epacts, xviii and xix, are excepted: for if they are in use together with golden number 19, a unit is not to be added to those surplus days; rather the surplus days themselves exhibit the epact of the following year. This is because at that time one day is taken from the lunations of these two epacts in December, so that they comprise only 29 days, whereas otherwise they always comprise 30. The result is that the lunation of each of these two epacts then ends in December one day earlier than it should, and consequently a day is left over at the end of December which otherwise would have to be added to the other surplus days. But

why, when golden number 19 is running with those two epacts, their lunations in the month of December contain only 29 days, we shall explain in the next chapter, where the embolisms will be treated.

[Margin: By what method the equation table of the epacts is to be renewed, should another magnitude of the year be found.]

Now if, after some centuries have elapsed, a magnitude of the year is discovered by astronomy different from the one we now follow — such that the Alphonsine year is no longer a mean between the greatest and the least year, and consequently the omission of three intercalary days in every span of 400 years forces the vernal equinox to recede further from 21 March, so that it cannot return to it — then the equinox will have to be restored to 21 March by intercalating, or omitting, out of the ordinary course, as many days in some year as the number by which it has departed from the 21st, whether toward the end of the month or toward its beginning, as we taught in Chapter 5 of the earlier book. And once the equinox has been restored in this way, our equation of the solar year — which orders three intercalary days to be omitted in every span of 400 years — must be resumed, or another more convenient one instituted, according to the known magnitude of the solar year to be found. Then the equation table must be renewed in this manner. If, in order to bring the equinox back to 21 March, several days have been intercalated, one must ascend in the expanded table from the line of epacts then in use by as many lines as there were intercalary days interpolated, so that the line be used whose epacts are greater, by as many units, than the epacts of the other line that was employed before that extraordinary intercalation — greater by as many days as were intercalated; for the new moons will accordingly occur just so many days earlier than before, on account of those adventitious days added to the year out of course. But if, in order to restore the equinox to 21 March, several days have been taken out of the year, one must descend in the expanded table by as many lines from the line of epacts then in use as there were days removed from the year, so that for investigating the new moons the line be adopted whose epacts are smaller, by as many units, than the epacts of the other line that was in use before this removal of days — smaller by as many days as were removed; for the new moons will accordingly occur just so many days later than before, on account of those days taken out of the year out of course. The letter afterward assigned to this line of epacts — the line up to which the ascent or descent was made — is to be prefixed in the equation table to that year in which the extraordinary intercalation or removal of days was made. Finally, beyond that year the equation table must be continued according to the precepts handed down earlier, beginning from the centennial

year that will be nearest to the year in which the equinox was restored (if that year is not itself a centennial): so that when the solar year needs equating, but not the lunar, a descent is made in the expanded table to the next lower line; when the lunar year, however, requires equating, but not the solar, an ascent is made to the next higher line; and when finally neither year, or both, is to be equated, one remains on the same line of epacts — as was said above in that threefold rule.

[Margin: By what method the equation table of the epacts is to be renewed, should the Moon perhaps be found to advance by one day not in $312\frac{1}{2}$ years, but in fewer or more.]

And if some defect should be detected in the table in the equation of the Moon — such that the Moon advances its seat forward by one day in the Calendar not in $312\frac{1}{2}$ years, but in fewer or more — the method of the Moon's equation in the table can easily be changed, by carefully observing when the years omitted at the centennials make up a sum of 100 years, so that the equation of the Moon is then deferred to the next centennial.

[Margin: That the epacts do not change their places in the Calendar, even if the equation table of the epacts is renewed on account of some other magnitude of the year perhaps found, or on account of some other period of the lunations.]

Even though, after the lapse of some centuries, the equation table must of necessity be corrected in the way we have described — by the authority of the Roman Pontiff, through skilled astronomers — nevertheless no change on that account will have to be made in the Calendar itself. Rather the disposition of the epacts, which we described above, will remain wholly intact and unimpaired. For since the epacts are so distributed among the days of the year that no day is left empty, it comes about that, whether the new moons descend or ascend in the Calendar, other epacts — always answering to the same golden numbers — can be assumed for tracing them, as the equation table shall direct, without any change of the epacts in the Calendar. And this can suit neither the golden number nor any other cycle which, disposed in the Calendar, does not fill all its places. For if the new moons must, on account of the equation, ascend or descend, then in those places of the Calendar that are empty and destitute of the numbers of the cycle we shall of necessity lack the index numbers of the new moons — unless the cycle be disposed otherwise, namely so that the number indexing the new moons then falls into those empty places to which the new moons have slipped. In which case 30 Calendars would have to be made — as many, that is, as there are days by

which the new moons can ascend and descend — the 30 Calendars which we described at length in the exposition of the Gregorian Calendar.

[Margin: Why the golden number, or any other cycle that does not fill all the places of the Calendar, cannot be immutable in the Calendar.]

But if someone should say that it is not necessary for the cycle to be arranged otherwise in the Calendar, and that it is enough to take the number nearest to those empty places for tracing the new moons — since indeed no notable error can be committed in this, seeing that the cycle cannot show the new moons exactly and precisely, however it is placed in the Calendar, but must indicate them now earlier, now later — if, I say, someone should speak thus, who does not see that the new moons cannot in this way ascend or descend by [the required] days as often as the equation table prescribes? Who, too, does not observe that a different number of the cycle then indicates the new moons than the one which the customary rule for finding the golden number — or the number of some other cycle — exhibits, and that consequently, at every time the new moons change, new canons for finding that number would have to be composed? And how much disturbance this would bring to affairs both ecclesiastical and political, no one fails to see.

[Margin: Why the Gregorian Calendar is called perpetual; by what method the cycle of epacts of the new Calendar is said to be adaptable to any magnitude of the year.]

Now it is on account of this stability alone of the cycle of epacts in the Calendar — namely, that nothing in it need be changed even if another magnitude of the year, or another period of the Moon, be found, and the equation table must accordingly be altered — that we have called this Gregorian Calendar Perpetual and everlasting, and never liable to any change; and rightly so, indeed, since in it the cycle of epacts fills all the places and, directed to the customary golden number, is accommodated to any magnitude of the solar year, and also of the lunar year, provided only the equation table is constructed as we have just explained.

[Margin: That the new Calendar is not called perpetual on account of the restitution of the equinox effected and its equation prescribed.]

Nor did it ever enter the mind of any of us who were summoned by the Supreme Pontiff to this task of correction, to suppose that the Calendar is perpetual on account of the restitution of the equinox and the equation of the solar year prescribed in it — as Maestlin wrongly and insolently objects. For since it has been observed by the more expert astronomers that the year is now greater, now

smaller, and its magnitude has not yet been surely ascertained — as the great variety of the tables testifies — who would be so shameless and rash as to dare to affirm and accept that the equinox will remain perpetually in the seat to which it is recalled, even if the equation of the solar year be instituted with every precaution? And that we certainly did not assert this, that most abundant witness testifies — the little book of the Compendium concerning the restoration of the Calendar, sent to the Christian princes, in which a twofold ratio of equating the solar year was proposed, one from the Alphonsine [tables], the other from Copernicus: which we should certainly never have done had we judged our equation, instituted according to the opinion of the Alphonsines, to be so certain that it could never be liable to any change.

[Margin: Why a twofold method of equating the solar year was proposed in the Compendium sent to the Christian princes.]

The same is testified most plainly by these words, nearly the last of that Compendium: "The vernal equinox, therefore, having been restored to the place from which it had fallen — or rather, since, once the cycle of epacts (which can be accommodated to any magnitude of the year) has been set in the Calendar, and the manner of intercalation which we have described, together with the equation of that cycle, has been applied — the years and months will hereafter agree with the reckoning of the Sun and of the Moon; and [if] much variety or disagreement should thereafter arise — should this ever happen — they can most beautifully be restored to their state by this same means. But if to anyone the Alphonsine computations seem too uncertain to be trusted, and he thinks the more recent ones rather to be adhered to, he will assuredly understand that the disposition and arrangement of this ingenious cycle, and of the table of epacts devised by Lilius, is such that it can without any trouble be fitted to the computations of Copernicus, or of anyone else, if a table of the equation drawn from them be substituted for the one we have written in the margin." See how clearly and openly we profess that our equation of the solar year is not so firm and settled that, should restoration at any time be needed, it cannot want it.

[Margin: How easy the restitution of the equinox is, by the omission or intercalation of some days.]

And indeed, as far as the equinox is concerned, it can easily be recalled to its former seat, whenever it shall have deserted it, by the omission or intercalation of some days, by edict of the Supreme Pontiff — as in this very correction of the year it was done by the removal of ten days.

But to arrange in the Calendar a cycle for showing the new moons that could be accommodated to every magnitude of the year and be perpetual — so that nothing should ever have to be changed in its disposition in the Calendar — this always seemed to the ancient Fathers and to astronomers exceedingly difficult, not to say impossible; because, since the Sun requires fewer days than the Moon in order to advance its seat by a whole day in the Calendar, it did not seem possible that one and the same cycle inscribed in the Calendar should show the new moons over a long time. For when, for the equation of the Sun, one day is removed from the year, the new moons must necessarily descend by a day in the Calendar, since the Moon does not yet need equating, as we said above. Unless, then, the cycle is disposed otherwise in the Calendar, it can in no way come about that the same number of the cycle as before indicates the new moons. By the same reasoning, when the Moon requires equating but not the Sun, the new moons will necessarily ascend by a day in the Calendar. Therefore neither then will the same number of the cycle as before rightly show the new moons, unless it be moved upward into those places to which the new moons have advanced. But if someone should [tali...]

that a single day had to be removed from the year, in such a matter and at such a time, so that the new moons might be kept on the same dates, would thereby drive the equinox out of its own proper seat and force it to slide toward the end of the month. And so, if one applies an equation to the solar year, he will incur no small loss of the new moons; whereas if he sets out to equalize the lunar year, he will necessarily throw the equinox out of its proper place. So that the common saying fits his case exactly:

He falls into Scylla, wishing to avoid Charybdis.

But if the equinox and the new moons were both to advance by one day, over the same interval of time, toward the beginnings of the months in the Calendar, this whole difficulty would be entirely removed. Since this is so, it must be reckoned no small achievement in the correction of the Calendar that the discordant motions of the Sun and Moon have been brought into such a concord that the equation of the one does not obstruct the equation of the other, whatever that may be. Hence the Calendar may fairly be called perpetual, even though the equinox, over and above the prescribed equation, occasionally needs some further remedy to keep it from straying too far from the 21st. The greatest thanks and praise, therefore, are owed to Aloysius Lilius [Luigi Lilio], who devised so ingenious a Cycle of Epacts, one that, inscribed in the Calendar, points out the

new moons perpetually and can so easily be accommodated to any length of the year.

[Margin: The new Calendar I judge worthy of praise, in that in it the discordant motions of the Sun and Moon are brought into concord, even though the equinox, on account of the unevenness of the solar year, sometimes needs another equation besides the one applied every 400 years.]

And if anyone thinks that this perpetual method of ours for finding the new moons from the Epacts — the one set out by means of the expanded table, once the equation has been applied at its proper time — is foreign to the customary form, which investigates the new moons by means of the golden numbers written in the Calendar, let him consult the thirty nineteen-year Cycles of golden numbers that we drew out of the Cycle of thirty Epacts in our Exposition of the Gregorian Calendar, in which the whole reckoning of the lunar year according to the practice of the Church consists — so that they are, as it were, the equivalent of the 30 Calendars that we said would have to be drawn up, if the golden numbers were to be retained in the Calendar. From these he will plainly understand that the method of finding the new moons by the Epacts and the method by the golden numbers arranged in 30 Calendars are entirely one and the same, and that the one agrees with the other in every respect. But since the multitude of 30 Calendars is inconvenient — both because from them confusion could easily arise in various regions, one region using this Calendar and another that one at the same time, and because, in order to construct the Paschal tables from them and to announce correctly the age of the Moon in the Martyrology, 30 Paschal tables and 30 Martyrologies would have to be made — it is safer and more consonant with the affairs of the Church, both in the Calendar and in the Paschal tables and the Martyrology, to use the numbers of the Epacts, since a single row of Epacts distributed through the Calendar accomplishes all of this most conveniently, as is evident from the new Calendar and from the Martyrology adapted to the restoration of the year.

[Margin: The method of finding the new moons from the Epacts is no different from the one carried out by means of the golden numbers.]

In that same Exposition of the Gregorian Calendar we also described another thirty tables of lunations, corresponding in order to the thirty Cycles of Epacts of the expanded table, or to the thirty Calendars of golden numbers. From these too it is manifest how aptly and fittingly both the Epacts in the new Calendar and the golden numbers drawn out of the Epacts in the 30 Calendars have been positioned for indicating the new moons, and how distinctly and orderly the

lunations advance through the Calendar in alternations of 30 and 29 days. Let the kind Reader consult both sets of tables there; for we did not think it worth the trouble to repeat them here, since they are rather long.

ON THE EMBOLISMS, AND THE LEAP (AS THEY CALL IT) OF THE MOON. CHAPTER V.

Now that we have inscribed all 30 Epacts in the Calendar, and have set up their expanded table together with the equation table, so that for any century it may be known which 19 of the 30 Epacts are to be taken up — the ones corresponding to the nineteen golden numbers and demonstrating the new moons — it will not be out of place to discuss here also a few things about the embolisms and the leap of the Moon. For from this it will become clearer that the Epacts have been rightly positioned in the Calendar, and that their Cycle performs exactly the same as the Cycle of the golden number, or as any other Cycle formerly performed. But two things must first be explained. First, that any lunation is assigned by the Computists to the month in which it ends, even though it may have had its beginning in another month. On this matter there is this little verse:

[Margin: Why a lunation is assigned to the month in which it ends.]

Let the lunation be given to the month in which it is completed.

If, however, anyone should want the reason for this, the following may be offered. When the Epact * is current, there is no doubt that the first lunation of the whole year begins on the very Kalends of January, together with the year itself, and is to be assigned to January, ending on the 30th of January. Therefore the second lunation, whose end falls on the last day of February, will have to be assigned to February, even though its beginning falls at the end [è vltimo] of January. The third, beginning on the Kalends of March and ending on the 30th, must be given to March. The fourth then to April, whose end falls on the 28th day of April, even though its beginning occurs on the last day of March. The fifth to May, which ends on the 28th day of May, although it begins on the 29th of April. And so, throughout that whole year, the lunations will have to be assigned to the months in which they end, even though they begin in others: so that the twelfth lunation, whose end falls on the 20th day of December, is to be assigned to December, even though it begins on the 22nd of November. And since in a common lunar year only 12 lunations are contained, the following lunation — beginning on the 21st of December and ending on the 19th of January — will have to be called the first of the following year, and consequently assigned to January, the first month of the year; since on the 20th of December the

common lunar year of 12 lunations is now finished. From which it follows that the ensuing lunation, which begins on the 20th of January, must be assigned to February, in whose 17th day it ends; and that likewise the other lunations of the same year must be granted to the months in which they end, even though they take their beginning from others. In just the same way, in an embolismic lunar year, the last, that is the thirteenth, lunation will have its end in December; and the one next following — whether it begins on some day of December, or at the start of January — will have to be called the first of the following year. This appears to be altogether the reason why all the Computists assign lunations to the months in which they terminate: namely so that the first lunation of the year, having its end [in Januarie] would be ascribed to the first solar month of the whole year [?], reason itself so demanding.

In the second place, it must be declared from which Epact any nineteen-year Cycle takes its beginning — that Cycle, namely, in which are contained the 19 Epacts of some one row out of those 30 described in the expanded table, corresponding to the nineteen golden numbers. For those thirty Cycles of the expanded table do not begin from those Epacts which hold the first place in them and are set under golden number 3, as someone considering the matter not attentively enough might perhaps suppose; rather, every nineteen-year Cycle of the expanded table begins from the Epact * — and from the first day of January — if * is contained in that Cycle; or else from Epact 1, if * is not found in the given Cycle.

[Margin: That the 19-year Cycle of Epacts begins either from *, if * is contained in the cycle in question, or from 1, if * is not found in the given cycle.]

Now the Epact * is contained in Cycles 1, 2, 4, 5, 7, 9, 10, 12, 13, 15, 16, 18, 20, 21, 23, 24, 26, 27, and 29; and therefore each of these Cycles takes its beginning from it, under whatever golden number it may be positioned. But in the other 11 Cycles — namely in 3, 6, 8, 11, 14, 17, 19, 22, 25, 28, and 30 — the * is not found. Therefore these Cycles take their beginning from Epact 1, under whatever golden number it may be found positioned.

[Margin: Which of the nineteen-year Cycles of the expanded table begin from *, and which from Epact 1.]

For although in every Cycle one is free to take the beginning wherever one pleases, nevertheless, because 19 lunar years are made equal to just as many solar years — though not in every respect, as was said above — it is fitting that the beginning of the 19-year Cycle in the Epacts be taken there where the custom

of the Church places the beginning of the solar year in the Calendar, namely on the Kalends of January, or at least near the Kalends. So that, whenever in a nineteen-year Cycle the Epact * inscribed at the Kalends of January is in use, the beginning of the Cycle is taken from it, and that new moon falling on the first of January is the first in that whole nineteen-year Cycle. But since it not rarely happens that in the whole span of 19 years no new moon falls on the Kalends of January — because throughout that whole time the Epact * is not in use, as is manifest from the eleven higher Cycles of the expanded table, namely from 3, 6, 8, 11, 14, 17, 19, 22, 25, 28, and 30 — the beginning of our Cycle cannot then be taken from the Kalends of January, nor from the Epact *, since it is not contained in that Cycle. Rather, the Cycle will have to be begun from that Epact which is nearest to the Kalends of January: either from Epact xxix, set before the second day of January, or from that Epact which would have to be inscribed at the last day of December, if the year began from there. So that the new moon nearest to the beginning of the solar year — such as the one that falls either on the second day of January or on the last day of December — is called the first in that whole Cycle. But since the new moon falling on the second day of January is not the first of the whole year, but the second — for the preceding lunation, which has its end on the very Kalends of January, is assigned to January and called the first of the whole year, as we wrote a little earlier — the new moon falling on the last day of December must be taken instead. For this one is then the first of the whole year, and is assigned to January, and is nearest to the beginning of the solar year in that whole nineteen-year Cycle; since all the other new moons assigned to January in that Cycle fall on other days of December that precede the last.

[Margin: That each nineteen-year Cycle begins either from the first day of January or from the last day of December. That the nineteen-year Cycle of the golden number begins either from the golden number written at the Kalends of January, or from the one that would have to be ascribed to the last day of December, if the solar year began from there.]

There are, therefore, two days to be assigned to the beginning of our Cycle: namely, the Kalends of January, where the Epact * is placed, and the day before the Kalends of January, where Epact 1 would have to be positioned, if the solar year began there — just as in other places of the Calendar Epact 1 is positioned next above Epact *. But since the solar year begins from the first day of January and ends on the last of December, and the Epacts in the Calendar — by reason of [their arrangement] — [Epact 1] set before the last day of December precedes Epact *, and Epact xx, which by natural order falls below E[pact 1], is still in use in the month of December, in those years [in which] the Epacts change in the

month of January [?], just as our Epacts too change in the month of December; so that the beginning of any nineteen-year Cycle of our Epacts is in use either from Epact *, when that is contained in the nineteen-year Cycle, or from Epact 1, when * is not found in it.

From this it is gathered that the beginning of any nineteen-year Cycle of ours is either from the first day of January and from Epact *, when that is in use in the nineteen-year Cycle, or from the last day of December and from Epact 1, when * is not found in that Cycle.

And this is the reason why, in the 30 tables of lunations, we began each nineteen-year Cycle either from Epact * or from Epact 1, and why the first lunation of the whole Cycle takes its beginning either from the Kalends of January or from the last of December; while meanwhile all the golden numbers gave the beginning to the nineteen-year Cycle [at the same points].

Furthermore, that you may see that those two days must necessarily be assigned to the beginning of our nineteen-year Cycle, we shall show that the same thing would have to be done in the Cycle of the golden number, if it were described in the Calendar. Let us therefore take in hand the ancient Roman Calendar, in which golden number 3 is placed at the first day of January, and in which both equations — namely of the solar year and of the lunar — were preserved. For the beginning of the Cycle of the golden number has always been taken from the point at which golden number 3 is placed at the first day of January; because, right up to our correction, the beginning of the Cycle was always taken there, for the reason that from golden number 3 the embolismic years are numbered, as will be most plainly established from what we shall deliver a little further on, concerning the embolisms, in this same chapter.

[Margin: That the Cycle of the golden number, before the correction, always began from golden number 3.]

And so, if on account of the equation of the solar year — the Moon not yet requiring an equation — the several golden numbers must be moved downward by one day, golden number 3 will be written at the second day of January, and to the first day will be prefixed golden number 14, since this is always positioned next above it in other places of the Calendar. Therefore the beginning of the Cycle will then be made from golden number 14; and if from the same first day the golden numbers must be moved downward, golden number [3] will fall

onto the third day of January, and golden number 14 onto the second, while the first day will appear empty — because above golden number 14 is set golden

number 6, not immediately, but with one empty day left between, as is clear from Chapter 2 of this book. Therefore the beginning of the Cycle cannot then be made from the first day of January, since no golden number is placed there; nor indeed will golden number 14, now written [in that place], give the beginning: because the lunation beginning on the second day, while golden number [14] is current, is the second of that year, not the first, as we taught before. The Cycle must therefore then be begun from that golden number which would have to be ascribed to the last day of December, if the solar year began from there — that is, from golden number 6, which in the Calendar is always two days higher than 14. For the lunation then falling on the last day of December is the first of the whole following year, which indeed golden number 6 indicates, the one that shows the new moons in the preceding year; and it is then ascribed to the last day of December, since it must be moved forward by two days from the 29th day of December, where it is described in the ancient Calendar. But the reason why golden number 6 must then be placed at the last day of December — the number which in the ancient Calendar is found always written above 14 — is that the golden numbers cannot preserve in the Calendar the order in which they are placed, as was stated [declared] in Chapter 2 of this book, [in the discussion] of the golden numbers, whose index letter is a capital M. This is clear if, on account of the equation of the Moon (the solar year then not requiring an equation), the several golden numbers had to be moved upward in the Calendar by one day: [golden number 14, previously] inscribed [at the second day], would ascend to the second day [?], golden number 3 would be [at] the last of December, with the first day of January left empty, since there [is] no golden number there — [so that the Cycle would begin] not from the first day of January, but from the last day of December, according to the argument brought forward above, if we were to begin the solar year from there. Although, because [the golden numbers] do not preserve in the Calendar the order [?] of the Cycle of the golden number, as we said, [golden number] 2 [falls] under golden number 13, which then [falls on the second-to-last day of December];... in the thirtieth Calendar of golden numbers [?].... the beginning of the Cycle of golden numbers thereafter [is taken] from the first day of January, if a golden number is placed there,... [or from the last day, if] the first day of January has no golden number,... since all the golden numbers..., on the first day of January and on the last of December,... in which the same golden numbers occupy various days, according, that is, to the 30 rows [of the expanded table] to which they correspond.

[Margin: That the beginning of the Cycle of the golden number is taken successively from all the golden numbers, if the equation of the solar year and of the lunar year is applied.]

Our Cycle of Epacts in the Calendar is fixed, and Epact 1 would always have to be placed at the last day of December, if the year began there — so that Epact 1 at the last day of December would perpetually be the point from which the beginning of the nineteen-year Cycle of our Epacts must be taken, namely from Epact 1, as has been declared.

The Alexandrians, moreover, always [began the Cycle of the golden number] from the last day of their year, which corresponds to the 28th day of our August; for at the first day of the year — that is, of the month Thoth, which corresponds to the 29th [of August] — they placed a golden number, because at that time no new moon fell on the first [day]. But on the last day — that is, on the 35th day of the month Mesore, which corresponds to the 28th of August — golden number 19 was placed, which then stood as the equivalent of golden number 1; since golden number 1 was taken in place of golden number 19, which gave the beginning in the following year. [?] Their Cycle began from golden number 1. But in the Ecclesiastical Calendar, according to the practice of the Church, [it was] on golden number 3 [that] a new moon fell, by the usage of the Church, on the first day of January [?];... and so the Cycle of the golden number always took its beginning from it, that is, from golden number 3, as we said above.

[Margin: Why every nineteen-year Cycle of Epacts always begins from *, or from Epact 1. That the Cycle of the golden number, among the Alexandrians, always began from the last day of their year, and from golden number 1.]

But let us now proceed to the explanation of the embolisms. An embolism, then, is a lunar year [containing 384 or 383 days], as we shall shortly say. Nor should it seem strange to anyone that, in a single [solar] year that contains only 365 days, 13 lunations can occur. For since, as was stated above, the lunations are assigned to the months in which they end, so that every lunation beginning in the month of December and ending in whatever [month] is to be ascribed to January and called the first of the whole year, it can happen that in certain years, after the first lunation of some year, there still remain 12 whole lunations before we come to the first lunation of the following year — namely, if after the first lunation of some year there remain 353 days, which is precisely the number comprehended by 12 lunations. When, then, this happens, there are 13 lunations in that lunar year, and it is called an embolismic year, containing 384 or 383 days, although the solar year consists of only 365 days. But when, after the first lunation of some year, there remain only 11 whole lunations, [the year] is called common, containing 354 or 353 days.

[Margin: By what reasoning 13 lunations can be contained in a single year. That in every nineteen-year Cycle there are 7 embolismic years, how this may be known, and which they are.]

And since the solar year described in the Calendar, of 365 days, exceeds the common lunar year [of] 354 [days] by 11 days, we shall easily recognize which years in each nineteen-year Cycle are embolismic — that is, of 13 lunations — and how many. For whenever, out of those 11 days [that remain over in each single year], which are left over in each solar year, the collected sum has become 30 or greater, then [the lunations] will be completed in that year — save in the nineteenth year of the Cycle, in which a sum of only 29 days [is collected]; because from that sum of days one lunation is produced [namely, a sum of 30 days yields one lunation, and a sum of 29 days combined also yields one lunation] — which, added to the other 12 lunations that were completed before it, makes 13 lunations. This

[Margin: Why in every nineteen-year Cycle the years 3, 6, 9, 11, 14, 17, and 19 are embolismic.]

This, moreover, happens in each Cycle only seven times — namely in the years 3, 6, 9, 11, 14, 17, and 19 of every Cycle — which are all, and the only ones, that are embolismic, as is clear from the 30 tables of Lunations. For in each Cycle there are found 7 years of 13 Lunations, and the reason for this is as follows.

In the first three years of the Cycle, 11 days are left over three times, making 33 days; of these, 30 are assigned to the thirteenth (or embolismic) Lunation of the third year, and 3 days still remain. Joined to the 11 residual days in the years 4, 5, and 6, these make 36 days, of which again 30 are assigned to the thirteenth (or embolismic) Lunation of the sixth year, and 6 days still remain. These, with the residual 11 days in the years 7, 8, and 9, make 39 days. Out of these, 30 complete the embolismic Lunation of the ninth year; the remaining 9 days, with twice-11 residual days in years 10 and 11, make up 31 days, of which 30 are assigned to the embolismic Lunation of the eleventh year, while 1 day is left over. This, with the thrice-11 residual days in years 12, 13, and 14, makes 34 days, of which 30 go to the embolismic Lunation of the fourteenth year, and the remaining 4 days, with the thrice-11 superfluous days in years 15, 16, and 17, make 37 days, of which 30 fill out the embolismic Lunation of the seventeenth year. But the remaining 7 days, with the twice-11 superfluous days in years 18 and 19, make 29 days for the embolismic Lunation of the nineteenth and last year. For it is necessary that one of the 7 extraordinary Lunations comprise only 29 days, since in 19 years the 11 days that are left over each year make up 209 days, which produce six Lunations

of 30 days each and one of 29 days — because it lacks one day to complete the number of 30 days. For 210 days would make 7 Lunations of 30 days.

[Margin: When an embolismic year contains 384 days, and when 383.]

Therefore an embolismic year whose Lunation contains 30 days will comprise 384 days; but one that has an embolismic Lunation of 29 days will contain 383 — because the 354 days of the twelve Lunations, together with the 30 days of the embolismic Lunation, make 384, whereas with the 29 days of the embolismic Lunation they make only 383.

And this is the natural order of the 7 embolisms contained in any nineteen-year Cycle: that the first six embolismic Lunations should each contain 30 days, and the seventh and last only 29. Yet this order is usually altered, so that the seventh embolismic Lunation is not always the one of 29 days, but sometimes some other — the alternation of 30- and 29-day Lunations requiring this — because the nineteen-year Cycle does not always begin from golden number 1, but from some other. For, of all the nineteen-year Cycles of Epacts in the 30 expanded tables, only two — those to which lines 8 and 9 of that table refer, prefixed by the capital letters **D** and **C** — take their beginning from golden number 1. Hence only in those is the nineteenth year, which is the seventh embolism, the one that contains the embolismic Lunation of 29 days; in the other Cycles the seventh embolism will have an embolismic Lunation of 30 days, and the embolismic Lunation of 29 days will be assigned to some other embolism, as will become clear from what we shall say a little further on — once we have first explained somewhat more fully how these 7 embolisms stand in each nineteen-year Cycle of our Epacts, which always begins either from Epact * or from Epact i, as was stated above.

[Margin: That the first Lunation of an embolismic year ends on one of the first 11 days of January, and why.]

Whenever, then, the first Lunation of some year ends on one of the first 11 days of January — (for we showed above that every Lunation ending in the month of January, even on its first day, is assigned to January and is the first of the whole year) — that year is necessarily embolismic. For if the first Lunation ends on 11 January, there will remain in that year, up to the end of December, 354 days, in which 12 more Lunations can still occur. Hence that year will comprise 13 Lunations, and so will be embolismic. But if the first Lunation ends before 11 January, more than 354 days will remain in that year up to the end of December; and so 12 more Lunations can occur in them, and some days besides — at least

one — will remain over. Thus this year too will be embolismic, since it comprises 13 Lunations.

[Margin: That eleven Epacts are always embolismic — that is, that a year is embolismic in which one of them is current, with whatever golden number is running — and which they are.]

From this it follows that these eleven Epacts — xix. xx. xxi. xxii. xxiii. xxiiii. xxv. 25. xxvi. xxvii. xxviii. xxix. (for we count xxv and 25 as one Epact) — set against the first 11 days after the Calends of January, are always embolismic; so that a year whose Epact is any one of those 11, whatever golden number is then current, is embolismic. This is because a Lunation beginning in January from any one of those Epacts is the second of that year, while the one preceding it began in the month of December, being completed [in January].

Hence, again, it is gathered that in any embolismic year the thirteenth (or last) Lunation necessarily ends on one of the last 11 days of December, to which these Epacts are ascribed: xxix. xxviii. xxvii. xxvi. xxv. 25. xxiiii. xxiii. xxii. xxi. xx. 19. For if some Lunation ends on any one of those 11 days, the following Lunation — which is the first of the next year after the embolism — begins from one of those 11 Epacts which are prefixed to the 11 days following the first day of January, and which we have said are embolismic. This is proof that throughout the year whose last Lunation ends on one of the last 11 days of December, that embolismic Epact was in use from which the following first Lunation of the next year begins, and therefore that that year was embolismic. There is only one exception: when the last Lunation of an embolismic year — with Epact xix running together with golden number 19 — begins not from Epact xix but from Epact *, which is not embolismic. The reason for this is that the last year [of the Cycle] passes over, in the following year, into Epact *. For if that year did not close on the last day of December, and Epact xix were then changed, the Lunation would have to be written — in its natural order, that is — under Epact xix, corresponding to the day now assigned to the first of December [?]; and thus the first Lunation after the embolismic year would then also begin from Epact xix, which is embolismic. [?]

And to make it plainer that these eleven Epacts — xix. xx. xxi. xxii. xxiii. xxiiii. xxv. 25. xxvi. xxvii. xxviii. xxix. — are all embolismic, and the only ones, all 30 lines of Epacts

of the expanded tables must be carefully considered. For in each of them you will always find seven of those 11 Epacts placed in the third, sixth, ninth, eleventh,

fourteenth, seventeenth, and nineteenth position from Epact * (if that is contained in the line taken), or from Epact j (if Epact * is not found in the line taken). Since, then, every nineteen-year Cycle of our Epacts takes its beginning either from Epact * or from Epact j, and in every Cycle these seven years — the third, sixth, ninth, eleventh, fourteenth, seventeenth, and nineteenth — are embolismic, as has been said, it is clearly concluded that those 11 Epacts which we said were ascribed to the 11 days following the first day of January are embolismic. The same is gathered still more evidently from the 30 tables of Lunations, in which all those 11 Epacts have 13 Lunations and so are embolismic, whereas the other Epacts comprise only 12 Lunations.

[Margin: That these enumerated Embolisms, and the 7 years in each nineteen-year Cycle, are all — and the only ones — that are embolismic, and how this is recognized from the expanded table and from the 30 tables of Lunations.]

To these eleven embolismic Epacts must sometimes be added Epact xviii. For this too is embolismic in the year in which the golden number is 19 — which indeed happens in one Cycle only, out of all 30 Cycles of the expanded table, namely the ninth, to which the capital letter **C** is prefixed. For in that one alone Epact xviii occupies the nineteenth place from Epact *, from which that Cycle begins; and it has been shown above that the nineteenth year of any Cycle is embolismic. In no other Cycle is Epact xviii found in an embolismic place — that is, in the third, sixth, ninth, eleventh, fourteenth, seventeenth, or nineteenth from Epact * or j, which is the beginning of the Cycle.

[Margin: That the year in which Epact xviii and golden number 19 concur is also an embolism, and why.]

The reason why Epact xviii is then embolismic is twofold. Let the first be this. When Epact xviii and golden number 19 concur, 12 must be added to it, so that Epact xxx (or *) of the following year is formed, as we showed in the previous Chapter. Hence the last Luration of the year in which Epact xviii, together with golden number 19, is in use ends on the last day of December, and so is to be assigned to December. From this it follows that in that same year 13 Lunations are contained, of which the first ends on 12 January, having its beginning on 14 December, from Epact viii, which was in use the previous year. The twelfth Luration of that same year closes on 2 December, and the thirteenth on the last day of that month. Let the second reason be this. Since the year in which Epact xviii and golden number 19 concur is the last of the nineteen-year Cycle — as is clear from that ninth line of the expanded table which has the capital letter **C** — the last, embolismic Luration in it will contain only 29 days, as we said above.

Therefore, since its first Lunation ends on 12 January, there still remain 353 days, which are enough to fill out 12 Lunations, of which the last comprises only 29 days; and so that year, containing 13 Lunations, will be embolismic, and will comprise only 383 days.

[Margin: Why the year in which Epact xviii does not concur with golden number 19 is not embolismic.]

But when Epact xviii concurs not with golden number 19 but with any other, only 11 (not 12) are added to it, so that Epact xxix of the following year is formed. Hence, once the twelfth Lunation of the year has ended on 2 December, while Epact xviii is in use, the first Lunation of the following year will begin on 3 December and will end on the Calends of January; and therefore the earlier year will be common, since it comprises only 12 Lunations, while the later year will be embolismic, of 13 Lunations, since its Epact is xxix, which we said above is embolismic. And so those 11 Epacts — xix. xx. xxi. xxii. xxiii. xxiiii. xxv. 25. xxvi. xxvii. xxviii. xxix. — inscribed against the 11 days following the first day of January, are always embolismic, with whatever golden number they concur; but Epact xviii, set against 13 January, is never embolismic, except when golden number 19 is used together with it. All this appears most clearly in the 30 tables of Lunations above. For in the ninth table alone you see Epact xviii, running with golden number 19, having 13 Lunations; in the others, only 12. Wherefore Epact xviii may be called ambiguous, or indifferent — now embolismic, now not — whereas all the other Epacts are perpetually either embolismic or common.

[Margin: Which seven golden numbers were embolismic in the old Calendar.]

In the old Calendar these seven golden numbers were embolismic: 2, 5, 8, 11, 13, 16, 19 — as Campanus [Campanus of Novara] rightly teaches, though some other Computists differ somewhat from him. For since all of them are written near some of the 11 days following the Calends of January — that is, since they are placed in the Calendar between the first and the thirteenth of January, just like our embolismic Epacts — the Lunation ending in January just before any one of them (namely on the second, fourth, fifth, seventh, eighth, tenth, or eleventh day) is the first of the whole year; after which, since at the least 354 days remain in the year, which are enough to fill out 12 other Lunations, that year comprises 13 Lunations, the second of which takes its beginning in January from one of those seven golden numbers. Hence the year whose golden number is any one of those seven will be embolismic.

[Margin: That in the old Calendar the golden-number cycle necessarily took its beginning from 3.]

And since only seven years in any nineteen-year Cycle — namely 3, 6, 9, 11, 14, 17, and 19 — are embolismic (because in them alone those superfluous days which, as we said, are left over each solar year can make up one extraordinary Luration, as we said before), it is clearly gathered that in the old Calendar the cycle of the golden number always took its beginning from golden number 3, as we said above — because those seven embolismic golden numbers occupy, counting from golden number 3 alone, the third, sixth, ninth, eleventh, fourteenth, seventeenth, and nineteenth place, as appears in this table.

| Ordo annorum Cycly | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|--------------------|---|---|---|---|---|---|---|----|----|----|
| Cyclus aur. num. | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| Aur. num. Embolis. | | | 5 | | | 8 | | | 11 | |

| Ordo annorum Cycli | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 |
|--------------------|----|----|----|----|----|----|----|----|----|
| Cyclus aur. num. | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 1 | 2 |
| Aur. num. Embolis. | 13 | | | 16 | | | 19 | | 2 |

(*Table.* Two stacked panels covering the 19 years of the Cycle. Row 1, "Ordo annorum Cycly / Cycli" [Order of the years of the Cycle]: 1–19. Row 2, "Cyclus aur. num." [Cycle of the golden number]: the golden number belonging to each cycle-year, running 3, 4, 5 ... 19, 1, 2. Row 3, "Aur. num. Embolis." [Embolismic golden numbers]: only the seven embolismic golden numbers are entered, each in its column — 5, 8, 11, 13, 16, 19, 2 — the remaining cells blank as printed. Note the printed variant "Cycly" in the upper panel's first label versus "Cycli" in the lower.)

[Margin: That in the old Calendar the golden-number cycle could take its beginning from no number other than 3.]

Furthermore, that in the old Calendar the cycle of the golden number could take its beginning from no other number than 3 will likewise be made plain. If golden number 3 is set first in the Cycle, 11 days are left over in that year after the twelfth Luration; 22 in the second year, with golden number 4 running; and 33 in the third year, with golden number 5 running — and therefore golden number 5 will be embolismic. By the same reasoning these golden numbers will be embolismic: 8, 11, 13, 16, 19, 2 — as Campanus held, and as reason itself requires, since, when these golden numbers are running, the first Luration of the year

always ends on one of the first 11 days of January, which is necessarily required for a year to be embolismic, as we said above. This would by no means happen if some other golden number were set first in the Cycle. For if, for example, golden number 1 were said to be first, 11 days would then be left over; and with golden number 2 running, 22; and 33 with golden number 3 running. So golden number 3 would be embolismic; and by the same reasoning golden numbers 6, 9, 11, 14, 17, 19 would be embolismic — which is false, and contrary both to Campanus and to reason, since none of these 7 golden numbers, except 11 and 19, contains 13 Lunations. Golden number 1, therefore, cannot be first in the Cycle; and for the same reason no other than 3 can be first.

[Margin: Which of the 13 Lunations of an embolismic year is to be called extraordinary, or embolismic.]

Now it is of no great importance which of the 13 Lunations of an embolismic year is called the extraordinary, or embolismic, one — provided that the magnitudes of the 12 [ordinary] Lunations, as the Cycle requires, remain intact and undisturbed as far as possible, that is, that they be set alternately at 30 and 29 days. To achieve this more correctly, this rule must be observed. Whenever, in an embolismic year, the last (or 13th) Luration contains 30 days, we shall call it the embolismic or extraordinary one, because then the preceding 12 Lunations alternately contain 30 and 29 days, as the reckoning of the Cycle requires. This happens when one of these embolismic Epacts — xix. xx. xxi. xxii. xxiii. xxiiii. — is in use, to which Epact 25 is to be added (marked with a different figure or colour, as is clear from the 30 tables of Lunations), provided that Epact xix and golden number 19 do not concur. For then the 13th Luration of the year comprises only 29 days, as happens in the 8th line of the expanded table, to which the capital letter **D** is ascribed, and to which the 8th of the 30 tables of Lunations corresponds.

But if ever those Epacts are used together with golden number 1 — as happens with those which, in lines 15, 16, 17, 18, 19, and 20 of the expanded table, are marked with the minuscule letters r, q, p, n, m, l, and likewise in the 6 tables of Lunations corresponding to those letters (excepting Epact 25, written with a different figure or colour, which can never concur with golden number 1, since it can concur only with golden numbers greater than 11) — then both the first Luration of the year and the second will contain only 29 days. For when the Epacts of the [preceding] year concurring with golden number 19 are increased by 12, so that the Epact of the following year concurring with golden number 1 is produced, as we showed above, it happens that three continuous Lunations of 29

days are set up — namely the two first Lunations of the embolismic year and the last, embolismic Luration of the preceding year — the middle one lying between the other two of the same number of days. Therefore the first Luration could indeed then be [reckoned embolismic], and only 29 days might deservedly be assigned to the embolismic Luration of that year, since the other six embolismic Lunations of that Cycle together comprise 383 days [?]. Yet, lest the other Lunations of that year disturb the order of 30 and 29 days, and lest the last, ordinary Luration, which is usually of 29 days, come to contain 30, it was decided to make the last Luration, of 30 days, the embolismic one — just as if, in the manner of the old Computists, one day were added to the embolismic Luration of that year (which ought to be of only 29 days), a day subtracted from the first Luration of the year on account of the addition of 12 to the Epact running with golden number 19. This subtraction the Computists called the "leap of the Moon" (*saltus Lunae*), of which we shall say a little more just below. Yet let it be free for anyone, if he prefers, to call the first Luration of 29 days the embolismic one, since no absurdity follows from this.

[Margin: Which embolismic Epact has its 13th Luration of 30 days and embolismic.]

[Margin: When an embolismic Epact, whose 13th Luration is of 30 days, has the first Luration of the year of 29 days.]

But when the thirteenth Luration of an embolismic year contains only 29 days, and that embolismic year is the last in the Cycle — which comes about when Epact xviii, as well as Epact xix and golden number 19, concur (which happens only twice in the whole span during which all 30 Cycles of the expanded table are used, namely when lines 8 and 9 of that table, marked with the capital letters **D**, **C**, and to which tables 8 and 9 of the Lunations correspond, are in use) — then that last Luration of the year will be called embolismic; because the preceding 12 Lunations alternate at 30 and 29 days, and the last, embolismic Luration in that Cycle ought to contain only 30 days, as is clear from what we said above, since the other six embolismic Lunations of that Cycle comprise 30 days.

[Margin: Epacts xviii and xix concurring with golden number 19 have the 13th Luration embolismic and of 29 days.]

[Margin: Which embolismic Epact has the first Luration of the year embolismic and of 29 days.]

But whenever the thirteenth Luration comprises only 29 days, yet that embolismic year is not the last in the Cycle — provided that the first Luration too

is set at 29 days (which happens when any one of these Epacts — xxv. xxvi. xxvii. xxviii. xxix. — and golden number 1 concur, as appears in lines 10, 11, 12, 13, 14 of the expanded table, which have the capital letters **B, A** prefixed, and the minuscule letters [u, t, s?], and likewise in the five corresponding tables of Lunations) — then that last Luration of 29 days will not be reckoned the embolismic one, but rather the first of that year, which is likewise of 29 days. For since the last Luration of the preceding year then also consists of only 29 days, the first Luration of the following year will not unfairly be called the extraordinary and embolismic one, since the other 12 following Lunations alternate through 30 and 29 days — especially since that embolismic Luration ought to contain only 29 days, seeing that the other six [embolismic Lunations] of the same Cycle contain 30. But if the first Luration is not of only 29 days, but both the first and the second comprise [30] days [?] — which happens when any one of those Epacts we mentioned, xxv. xxvi. xxvii. xxviii. xxix., runs with some golden number other than 1, as is clear from the 30 tables of Lunations — then the second Luration, of 30 days, will rightly be called the embolismic and extraordinary one, since the other 12 keep the alternating order of 30 and 29 days. Nor need it seem strange to anyone that we do not always place the embolismic Lunations in the same year and month, because these fall naturally, according to the reckoning of the Cycle, in such a way that

they fall out as we have explained, and among the old computists they were also assigned various places and months.

PORRO. Furthermore, whenever — because of the addition of 12 to the epact running with golden number 16 — a single day is subtracted from the first luration of a common lunar year, so that that year is completed with only 353 days (as happens in cycles 1, 2, 3, 4, 5, 6, 21, 22, 23, 24, 25, 26, 27, 28, 29, and 30 of the expanded table, which have prefixed to them the capital letters P, N, M, H, G, F, E and the small letters i, h, g, f, e, d, c, b, a, as may be seen in the tables of lunations that correspond to these cycles — for in all these, and these alone, the year in which the golden number is 1 is common, and the first luration of that year contains 29 days) — this subtraction is what the computists usually call the LEAP OF THE MOON [saltus lunae]. For since the true lunar year consists of 354 days, one day is taken from it and assigned to the last embolismic year, so that it may contain 384 days and each of the 7 embolismic lunations be constituted of 30 days; whereas the last embolismic year, by its own nature, ought to embrace only 383 days, and its last embolismic luration only 29. And so, on account of this subtraction, the Moon seems in a way to leap forward by one day in the calendar,

since that first lunation is made to be only 29 days when by itself it ought to have been completed at 30.

[Margin: What the leap of the Moon is among the computists, and from where the common lunar year is diminished.]

EADEM. By the same reasoning, when in an embolismic year the first lunation is embolismic at 29 days, while the other twelve are constituted alternately of 30 and 29 days (as happens in cycles 10, 11, 12, 13, and 14 of the expanded table, which are prefixed with the capital letters B, A and the small letters v, t, s, as is clear in the corresponding tables of lunations), one may rightly say that the leap of the Moon occurs in that lunation. For since the last lunation of the preceding year is 29 days, the first lunation of the following embolismic year ought to be constituted of 30 days. Therefore, since one day is subtracted from it and it is made embolismic, while the day removed is added to the last embolismic lunation of the same cycle so that it becomes 30 days (which otherwise ought to embrace only 29), even then the Moon seems in a way to leap by one day in the calendar.

[Margin: When, in an embolismic year, a leap of the Moon can occur.]

DENIQUE. Finally, when in an embolismic year the two first lunations comprise only 29 days (as happens in cycles 15, 16, 17, 18, and 20 of the expanded table, as may be seen in the corresponding tables of lunations), we shall likewise be able to say that the leap of the Moon then occurs in the first lunation — because from it, which ought to have 30 days, one day is taken and joined to the last embolismic lunation of that cycle, so that this contains 30 days when nevertheless it ought to embrace only 29.

QVIN. Moreover, when in the last embolismic year of some cycle the thirteenth lunation is embolismic and contains only 29 days (as occurs in cycles 8 and 9 of the expanded table of the letters D, C and the small letters, and in the 8th and 9th tables of lunations), one may not unreasonably suppose that here too a leap of the Moon in a way occurs. For since the twelfth lunation of that year consists of 29 days, the following thirteenth ought, according to the reckoning of the cycle, to be constituted of 30 days, and the subsequent first lunation of the next year of 29. Since, then, that lunation contains only 29 days, one day is taken from it and added to the first lunation of the following common year, so that it comes to be 30 days, which otherwise, as has been said, ought to be only 29.

[Margin: Which embolismic years are constituted of only 383 days, and which common lunar years of only 353 days.]

ATQVE. And all these embolismic years, in which we have said the leap of the Moon occurs, contain only 383 days, while all the others comprise 384. The common years, by contrast, in which the leap of the Moon occurs, are constituted of only 353 days, while all the rest of 354 — as is evident from the 30 tables of lunations above.

EX. From what we have said, it can be made plain that the leap of the Moon occurs only when two or three lunations of 29 days run continuously in the calendar, and never otherwise. This indeed always happens when the golden number is 1, whether that year be common or embolismic, because to the epact of the preceding year concurring with golden number 19 there are added 12, to make the epact of the following year concurring with golden number 1, as was said above. Excepted are the two embolismic years of epacts xix and xviii concurring with golden number 19; for in these the leap of the Moon occurs while golden number 19 is running, not 1, as is clear from the 8th and 9th tables of lunations.

[Margin: That the leap of the Moon always occurs when the golden number is 1, and never otherwise, whether the year be common or embolismic.]

NON. I am not unaware that this leap of the Moon is less approved by many, on the ground that no such leap at all occurs in the heavens. Nevertheless, since the reckoning of each cycle requires that now and then one day be taken from one lunation to be added to another, we were unwilling to depart from the customary manner of speaking of the computists. Yet let everyone be free in this matter to speak as he pleases, provided only that he rightly understands the thing itself, and that it be explained.

[Margin: Why the leap of the Moon displeases most people.]

HINC. From this too it follows that, on account of the embolisms and the leap of the Moon, the lunations do not always proceed alternately by 30 and 29 days, as their condition and nature seem to require, but that sometimes two consecutive lunations occur, now of 30 days, now of 29; indeed sometimes three of 29 days; and — what may seem more surprising — that in a bissextile year, on account of the intercalary day, four consecutive lunations may comprise 30 days. This is nothing new or absurd, since the reckoning of any cycle requires it, and the same was done among the old computists in the cycle of the golden number of the Council of Nicaea, which prevailed right up to this Gregorian correction — as is plain in the table set out below, in which all the lunations of the golden numbers of the old calendar are described, just as in the 30 tables above the lunations of

the epacts were expressed, as they occur in the 30 nineteen-year cycles. And from this table it is clear that the seven embolisms of the whole cycle, which begins from golden number 3, fall in those years of the cycle into which, according to our epacts, we showed above that they fall. It is likewise established that golden number 19 produces three consecutive lunations — namely the seventh, eighth, and ninth — of 29 days; and that golden number 11, if [the year] be bissextile [si à nis in bissextilis (?); text corrupt — the sense is "if the year be bissextile"], and the lunation of the month of February therefore be increased by one day, exhibits the first four lunations of the year as 30 days.

[Margin: That, on account of the embolisms and the leap of the Moon, it sometimes happens that two or three consecutive lunations are of [9 — recte 29] days, and two or four of 30 days.]

THERE FOLLOWS

A TABLE OF THE LUNATIONS OF THE GOLDEN NUMBERS described in the old calendar.

HOW MANY DAYS EACH LUNATION of the golden numbers contains in the old calendar, both in the common year and in the embolismic.

[Table title, verbatim: *QVOT DIES LVNATIO QVAElibet aureorum numerorum contineat in Calendario veteri tam in anno communi, quam in Embolismico.*]

The table has five heading columns on the left (golden number; beginning of the first lunar month, common and embolismic; end of the twelfth lunar month, common and embolismic; end of the thirteenth lunar month, in the embolismic year; magnitude of the lunar year, common and embolismic), followed by the block **NVMERVS ET ORDO Lunationum totius Anni** (Number and order of the lunations of the whole year), i.e. the lengths of the 1st through 13th lunation (Prima ... Tertiadecima Lunatio). The thirteenth lunation (Tertiadecima) is blank in common (354-day) years. Row order as printed: golden numbers 3–19, then 1, 2.

There follows

A TABLE OF THE NEW MOONS OF THE WHOLE YEAR, PERPETUAL.

A PERPETUAL TABLE OF THE NEW MOONS FOR THE WHOLE YEAR

[Table title, verbatim: *TABVLA NOVILVNIO RVM TOTius anni perpetua.*]

On which days of the months the new moons fall, whatever epact be running.

[*Quibus diebus mensium Nouilunia contingent, quacunque Epacta currente.*]

The left column gives the epacts (Epactæ), the twelve following columns the day of the month (Dies) on which the new moon falls in January through December, and the narrow right-hand column the year-type: **Coïs.** = *communis* (common), **Emb.** = *embolismicus* (embolismic), **Indiff.** = *indifferens*. The far right margin carries the vertical rubric **ANNI COMMVNES** ("common years") running down the lower rows. Note the doubled epact xxv / 25 (the Roman form and the Arabic form set as distinct sorts on adjacent rows, with slightly different columns). Entries of the form "1. 31" mean the new moon falls on both the 1st and the last day of that month.

Note beneath the table: *Quando Epacta xix. & aureus numerus 19. concurrunt, incidit aliud Nouilunium in diem 31. Decembris.* — "When the epact xix and the golden number 19 coincide, another new moon falls on 31 December."

What is to be Called the Paschal Fourteenth Moon, and Why the Epacts are Inscribed in the Calendar So That the New Moons Derived from Them Mostly Follow the Mean and True Conjunctions of the Luminaries

Caput VI

Since Maestlin vehemently attacks the new moons and the Paschal fourteenths — which in our new Calendar are laid out by means of the epacts in the manner we have described — on the ground (as he puts it) that the new moons do not correspond to the celestial motions, and that the Paschal fourteenths do not present the legitimate solemnity of Easter to be celebrated, I must here explain what is to be called the Paschal Luna 14, after which the Church, on the next following Sunday, has always been accustomed to celebrate Easter in accordance with the decrees of the Fathers and the Councils. I must also explain why, in order to determine this Paschal fourteenth correctly for any given year, we have deliberately equated the Cycle of Epacts inscribed in the Calendar in an expanded table, so that the new moons found from it for the most part follow the true and mean conjunctions of the luminaries. For in this matter, unless Maestlin is deliberately and maliciously pretending not to know a thing that is clear in itself and familiar to everyone, I do not see what he actually knows about the subject. He seems utterly ignorant of the custom that the whole Christian world has kept in the celebration of Easter, from almost the very beginning of the infant Church down to our own age, as we shall show later.

[Margin: The error of Maestlin and of others who think that Easter ought not to be celebrated on Luna 15.]

[Margin: That it was never forbidden that Easter be celebrated on Luna 15; otherwise Easter would often fall on Luna 22, contrary to the decrees of the Fathers and the Councils.]

[Margin: That the Church has frequently celebrated Easter on Luna 15.]

[Margin: That around the time of the Council of Nicaea Easter was never celebrated on the Luna 15 that preceded the mean full moon, and why.]

Above all, we proved at length in Chapters 1 and 3 of the previous book — both from the decrees of the Supreme Pontiffs and the Councils, and from various testimonies of writers, and from the unbroken usage of the Church — that Easter must be celebrated after the fourteenth Moon of the first month, up to the twenty-

first Moon, and therefore that it may rightly be celebrated on Luna 15 if that falls on a Sunday. So it is astonishing that some of the more recent writers — among whom is Maestlin, who fancy themselves wiser than those ancient Fathers, than the Councils, and than the continuous usage of the Church both Eastern and Western — are not afraid to assert so stubbornly that Easter must not be celebrated on Luna 15, that is, at the full moon, even if it falls on a Sunday; and this because they wrongly suppose that we would then be celebrating Easter together with the Jews. For Christians have never been forbidden to celebrate Easter at the mean full moon, that is, on Luna 15, even when the Jews are then performing the solemnity of their legal Passover; they have been forbidden only to celebrate Easter on Luna 14, when the Jews sacrifice the lamb toward evening. Otherwise, if Luna 15 (that is, the mean full moon) fell on a Sunday, and another Sunday had to be awaited, the Paschal feast would be celebrated on Luna 22 — that is, in the fourth week of the Moon — which is contrary to the decrees of the Councils and the Supreme Pontiffs, by which it is repeatedly enacted that Easter be celebrated after the fourteenth Moon of the first month up to and including the twenty-first, as we wrote in Chapters 1 and 3 of Book 1. Certainly in our own century, in which we live, we have more than once seen Easter celebrated, by the decree of the Council of Nicaea, on the 22nd of March — that is, on the Luna 15 that the cycle offered — since the Luna 14 of the cycle necessarily fell then on the 21st, before which day there can be no Paschal Luna 14, as we wrote in the previous book. Indeed, whenever the Luna 14 of the first month falls on a Saturday, Easter is celebrated on the very next Sunday, that is, on the Luna 15 that the cycle indicates.

But suppose someone objects that the Luna 15 found from the cycle, in these times before the correction of the year, always followed the mean full moon by a full four days and more, because the new moons had thus receded, advancing from their former places toward the beginnings of the months, and that Easter was therefore not celebrated on Luna 15 but after the mean full moon. The answer is that this happened by chance and (to speak with the philosophers) per accidens — namely, on account of that anticipation of the new moons — but that of itself, and by its own nature, that Easter fell upon the mean opposition; that is, it would have, had the new moons at that time been restored to their proper places. But grant that in our own age Easter was never celebrated at the mean full moon but after it, because of that anticipation of the new moons. Certainly around the time of the Council of Nicaea — that is, in the year 326 — by the decree of that same Council, Easter was celebrated on Luna 15 according to the cycle, on the 3rd of April, even though that Luna 15 then anticipated the mean full moon: for the golden number that year was 4, placing the Paschal terminus

(the Luna 14) on the 2nd of April, while the Dominical letter was B, assigned to the 3rd of April, and the mean opposition finally occurred on the 3rd of April at 12 hours 54 minutes after noon. The reason Easter then ran ahead of the mean opposition was the golden number, which at that time indicated the new moons too early. For from this it came about that the Luna 15 which the cycle offers — and which the Church observes in celebrating Easter, setting aside astronomical calculation — anticipated the mean opposition that the astronomical tables display, as we shall say below. The same thing happened in the years 330, 346, 350, 370, 394, 441, 475, 495, and others which it would take too long to recount here, in all of which Easter fell on Luna 15, and indeed before the mean opposition, for the reason we have stated, as will be clear from what follows.

[Margin: The erroneous opinion of Maestlin and of others concerning the Paschal Luna 14.]

Therefore, since Easter must necessarily be celebrated on the Sunday that next follows the Luna 14 of the first month — and thus on the Luna 15 itself, if that day is a Sunday — let us now set out what that Luna 14 is, and in what way, according to the most ancient usage of the Church, it is to be sought in the Calendar, so that no error or disagreement may arise in so great a solemnity. Some suppose that the Luna 14 is the very day of the opposition of the Sun and Moon; and Maestlin too seems to hold this view in this *Examen* of his, since he constantly objects against the new Calendar that the Luna 14 often precedes the opposition of the luminaries, and thus that Easter is frequently celebrated at this very full moon, if the day is then a Sunday — which he himself thinks absurd and contrary to the laws and usage of the Church. He therefore wants the Luna 14 to

fall upon the mean opposition itself, and never precede it, lest on the following day — if it be a Sunday — Easter should be able to be celebrated from Luna 15. But it is precisely here that Maestlin is most deceived. For since Easter can be celebrated at the full moon, as the usage of the Church has taught, along with the decrees of the Fathers and the Councils, which we showed above; and since it has been provided by those same authorities that Easter never be celebrated on the day of Luna 14 but always after it — who is so blind, except Maestlin (who nonetheless wants to be reckoned a Lynceus in this affair), as not to see that in the Church of God the Luna 14 and the full moon are not the same thing?

Others, granting that Easter can be celebrated on Luna 15, that is, at the full moon, because of the usage of the Church and the testimonies we brought forward in Book 1, suppose that the Luna 14 is the day that next precedes the true opposition. But not even this is true, since the Church never considers the true

motions — indeed, not even the mean — but only the cycles, as we demonstrated abundantly in Chapter 3 of the previous book.

[Margin: Another false opinion concerning the Paschal Luna 14.]

The Luna 14, then, is taken by the Church for the fourteenth day of the Paschal lunation, counting that day inclusively from the new moon [Neomenia], that is, from the beginning of the Paschal lunar month — that is, from the day to which is prefixed the number of the nineteen-year cycle [the golden number] that indicates the new moons in the Calendar for the year in question, whether that day agrees with the true or mean conjunction of the Sun and Moon or differs from it. This is confirmed by all who have written on the celebration of the feasts, and it appears most clearly from the ancient table of Easter and of the other movable feasts, which the Church used continually before the correction of the year: in it each golden number is prefixed to that day of March or April which is the fourteenth inclusively from the new moon shown by that same golden number, and after which the next following Sunday presents the most holy Easter. And this was always observed not only in the Western Church but also in the Eastern, as can be proved from the fact that before the restoration of the Calendar there never arose any disagreement or divergence in the celebration of Easter between the Easterns and the Westerns — which would not have been the case had the Luna 14 not been understood in the same way by both.

[Margin: The Paschal Luna 14 according to the usage of the Church, by which...]

Although in seeking the new moon — and the Luna 14 to be derived from it — the Church considers neither the true motions nor the mean, but measures them only according to the order of the cycle, it must nevertheless not be denied that the mean oppositions found from the astronomical tables are extremely useful for weighing and judging which cycle, out of many, is to be chosen: namely, one whose numbers, with the equation applied at their proper times, may perpetually display in the Calendar the new moons [Neomeniae], and from these the Luna 14 of the first month for duly celebrating the most holy Easter, in such a way that no Paschal Luna 14, counted inclusively from the new moon, ever runs ahead of the mean opposition by two or more days, but either by one day only, or falls upon the mean full moon itself, or at least follows it not long after. This we have striven to achieve in the cycle of epacts with the very greatest care and diligence we could. For we have so distributed it through the days of the Calendar that the new moons found from it very nearly follow the true and mean conjunctions of the luminaries by such an interval that the Paschal Luna 14 either precedes the mean oppositions by only one day, or coincides with them entirely, or at last occurs not

long after them. And this was done by us neither rashly nor by chance, but deliberately and with great forethought. For if the first day of the lunar month, as given by the cycle, were the one on which the astronomical tables truly place the new moon — what the computists call the kindling of the Moon [Accensio Lunae] — and not the day which usually follows the astronomical new moon by about one day, it would often happen that we should celebrate the holy Easter not only on Luna 14 (that is, one day before the full moon, together with the Jews and the Quartodeciman heretics, which would be absurd), but sometimes even, what would be more absurd, before such a Luna 14. This can be made plain as follows.

[Margin: That tables of the Moon's mean motion are useful for examining any proposed cycle.]

[Margin: Why the cycle of epacts in the new Calendar is so arranged that its new moons for the most part follow the true and mean conjunctions by such an interval that the Luna 14 either precedes the mean oppositions by one day only, or coincides with them, or at any rate occurs not long after them.]

Let there occur, for example, a mean new moon in some year at noon on the 8th of March, where the cycle sets the first Paschal new moon. Given this, let the mean full moon fall on the 23rd of March about sunrise — namely, 14 days 18 hours 22 minutes 2 seconds after the mean conjunction; for exactly that many days, hours, and fractions of hours necessarily intervene between the mean conjunction and the opposition, as we wrote at the beginning of this book. Since, then, the Luna 14 of that new moon falls by the cycle on the 21st of March, Easter will then be celebrated on the 22nd of March, if that is a Sunday — that is, a full day before the mean opposition. Nearly the same absurdity would occur if the mean new moon which happens 12 hours before noon of that same 8th of March were taken as the first day of the Paschal Moon; for its full moon will fall on the 22nd of March at sunset, and must therefore be assigned to the following 23rd. So if the 22nd were then a Sunday, Easter would again be celebrated at the mean full moon. Nor will this drawback be any better avoided if the day of the true new moon is called the first day of the Moon according to the cycle. For since it is established from astronomical calculation that the true full moon can be as much as $15\frac{1}{2}$ days and more distant from the true new moon — let the example be the true new moon in the month of February of the year 1588, which fell about noon on the 26th of February, while the true full moon fell on the 12th of March at 14 hours 14 minutes after noon; and it is evident that the interval between the two comprises $15\frac{1}{2}$ days and more, since February is then given 29 days on account of the bissextile — who does not see that, if the true new moon then fell at noon on

the 8th of March, the true full moon would occur on the 23rd at 14 hours 14 minutes after noon, and therefore, if the Sunday then fell on the 22nd of March, Easter would be celebrated before the true full moon?

[Margin: New moon and the kindling of the Moon [Accensio Lunae] are the same thing among the computists.]

This second example, which I will add, will illustrate the same matter still more clearly. In the year 1588 the true new moon occurred on the 26th of March at 14 hours 49 minutes after noon — that is, on the 27th at about 9 hours before noon — while the true full moon fell on the 11th of April at 1 hour after noon. If, then, the epact ij of that year had been assigned to the 27th of March — as some contend it should, so that the first day of the Paschal new moon found from the cycle might not differ from the day of the true new moon — the Luna 14 would fall on the 9th of April, and thus on the following 10th, since that is a Sunday, Easter would have been celebrated according to the ecclesiastical decrees, that is, before the true full moon, which would be absurd. By careful and prudent design, therefore, we assigned the epact ij not to the 27th of March but to the 29th — precisely so that the first day of its lunation might follow the 27th, the day of the true new moon.

[Margin: If the new moon of the cycle did not follow the conjunction that occurs in the heavens, Easter would often be celebrated before the full moon.]

Table of true new moons from Magini's Ephemerides compared with the new moons derived from the epact promoted forward one day (1582–1599).

The table is printed as two side-by-side blocks; each has the same five columns. The left-hand block runs 1582–1591, the right-hand block 1592–1599. Column headers (verbatim): *Anni Dñi* (Years of the Lord) | *Méfes* [Menfes] (Months) | *Nouilunia vera ex Ephemeridibus Magini* (True new moons from Magini's Ephemerides), with the sub-heading *D. H. M* (Days, Hours, Minutes) | *Epact.* (Epact) | *Nouilũia ex Epact. per vnũ diẽ furfum promotis* (New moons from the epact, promoted forward by one day).

Apologia adversus Maestlinum, Liber Secundus — Caput VI (continued)

Comparative table of true new moons and epactal new moons (p. 91)

This is the table to which the following page refers ("as appears in the preceding table"). It is set in **two parallel panels** across the leaf; together they form one continuous chronological list (1599–1611 in the left panel, 1615–1620 in the right). Both panels share the same five columns:

- **Anni Domini** — Years of the Lord
- **Menses** — Months
- **Nouilunia vera ex Ephemeridibus Magini** — True new moons from Magini's Ephemerides, given as *D · H · M* (day · hour · minute after noon)
- **Epacta** — Epact
- **Nouilunia ex Epactis per vnum diem sursum promotis** — New moons yielded by the epacts if these were advanced upward by one day (day of month)

[Note: the left panel's column-head is printed **Nouilnnia** and the right panel's **Nonilunia** — two distinct compositor misspellings of *Nouilunia*; transcribed as printed.]

[Margin: Why the epacts in the Calendar are not advanced upward by one day, so as to show the new moons earlier than they now do.] If you object that the epact ought to have been prefixed to the 28th day rather than the 29th, so that the new moon it gives would fall short of the true one by a single day and not by two, I answer that there was no reason to do so. For if that epact were moved from 29 March to the 28th, then every other epact would likewise have to be advanced upward by one day, since they cannot be arranged in the Calendar in any other order than the one we have used, so that the lunations may be constituted alternately of 30 and 29 days, as the reckoning requires. And if this advancing were adopted, the new moons of many epacts would run ahead of the true conjunctions by a whole day, as appears in the preceding table.

[Margin: Explanation of the preceding table.] In the first column of that table the years of the Lord are set down; in the second, the months; in the third, the days, hours, and minutes after noon at which the Ephemerides of Giovanni Antonio Magini [Giovanni Antonio Magini] show the true new moons; in the fourth, the epacts; and in the fifth, the new moons that those epacts would exhibit if they were advanced by one day. Here it is plainly established that these latter new moons are indicated by the epacts before the former ones occur in the sky — and indeed, in certain years, such as November 1598, December 1599, April 1603, June 1603, October 1615, February 1619, and June 1619, this anticipation amounts to more than a whole day, which would be quite absurd. We have here left out those true new moons that fall at noon itself, or one or two hours after noon, on the same days on which the epacts would show them, and have noted down only those that follow the epactal new moons by several hours. And yet, as you see, within a span of less than 40 years there would occur 128 epactal new moons — if the epacts were advanced by one day — earlier than the true conjunctions of the luminaries exist in the sky. This would run counter to the practice of all the nations among whom the lunar cycle has been in use. The epacts, therefore, are not to be advanced upward by one day; and accordingly epact 2 is rightly assigned to 29 March and not to the 28th.

[Margin: That in the equation-table of the epacts the capital letter D was rightly assigned for the year 1582 after the correction, not the capital letter E.] The same absurdities would follow if anyone, leaving the epacts in the Calendar as we have laid them out, were to construct the equation-table differently — namely by prefixing to the year 1582, after the correction, the capital letter E, as in the expanded table it answers to golden number 12 of the year 1588; whereupon epact 2 would stand in the line to which the capital letter E is assigned, which epact is one day higher in the Calendar than epact 2. The same absurdities, I say, would follow, because then the new moons would be shown by the epacts one day earlier in the same way — exactly as if the epacts had been advanced by one day. Rightly, therefore, in the equation-table did we assign the capital letter D to the year 1582 after the removal of the ten days, and not the capital letter E, lest the new moons be indicated in the Calendar by the epacts earlier than is proper. In the same way we shall confirm that the other letters have been fittingly prefixed to their several years in the equation-table, lest — if the equation were set up otherwise — the epactal new moons should fall on the true new moons, or run ahead of them, instead of following after them, so that the Paschal 14th moons may always, so far as can be, forestall the mean full moons by a single day only.

[Margin: That around the time of the Council of Nicaea Easter frequently fell on the 14th moon, because the new moons were shown by the golden numbers too early.] Again, that it is not expedient for the new moons to coincide with the mean conjunctions of the cycle, or with the golden numbers, but rather more in keeping with ecclesiastical use that they should follow after them — this the cycle of the golden number, once inscribed in the Calendar, can plainly teach us. For since, around the time of the Council of Nicaea, that cycle indicated the new moons on nearly the same days on which they occurred in the sky, the result was that very often Easter then fell on the 14th moon — that is, was celebrated before the mean opposition, contrary to the decrees of that same Council. And this is evident from the table set out below.

Table of Easters celebrated on or before the mean full moon (p. 92)

Columns: **Anni Dñi** (Years of the Lord) · **Aurei num.** (Golden number) · **Literæ Dñic.** (Dominical letters) · **Pascha** (Easter day) · **Oppositiones mediæ Paschales** (Mean Paschal oppositions, *D · H · M*).

[Margin: Explanation of the table above. Why in the celebration of Easter there were so many dissensions between the Eastern and the Western Church.] In the first column are noted the years in which Easter was celebrated before the mean full moon — or at any rate not after it, but on those days that hold the full moon some hours after noon. In the second column are contained the golden numbers current in those years; in the third, the Dominical letters; in the fourth, the days of Easter; and in the fifth, finally, the mean Paschal oppositions. Here you see that this error was committed, within a span of 173 years, in 10 of those years — so that it is no wonder that so many discords over the celebration of Easter arose, even after the Council of Nicaea, between the Eastern and the Western Church, right down to the time of the Emperor Justinian, when the cycle of the golden number was inscribed in the Calendar by the Abbot Dionysius [Dionysius Exiguus]. At that time the golden numbers already showed the new moons and the Paschal 14th moons more correctly than in the days of the Council of Nicaea — that is, later than they occurred in the sky.

[Margin: That many errors in Easter would arise if the epacts indicated the new moons earlier than they do by the prescription of the new Calendar, especially in the year 1598.] To this may be added that, unless the new moons of the epacts followed after the conjunctions of the luminaries in the manner in which they are shown in the Calendar by the epacts (with the equation-table applied), notable and intolerable errors would very often arise in the celebration of Easter. The clearest example of this is the year 1598, which Maestlin [Michael Mästlin] and several others bring forward to show that the epacts do not exhibit the legitimate Paschal 14th moons. For if, according to the opinion of those who hold that the

new moons are indicated by the epacts later than the matter warrants, the individual epacts were advanced upward by one day each — or, what comes to the same thing, if the equation-table were so set up that, in place of the line of the capital letter D, the line of the capital letter E were taken in the expanded table — then the Paschal new moon of that year would fall on 5 April, where epact 23 of the same year would then stand if that advancing of the epacts were made; or where epact 24 is placed, which would indicate the new moons of that same year if the equation-table were constructed otherwise, namely so that the year 1582, after the correction, had the capital letter E prefixed to it and not the capital letter D. For the preceding new moon, which would then fall on the 7th day of March, would not be Paschal, since it falls outside the Paschal limits, as is clear from what we wrote in Chapter 1 of the previous book. Granting this, Easter would be celebrated on 19 April — that is, on the first Sunday after the 14th moon, which would then fall on the 18th. Since, therefore, in that year the mean opposition occurs on the 20th at hour 9, minute 20 after noon, but the true full moon on the 20th at hour 22, minute 39 after noon, the solemnity of Easter would run ahead of both the true and the mean full moon by nearly two days — which is contrary to the sacred Canons and Councils. And the same can be shown to happen in several other years.

[Margin: That Easter for the year 1598 was rightly celebrated by the prescription of the new Calendar, against Maestlin, Giovanni Antonio Magini, and several others.] Therefore, lest such foul and shameful errors be admitted in a solemnity of such importance, the epacts have by excellent counsel been so arranged in the Calendar, and their equation so instituted, that the epact of the year 1598 is 23, assigned to 8 March. For in this way the Paschal new moon will then fall on 8 March, and its 14th day on the 21st; and accordingly Easter will be celebrated on the following day, the 22nd, which is a Sunday — the day, namely, on which the 15th moon falls, that then coincides with the mean opposition, since this occurs on the 21st at hour 20, minute 36 after noon, that is, on the 22nd at nearly 4 hours before noon. Nor does it stand in the way of Easter being duly celebrated then that the true full moon occurs on the 22nd at hour 9 after noon; for the Church in this matter subordinates the true motions to the mean, as we showed in Chapter 4 of the first book.

[Margin: That Magini wrongly, in his Ephemerides, throws the Easter of 1598 back from 22 March to the 29th day.] So that I wonder what came into the mind of Giovanni Antonio Magini — a mathematician otherwise most eminent in our age — that in that year, in his Ephemerides, he should throw Easter back to 29 March on account of that true opposition. For if that March new moon is the

Paschal one, as it truly is — even on his own showing, since epact 23 exhibits it on 8 March and its 14th day falls on the 21st — then the Church, if it means to abide by the decrees of the Councils and Fathers and by long-standing custom, cannot but celebrate Easter on the 22nd, since that is the Sunday next following the 14th moon which the cycle exhibits. For we do not read that the Church has ever deferred Easter past the 15th moon — should this fall on a Sunday — into another week, namely the fourth, and so onto the 22nd moon, since this would conflict with the decrees of the Church. Nor can he say, in his own defence, that the Church ought to throw that new moon back to 9 March, so that the 14th moon would fall on 22 March, that is, on the Lord's day, and Easter be accordingly transferred to the following Lord's day, the 29th. This, I say, he cannot maintain; for then either epact 23, with all the others, would have to be advanced downward by one day, or — what comes to the same thing — in place of epact 23 epact 22 would have to be taken, and therefore for the year 1582 the capital letter C would have to be prefixed in the equation-table. And this is absurd, since on this reckoning the new moons of the cycle would follow the celestial conjunctions too late, seeing that in most cases they appear, from the epacts as arranged in the new Calendar, to be shown later than is proper. What, then, would they say if the new moons were still further postponed by a whole day? It is settled, then, that Easter in the year 1598 was, by the use of the Church, rightly celebrated on 22 March, and by no means to be deferred to the 29th, as Magini would have it. This lapse of a most learned man I would most gladly have passed over in silence — especially since he departed from the prescription somewhat more through imprudence than through obstinacy — had not his authority drawn many others, and Maestlin himself in particular, into the same mistake.

[Margin: That even though the epactal new moons in the Calendar are for the most part postponed, many of them nonetheless agree with the celestial new moons.] Since these things are so, who will dare to accuse or reproach us — unless one who is wholly ignorant of the ecclesiastical practice in the use of the cycles — for having made the new moons that are to be found by the epacts follow after the new moons found by the astronomical tables? We did this precisely so as not to fall so often into the error we have described — that is, so as not to celebrate Easter, so frequently, before the mean opposition, as used to happen in the days of the Council of Nicaea. And this the more, since not even so could we altogether escape it, seeing that our own cycle of the epacts does sometimes present Easter for celebration before the well-nigh mean opposition (although this happens very rarely — at most once or twice in a span of 3000 years), and that many of the new moons shown by that same cycle in the Calendar do agree with the celestial new moons — all those, namely, that we said

above would fall before the true conjunctions if the individual epacts were advanced day by day toward the beginnings of the months. Certainly, if anyone wishes to be so severe a judge of the epacts, he ought to reflect that no cycle described in a Calendar can avoid every drawback — such that its new moons should neither disagree with the celestial new moons, nor its 15th moons at times run ahead of the true or mean oppositions. Witness the cycle of the golden number approved by the Council of Nicaea, which, in showing the new moons around the time of that Council on nearly the same days on which they occurred in the sky, would often have its 14th moon run ahead of the mean opposition, and therefore not rarely had Easter celebrated before the mean opposition, as we said a little earlier. Witness also our own cycle of the epacts, which — while it takes care that its 14th moons should not forestall the mean oppositions by two days — for the most part indicates new moons later than the celestial conjunctions.

[Margin: That no cycle can fully correspond to the celestial motions, for various reasons.] There are, however, many reasons why no cycle can wholly correspond to the celestial motions. First, because in the lunations of the cycle, which are constituted alternately of 30 and 29 days, no small hours are neglected, since any mean lunation does not contain those 30 or 29 days exactly, but 29 days and nearly 12 hours, 44 minutes, 3 seconds, 11 thirds. Next, since in the lunations of the cycle no account is taken of...

[Margin: In a bissextile year the lunation sometimes comprises 31 days.]

and because no account is taken of the intercalary days in bissextile years, it happens that a lunation which ought to be only 29 days long sometimes contains 30; indeed — what is more — a lunation which ought to embrace 30 days is made to be 31.

Third: because, on account of the equation of both years — the solar and the lunar — one must pass from one line of the table of expanded epacts to another, the lengths of the lunations of January and February are altered by no small amount.

Fourth: because the mean conjunction of the luminaries — with which the cycle ought to agree more closely than with the true conjunctions — can precede or follow the true conjunction by nearly 14 hours; so that it ought not to seem surprising if the new moons of the cycle diverge from the true conjunctions. This variation is increased by the variety of meridians: because of it, the same conjunction which at Rome, for example, occurs exactly at noon must necessarily

occur for the eastern peoples several hours after noon, and for the western peoples before noon.

[Margin: New moons placed too late cause Easter to be celebrated in the last month.]

Although it sometimes happens, as we have said, that the paschal 14th Moon reckoned by the epacts anticipates the mean opposition by nearly two days, the new moons were nevertheless not for that reason thought worth postponing any further, both because they would then stand too far from the celestial new moons and would be shown in the calendar later than is proper, and also because that anticipation of the 14th Moon occurs very rarely, and the Dominical letter frequently corrects it — so that even in that case Easter is not always celebrated before the mean opposition, since the Sunday does not fall on that opposition but follows it. There is the further point that Easter, if the new moons were postponed more, would not rarely be celebrated in the last, that is, the twelfth month. For it could then happen that some mean full moon fell on the very day of the equinox, or preceded it, and that the lunation would on that account belong to the last month and not to the first (since the full moon of the first month must follow the day of the equinox: for the 14th Moon of that same first month, which precedes the full moon by one day, must never go before the equinox day, as we showed above); yet the cycle, thus postponed, would present that lunation as the paschal one — namely, when its new moon fell on 8 March and the 14th Moon on the 21st, on the equinox itself. And this results solely from the postponement of the new moons. For it comes about from this that the mean new moon — anticipating the cycle's paschal new moon [neomenia] by two days or more — may have its full moon on the very day of the equinox, or before it, and must therefore be assigned to the last month, even though the cycle ascribes that new moon to the first month.

[Margin: Bede: the Moon is not to be called "first" on the day it is conjoined with the Sun, even if the conjunction occurs 23 hours before sunset, the point at which the day begins.]

[Margin: Campanus: the Moon is not to be called "first" on the very day of conjunction, but on the following day.]

[Margin: For Theophilus of Alexandria and Saint Cyril, the 14th Moon of the cycle is the one which by the astronomical tables is the 16th from the conjunction.]

Now, that the new moons found by the cycle ought rather to follow than to accompany the conjunctions of the Sun and Moon which occur in the heavens,

we can also confirm by the authority of the weightiest writers. For the Venerable Bede [Beda] — a man very well practised in this matter — asserts, in his book *On the Reckoning of Time* [*De Ratione temporum*] chapter 41, that the Moon is not to be called "first" on the day on which it is conjoined with the Sun, but on the following day, even though the conjunction occurs 23 hours before sunset, the point at which the day begins for him. You see, then, that the Moon can be called "first" according to the cycle, in the judgement of Bede — a most diligent writer on the correct celebration of Easter — even though the Sun has already been conjoined with the Moon for a whole day and more. The same thing is prescribed by Campanus [Campanus of Novara] in his *Greater Computus* [*Computus Maior*] chapter 28, in these words: "*The Moon ought to be called first not on the very day of its conjunction with the Sun, but on the next following day, when its beginning is already starting to appear.*" Here he plainly teaches that the cycle's new moon ought to follow the conjunction of the Sun with the Moon by a whole day. In this same opinion were most of the ancient Fathers, and especially Theophilus of Alexandria, the bishop, whose authority in this matter of Easter carried so much weight with the Roman pontiffs that for many years the Church celebrated Easter according to his computation and prescription — as is clear from the letters of the great Pope Leo [Leo I] to the Emperor Marcian and the Empress Eudoxia. Now this Theophilus, as Saint Cyril — his successor in the bishopric — reports (and as Paul of Middelburg [Paulus Middelburgensis], Johannes Stöffler [Ioann. Stoflerinus], and other computists also testify), judged that the Moon which by the cycle and by the usage of the Church is to be called the 14th is the one which others, from the astronomical tables, called the 16th from the conjunction; and this very opinion Saint Cyril himself strives with all his might to confirm. From which it is sufficiently clear that he did not take the first Moon, for the celebration of Easter, on the day on which the Sun is conjoined with the Moon, but nearly two days afterward. And so it has not turned out unhappily with our epacts, since they have been so distributed in the calendar that their new moons, for the most part, follow the mean conjunctions — now by fewer hours, now by more, as the nature of the cycle brings about and as the arrangement of alternating lunations of 30 and 29 days allows: seeing that in this matter we have both imitated those ancient Fathers, and, by keeping that arrangement of the epacts, have brought it about that Easter is celebrated at a more fitting time, as is clear from what we have said.

[Margin: The epacts of the new calendar rightly indicate the new moons after the mean conjunctions.]

[Margin: In the political solar year a day is sometimes called the first which ought more truly to be called the last; and a day is sometimes called the last of a given month which ought more truly to be the first of the following month.]

Finally, that it is neither absurd nor new nor unusual in the Church of God to call a Moon "first" — that is, to call it the first day of the lunar month — when the conjunction of the luminaries has already preceded in the heavens by a whole day and more, so that it is really the second, or the second day, of the lunar month: anyone will easily persuade himself of this, if he considers a little more carefully that in the political solar year, too, a day is sometimes called "first" which ought more truly to be called the last of the year; and likewise that in the months of the solar year a day is sometimes called the last of one month which in reality ought to be the first of the next following month. This will become clear as follows. Suppose the Sun is at exactly noon, on the first day of January, say, in the first year after a bissextile, at some fixed point of the zodiac. It is agreed that, after 365 days are completed, it cannot return to the same point at the noon of that same first day, but will return to it after about 6 hours — hours which in common years are neglected — at sunset; in the second year, after about 12 hours, around the following midnight; and in the third, after 18 hours, that is, at the sunrise of the second day of January. This second day, then, ought more properly to be called the first day of January, because the Sun has by then completed the period of its course; and yet we still name it the first day of the year — the day which ought more truly to be reckoned the last of the preceding year. Again, suppose we set the Sun on the first day of, say, March, in the third year after a bissextile, at 6 hours before noon — that is, about sunrise — holding some fixed point in the heavens: it follows that in the next year, the bissextile,

because of the intercalary day added, it returns to the same point on the last day of February — which then contains 29 days — not at sunrise but nearly 6 hours later, that is, about noon. This last day of February, then, would rightly be called the first day of March, because on it the Sun has returned to the same point of the heavens at which we had placed it on the first day of March of the preceding year; and yet we still call that same day the first of March, though it would more truly be the second day of March. And so, as you see, we are compelled at times to call some day in the political solar year "first" or "second" which is nevertheless 6, or 12, or 18 hours short of the true first or second; and we tolerate an error of this kind until, when four years are completed, it is corrected by the intercalation of one day. By the same reasoning, therefore, in the political lunar year — on account of the hours and fractions of hours omitted in a single lunation, and on account of the day added in the bissextile year, and finally on account of other

causes — the Church is compelled sometimes to declare a Moon "first" which is more truly the second, and it tolerates this error until it is compensated by the embolisms and the other equations of the Moon.

But before we come to the last chapter of this book, in which Maestlin's arguments are to be resolved, I judge it will be worth the effort if in this place I set out a certain simple and easy method by which anyone may, without great labour, investigate the mean new moons and full moons by means of the epacts. This method, although it is not so exact as the one drawn from the tables of the mean motions, nevertheless departs but little from the truth; it is handed down in the Prutenic Tables and in the tables of Giovanni Antonio Magini [Ioann. Antonii Magini], and is carefully described by Paul of Middelburg in his *Paulina* — so that in this business of Easter we may safely rely on it. For by this method it will come about that we shall have ready to hand the mean opposition of the luminaries, whenever there is need, or whenever the cycle of epacts is to be examined to see whether or not it correctly presents the paschal 14th Moon: especially since in the next chapter we shall be compelled to compute a great many mean paschal oppositions, in order to repel the calumnies and cavils of Maestlin — as was also done by us a little earlier, in examining the golden number of the Council of Nicaea.

[Margin: How the epact of years and of months is gathered and reduced into tables, for investigating the new moons and full moons.]

Besides the epacts, then, which have been explained so far — which arise from the days by which the lunar year is exceeded by the solar, when each year is reckoned in whole days and the hours and their fractions are neglected — the astronomers consider other, more refined epacts, in which the hours too, and the fractions of hours, are observed; and these are the days, hours, and fractions of hours which, in any given year or even month, remain over and above the whole mean lunations without completing one whole mean lunation. These are called the epacts of years and of months.

And so, if from the solar year of 365 days you subtract the lunar year — that is, 354 days 8 hours 48 minutes 38 seconds 12 thirds — the remainder will be the epact of one common year: 10 days 15 hours 11 minutes 21 seconds 48 thirds. The epact of a bissextile year will be 11 days 15 hours 11 minutes 21 seconds 48 thirds. From this you will easily make up the epacts of two, three, or four common years, and so on up to 100, by continually adding the epact of one year — always casting out a whole lunation, that is, 29 days 12 hours 44 minutes 3 seconds 11 thirds, whenever the sum made up is greater — and by adding besides

one day in the bissextile years, which are the years 4, 8, 12, 16, and the rest that are counted by fours, as you see has been done in the following table of 100 expanded years.

By the same reasoning you will compose, from the continual addition of the epacts of 100 years, the epacts of 200, 300, 400, and so on, of the following centenary years, always rejecting a whole lunation whenever it can be done: which is seen in the other table, of collected years up to 4000. But to each of these epacts of collected years, taken by hundreds, there has been added the Epoch of Christ (commonly called the "radix of Christ"), which, on Magini's authority, contains 16 days 18 hours 12 minutes 30 seconds. We have chosen this radix rather than the one which in the Prutenic Tables contains 17 days 5 hours 27 minutes 30 seconds, or the one which Paul of Middelburg sets at 16 days 16 hours 41 minutes 9 seconds, since it is in a manner midway between these two. But if anyone wishes to extend this table further, let him continually add 25 days 4 hours 30 minutes 33 seconds, always casting out a lunation of 29 days 12 hours 44 minutes 3 seconds 11 thirds whenever it can be cast out.

Again, if from the 31 days of the month of January we take away a whole lunation of 29 days 12 hours 44 minutes 3 seconds 11 thirds, the remainder will be the epact of January: 1 day 11 hours 15 minutes 56 seconds 49 thirds. If to these you add the days of the following months — again casting out, whenever it can be done, a whole lunation, and in the bissextile year assigning 29 days to February — you will build up the epacts of all the months, both of the common year and of the bissextile, as you see has been done in the double table of the months.

Lastly, if from the half lunar month of 14 days 18 hours 22 minutes 1 second 36 thirds you proceed by the continual addition of the half month, casting nothing out, until you reach the fourth conjunction of 118 days 2 hours 56 minutes 13 seconds — as may be seen in the adjoining little table, which the astronomers call the Table of the Revolutions of the New and Full Moons — the tables will thereby be composed by which both the mean new moons and the mean full moons will be reckoned with little trouble, as we shall shortly say. And it is enough to reach the fourth conjunction, because the sum to be subtracted from these revolutions can never be greater than the number of this fourth conjunction. Moreover, in all these tables, which we have transferred here from Giovanni Antonio Magini, the thirds have been neglected — yet in such a way that, in composing the tables, whenever there were more than 30 thirds in the sum, 1 second was taken.

TABLES FOLLOW FOR CALCULATING THE NEW MOONS AND FULL MOONS

Table of the epacts of the 100 expanded years [Anni 100. Expansi — Epactae].
(D = days, H = hours, M = minutes, S = seconds.) Printed across the page in three
side-by-side blocks (years 1–42, 43–84, 85–100); reproduced here as one
continuous run.

[Caput VI, continued — Table of Epacts of the Collected Years, with the Radix of Christ and the monthly epacts for common and bissextile years]

Table of epacts for the collected hundreds of years, reckoned from the Radix of Christ, together with the monthly epacts.

The table is set in three panels across the page. In every panel the four sub-columns are **D** (days), **H** (hours), **M** (minutes), **S** (seconds).

Panel 1 — Collected years by hundreds [Anni collecti per 100], from the Radix of Christ [Radix Christi]. Radix of Christ = D 16 · H 18 · M 12 · S 30.

| Years | D | H | M | S |
|-------|----|----|----|----|
| 100 | 12 | 9 | 59 | 0 |
| 200 | 8 | 1 | 45 | 30 |
| 300 | 3 | 17 | 31 | 59 |
| 400 | 28 | 22 | 2 | 32 |
| 500 | 24 | 13 | 49 | 2 |
| 600 | 20 | 5 | 35 | 32 |

| Nov. [Nou.] | 10 | 3 | 55 | 25 |
| Dec. | 11 | 15 | 11 | 22 |

[Margin: How the mean new and full moons are to be found from the epact tables.]

The use of the tables just set out, for finding the mean new and full moons, is as follows. Gather into a single sum three quantities: the epacts of the elapsed complete hundreds of years [anni collecti per 100], the epacts of the completed individual years [anni expansi], and finally the epact of the month immediately preceding the one in which the mean new moon or full moon is sought — just as is customary in astronomical tables. Then, in the table of revolutions, cast out this sum by the next-lower entry standing under the heading of the conjunctions (marked by the syllable *Cor.*, for *Coniunctio*) or of the oppositions (marked by the syllable *Opp.*, for *Oppositio*), according as it is the mean conjunction or the mean

opposition that is being sought. The remainder will give the time of the conjunction or opposition in question.

For example. Suppose we wish to find the new moon of the month of September in the year 1725. The epacts of the 1700 years are 1 day, 23 hours, 51 minutes, 2 seconds. The epacts of the 22 completed years are 2 days, 16 hours, 17 minutes, 36 seconds. And the epact of the completed month of August in a common year is 6 days, 18 hours, 7 minutes, 35 seconds, as is plain from the tables above. These make a sum of 11 days, 10 hours, 16 minutes, 13 seconds. Subtracting this sum from the next-smaller number of the conjunctions — that is, from 29 days, 12 hours, 44 minutes, 3 seconds — leaves 18 days, 2 hours, 27 minutes, 50 seconds. Adding the 11 days that will have been dropped from the year up to that time (for the dropped days must always be added on account of the equation of the equinox [aequatio aequinoctii]) gives 29 days, 2 hours, 27 minutes, 50 seconds. The mean new moon therefore falls on the 29th of September, at 2 hours, 27 minutes, 50 seconds after noon, as appears in these formulas:

| D. | H. | M. | S. |
|-----------|-----------|-----------|-----------|
| 1 | 23 | 51 | 2 |
| 2 | 16 | 17 | 36 |
| 6 | 18 | 7 | 35 |
| 11 | 10 | 16 | 13 |
| | | | |
| D. | H. | M. | S. |
| 29 | 12 | 44 | 3 |
| 11 | 10 | 16 | 13 |
| 18 | 2 | 27 | 50 |
| 11 | | | |
| 29 | 2 | 27 | 50 |

If from this time you subtract the time of one mean lunation — having first added the 31 days of the preceding month of August, because the subtraction cannot otherwise be made — the remainder will be the time of the preceding mean new moon, which occurs in August on the 30th day, at 13 hours, 43 minutes, 47 seconds. If, on the other hand, to that same found time you add the time of one mean lunation and then subtract from the sum the 30 days of the month of September, you will find that the following new moon occurs in October on the

28th day, at 15 hours, 11 minutes, 53 seconds. But if from the time of any new moon you take away half a lunar month — that is, 14 days, 18 hours, 22 minutes, 2 seconds — or add the same to it, you will find the time of the preceding or following mean full moon. Thus you will find the full moon in September occurring on the 14th day, at 8 hours, 5 minutes, 48 seconds; and in October on the 13th day, at 20 hours, 49 minutes, 52 seconds. But always remember that the days of the preceding month must be added when the subtraction cannot be made, and that the days of the given month must be taken away when the collected sum exceeds the days of that month.

Now let the mean Paschal full moon be sought, in March or April of the year 2673. I say "in March or April" because it is not yet settled in which month the Paschal full moon will fall. For the 2600 years take the epacts 21 days, 23 hours, 17 minutes, 36 seconds; for the 72 completed years, the epacts 15 days, 18 hours, 32 minutes, 52 seconds; and for the elapsed February of a common year, the epacts 29 days, 11 hours, 15 minutes, 57 seconds. Their sum is 67 days, 5 hours, 6 minutes, 25 seconds. Since this sum, subtracted from the next-larger number of the oppositions — namely from 73 days, 19 hours, 50 minutes, 8 seconds — leaves 6 days, 14 hours, 43 minutes, 43 seconds; and since, with the addition of the 18 days that will have been dropped up to that time, the mean Paschal opposition occurs in the month of March on the 24th day, at 14 hours, 43 minutes, 43 seconds — this must be assigned to the following day, the 15th [recte: 25th], on which the 14th Moon then falls, of epact xix, which concurs with golden number 14.

But if, instead of February, you had taken for March of a common year the epacts 1 day, 9 hours, 47 minutes, 50 seconds, you would have made a sum of 39 days, 3 hours, 38 minutes, 18 seconds; and this, taken from 44 days, 7 hours, 6 minutes, 5 seconds (which is the next-larger number of the oppositions), leaves 5 days, 3 hours, 27 minutes, 47 seconds. Adding the 18 days that will have been withdrawn from the year, the full moon falls in April on the 23rd day, at 3 hours, 27 minutes, 47 seconds — which is not Paschal, since it follows the 19th of April, the day at which the mean Paschal full moons are closed off. Take away, therefore, a whole lunation from that time (having first added the 31 days of the preceding month of March), and you will find the full moon in March on the 24th day, at 14 hours, 43 minutes, 44 seconds, very nearly as before.

Further, let the mean Paschal full moon be sought in March or April of the year 1591. For the 1500 years take the epacts 10 days, 16 hours, 18 minutes, 2 seconds; for the 91 completed years, the epacts 15 days, 2 hours, 0 minutes, 26 seconds; and for the elapsed February of a bissextile year, the epacts 0 days, 22 hours, 31

minutes, 54 seconds. These make a sum of 26 days, 16 hours, 50 minutes, 22 seconds. When this sum is subtracted from the next-larger number of the oppositions — that is, from 44 days, 7 hours, 6 minutes, 5 seconds — and the 10 days dropped from the year are added, the mean Paschal full moon falls in March on the 27th day, at 14 hours, 15 minutes, 43 seconds — that is, on the 28th day, on which the 14th Moon also falls, of epact xvj, which concurs with golden number 16.

But if, instead of February, you had taken for March of a bissextile year the epacts 2 days, 9 hours, 47 minutes, 50 seconds, you would have found the full moon in April on the 26th day, at 2 hours, 59 minutes, 47 seconds — which is not Paschal. When, therefore, a whole lunation has been taken away (with the 31 days of the preceding month of March added first), the Paschal full moon presents itself in March on the 27th day, at 14 hours, 15 minutes, 44 seconds, very nearly as before.

Finally, if you wish to know the mean Paschal full moon in March, [or April,] of the year 388: for the 300 years take the epacts 3 days, 17 hours, 31 minutes, 59 seconds; for the 87 completed years, the epacts 1 day, 1 hour, 59 minutes, 1 second; and lastly, for the elapsed February of a bissextile year, the epacts 0 days, [numeral: ?] hours, 31 minutes, 54 seconds. Subtract the sum of all of them — 5 days, 18 hours, 2 minutes, 54 seconds — from the next-larger number of the oppositions, namely from 14 days, 18 hours, 22 minutes, 2 seconds, and you will find that the full moon sought occurs in March,

on the 9th day, at 0 hours, 19 minutes, 8 seconds — which cannot be Paschal, since it does not follow the 21st day, assigned to the equinox. Therefore, when a whole lunation has been added, there result 38 days, 13 hours, 3 minutes, 11 seconds; and when the 31 days of the month of March are taken away, that full moon will fall in April on the 7th day, at 13 hours, 3 minutes, 11 seconds — that is, on the 8th day. And the 14th Moon of golden number 9 then falls on the 7th of April, as the reckoning requires.

And indeed, if instead of February you had taken, with March of a bissextile year, the epacts 2 days, 9 hours, 47 minutes, 50 seconds, you would at once have found the full moon in April on the 7th day, at 13 hours, 47 minutes, 50 seconds — nearly the same as before.

[Margin: Why all the dropped days must be added to the reckoning of the lunations, so that the mean new and full moons may be found truly, even though

in the expanded table the descent has not been made through as many lines of epacts.]

But if you should ask why all the dropped or omitted days must be added to the calculation, given that the descent through the expanded table has nonetheless been made throughout by so many lines of epacts, know that the reason is this. Astronomical calculation exhibits the lunations as they truly occur in the heavens, as though no day had been removed, taking no account of the equation of the Moon [aequatio Lunae] — since the calculation itself equates the Moon on its own, and the equation of the Moon is applied only to correct the nineteen-year cycle. Consequently, if up to the time at which the calculation is set up some days have been removed on account of the equation of the equinox, the lunations will fall that same number of days later; for in the calculation those very days had been assumed. Necessarily, therefore, all the removed days must be added, so that the lunations may fall on their proper days.

The Arguments of Maestlin against the New Moons, the Paschal Fourteenths, and the Equation both of the Epacts and of the Solar Cycle of the New Calendar, and their Refutations

CAPVT VII.

[Margin: Solution of the arguments of Maestlin and of others against the new moons of the epact cycle of the new Calendar.]

From what we wrote in the immediately preceding chapter, all the arguments — not only of Maestlin but of others too — that have been, or can be, devised against the new moons of the new Calendar are dissolved with no trouble at all. For they all establish only this one thing: that the new moons found from our epacts do not entirely agree with the true or the mean new moons, but for the most part fall before them. This we grant freely and of our own accord, and in the preceding chapter we laid open the reason why it must necessarily be so — so that there is no need (as Maestlin, jesting ineptly and insipidly, would have it be voiced abroad) for us, the mathematical Fathers or Patrons of this Calendar, to come running up and bring relief to our feeble client. For we showed most clearly in the preceding chapter that this new Calendar is entirely correct in setting out the new moons according to the use of the Church. Nor, in this restoration of the Calendar, did we (as he falsely supposes) attempt an impossible task, on the ground that, by our own admission, no cycle can correspond in every respect to the celestial motions — unless perhaps he should wish to say that Julius Caesar

[Iulius Caesar], the Alexandrians, the Council of Nicaea [Concilium Nicaenum], and all antiquity undertook an empty labor in inscribing cycles in the Calendar, which would be the height of madness. For although the cycle, of set purpose, subordinates the new moons for the sake of the correct celebration of Easter, it does not on that account allow them to stray far from the true ones; so that it is worth the trouble to know them even when they are thus subordinated — especially since from the cycle we learn how many days the Moon usually has after conjunction, so truly that, when the Moon is called first, second, third, fourteenth, and so on, we understand it to be roughly the first, second, third, fourteenth day, and so on, elapsed since the conjunction.

[Margin: That the cycle of epacts in the Calendar does not show how many days have usually elapsed after the true conjunction.]

As for the fourteenth Paschal Moons [Lunae xiiii Paschales], Maestlin shows himself so ignorant of and unacquainted with ecclesiastical custom, and this with such great arrogance and effrontery, that I am ashamed — such as I am — to dispute with a man of his kind. For, in order to prove that our fourteenth Paschal Moons are erroneous and false and do not agree with the celestial motions, he heaps up, on pages 24 and 25, seventy years from the year 1500 up to the year 1700, in which our Paschal terms either precede the mean oppositions by only a single day or follow them — on his own testimony too. And this fact not only does not undermine our cycle; it actually confirms it so far that we must own ourselves indebted to him for a great favor, with whatever intention he did it. For in the preceding chapter we amply demonstrated that, in any cycle, in order that it may correctly indicate the Paschal terms (that is, the fourteenth Moons), it is enough that its numbers never present the fourteenth Paschal Moon two days before the mean opposition, but only a single day before it, or at any rate at the mean opposition itself, or a little after it. And this is exactly what is observed in the years adduced by our adversary.

[Margin: Maestlin's ignorance and arrogance in attacking the fourteenth Paschal Moons.]

For the rest, in this very matter he has slipped shamefully, and almost childishly, when he supposes that the Paschal Moon does not differ from the mean opposition, and that accordingly, whenever the former does not agree with the latter, an error — on his view — is committed in the Paschal term. This is a thing unheard of and novel in the Church of God, as is plain from the preceding chapter. But what wonder is it, if a man not only ignorant of ecclesiastical matters, but also carried away by his zeal for contradiction, comes to grief so

fouly and so often? For he shows himself no more skilled in these seven years — 1576, 1578, 1579, 1580, 1581, 1582, 1583 — in which he rages so wildly that he cries out that we have prostituted ourselves to the whole world to be mocked, since in these years too, in which we brought forth and delivered this offspring into the light, we erred most enormously. But let him see to it that he does not, like a madman deriding sane men, prostitute himself to be mocked by everyone — since, gathering up the witnesses of his own folly, he plainly declares that he has not touched even with the tips of his lips, as the saying goes, the things that the Fathers and Councils decreed concerning the correct celebration of Easter. For in these seven years the fourteenth Paschal Moons, according to our epacts, do not disagree with the decrees of the Councils, since they always either precede the mean oppositions by a single day, or coincide with them, or finally fall a little after them, as is clear in this little table.

[Margin: That Maestlin's arguments against the fourteenth Paschal Moons confirm rather than weaken the cycle of epacts. Maestlin's error in thinking the mean opposition and the fourteenth Moon to be one and the same thing.]

The mean oppositions for these years (the table standing at the head of the page):

| Year of the
Lord | Golden
number | Ep
act | 14th [moon],
Paschal | Mean opposition (D. H.
M.) |
|---------------------|------------------|-----------|-------------------------|-------------------------------|
| 1576 | 19 | xxi
x | 14 Apr. | 13. 1. 37 |
| 1578 | 2 | xxi
i | 22 Mar | 22. 19. 15 |
| 1579 | 3 | iii | 10 Apr. | 10. 16. 47 |
| 1580 | 4 | xiii
i | 30 Mar. | 30. 1. 36 |
| 1581 | 5 | xx
v | 18 Apr. | 17. 23. 9 |
| 1582 | 6 | vi | 7 Apr. | 7. 7. 57 |
| 1583 | 7 | vii | 6 Apr. | 6. 16. 46 |

[Margin: On Maestlin's consideration, in which he examines the years before the correction as if 10 days had been removed from them.]

Nor was he careful enough — to put it as gently as possible — with these four years, 1511, 1527, 1571, and 1579, in which he set out to show that the Paschal 14th moons of the epacts stand further from the true full moons, that is, that they

anticipate them by two days. (This is in any case beside the point, since in this matter it is the mean motions that must be considered, not the true ones.) He fixed his mind so intently on overturning the new Calendar that, all but forgetting his own purpose and not considering what he was doing, he computed the full moons of those years exactly as if 10 days had already been removed from them — when in fact those years precede the year of the correction. This is utterly ridiculous. For since the beginning, or root, of the removal of the 10 days is set in the year 1600, from which the equation to be applied thereafter advances every four-hundredth year, one must not subtract 10 whole days from the years that precede our correction, but something less — especially from years further removed from 1600, such as the year 1511. It would therefore be no wonder if the Paschal 14th moon of that year did not correspond exactly to the mean, or indeed the true, full moon. That Maestlin has in fact extracted 10 days from those years is clear from this: his calculation only works out if the days I have mentioned are treated as removed — which is what this table shows.

| Year of
the Lord | Golde
n
numb
er | Epact, if 10
days had
been
removed
from these
years | 14th
[moon],
Paschal | Mean full
moon (D. H.
M.) | True new
moon acc. to
Maestlin (day) |
|---------------------|--------------------------|--|----------------------------|---------------------------------|--|
| 1511 | 11 | xxi | 23 Mar. | 23. 22. 35 | 25 Mar. |
| 1527 | 8 | xviii | 26 Mar. | 26. 23. 57 | 28. Mar |
| 1571 | 14 | xxiii | 18 Apr. | 9. 4. 6 | 20. Apr. |
| 1579 | 3 | xxiii | 21 Mar | 22. 4. 3 | 23. Mar. |

Here you see that the Paschal 14th moons precede the mean full moons by a single day only, which is quite enough for the correct celebration of Easter, as we have often said. And so, even though he maliciously subtracted 10 days from those years, he accomplished nothing; rather, he confirmed our 14th moons. But if those years are taken before the correction of the Calendar — that is, without the subtraction of the 10 days, as is proper — then their epacts, Paschal 14th moons, and mean full moons would stand in the new Calendar as this second table sets out, in which again you see that the 14th moons are legitimate according to the prescription of the Council of Nicaea, and indeed that the Paschal 14th moon of the year 1571 is more legitimate than if 10 days were removed.

| Year of the Lord | Golden number | Epact before the correction of the year | 14th [moon], Paschal | Mean full moon (D. H. M.) |
|------------------|---------------|---|----------------------|---------------------------|
| 1511 | 11 | j | 12 Apr. | 12. 11. 19 |
| 1527 | 8 | xxviii | 15 Apr. | 15. 12. 41 |
| 1571 | 14 | iiii | 9 Apr. | 9. 4. 6 |
| 1579 | 3 | iii | 10 Apr. | 10. 16. 48 |

[Margin: Maestlin's argument, that because of the elision of 3 intercalary days in every 400 years most of the Paschal full moons of the new Calendar belong to the second month.]

Next he attempts to show that in the new Calendar the Paschal full moons of many years belong to the second month, even though they are assigned to the first. He gives as his example these years: 1571, 1590, 1609, 1628, 1647, 1666, 1685, in all of which the golden number is 14 and the epact xxiii, which has its Paschal term on 18 April — provided, that is, that 10 days are imagined removed from the year 1571 (as he also did above), even though that year precedes the correction and therefore had its Paschal term, or 14th moon, not on the 18th but on 9 April. For in all these years he says that calculation from the most recent observations proves [?] that the Paschal 14th moon belongs to the second month. Here he sharply censures all of us who took part in this correction, alleging — falsely, as he supposes — that we were not engaged in fresh observations, whereas, as he says, careful work tested by new observations is required in this matter, because the slightest slip causes an error of a whole month. He throws the cause of the error back onto the table of the equation of the epacts and onto the unequal anticipation of the lunations and of the equinoxes, since the latter anticipate by one

day sooner than the former. For he does not understand how it can happen that from the year 1500 to 1700 exclusive the golden number 14, presenting according to the equation table the epact xxiii, places the Paschal 14th moon on 18 April, ruling that it belongs to the first month.

[Margin: Maestlin's error in defining the first month.]

(In defining the first month, however, he falls back into his old error, calling the first month the one whose new moon is nearest the vernal equinox, whether it be counted among the preceding or the following days — which we refuted in Chapter 1 of the previous book.) Whereas from the year 1700 to 1900 exclusive

the same golden number 14, presenting the epact xxij, moves the Paschal 14th moon from 18 April to 21 March, exactly as if it no longer belonged to the first month but to the second. And he asserts that far grosser absurdities follow in the years thereafter. For in the same way, from 2200 to 2300 exclusive, the golden number 17 presents according to the equation table the epact xxij and throws the Paschal 14th moon onto 18 April. But from 2300 to 2400 exclusive the same golden number 17 indicates the epact xxij, and hence the Paschal term on 21 March. Then from 2400 to 2500 exclusive the same golden number 17 again presents the epact xxij and the Paschal term on 18 April, as before from 2200. And so — he says — in the new Calendar, in those years in which the golden number is 17, from 2200 to 2300 exclusive it holds that the mean opposition occurring in March (he should have said the 14th moon, which is what he always meant) will always precede the equinox, and therefore cannot be Paschal; but in the years to come from 2300 to 2400 exclusive, that same mean opposition (that is, the 14th moon) will fall on the equinox or follow it, and therefore cannot fail to be Paschal; and finally, from 2400 to 2500 exclusive, the same mean opposition (that is, the 14th moon) will again precede the Sun's entry into Aries, and so will cease to be Paschal — which seems to him false. For "How is it possible," he says, "that the equinox, whose anticipation is always faster than the anticipation of the lunations, should produce a full moon (that is, a 14th moon) which had begun to be the Paschal term, and then presently strip it of that office again? This thing is surely by far most absurd, utterly unheard of, and diametrically contrary to the whole certainty of astronomy and to truth," and so on.

[Margin: Two closely related arguments which, if they were worth anything, would abolish entirely the restitution of the equinox and the correction of the year.]

By a similar argument he tries to prove that many Paschal terms in the new Calendar belong to the last month rather than the first, in these words: "It has been demonstrated above (if it please GOD) that the true vernal equinox can recede from 21 March as far as the 27th. It will therefore follow that every full moon (that is, every 14th moon) that falls between the 21st and the true day of the true equinox — after the 21st — is taken by the new Calendar as the Paschal term. But such an opposition (that is, such a 14th moon) does not then belong to the first month of the following year, but to the last month of the preceding year."

Here I cannot sufficiently marvel at Maestlin's arrogance — not to say malice.

[Margin: Solution of the two preceding arguments of Maestlin.]

While with ill will he seeks to abolish the new Calendar entirely, he simultaneously accuses all the mathematicians of the whole world — who declare with one voice (as the matter itself proclaims) that the equinox cannot be restored to its former seat except by the removal of a number of days from some year in which it is found to have advanced toward the beginning of the month. Yet Maestlin, of some new breed of astronomers, reproaches the new Calendar even on this ground: that by the omission of the intercalary day in certain centesimal years (which is to remove one day from the year) it restores the equinox to the very day from which it recedes. "Because," he says, "from this removal of a day it follows that a full moon which was previously Paschal presently ceases to be Paschal, and one which previously could not be Paschal presently cannot fail to be Paschal." A great sin indeed — that, to avoid its being committed, the equinox must never be recalled to its own seat (however far it has slipped from that seat toward the beginning of the month), when it cannot be recalled otherwise! A fine mathematician, truly, who — to make the new Calendar suspect to everyone, or rather hateful, as though it were stuffed with countless absurdities and manifold falsehood — would have every correction of the year whatsoever that could possibly be devised rejected; since in any emendation of the year some days must be removed so that the equinox may return to the day from which it had departed, which seems to him absurd and by no means to be granted. For if he would admit this subtraction, he would surely not be carried against the new Calendar with such violence; since, once it is granted, it necessarily follows — whether he likes it or not (a thing that seems to him an inexpressible crime) — that a 14th moon which, under a certain current cycle number, is now Paschal, will presently, after the elision of one day, no longer be Paschal, and vice versa. By what reasoning this can happen, I shall not be reluctant to teach him here, if he is willing to learn, since he confesses he does not know it. Listen, then, Maestlin.

[Margin: When the transition is made from the upper line of the expanded table to the lower one: the Paschal new moon of the fifth day of April ceases to be Paschal, and the non-Paschal new moon of the seventh day of March begins to be Paschal.]

Whenever a passage is made from some line of the expanded table of epacts to the line below it — as necessarily happens in the centesimal years that are not leap years, in which nevertheless the Moon is not to be equated — then, if in the upper line some golden number corresponded to the epact *xxiiij*, the Paschal new moon of that golden number was on 5 April, where the last Paschal new moon falls; but the new moon of the same golden number on 7 March was not Paschal.

In the lower line, however, the new moon of the same golden number will no longer be Paschal in April, since that same golden number now corresponds to the epact *xxiij*, which has its 14th moon on 19 April and its new moon on 6 April — beyond the Paschal limits, of course. Yet the same golden number will then have its Paschal new moon in March, because the epact *xxiij* corresponding to it is placed on 8 March, where the Paschal new moons begin. You see, then — unless perhaps you wish to be blind — that the new moon of that golden number is Paschal in April while the upper line of epacts is in use, but ceases to be Paschal when the lower line of epacts is employed; and likewise that the new moon of the same golden number in March is not Paschal while the earlier line of epacts is in use, but begins to be Paschal when the later line of epacts serves. The astronomical reason for this too is plain. For when the intercalary day is omitted in some centesimal year, if the Moon then needs no equation, all the new moons descend one day in the Calendar toward the ends of the months. Therefore the new moon that previously fell on 5 April, and was Paschal, but afterward falls on 6 April, ceases to be Paschal. Conversely, the new moon that previously fell on 7 March, and was not Paschal, but afterward falls on 8 March, becomes Paschal.

[Margin: When the transition is made from the lower line of the expanded table to the upper one: the Paschal new moon of the eighth day of March ceases to be Paschal, and the non-Paschal new moon of the sixth day of April begins to be Paschal.]

Again, whenever a passage is made from some line of the expanded table of epacts up to the line above it — as necessarily happens in the centesimal leap years, in which the Moon is to be equated — then, if in the upper line some golden number corresponded to the epact *xxiij*, the Paschal new moon of that golden number was on 8 March, where the Paschal new moons begin; but the new moon of the same golden number on 6 April was not Paschal. In the upper line, however, since the same golden number now indicates the epact *xxiiij*, the new moon of that golden number falling on 7 March ceases to be Paschal, while another falling on 5 April becomes Paschal. Here again you see that the new moon of that golden number is Paschal in March while the lower line is in use, but ceases from that office when the upper line is taken up; and likewise that the new moon of the same golden number in April is not Paschal so long as the lower line is employed, but becomes Paschal as soon as the upper line is received into use. The astronomical reason for this too, if you ask, is as follows. When the intercalary day is retained in some centesimal year and the Moon is to be equated, all the new moons ascend one day toward the beginnings of the months in the Calendar. Therefore the new moon falling, before the equation of the

Moon, on 8 March, is Paschal; and falling, after the equation, on 7 March, can no longer be Paschal. By the same reasoning, the new moon falling, before that equation, on 6 April, is not Paschal; and falling, after the same equation, on 5 April, becomes Paschal. This thing, then, is not "by far most absurd, utterly unheard of, and diametrically contrary to the whole certainty of astronomy and to truth," as you falsely rail, but is fully consonant with the precepts of astronomy — so that your ignorance in this matter cannot be excused in any way, seeing that you confess yourself unable to understand a thing that is perfectly clear in itself.

[Margin: The Paschal full moons in April of certain years cited by Maestlin do not belong to the second month, as he falsely supposes, but to the first.]

Moreover, that it is untrue that in these 7 years — 1571, 1590, 1609, 1628, 1647, 1666, 1685, adduced by Maestlin — the full moons which in the new Calendar are Paschal in April belong to the second month and not the first, as he asserts, is clearly established from the following table, in which it is plainly seen that their mean full moons of March do not belong to the first month, as he wrongly maintains, but to the last, or twelfth; inasmuch as they do not follow 21 March, on which the equinox is fixed by the Church, but rather precede it — whereas mean Paschal full moons, that is, those of the first month, ought to follow the equinox, and the Paschal 14th moons ought never to run ahead of the very day of the equinox, as is manifest from what we said before.

| Year of the Lord | Golden number | Epact | Mean opposition of March (D. H. M.) |
|--------------------|---------------|--------|-------------------------------------|
| 1571 | 14 | xxiiij | 20. 15. 22 |
| 1590 | 14 | xxiiij | 20. 7. 54 |
| 1609 | 14 | xxiiij | 20. 0. 27 |
| 1628 | 14 | xxiiij | 19. 16. 59 |
| 1547 [recte: 1647] | 14 | xxiiij | 20. 9. 32 |
| 1666 | 14 | xxiiij | 20. 2. 4 |
| 1685 | 14 | xxiiij | 19. 18. 37 |

[Margin: The 14th moons of the first month are referred by the Church to 21 March, the day appointed for the equinox, even though the equinox is sometimes distant from that day.]

Nor is it an objection that these full moons, by the Alphonsine calculation, are later than the equinox, since by the Prutenic Tables they are earlier — as Maestlin himself admits. Indeed, whatever the case may be regarding the

equinox, whether by the Alphonsine calculation or the Prutenic, it is of no concern to us, since the Church, setting the tables aside, fixes the equinox to a single day, namely 21 March, even though the true equinox sometimes nods to either side, provided it does not depart too far from it. And indeed the Church very often rejects some full moons as non-Paschal, on this ground alone: that their 14th moons anticipate the 21st of March, the day assigned to the equinox, even though in reality they fall on the equinox; and likewise accepts others as Paschal because their 14th moons fall on the 21st, the equinoctial day, even though they really run ahead of the equinox itself. This is clearly seen in the leap years and in those that are third from the leap year. For in the former, although the equinox reaches 20 March, the Church nevertheless rejects all the lunations whose 14th days fall on 20 March, that is, on the equinox; while in the latter it approves all the lunations whose 14th moons fall on the 21st, even though in them the equinox occurs after the 21st. This too we taught in Chapter 5 of the previous book.

[Margin: Refutation of Maestlin's other calumnies against the Paschal lunations.]

But so that this too may be apparent — that the golden number 14, from 1700 to 1900, rightly throws the Paschal lunation from April back into March (which he himself cannot stomach), and that the golden number 17, from 2200 to 2300, fittingly presents the same in April, but from 2300 to 2400 in March, and finally from 2400 to 2500 most fitly assigns it to April — we have computed the following mean oppositions. Here it appears that the mean full moons of golden number 14, or of epact xxiiij, in April from 1700 to 1900 are not Paschal, since they follow the 19th, after which no mean full moon is Paschal, lest Easter — which sometimes falls on 19 April — be celebrated before the mean full moon. And that from 2200 to 2300 the mean oppositions of the month of March, when the golden number is 17 and the epact xxiiij, are not Paschal, because they do not follow 21 March, the day appointed for the equinox. Likewise that the mean oppositions of April from 2300 to 2400, when the golden number

Table of mean full moons (mean full moon = day · hour · minute; month). The years of the Lord in which golden number and epact combine to place a mean full moon near the paschal limit, with the resulting month.

Continuing the argument from the preceding leaf: ... [golden] number 17 and epact xxiii coincide, these full moons are not paschal, because they fall after 19 April — just as happens from the year 1700 to 1900. Likewise, in the month of March, from the year 2400 to 2500, when golden number 17 and epact xxiii coincide, they are again not paschal; nor are they paschal from 2200 to 2300, for the reason I set out there. From all this one may conclude that Maestlin, driven more by an eagerness to slander than by love of the truth, so shamelessly maligns the new Calendar — since in our new Calendar everything is preserved exactly as the sacred Councils and the Fathers decreed concerning the celebration of Easter.

It is established, therefore, that Maestlin asserts falsely that in the new Calendar many full moons are assigned to the first month, in April, which in truth belong to the second.

As for his claim that the equinox will advance from 21 March all the way to the 27th, and that consequently at that time all the full moons falling after the 21st but before the 27th belong to the last, or twelfth, month of the year, though in the new Calendar they are assigned to the first month — he is merely guessing, and, as the saying goes, is wrong by the whole sky. For not even according to the Prutenic Tables [Tabulæ Prutenicæ], in which he places his greatest trust, can the equinox recede from 21 March by more than two or three days, and a little more, even over a span of 10,000 years, as we showed in Chapter vi of the preceding Book. And should it happen that the equinox falls after 21 March, so that some lunation is taken as paschal whose fourteenth day precedes the equinox; or should it happen that the equinox precedes 21 March, so that some lunation whose fourteenth day falls on the equinox itself or after it is not reckoned paschal, even though it belongs to the first month — this is not to be charged as a

fault against the Church, which in this matter, setting aside the true and the mean motions, follows something uniform and regular that does not stray far from the truth, so that this inconvenience can in no way be avoided, as we explained more fully in Book 1.

[Margin: It is false that the equinox can recede from 21 March to the 27th, as Maestlin holds.]

Hence Maestlin turns his weapons against the table of the equation of epacts [tabula æquationis Epactarum] — which nevertheless, compelled by the truth, he in part praises and commends, as constructed with great labor and no little skill, and, as he says, contrived with a fine ingenuity; and not undeservedly, since in it the omission of three days every 400 years, on account of the anticipation of the equinoxes, agrees so well with the equation of the Moon to be applied every three-hundredth year, on account of the ascent of the lunations, that the solar year and the lunar year are seen to be perpetually in mutual agreement, and the very method of the equation can be fitted to any magnitude whatever of the solar year, as we have said. And indeed I do not doubt that he would have judged it worthy of still greater praise had he understood its root [radix], which we fixed — not rashly nor by chance, but after mature consideration — at the year of the Lord 550. Nor, had he understood it, would he have dared either so boldly to censure, or so foully to correct — or rather to corrupt — the equation restored for the years before the correction, since the equation table cannot be constructed otherwise than as we constructed it, as is clear from Chapter 4.

But so that the rashness and ignorance of Maestlin in this matter of the equation of epacts may be plain to all, let us examine a little more carefully what he wrote about it in his *Examen*. After he had set out the perpetual table of the cycle of epacts — in which, however, he confesses that he cannot understand what mystery lies hidden in the epact 25 of a different color or character, and why the letters of the alphabet were not written above the epacts that correspond to golden number 1, but rather above those that correspond to golden number 3 (we gave the reason for both above, in Chapters 3 and 4) — he attempts to construct a table of the equation, and to correct, or rather to corrupt, that same table, as follows, having first set out the equation table as it is described in the new Calendar. In this table, however, and in the others he made, we placed this sign ☾ whenever the Moon needs an equation, just as we did above in the equation table of epacts of the expanded table.

TABLE OF THE EQUATION OF THE PERPETUAL CYCLE [Tabula æquationis Cycli perpetui], placed in the new Calendar.

The source prints this as three side-by-side panels forming a single continuous series of centennial years (1 → 4900); the panels are concatenated below in sequence. Columns: epact index letter · Anni Dñi (years of the Lord) · bissextile mark · lunar-equation mark (☾ = one equation, ☾ ☾ = two).

The following is Maestlin's quoted reconstruction and critique of the table (introduced by "says Maestlin"); it is set in italic throughout and continues to the end of the leaf and beyond.

"Since, then (says Maestlin), according to the author's view those epacts whose index is D belong to the years from 1600 to 1700, as was said above, therefore at the year 1600 the epact-index letter D is prefixed. But in the year 1700 the intercalary day is dropped, the lunation being at rest — for its anticipation has not yet completed a whole day; and therefore all the lunations become one day later. Thus, whereas between 1600 and 1700 all the years whose golden number is 3 had epact xxij — that is, since in the new Calendar, wherever the epact is xxij the Moon in those years would become new on that day, or since in the paschal table (which will follow shortly) epact xxij would show, in those years, the paschal limit on 21 March — this same thing, after the bissextile day of the year 1700 has been removed, will occur on the day immediately following, on which the epact is xxv. Therefore golden number 3 will then have epact xxv. Its index in the table of epacts is C. Therefore the letter C is prefixed at the year 1700. What is said of the years whose golden number is 3 is to be understood likewise of all the rest. It pleased [the author], however, to choose golden number 3 as an

example in place of all the others, because the author placed the index letter above it, as I noted before.

"Next, in the year 1800 one intercalary day is dropped, and at the same time the anticipation of the lunation completes a whole day. Therefore, a mutual compensation being made, the cycle of epacts is not interrupted for this century, but the index C remains here also.

"Moreover, in the year 1900 the same thing happens as in 1700. Hence golden number 3 passes to epact xxi, whose index is B.

"Again, in the years 2000 and 2100 this cycle is not interrupted. For in the former both the lunation and the intercalary day are at rest; in the latter the reasoning is the same as in 1800. Therefore the index B is retained, through 300 years, in the office of showing the equation of epacts.

"Once more, the years 2200 and 2300 agree with the year 1700; hence golden number 3 descends, in the former year, to epact xx, and in the latter to xix, having there as its index letter A for the former and u for the latter.

"But in the year 2400, after the lunation has again consumed a day by anticipating, no omission of an intercalary day takes place; therefore the lunation, from golden number [epact] xix, ascends again to epact xx, and again obtains the index A. The same is to be understood of the rest. For by a similar procedure the several index letters were found, reckoning back from the year 1582 of the correction. Nor has this table any other, subtler foundation, although the author studiously — not to say maliciously — concealed it.

"As for what is to be thought of the remaining years, those preceding the year 1582 of the correction, the author has indeed set it out rather intricately; yet if one examines a little more carefully, he will easily be able to gather what foundations he used, and in what regard they deserve to be held.

"From the letters indicating the equation of epacts, which the author set out in the next table for the years preceding 1582, one may observe that from the beginning of the years of Christ up to the year 320 he assigned to golden number 3 the epact xxix — for its index letter is N; but from the year 320 to 800 he attributed to it the epact xxx, which he himself marks with an asterisk *. Likewise, that for the years from 800 to 1100 he granted to the same golden number 3 the epact j, and from there to 1400 the epact ij, and again from 1400 to 1582 the epact iij, which

(Maestlin's quoted argument continues.)

after the correction he changed into xxiiij. And what I note about this golden number 3 is understood likewise of the rest that correspond to it, as I said a little before. Therefore throughout this whole time the lunations are held to anticipate gradually. Hence he applies to this period the Cycle of epacts corrected, but omits the anticipation of the equinoxes, as the following little table shows."

TABLE OF THE EQUATION OF EPACTS, EXPANDED [Tabula æquationis Epactarum expansa], which the author of the new Calendar contracted for the years before the correction.

The source prints three side-by-side panels forming a single continuous series (0 → 1800); concatenated below. Columns as before.

(This table is derived from the immediately preceding critique; Maestlin continues:)

"From this table, which according to the author's view is drawn from the immediately preceding one, one may see in what esteem this whole work is to be held. For in the first place, how the author's reckoning agrees with astronomical calculation is shown by the equations of the lunations between the years 1400 and 1800, and, in the preceding table, between the years 3900 and 4300. It was said a little before that the anticipation of the lunations requires 304 years for one day, and that for their sake the equations, which are to be distributed only over hundreds of years, sometimes demand not merely 300 but 400 years. But a period of this kind requires twenty-five times three hundred years [25×300]: for those 4 years added to 300 do not complete a fourth hundred [a 400-year span] until they are accumulated twenty-five times over. Yet the author divides an equation of this kind only over twenty-five times a hundred years — namely, from the year 1600 to 4100 — which is plainly contrary to astronomical calculation, and can bear no excuse, nor any acquittal from falsehood.

"Next, lest this faulty reckoning be thought committed through mere imprudence, the author is not ashamed to compensate for it by another still more faulty, and, of set purpose, to collide the more grievously against astronomical truth. For in place of the equation of the lunations from the year 300 (or 320) up to 800 — that is, over 500 years — he substitutes but a single day of anticipation. And this is by far the most absurd of all, and utterly false in astronomy. For it can indeed sometimes happen, as has just been said, that on account of the 4 years adhering to the 300 the anticipation of the lunations requires 400 years to complete a single day; but to 500 years such a reckoning can never be extended. And in particular it is not the place to insert an equation of this kind beyond 300 years. For the year 800 is distant only 600 years from 1400, where the equation of this fourth hundred is interposed — a span that lies far too far from the period of this equation, which is twenty-five times three hundred years. Nor is it possible that this error was unknown to the author, for it is far too gross. But the reason the author chose to depart from manifest truth is doubtless this: that he attended with singular zeal to the customary golden number, and therefore forced his epacts, resisting in every way, dragging them by the hair, to agree with the golden number for the time of the Council of Nicæa. And this could not be done except by committing this enormous solecism. He preferred, therefore, that his numbers should agree with the golden number (which he did not notice by no means satisfies the lunations of that age) rather than that they should accord with [those of] the Council of Nicæa. Behold, these are the foundations of the table which,

above all the other numbers and tables of the whole new reformation, is the most artful.

"But if the author had continued this anticipation of the lunations in the same manner as before, through each 300 years, he would surely have found a different index letter of the equation of epacts for the time of the Council of Nicæa, as this following table makes clear."

TABLE OF THE EQUATION OF EPACTS, SUCH AS IT OUGHT TO HAVE BEEN MADE BY THE AUTHOR of the new Calendar [Tabula æquationis Epactarum qualis ab auctore novi Calendarii conficienda fuisset] for the years preceding the correction.

"In this table, the epact index letter that agrees with the years of the Council of Nicæa is not P, but N."

And so that the pointlessness and emptiness of this whole table drawn up by the author of the new Calendar may appear more clearly, we shall examine it with the correction of the equinoxes also applied, just as was done in Chapter 1 — since indeed the whole foundation of this correction, that is, of the new Calendar, and thus its very first origin, depends on the Council of Nicaea. The following table therefore shows the index letter of that century.

TABLE OF THE EQUATION OF THE CYCLE OF EPACTS FOR PAST YEARS, by which the correction both of the lunations and of the equinoxes is observed in the same way in which it is handed down by the author of the new Calendar to be observed in future time.

Here again, you Mathematicians, patrons of the new Calendar, may observe how much certainty underlies your Calendar. For the age of the Council of Nicaea you see, from this last table — which follows the correction of the new Calendar as observed in the anticipation both of the equinoxes and of the lunations — that the index letter of the epacts that fits is the letter M. But from the immediately preceding table, in which only the correction of the lunations is retained, you see that the letter N is due for that same century. Yet the author of the Calendar, in order to impose falsely upon you, contrary to his own calculation and intent, foists on you the letter P. So for the same years — for example, those whose golden number is 13 — you have three epacts: namely, on account of the index letter of the equation M, the epact xxviii; on account of the letter N, the epact xxix; and on account of the letter P, the epact xxx, which is marked with an asterisk (*). But why do I find fault with this? I would rather congratulate you on the abundance of your Calendar. For if by this threefold calculation only a single index letter were yielded — as otherwise regularly happens in astronomical, indeed in every arithmetical, calculation, since however it may be varied it is never found to disagree with itself — perhaps you could not be so certain in determining the days of the new moons, or of the Paschal full moons. But as it is, since for a single day you have three, it can scarcely happen that you stray from the truth. Yet meanwhile it is clear from this that the author of the new Calendar did not exert himself much in examining the astronomical calculation precisely and comparing it with his own numbers. Judge therefore for yourselves whether, if the author did not understand these things, he deserves to have any authority granted him in the rest — and that on account of your shameful or affected ignorance; but if you were aware of these things, is he not to be cursed with imprecations, since he has maliciously cast a deception over your Pontiff, over all of you his followers, and over the whole world of Christians?

[Margin: Maestlin did not fully understand the table of the equation of the epacts.]

These, then, are the matters. As regards the table of the equation of the epacts, although he seems to himself to have thoroughly understood the matter, he has nevertheless not grasped everything. For, being ignorant of the root of our equation — which we have fixed in the year of the Lord 550 — he was unable to give the reason why the equation of the Moon was rejected by us: then from the year 1700, which stands three hundred years distant from the year 1400 (where the immediately preceding equation of the Moon was made), into the following hundredth year 1800; and again from the year 4200, which likewise stands three hundred years distant from the year 3900 (where the Moon was last equated), into the following hundredth year 4300. Yet we have explained the reason for this at length in Chapter 4. As for his saying that the author set out the equation, in the years preceding the correction, quite intricately, and that if anyone examines the matter a little more carefully he can easily gather what foundations the author used and what standing they deserve to be held in — no one should be surprised, since he himself was wholly ignorant of the author's foundations, and therefore judged, in conflict with the astronomical calculation, that the equation was rejected then from the year 1700 into 1800, and then from 4200 into 4300; in which he is plainly mistaken.

[Margin: The equation of the new Calendar agrees with the astronomical calculation between the years 1700 and 1800, against Maestlin.]

Take as an example the year 1723, between the year 1700 and 1800, whose epact, by our equation, is xxiii, throwing back its fourteenth Paschal moon to 21 March — a little before the mean opposition, which falls on the 21st day at about the 4th hour after noon, as reason requires. But if the Moon were equated in the year 1700, as Maestlin wishes, and this equation were not deferred into the following hundredth year, as is done by us, then in that year the epact would be xxiii, placing its fourteenth on 20 March, before the limits set by the Fathers. The epact xxiii would therefore have to be taken in April, which throws its fourteenth to 18 April; and therefore, if the following 19th were a Sunday, Easter would be celebrated before the mean full moon — which in that year fell on 19 April at the 16th hour after noon, namely a little before the sunrise of the 20th day — which would be absurd. The same difficulties would follow Maestlin's equation in many other years, which our equation easily avoids. Let Maestlin therefore see with what face, with what effrontery, he has said that our equation conflicts with the astronomical calculation, when his own equation — the one he would have established — is instead opposed both to astronomy and (what is greater) to the decrees of the holy Fathers, whereas ours agrees marvelously with both.

[Margin: Maestlin's error in defining the anticipation of the Moon.]

I WONDER greatly, moreover, that in this passage Maestlin — so well-versed in the Prutenic and Alphonsine Tables, as he wishes to appear, being one who studies to examine everything through tables not only diligently but even inquisitively — has been so easily led into error (evidently only in order to have something with which to carp at that equation of ours) as to believe, with the common crowd, that the lunations anticipate one day over a span of 304 years, and therefore, once twenty-five times three hundred years are completed — that is, after 7500 years, in which the 4 [days] omitted at each 300 years fill up the number of 100 years — that the equation of the Moon must be made not at the three-hundredth year but at the four-hundredth. In which matter indeed Maestlin has stumbled quite disgracefully. For this manifestly conflicts with all the astronomical tables he so loudly boasts of, in which a single mean lunation is set at 29 days, 12 hours, 44 minutes, 3 seconds, 11 thirds, roughly. From this it follows that the lunations anticipate one day in about $312\frac{1}{2}$ years, as we showed in Chapter 1 of this book — so that, when eight times three hundred years are completed, that is, after 2400 years, the equation to be made at the three-hundredth year is deferred into the following hundredth year, so that it then occurs at the four-hundredth year, just as we have done in the equation-table. And so what he falsely affirms of us can most truly be said of him: namely, that what he here teaches about the lunations is plainly contrary to the astronomical calculation, and can bear no excuse, nor any acquittal from falsehood. For our reckoning (whatever he may say) rightly agrees with the astronomical calculation, and the equation was aptly set up by us between the year 1400 and 1800, as was clear from the earlier example of the year 1723; and likewise between the year 3900 and 4300, the equation of the lunations requiring that in both cases the equation be rejected from the three-hundredth year into the four-hundredth — since the $12\frac{1}{2}$ [days] omitted at every three hundred years had then grown into a total of 100 years, as we demonstrated in Chapter 4 of this book.

[Margin: The childish deception of Maestlin, in that he supposed that in our Calendar, from the year 320 to 800, by three [steps], the Moon anticipates one day over a span of 500 years.]

In this too our adversary was deceived almost childishly: he supposed that he had established that the lunations, from the year 320 to the year 800 — that is, over a span of about 500 years — anticipate by only a single day, because he saw in the table of the equation the capital letter P before the year 800. There he claims that we deliberately clash more seriously with astronomical truth, and that this is by

far the most absurd thing of all, and utterly false in astronomy. Deceived, I say, is he; whereas we, in this passage, have committed no fault in astronomy, nor introduced anything absurd or false into astronomy. For this change of the capital letter P into the small letter a was made rightly and necessarily in the year 800, and not before; since from the year 500 — where we fix roughly the root of the equation (which entirely escaped Maestlin) — with the capital letter P, for the reason adduced above, three hundred years are counted up to the year 800. Let Maestlin therefore be ashamed to censure so impudently what he does not understand, and let him cease at last to provoke us with taunts and mockeries, with which all the pages of his book are sprinkled, and which apply to himself more than to us.

As for his saying that, if the table of the equation is continued back to earlier years through 300-year steps, the capital letter N — not P — agrees with the years of the Council of Nicaea, as appears from the second-to-last table of his equation: this is indeed true, since the epacts of the capital letter N indicate the new and full moons, according to the Church's usage, more correctly than the epacts of the capital letter P do for those times. But it is beside the point. For we did not intend to correct the new moons of the Council of Nicaea, but only to indicate on what days at that time they were shown by the golden numbers — which is accurately supplied by the epacts of the capital letter P, as is clear from the above. But that, as regards the Church's usage, the Paschal full moons are more correctly indicated for the years of the Council of Nicaea by the epacts of the capital letter N than by those of the capital letter P, will be plainly established from the table of 19 years around the time of the Council of Nicaea, which will follow shortly. For since in it the epacts of the capital letter P present the fourteenth Paschal moons nearly two full days before the mean oppositions, who will doubt that the epacts of the capital letter N — which in the Calendar are one day lower — more suitably display those same fourteenth Paschal moons? But, as we have said, this does not overturn our equation, which we intended, but only confirms what we have declared more than once: that the golden numbers of the Council of Nicaea indicated the new moons — and from these the fourteenth Paschal moons — earlier than they should have; and that therefore the root of the equation was rightly fixed at the year 550 rather than at the years of the Council of Nicaea. Wherefore with the fullest right we prefixed the capital letter P to the year 320, and not the capital letter N, so that indeed the new moons of the epacts would not differ from the new moons of the golden numbers of that time. But evidently Maestlin — a better Grammarian here than Astronomer — since he was wholly ignorant of this root of our equation, supposed that we commit this enormous solecism (for so he speaks): namely that, in assigning the equation of the Moon of

one day to the year 500, we did not change the capital letter P, from the year 320 up to the year 800, into the small letter a. Yet in this he himself commits an enormous solecism in the ecclesiastical computus, not understanding the concord that must be established between the capital letter P and both the 300th and the 500th year, so that the same new moons may be kept which the Church used at the time of the Council of Nicaea — a concord which he himself wrongly wishes to break, when he removes the letter P from the year 300 and substitutes in its place the capital letter N, as may be seen in the second-to-last table of his equation.

[Margin: Maestlin wrongly wishes that the capital letter N, and not the capital letter P, ought to have been assigned to the year of the Council of Nicaea.]

FINALLY, it is utterly false, what he asserts: that the capital letter P is rightly prefixed in the new Calendar neither to the year 500 nor to the year 300, but that the capital letter M ought to be prefixed to both years. For this follows only from the equation of the solar year, applied by him to the years preceding the correction inopportunately and rashly — an equation that, before the year 1582, in which the Calendar was restored, was never used, nor indeed can be applied, if the lunations of past years must be left as they occurred, as the matter itself requires. This is because our equation of the solar year — like no other whatever — cannot in every respect correspond to the past years back to the times of the Council of Nicaea, as we showed in the previous book; so that the equation of the solar year has been applied by Maestlin to past years quite inopportunately, in order that he may investigate the new moons at the time of the Council of Nicaea. For in order that we may understand in what state the lunations were before the correction, it is enough that the reckoning of the equation which was in use be kept.

[Margin: Maestlin improperly applies the equation of the solar year to past years, although it was in use, in order to investigate the letter of the epact-equation of the Council of Nicaea.]

The Moon requires that no mention at all be made of the equation of the equinoxes, so that no day has yet been removed from the year, but the lunations have only anticipated their places in the Calendar — the same length of the year, 365 days and 6 hours, being always retained, which we see the Church always observed before the year of the restoration, however much the year is not really so great. And so, although the equinox in past years continually shifted its seat, nevertheless, since through the table of the equation of the epacts we do not seek its place, but only investigate the days of the new moons, that is enough. Nor

should it move us — a thing Maestlin frequently has in his mouth — that any astronomical calculation whatever fits past times just as it does future ones, if it is rightly set up. For why should our equation of the solar year, to be applied at the four-hundredth year, not fit past years in every respect back to

the times of the Council of Nicaea — that is, why it does not present to us a full ten days to be removed, as many as were removed together from the year 1582, but only 9 — this has been sufficiently set out by us above in Chapter 7 of Book 1. And indeed, even if it did agree entirely, still, by applying the equation of the equinoxes, only the day of the equinox would be found for any past year; but meanwhile the lunations too would be marvelously disturbed by applying their own equation, so that the epacts could not indicate them on the same days on which they occurred, but on the days on which they would have occurred if the equation of both the solar and the lunar year had been applied — provided, however, that the root of both equations be fixed at some definite point; which happens also for future years. For whether the equation of the solar year keeps entirely to 21 March or not, the equation of the Moon, applied at the same time, nonetheless yields the new moons on those days on which they truly occur, as far as the usage of the Church is concerned. To this is added that, since in the year 1582 ten days were removed together, a descent was made in the expanded table through ten lines of epacts, because by that many days the new moons, on account of that removal, occur later. But if the equation of the solar year were accommodated to past years, so that those ten days were consumed not all at once but gradually, a change of ten lines would not on that account occur in the epacts, since the index letter is not always changed when an intercalary day is omitted, but sometimes the same index letter is retained — as happens in Maestlin's own last equation-table at the years 500, 1100, 1400 — indeed, sometimes a return is made to the higher letter, on account of the retention of the intercalary day and the equation of the Moon then to be applied, as happens in the same table at the year 800.

But, to test in what way the lunations — even if disturbed by the equation of both years applied to past years — correspond to the astronomical calculation, let us fix the root of both equations at the year 500, when already the capital letter P displayed the new moons more correctly, according to the Church's usage, than it did at the time of the Council of Nicaea, as we have said. This being posited, the equation-table will stand as follows.

| Index | Anni Dñi | Biss. | Lunar mark |
|-------|----------|-------|------------|
| P | 500 | Biss. | |

| Index | Anni Dñi | Biss. | Lunar mark |
|-------|----------|-------|------------|
| N | 600 | | |
| M | 700 | | |
| M | 800 | | ☾ |
| M | 900 | Biss. | |
| H | 1000 | | |
| H | 1100 | | ☾ |
| G | 1200 | | |
| G | 1300 | Biss. | |
| G | 1400 | | |
| F | 1500 | | ☾ |
| E | 1600 | | |

Let the year 1589 then be proposed, whose golden number is 13. Its epact from this table is xv, placing its fourteenth Paschal moon on 29 March — on which day the mean opposition occurs around noon, if account is taken of the 8 intercalary days then omitted, according to the prescription of this table. Here it is manifest that the fourteenth Paschal Moon agrees with the astronomical calculation, whether the equation of the solar year keeps the equinox to 21 March or throws it onto another day, provided only that the equation of the Moon is duly set up. The demonstration of this matter is as follows. The calculation from the astronomical tables yields the mean opposition, as it truly occurs in the heavens, if no intercalary day has been omitted. If, then, to that calculation the removed days are added — the days by which, of course, the lunations have descended toward the ends of the months — the mean opposition will be found to agree with the applied equation of the solar year, whether that equation be true and exact or not true. Therefore, if the equation of the Moon is then applied (which cannot rightly be applied unless the equation of the solar year is observed at the same time, as is clear from the construction of the equation-table in Chapter 4), so that the nineteen-year cycle is equated, the Cycle will necessarily correspond to the astronomical calculation, if it corresponded before, prior to when both equations were in use. You see therefore, Maestlin, that it can in no way happen that, with the equation of both years applied to past years, that same index letter should be yielded which truly, at the times of the Nicene Council, presented the epacts as indices of the new moons. Rightly, therefore, has the table of the equation of the epacts been established by us. If you wish to tear it up from the roots, you certainly need other weapons than those with which you have fought so far. For

those, as you see, are too weak, and altogether of lead. *Here is Rhodes, here is the leap.* There is no ground, then, for your objection that the author of the new Calendar did not exert himself much in examining the astronomical calculation precisely, since his calculation does not disagree with the astronomical one, as we have shown. If, then (to address you in your own words), you have not understood these things, judge for yourself whether you are worthy that any authority be granted you in the rest — and that on account of your shameful or affected ignorance; but if you were aware of these things, shall I not say that you are to be devoted to the Furies (which you invoke upon the author), since you maliciously cast a deception over all Germany and over the whole world of Christians?

But grant that this — in the matter of the equation of the epacts — belongs to your impudence and rashness; that other charge, which belongs either to malice or to ignorance, is this: that you object that our epacts, according to the capital letter P of the expanded table, do not correctly indicate the Paschal limits at the time of the Council of Nicaea — whereas our epacts yield exactly the same limits as the golden numbers of the old Calendar. As if you would now impugn not this Calendar of ours, but the old one approved by the Fathers of the Council of Nicaea — against your own opinion, by which everywhere you try to prefer the old Calendar to the new. To this is added that you again take the full moon for the fourteenth Moon, or Paschal limit, and therefore wrongly call false all the Paschal limits that precede the mean oppositions by a single day — while you yourself are deceived. For we have demonstrated the contrary of this above, from the received usage of the Church and from the weightiest authors. But so that all may see how the Paschal limits stood at the times of the Council of Nicaea, and that the same limits are indicated both by the golden numbers of that same Council and by our epacts, we have set out a table of 19 years around those times, which you too presently bring forward. We have, however, omitted the epacts and Paschal limits according to your index letters N and M (capital), because these are irrelevant, since they are falsely assigned by you to those years, as we showed a little before.

[Margin: That Maestlin fights in vain against the fourteenth Paschal moons of the new Calendar around the times of the Council of Nicaea, since they do not differ from the fourteenth Paschal moons of the golden numbers of that time.]

From this table it is clear that the epacts of the index letter N indicate the fourteenth Paschal moons more correctly, at the time of the Council of Nicaea, than the epacts of the letter P, since the fourteenth Paschal moons of the former

are one day later than the fourteenth moons of the latter. This is what we noted a little before.

The following table gives, for the years 323–341 (one complete nineteen-year cycle), the golden numbers, the epacts by the index letter P, the Paschal fourteenth Moons, and the mean full moons.

| Anni Domini | Aurei numeri | Epactæ secundū literā indicē P | Lunæ XIII Paschales | Plenilunia media (D · H · M) |
|------------------|--------------|--------------------------------|---------------------|---|
| 323 | 1 | vij | 5 Apr. | 6 · 22 · 45 |
| 324 | 2 | xix | 25 Mar. | 26 · 7 · 33 |
| 225 [recte: 325] | 3 | * | 13 Apr. | 14 · 5 · 6 |
| 326 | 4 | xj | 2 Apr. | 3 · 13 · 54 |
| 327 | 5 | xxij | 22 Mar. | 23 · 22 · 43 |
| 328 | 6 | ij | 10 Apr. | 11 · 20 · 16 |
| 329 | 7 | xiiij | 30 Mar. | 33 · 5 · 5 [day 33 impossible — see note] |
| 330 | 8 | xxv | 18 Apr. | 19 · 2 · 38 |
| 331 | 9 | vj | 7 Apr. | 8 · 11 · 26 |
| 332 | 10 | xvij | 27 Mar. | 27 · 20 · 14 |

| 336 | 14 | j | 12 Apr. | 12 · 8 · 57 |
| 337 | 15 | xij | 1 Apr. | 1 · 17 · 46 |
| 338 | 16 | xxiiij | 21 Apr. | 22 · 2 · 34 |
| 339 | 17 | iiij | 9 Apr. | 10 · 0 · 17 |
| 340 | 18 | xv | 29 Mar. | 29 · 8 · 56 |
| 341 | 19 | xxvj | 17 Apr. | 17 · 6 · 28 |

That the Paschal fourteenth Moons of the epacts are the same as those of the golden numbers in the time of the Council of Nicaea is clear from this: the epacts are written against the very days of the new Calendar that the golden numbers occupied in the old Calendar, as is plain from the preceding thirty Calendars of

the golden numbers set in the Calendar under the capital letter P. From this it follows that you object against us not only falsely but even impudently when you assert that, of these nineteen Paschal termini — which do not differ from the termini of the golden numbers of the Nicene Council — only one is true and eighteen are erroneous. For only the twelve termini of these twelve years — 323, 324, 325, 326, 327, 328, 329, 330, 331, 334, 335, 338 — anticipate the mean oppositions by more than is proper, that is, by nearly two days; the other seven anticipate by a single day only, as reason requires. We have explained above the cause of this anticipation: the new moons of the golden numbers of the Nicene Council fall on almost exactly those days on which, by their mean motion, they occur in the heavens — something we have taught must be avoided in every cycle for the use of the Church, and have in fact avoided in our own cycle of epacts, as can be understood from what has been said. But however that may be, at least this ought to be settled among everyone: that in this passage Maestlin is not contending against the new Calendar, but against the arrangement of the golden numbers in the Calendar at the time of the Nicene Council. For the new Calendar, in order rightly to perform its office, only declares in what state the new moons and the Paschal fourteenth Moons stood according to the golden numbers in the time of the Nicene Council; it does not approve them — indeed it could not approve them, since the golden numbers then displayed the new moons earlier than is proper, as we have taught in its place.

[Margin: Maestlin falsely charges us with having so assigned the equinox to 21 March as to hold that this is its only proper seat.]

But this is Maestlin's plain malice, that he cunningly slanders — as though it were the head of the whole matter — that the equinox has been rashly recalled by us to 21 March, where it had been fixed by the Council of Nicaea; just as if (as he cavils after his manner) we wished this to be the sole proper seat of the vernal equinox. And here, so that we may understand how well and piously he judges of religion and the Church, he doubts whether the Christian Church ought to obey that decree of the Nicene Council. But since we are not here dealing with the Faith or with religion, let us set aside this doubt of his — which smacks of heresy — and defend the new Calendar so far as it concerns astronomical matters. Therefore the equinox has been restored by us to 21 March not because we judged that day necessarily to be the sole proper seat of the vernal equinox, but so that all the Paschal termini which that most holy and ecumenical Council of Nicaea appointed might be kept whole and untouched, and so that no novelty might be introduced into the Christian world in the feast of Easter, as was fully explained in Book I, Chapter III.

[Margin: Five errors to be avoided in the celebration of Easter.]

Besides this, he tries to make the new Calendar hateful to the whole world, on the ground that in the celebration of Easter it has not avoided five notable errors — errors which we most of all wish to be shunned as though they were some monstrous reefs, and in whose avoidance in this correction we greatly glory. The errors to be guarded against in the feast of Easter can be reduced to these five: I. that it not be celebrated on the fourteenth Moon, along with the heretical Quartodecimans; II. that it not be kept before the fourteenth Moon, which would be still more absurd; III. that it not follow the twenty-first Moon, that is, that it not fall in the fourth week of the lunar month; IV. that it not be found in the last month, whose terminus, namely, precedes the vernal equinox; V. that it not be thrown back into the second month.

[Margin: Easter, in certain years which Maestlin adduces, does not fall on Luna 14, as he falsely supposes, but on the mean opposition — two years excepted.]

First, then, Maestlin says that in the new Calendar the Paschal Sunday not rarely falls on the full moon itself, that is, as we put it, on the fourteenth Moon. For he always persists in this error, that the mean opposition, or fourteenth Moon [text of the following clause abraded/short — reason not legibly stated] [?]. But we have already refuted this abundantly above. He brings forward these years: 1503, 1507, 1514, 1531, 1551, 1555, 1558, 1578, 1582, 1598, 1609, 1622, 1693, in all of which he affirms that the Paschal Sunday falls on the fourteenth Moon — which is false. For they all fall on the mean opposition, and hence are legitimate by the decrees of the Fathers, so that the first error can have no place in them, as is evident in the table below.

[LIB. SECVNDI — printed p. 110] But from the years before the correction Maestlin removes 10 days, which is indeed beside the point — as we said above — since in those years Easter was not celebrated after the removal of the 10 days, in the way in which they are laid out in this table. Yet, to gratify him, suppose the 10 days were removed, and let us see whether he speaks the truth. In two years only, 1503 and 1514, Easter would have been celebrated a little earlier than is proper, had the 10 days been taken away. The cause of this anticipation is that those years do not require the subtraction of 10 days. For since the root of this subtraction of 10 days agrees with the year 1600 (as appears from the table of equation), so that from this point 400 years are always counted,

[Margin: In the same years 1503 and 1514, Easter was also rightly celebrated before the correction, provided the 10 excepted days are not reckoned, as is fitting.]

— from those years which are more remote from the year 1600 and nearer to the year 1500, only 9 days, and a little more, should be removed, as we said above; and thus Easter would then fall either on the opposition itself, or a little after, as happens in the other years of this table. But if the 10 days are not thought of as removed from those two years, the Paschal Sunday of each will fall on 16 April — on which days Easter was in fact celebrated in those years before the correction of the Calendar. The Paschal terminus of the earlier year will fall on 10 April, almost a whole day before the mean opposition, and immediately after the Dominical letter, which is A; but the Paschal terminus of the later year falls on the Dominical letter itself, which is also A, and on almost the middle of the opposition itself; and therefore in both cases Easter

[Margin: The cycle cannot be faulted, even if occasionally Easter falls on Luna 14.]

| Anni Domini | Aurei numeri | Epa ctæ | Lit. Dñic. | Termini Paschales | Pasc ha | Plenilunia media (D · H · M) |
|-------------|--------------|---------|------------|-------------------|---------|------------------------------|
| 1503 | 3 | iiij | A | 10 Apr. | 16 Apr. | 10 · 22 · 37 |
| 1514 | 14 | iiij | A | 9 Apr. | 16 Apr. | 9 · 2 · 29 |

was celebrated after the mean opposition, yet, as is fitting, in the third week of the lunar month — that is, before the last quadrature aspect of the Moon — as appears in the table set out for the two years 1503 and 1514.

[Margin: Fewer errors are contained in the epact-cycle of the new Calendar than in the golden-number cycle, even about the time of the Nicene Council.]

Where, then, Maestlin, do you see Easter celebrated on the fourteenth Moon in any of your thirteen years? You are truly unworthy of an answer, since you lie so conspicuously in this examination of yours, so as to impose upon the whole world and to thrust out the new Calendar with importunate shouts and outcries, as though it were stuffed with a thousand errors. But truth is strong, and yields to no terrors; and it is well established that it is generally those whose cause is the weaker who fight by clamor. Now if it should sometimes happen that, by the prescription of the new Calendar, Easter falls on the fourteenth Moon — that is, on the day before the mean opposition (which, as we said above, can occur in our cycle, though very rarely) — this is not to be charged as a fault to this our new cycle of epacts, but to all cycles whatsoever; for none, however skillfully arranged in a Calendar, can agree so exactly with the celestial motions as never at some time to depart from the truth. Yet we do not hesitate to affirm this of our Calendar

with certainty: that far fewer errors are contained in it than in the old one approved by the Fathers of the Nicene Council, as sufficiently appears from what we have taught before, where within the space of a few years the most holy Easter was more often celebrated on the fourteenth Moon.

[Margin: Maestlin's cavil, that Easter can fall on Luna 14 in the new Calendar.]

It is also certain that in those thirteen years just brought forward — which Maestlin investigated with the greatest zeal in order to convict the new Calendar of falsity — no error is found except that of Maestlin himself, who rashly calls the mean opposition the fourteenth Moon.

Next, our adversary says that our Easter not rarely falls on the thirteenth Moon — that is, before the full moon, which he wrongly calls the fourteenth Moon, as was said above. But who does not see that this is sheer calumny? For if Easter scarcely, or at any rate very rarely, falls on the thirteenth Moon, as was just said, how can it be that it should be found on the thirteenth Moon? He will certainly never show this, not even if he strains every nerve, not only of talent but of cunning. And indeed, if he were to find some year (which I do not believe) in which this happened,

[CAPVT VII — printed p. 113]

— the answer has already been given a little before: it must be ascribed to the nature of cycles, which is such that in none can all inconveniences be avoided. For as regards these two years, 1527 and 1598, in which he asserts that this error has been committed, he cavils splendidly, after his manner. For in the later year, that Easter was legitimately celebrated by the decree of the Council of Nicaea, so far as concerns the mean motion, is clear from the preceding table of thirteen years. But in the earlier year, in which the golden number is 8 — the epact (once the 10 days have first been removed, which the adversary took away out of his own caprice, even though that year was before the correction) being xviii, the Dominical letter B, the Paschal terminus 26 March, and Easter itself 27 March — the decree of the Nicene Council is likewise observed, since Easter is celebrated on the mean full moon itself, which occurs on 26 March at 23 hours 57 minutes after noon. But that same year's Easter is exhibited far more exactly by the new Calendar according to the ecclesiastical laws, if the 10 removed days are taken away, as reason requires, since it precedes the correction. For the golden number was then 8, the epact xxviii, the Dominical letter F, the fourteenth Moon on 15 April, Easter on 21 April, and the opposition on 15 April at 12 hours 41 minutes after noon — so that Easter was then celebrated after the mean full moon, yet

before the second quadrature aspect of the Moon, as the Fathers and the Councils prescribe.

[Margin: Easter, on account of the imperfect nature of the cycles, must of necessity sometimes fall at the beginning of the fourth week.]

As regards the third error — if it is to be called an error, since it cannot be avoided in any cycle — we frankly confess that, by Canon 2 of the new Calendar, on account of the necessary postponement of the new moons, it sometimes happens that Easter falls at the beginning of the fourth week, that is, on the twenty-second Moon, or on the later quadrature aspect of the Moon. But this error is of no such moment that on its account the new moons ought to be shown by the epacts one day earlier in the Calendar; for from that anticipation there would follow almost innumerable absurdities far greater. For most often the new moons of the cycle would precede the conjunctions, both true and mean, and frequently the solemnity of Easter would fall on the fourteenth Moon, as is evident from what we have said. Maestlin therefore raises nothing new against us in this passage, since — on account of the greater absurdities we have enumerated — the epacts must be so arranged that the new moons more often follow, for the most part, the celestial new moons; and we accordingly admit that Easter is sometimes, though rarely, deferred for one week. In this our Maestlin shows himself scarcely fair, who now makes so much of any necessary error whatsoever — and one that is admitted — when he himself thrusts upon the whole world so many and so foul errors. But it must not be passed over that Maestlin is here inconsistent with himself. For whereas in the earlier passages he always cried out, though falsely (not understanding the Church's sanctions and custom concerning the celebration of Easter), that Easter ought not to be celebrated on the mean full moon, here nevertheless, in these three years — 1629, 1680, 1700 — whether through a lapse of memory or rather through the inconstancy of his lying, he contends that it ought to be celebrated on the mean full moon, only in order to show that in those years we defer Easter into the following week. But this is plain from the table below, where Maestlin's own Easter falls on the mean full moon — which before he was unwilling to allow.

[Margin: Maestlin's inconstancy and self-contradiction.]

For all these full moons are to be assigned to the days next following — the first to the eighth, the second to the fourteenth, and the third to the fourth — since they occur after sunset. From which it comes about that those feast-days, by Maestlin's own reckoning, fall on the full moons themselves — which nevertheless he has hitherto always cried out to be absurd, as we said just now. If, then, he wished to be consistent with himself, he would at any rate relax the new Calendar for deferring those Easter-days from the mean full moons to the following Sunday; although in fact we do not defer Easter then because it falls on the mean opposition, but because the fourteenth Moon, found by the epacts, runs into a Sunday. But it is no wonder that Maestlin is inconsistent with himself. For so great was his eagerness in finding fault that, blinded by the impulse of attacking, he did not see that he brings forward things at war with one another.

[Margin: Maestlin wrongly charges the new Calendar with often throwing Easter back into the last month and into the second.]

Furthermore, that the new Calendar often defers the celebration of Easter, now into the last month, now into the second (which are the last two errors), Maestlin confirms by no other reasoning than by the earlier examples, by which he supposed that, when one passes from one line of the expanded table of epacts to another, Easter is not rarely transferred from the second month into the last, and from the first into the second. To this he also adds that, not only for that reason can Easter sometimes be celebrated in the last or in the second month, but also before the vernal equinox — namely when the equinox has, as he falsely supposes, slipped back to 27 March, and the fourteenth Moon is found on the 21st, the day appointed for the equinox, or 4 or 5 days after the 21st, and finally a Sunday falls between that fourteenth Moon and 27 March. But to this too an answer has already been given above. For, in order that Easter not be said to fall in the twelfth month, it is enough — as pertains to the most ancient usage of the Church — that its Paschal terminus, or fourteenth Moon, not run before 21 March, the day assigned to the equinox, even though the true equinox sometimes follows the 21st and that fourteenth Moon. Likewise, in order that Easter cannot be said to fall in the second month, it is enough if the immediately preceding fourteenth Moon in March comes before that same 21st day of the equinox, even though the true equinox sometimes occurs before that fourteenth Moon and

before the 21st — which indeed can happen, as we have more than once granted above. Nor was the Church ever bound by these astronomical subtleties; it is enough if she prefixes some fixed day, such as 21 March, to the equinox, beyond or short of which the equinox does not stray far. Indeed, whether he will or not, Maestlin must necessarily admit that in a bissextile year Easter can be celebrated in the second month, and that the same can fall in the twelfth in the third year after the bissextile, as we demonstrated above — even if the equinox never receded further from 21 March than the 6 hours omitted in a common year require.

[Margin: According to the usage of the Church, Easter can sometimes be celebrated in the last month and in the second, on account of bissextile and common years, even if the Julian year were the true one.]

[Margin: That Maestlin, once again by way of slander, faults the epacts of the new Calendar as reduced to the times of the Council of Nicaea.]

Moreover, so as never to run out of grounds for censure and slander, he returns yet again to those same nineteen years around the time of the Council of Nicaea. In these, as I said above, he holds not only that the fourteenth Moons (that is, the Paschal terms) are for the most part false, but also that Easter itself was repeatedly appointed to be celebrated contrary to the decrees of the Fathers — namely, on the full moon itself, or even before it. But since it has been abundantly demonstrated, both in this book and in the preceding one, that Easter can lawfully be celebrated on the full moon; and since, when Easter was on occasion celebrated before the full moon at that period, this is not to be laid to the charge of this cycle of epacts of ours, nor of their equation, but arises from the fact that the golden numbers then showed the new moons earlier than was proper — and it was to the arrangement of those golden numbers that we tried to make the equation of our epacts conform, so that it might match (this indeed is why we placed the capital letter P before the year 320) — there is no reason to waste any more time uselessly on this point. And from these errors that Maestlin has rashly thrown at the new Calendar it readily appears how prudent, how careful a corrector and reformer of the world he is — a man who has so often betrayed his own ignorance in ecclesiastical matters, and so often erred himself, every time that, straining to produce some novelty, he has cast errors in our teeth.

[Margin: That Maestlin maliciously faults the solar cycle as equated in the new Calendar.]

LASTLY, so as to leave nothing untouched, Maestlin — that most ferocious adversary and disparager of the new Calendar — attacks in hostile fashion the ancient cycle of Dominical letters of 28 years, which is perpetual enough in the new Calendar, provided that in every span of 400 years three intercalary days are omitted. He carps at the equation of this cycle in Chapter 1 of his examination (although we have deferred our reply up to this point), asserting that from it a false Dominical letter is derived for the years preceding the correction — that is, if the equation of the equinox is applied to the years now past (which he also tried to do above in the case of the equation of the epacts), and if an equation of the solar cycle is set up like the one applied in the Calendar after the correction. But who here would not laugh, who would not marvel at the man's absurdities — not to say his malice? For since, by the equation of the solar year prescribed in the Calendar, the Dominical letter agreeing with any given year before the correction is in fact found — as he himself testifies — for what reason does he contrive a new equation according to his own whim and caprice, one by which the Dominical letters are thrown into extraordinary confusion? I see no reason, except that he wants by every means, if he can, to make the new Calendar out to be false and altogether useless.

[Margin: Why the equation of the solar cycle cannot be made to fit the past years exactly.]

For in thinking that the reckoning of our equation ought to be carried back into the past years just as well as forward into future ones, he is gravely mistaken. For since the equation of the solar year — by which in any span of 400 years three intercalary days are omitted — does not fit exactly the years near the Council of Nicaea, on account of the uneven magnitude of the solar year, as was set out in Book I, Chapter VII, it is useless to try by it to find the Dominical letter that was then in use in any given year; for from the birth of CHRIST down to the year of the correction the order of the Dominical letters was never interrupted. In time to come, however, once the equation of the equinox has to be applied, this equation will have its place, because with every omission of an intercalary day the series and order of the Dominical letters must be interrupted, even if that equation of the equinox does not answer exactly and entirely to the celestial motions, as we set forth in Chapters V, VI, and VII of the first book. Let him therefore prove this, if he wishes to accomplish anything — though he never will: namely, that the equation of the solar cycle does not correctly indicate the Dominical letter for future years, in which intercalary days are genuinely omitted and the order of Dominical letters is consequently of necessity interrupted. And so what was said above about the equation of the epacts — that if it, together with the equation of

the equinox, is carried back into the past years — the same must be said here of the equation of the solar cycle, if it, together with the equation of the equinox, is applied to the past years: namely, that it throws the order of the Dominical letters into extraordinary confusion, so that it in no way yields those Dominical letters that were genuinely in use in the past years (unless perhaps the equation of the equinox offers up just as many days to be removed as were in fact removed down to that time from which the equation of the equinox began), but rather those that would have had to be used had this equation of the solar year been applied — provided only that the root of the equation is fixed to some definite year.

Now if the equation of the solar year established by us were to fit in every respect the times of the Council of Nicaea — that is, if it yielded exactly 10 days to be removed — then without doubt the numeral index-letter placed there, which would then be V, would show the Dominical letters correctly. But to make this clear, we must explain in what way the ancient cycle of Dominical letters has been equated in the new Calendar. The equation, then, is as follows.

CYCLI SOLARIS, SIVE LITERARVM DOMINICALIVM antiquus 28. annorum perpetuus.

(The ancient perpetual solar cycle, or cycle of Dominical letters, of 28 years.)

Top block:

| V | | | | VII | | | | II | | | | IV. | | | |

TABVLA AEQVATIONIS CYCLI SOLARIS ANTIQVI.

(Table of the equation of the ancient solar cycle.)

[Printed page: 113]

The table runs as three panels across the leaf, read as one continuous list; each entry gives the numeral index, the year of the Lord (Anni Dñi), and a bissextile mark (Biss.) where applicable. The full-width note "Detractis 10 dieb." (10 days having been subtracted) falls within the first panel, after the year 1582.

| Index | Anni Dñi | Biss. |

[Margin: Perpetual construction of the table of the equation of the Dominical letters.]

Since the order of the Dominical letters is necessarily interrupted in the common centennial years — because then a single letter runs on, not a double one — the

ancient cycle of letters cannot always begin from the cell of the letters g, f, as it did before the correction, but now from b, A; now from d, c; or f, e; or A, g; or c, b; or e, d — in this order. Before the Calendar was restored, the cycle always took its start from the first cell, of the letters g, f, so that when the solar cycle was 1 the Dominical letters were g, f; when the cycle was 2, the Dominical letter was e; and letter d answered to cycle 3, and letter c to cycle 4, and so on. But after the correction of the year, on account of the 10 days removed, the cycle will have to begin from another cell of two letters — namely, from the one that holds the tenth place after the letters g, f — that is, from the letters c, b of cell 21, since letter c is the tenth after g, as appears here: g, A, b, c, d, e, f, g, A, b, c; just as letter b is the tenth after f, as appears here: f, g, A, b, c, d, e, f, g, A, b. The reason for this is as follows: since the Dominical letters in the Calendar follow one another in the natural order of the letters, it comes about that in the year of the correction, after the day sacred to St. Francis — that is, after the 4th of October, to which letter d is assigned — in place of the following letter e, assigned to the 5th day, the tenth letter after it was taken, namely letter A of the fifteenth day, as appears here, since the ten letters e, f, g, A, b, c, d, e, f, g, answering to the ten days removed, were omitted in that year. And for the same reason, after any Dominical letter in the Calendar, the one to be taken is that which stands as many letters distant from it as there are days removed. Thus if, for example, one day is removed, the letter to be taken after A is c, in place of letter b, which would have to be taken after A if that day were not removed. But if two days are removed, then

| | | | | | | | | | | | | | | | |
|-------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | 1 | 1 | 1 | 1 | 1 | 1 |
| Dies Octob. | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 0 | 1 | 2 | 3 | 4 | 5 |
| Lit. Domin. | A | b | c | d | e | f | g | A | b | c | d | e | f | g | A |

letter d is to be taken in place of letter b, which would have to be taken after A were those two days not removed; for letter d occupies the second place after b. And the same reasoning holds in the other cases. Upon the cell of the letters c, b, then — which we said was to be taken after the removal of the 10 days — we shall superimpose the numeral index-letter I, and we shall prefix it to the year 1582 after the 10 days had been subtracted, to signify that the cycle then takes its beginning from cell 21; that is, that in the first year of the solar cycle the Dominical letters are c, b; in the second year the Dominical letter is A, and so on. The same numeral index I we shall set against the year 1600, because, since that year is bissextile, the cycle does not change its beginning, and no interruption of the Dominical letters occurs. Then, because in the year 1700 an intercalary day is omitted, the cycle will begin from the letters d, c of a new cell, since each letter follows next after each of c, b of cell 21 in the alphabet — namely d after the letter

c, and c after the letter b. Upon this new cell, therefore, we shall superimpose the index number II, and we shall prefix the same to the year 1700, to indicate that in the year 1700 the cycle takes its beginning from the ninth cell, of the letters d, c. Again, in the common year 1800 the cycle will have to begin from cell 25, of the letters e, d, which follow next in the alphabet after the letters of the ninth cell, d, c; and accordingly we shall assign the index number III both to cell 25 and to the year 1800. By the same reasoning, in the non-bissextile year 1900 the cycle will begin from the thirteenth cell, of the letters f, e, which follow next after the letters e, d of cell 25; and therefore the Index number IV must be set against both cell 13 and the year 1900. This index number will not be changed in the bissextile year 2000. Then in the non-bissextile year 2100 the cycle will take its beginning from the first cell, of the letters g, f, which follow next after the letters f, e from which the cycle began in the year 2000; and therefore the index number V must be prefixed to the first cell and to the year 2100. In the year 2200, moreover, which is likewise common, we shall assign the index number VI, and superimpose the same upon the seventeenth cell, of the letters A, g, because these letters follow next after the letters g, f of the first cell. And in the non-bissextile year 2300 we shall set the index number VII against cell 5, of the letters b, A, which follow next after the letters A, g; and this same index number VII will also have to be assigned to the bissextile year 2400. Afterwards, in the non-bissextile year 2500, the numeral index-letter I must again be assigned, because the cycle then begins once more from cell 21, of the letters c, b, which follow next after the letters b, A. And in this way the same index numbers will be repeated in the years to come, assigning nonetheless to the bissextile centennial years the same index numbers as were assigned to the immediately preceding non-bissextile centennial years. Lastly, to the years before the correction we assigned the index number V, which is superimposed upon the first cell — the cell from which the cycle always took its start before the restoration of the year.

[Margin: By what method the Dominical letter is found from the perpetual cycle for any proposed year.]

The use of this table is as follows: the first year of the solar cycle is to be assigned to that cell over which is placed the same index number as is prefixed to the proposed centennial year; the second year of the cycle is to be given to the next cell, and so on. For the cell into which the solar cycle of the proposed year falls will yield the Dominical letter — in common years only the lower letter is to be taken. For instance, in the year 1589 the solar cycle is 2. Since therefore the num-

-eral index I, set after the correction against the year 1582, is placed over cell 21, cycle 2 will fall into cell 22, of letter A, which will be the Dominical letter in that year. Again, in the year 1900 the solar cycle is 5, and the index number 4 is superimposed upon the thirteenth cell. Therefore cycle 5 will fall into cell 17, which is the fifth counting inclusively from the thirteenth; and consequently the Dominical letter of the year 1900 will be g, the lower one. Lastly, in the year 325 the solar cycle is 26, and the index number V is over the first cell. And since cycle 26 falls into cell 26, where letter c is, c will be the Dominical letter of the year 325.

NOW, to make it plain that Maestlin has rashly — not to say maliciously — carried back this table of the equation to the past years, as if the 10 days were not removed all at once but consumed little by little, we shall set out his table of the equation, which is of this sort.

TABVLA AEQVATIONIS CYCLI SOLARIS ANTIQVI, tanquam ea iam olim fuisset vsitata.

(Table of the equation of the ancient solar cycle, as though it had already long been in use.)

Read as three panels across the leaf, forming one continuous list:

| Index | Anni Dñi | Biss. |
|-------|----------|-------|
| III | 1 | |
| IV | 100 | |
| V | 200 | |
| VI | 300 | |
| VI | 400 | Biss. |
| VII | 500 | |
| I | 600 | |
| II | 700 | |
| II | 800 | Biss. |
| III | 900 | |
| IV | 1000 | |
| V | 1100 | |
| V | 1200 | Biss. |
| VI | 1300 | |

| Index | Anni Dñi | Biss. |
|-------|----------|-------|
| VII | 1400 | |
| I | 1500 | |
| I | 1600 | Biss. |
| II | 1700 | |

Here indeed you see that, before the index number I set against the year 1500, proceeding back toward the beginning of the years of Christ, only nine changes of the index numbers had been made — namely these: VII, VI, V, IV, III, II, I, VII, VI — of which VI is prefixed to the year 300. Since, therefore, not just 9 but 10 days have been removed, what wonder is it that the index number VI does not display the true Dominical letter at the time of the Council of Nicaea? It would necessarily have had to be carried, by change, all the way to the tenth index number V, so that this might offer the Dominical letters that were then in use. But if this equation of Maestlin's had been in use from the Council of Nicaea down to our own age, the root would have had to be fixed in the year 300 — that is, the index number V would have had to be set before the year 300, the number that then genuinely offered the Dominical letters. Yet on this reckoning it would be not the index number I but VII that fell on the year 1500 (if the same centennial years are left bissextile as are bissextile in our equation); and it would indeed at this present time show the Dominical letters, though not those we now use — because not 10 but only 9 days would have been taken away.

[Margin: That Maestlin does not rightly attack the equation of the epacts or of the solar cycle, since he only proves that the equation of the equinox does not entirely agree with the times of the Council of Nicaea.]

FINALLY, while the adversary strives to shake and utterly overturn the equation both of the epacts and of the solar cycle — on the ground that at the time of the Council of Nicaea neither of them fits exactly if it is carried back into the past years — he proves nothing else than that the equation of the equinox described in the first book does not exactly agree with the time of that Council; which we freely grant, and the reason for this we have explained fully and more than fully in the same book. He therefore brings nothing to bear at this point, nor indeed has he dared to disapprove the construction itself of either equation; seeing that he has plainly recognized that the equation of the solar cycle proceeds correctly through the centennial years, so that in the common centennial years the order of the Dominical letters is of necessity interrupted and the cycle takes its beginning from elsewhere, whereas in the bissextile centennial years the same order of

Dominical letters and the same beginning of the cycle are retained — just as he has also rightly understood that the equation of the epacts depends both on the 300 years in which the Moon anticipates by nearly one day, and on the 400 years in which the equinox shifts its seat forward by nearly three days. In this one thing only has he erred: that, along with the common view, he attributed to the anticipation of the Moon 304 years, and not $312\frac{1}{2}$, as the astronomers' tables require. Let him therefore cease to insult us, as though by our equation we did not know how to find the Dominical letters of the years of the Council of Nicaea. For the index number V, which our equation offers us before the correction — that number displays the Dominical letters for all the years preceding the restoration of the Calendar, since before the year of the correction no interruption of the Dominical letters was ever made; so that Maestlin can in no way be excused for his malice and rashness in dragging our equation — by force, against right and lawfulness, "by the hair" (as he himself puts it) — off to the past years. Rather, to convince us that it is false, he ought to have demonstrated that it will prove faulty for future years; which he not only failed to do, but did not even dare to attempt, nor will he ever accomplish it, though he bring all his strength to bear on it and strain every sinew. But clearly this Tübingen mathematician — more like the poets than like the mathematicians — in the manner of the poets, seeking matter, gathers everything from every quarter and fastens falsehoods onto truths. For consider: is it not false — indeed, an impudent lie — that we cannot by our equation (if it be correctly applied to the past years, leaving aside, as we have done, the equation of the equinox, which he nonetheless most inopportunately thrusts in) find the Dominical letter for the times of the Council of Nicaea? Can he be thought, deservedly, anything but a man wholly compounded of fraud and falsehood, who, though he set out to prove that the equation both of the epacts and of the solar cycle prescribed in the new Calendar is utterly empty and faulty, does nothing less than prove this, but aims only at this: to show that our equation of the solar year — which is very far different from that — does not entirely agree with the true celestial motions? This indeed is beside the point, and was more than once freely conceded by us; and we explained the reason why neither our equation, nor any other equation of the solar year that is even and uniform, can in every respect answer to the true motion of the Sun.

BUT the adversary contends with all his might that our equation, if it is true, as we assert, ought to agree with the years of the Council of Nicaea — in these words: *Was not the new Calendar sworn to the decree of the Council of Nicaea, and is it not said to have been reformed to accord with it? Should it not, therefore, have agreed with it most exactly? But if that [equation], at the time of that Council, from the old com-*

...must be reckoned by the old computation, are you not by that very fact approving the old Calendar and condemning this new one of yours? On the contrary, the starting point of these equations — and indeed of the whole correction — lies not in the year 1582 but in the Council of Nicaea itself. For nothing else can or should be meant by it, and nothing else is hinted at by your complaints against the old Calendar, than this: that if these equations had been employed long ago, the Church would have had throughout all this time — and would go on having in perpetuity — a Calendar of the utmost accuracy; but that, since they were neglected down to the year 1582, they are now recalled by this reformation as it were from exile, restored in full, and given back everything that had been lost to them in the intervening time. The author himself confirms this very point by his own example. For in his table of the equations of the perpetual cycle of epacts he likewise applies the equation of the lunations not merely to the years that follow, but also to past years, right back to the beginning of the years of Christ. So it will be quite proper to use a similar equation here as well.

Since that is so, why, I ask, do you forever have on your lips "the Council of Nicaea, the Council of Nicaea"? Why do you insist that the Calendar had to be reformed to the decree of that Council, and that it has now been reformed by your efforts — when you can point neither to the day of the vernal equinox nor to any Sunday, nor to any other fixed day of the week, for the time of that Council, but instead your own calculation puts 20 March in place of the 21st, and Monday in place of Sunday, and so on? If you have any shame left, will you not be ashamed of the labour you undertook in making this Calendar? Do you not blush — you who accepted it once made, and who by your advice urged others to accept it — that you were unable to look into its calculation any more closely than this; or, if you were able, that you did not examine it better before, moved by the Pope's authority, you proclaimed it a work finished with singular skill? Be ashamed, I say, either of your ignorance or of your rashness. And who in future will trust the numbers of this Calendar, when they themselves fail so ridiculously for times past?

[Margin: In what sense the Calendar is said to have been restored to the times of the Council of Nicaea.]

WE, on the contrary, maintain most firmly that our equation, true though it is, need not necessarily agree with the times of the Council of Nicaea; and that our opponent has not grasped what the new Calendar, restored to the decree of the Council of Nicaea, actually sets out to do. The Calendar was restored to the times of the Council of Nicaea for this purpose: that the Paschal termini might remain wholly unharmed and untouched. That was accomplished by removing 10 days,

so that the equinox was brought back from 11 March, where it fell before the correction, to the 21st, on which the Fathers of that Council laid down that it should fall — since the Paschal termini depend entirely on the day of the equinox. We have never supposed on that account, however, that our equation, had it begun from that Council, would have kept the equinox on the 21st day itself in such a way as never to depart from it by even a little. Just as now[?], after the correction, the same equation cannot keep the equinox on the 21st day itself so that it does not sometimes stray from it in one direction or the other — which happens because of the uneven and irregular advance of the equinox, as we showed in the previous book. Yet I do not deny that if this equation of ours for both years had been in use from the time of that Council, errors so many and so great would not have been committed — the equinox, that is, standing 10 days away from the day assigned to it, and the Moon nearly five days from its proper place: which is precisely how far apart we saw them in our own day, before the year was corrected, because that equation was not being applied.

That the equation of the solar year need not correspond to the number of days removed for the restoration of the equinox, we shall make plain by this example. Suppose the equinox had had to be restored to 25 March, as many wished. Would not 14 days have had to be removed to bring this about? Certainly. For in this way the equinox would have been shifted to 25 March from the 11th, where it was then falling. On that supposition, who does not see that if our equation of 400 years were applied to past years — and no more suitable equation can be established, since it agrees with the mean length of the year, as even Maestlin himself has admitted — it would not yield 14 days to be removed; indeed it ought not to yield so many, since from the Incarnation of the Lord down to our own age the equinox has anticipated its seat by 12 days at most? So a man would be wrong to apply the equation to years gone by in order to show it false on the ground that it does not present 14 days to be taken away — the number that would in fact have been taken from the year, had that restoration of the equinox been carried out.

Understand, then, that exactly this is what was done in our correction. Ten days were of necessity removed from the year 1582 so that the equinox might be brought back from the 11th to the 21st, immediately after which the 19 Paschal termini established by the Council of Nicaea would be reckoned — whether the equinox in the time of that Council really did fall on the 21st or on some other day, and whether our equation yields 10 days truly to be removed, or more, or fewer; provided only that in the years to come it keeps the equinox at the 21st in such a way as not to let it stray far from that day, and of its own accord and

unprompted brings it back to the 21st. We showed above that our equation performs this with sufficient exactness. Indeed, even if the equinox really did fall on the 21st in the time of the Council of Nicaea, our equation, correctly framed though it is, still cannot yield 10 days, but necessarily fewer, because of the inequality of the year and, still more, because of the very small length of the year in the interval lying between the time of that Council and the year of the correction, as we said above in its proper place.

Since this is so, it is perfectly clear that Maestlin is not dealing honestly when he drags our equation back into past years in order to find the Dominical letter for the time of the Council of Nicaea. For the equation need not offer as many days to be removed — and so need not show the solar cycle to be interrupted as many times — as were in fact removed all at once in the year of the correction. It is enough that the old solar cycle be used to bring out the Dominical letter for past years, since no interruption was made in it before the correction.

[Margin: Why the equation of the lunations, but not that of the solar cycle, is to be applied to the years before the correction.]

Nor is it any objection that we have applied the equation of the Moon to past years: the lunations really did anticipate their places in the Calendar, even though the solar year was never equated. Therefore, in order to know the state of the lunations in the years preceding the correction, the equation of the lunations must be applied. This is not the case with the solar cycle, since it cannot be interrupted or altered unless the solar year is equated by removing a number of days, or by omitting or adding an intercalary day. There you have the reason — the one he keeps hunting for — why we always have the Council of Nicaea on our lips: because we restored its equinox and kept the same Paschal termini. And that could not have been done had we not taken 10 days out of the year and laid it down that the equation was to be applied in every four-hundredth year.

If you have any shame left, Maestlin — to deal with you in your own words — will you not be ashamed of the labour you undertook in attacking this Calendar? Do you not blush at having tried so slyly to overturn the equation of the solar cycle? Be ashamed, I say, either of your ignorance or of your rashness. And who in future will trust your slanders, when in a matter perfectly plain in itself you have blundered so ridiculously as to attempt to carry the equation of the solar cycle back into past years, at a time when it needed no equation at all? But let this be enough about the new moons, the Paschal fourteenths, and the cycle of Dominical letters of the new Calendar, against this mathematician of Tübingen.

[Margin: Conclusion of the Apologia against Maestlin.]

DO you not plainly see, Maestlin, that you have taken up so great a war against the new Calendar to no purpose? For my reply has demonstrated that, so far as the use and practice of the Church is concerned, the Calendar is perfect in every respect. (As for the true motions of the heavens — which come into this business least of all — no Calendar whatever can be devised that answers to them at every point.) And so much so that, not in my judgement only but in that of other men of the greatest expertise as well, none more exact or more certain can be devised in which the reckoning of the Cycle is preserved as it is in ours — a thing we have shown at sufficient length to be absolutely necessary in civil affairs. For my part I do not doubt that you would be of one mind with us, were it not that your longstanding hatred of the Roman Church and of her head, the Supreme Pontiff — the lawful successor of the Apostle Peter, the first Roman Pontiff, and the Vicar of CHRIST the Lord on earth — so blinds you that you snatch most greedily, from any quarter you can, at every opportunity to trample, to slander, and, if you could, utterly to overthrow all his commands and decrees, even those which have no bearing whatever on the Faith, such as this ordinance of the new Calendar.

Since this is how matters stand, you cannot but be ashamed — if any room for shame is left in you — of having so boldly challenged all mathematicians, in the title of your *Examen*, to answer it, unless they wished to be taken for impostors and disturbers of the public peace in the Holy Roman Empire; or else, if they could not answer (of which you were entirely convinced), to admit frankly, for the common good of their country, that they had praised this Calendar with over-hasty applause and premature judgement, and had everywhere urged its acceptance. For I judge that your absurdities and slanders have been so fully met by this reply that no room now seems left for fresh quibbling, unless someone should wish to abolish altogether the use of any Calendar in which the nineteen-year cycle is employed, and in which years and months are counted by whole days, hours and their fractions being disregarded — a Calendar framed, that is, to the grasp of ordinary people and to the daily dealings of men. No one of sound mind, I think, could be persuaded of that. This, I believe, is quite clear to all who have read your *Examen* and weighed my *Apologia* with some care: that you bring no objection against us which we did not know before, and none that can shake the Gregorian Calendar; for you show nothing else than that the true equinox cannot always remain on the 21st day if our equation is applied. That we have never denied, since we know it to be in no way possible for any even and uniform equation to achieve this, given the inequality of the true motions.

LIBRI SECVNDI FINIS. [End of the Second Book.]

DEFENSIO ANTONII POSSEVINI E SOCIETATE IESV CONTRA MICHAELEM MÆSTLINVM

AVCTORE CHRISTOPHORO CLAVIO BAMBERGENSI

**A Defence of Antonio Possevino [Antonio Possevino] of the Society of Jesus,
against Michael Mästlin. By Christoph Clavius of Bamberg.**

[Margin: Another pamphlet of Maestlin's, in which he attempts to defend this second *Examen* of his against Possevino and the others who try to refute his arguments.]

I HAD scarcely committed this *Apologia* of mine to the press when another pamphlet of Maestlin's suddenly reached me from Germany, which he entitles a *Defence* of his second *Examen* — the work we have in hand and have examined not altogether carelessly. He seized the occasion for publishing this *Defence* from a certain writing (as he puts it) of Antonio Possevino of the Society of Jesus, who had taken him to task on precisely this ground, that he had attacked the new Calendar — and far more gently, at that, than the case demanded. Our opponent took this so ill that he thought it worth his while (so much did anger and the appetite for revenge prevail with him) to publish a pamphlet of his own, harrying that piece of Possevino's with truly incredible abuse and utterly destroying the good name and reputation of that good man. Our long silence also made him bolder in bringing this pamphlet out. For when in the whole two years just past he saw no one who dared to tear his *Examen* apart or shake it, he gained such boldness that he now challenges everyone anew, most insolently, to answer it, and is fully persuaded that there will be no one — whoever he may be, and however great a mathematician he may think himself — who can refute his demonstrations. All this can be plainly seen from the opening of his *Defence*, which I have decided to insert here word for word, so that everyone may see that in slander, and in puffing up his own fabrications to win belief, he is always true to himself. Here, then, is how he begins his *Defence*.

TWO YEARS have gone by since I published my second Astronomical Examination of the New Gregorian Calendar. In it, setting aside all the other questions and disputes capable of standing in the way of the Calendar's reception, I discussed that one argument of the papists which is, above all the rest, their chief and fundamental one — the argument of those who say: that the new Gregorian Calendar has been reformed and perfected with such completeness that in it all the errors of the old

Calendar, which laboured under manifold imperfection, have not merely been removed, but provision has been made for time to come with such foresight that its calculation will in no age whatever, right on IN PERPETUITY, be liable to any change. In that examination of mine, therefore, I demonstrated — from the very sources from which this whole question must be drawn and decided — that this new Gregorian Calendar in no way deserves such commendation. For in each and every one of those parts in which it either ought to have been reformed with the greatest accuracy, or is supposed to have been so reformed, I found it faulty in countless ways: so much so that nothing at all blameworthy can be found in any Calendar whatever in which this Gregorian one is not defective too. For that reason it ought rather to have been called A CESSPOOL OF ALL ERRORS than a reformation, since into it, as into a bilge, the errors of all Calendars flow together in troops. Relying then upon the certainty of astronomical reasoning, and hedged about by it, I did not fear to challenge boldly all mathematicians — whether those who first composed this Calendar or those who have defended it hitherto — to answer, and so on.

[Margin: Maestlin will not allow that the new Calendar can be called perpetual; instead it is a cesspool of all the errors that can be found in any Calendar.]

THE moment my Examen appeared in public it came as the greatest of surprises to the papists, and especially to those to whom the New Calendar was agreeable; for they had convinced themselves for certain that this new creature of theirs could not be charged with a single blemish, much less convicted of one. And so those very men began, with premature censure, to abuse me strangely among themselves, as though I alone wished to seem wise all by myself, in preference to certain most learned and most celebrated mathematicians, the authors and approvers of your new Calendar. Hence they promised themselves outright, and threatened me, that those demonstrations of mine would be taken up as they deserved and solidly refuted out of the very foundations to which I had (in their judgement) ignorantly appealed. But what happens? Such is the strength of unconquered truth that not only does it not give way before these men's outcries — like the yapping of feeble little dogs — but it even challenges of its own accord anyone who will meet it with equal strength, and waits eagerly for him to come forward. And so I await a refutation of the said Examen of mine, not at all fearfully, but with a stout heart. Yet in this whole two years I see nothing of the kind, apart from a single writing by one Antonio Possevino, a Jesuit — and that, as I shall shortly show, utterly inept. A year has indeed gone by since I learned, from the report of certain people, that there were some, somewhere, who had not merely planned a refutation but had by then already handed it over to the press to be printed. Yet neither has that come to me in all this time, careful search though I have made. So while these men shirk coming

out into the light by weaving delay upon delay[?], they tacitly bear witness that, convicted in their own conscience, they cannot resist the truth. For if they were not fostering a bad cause, why is it that out of so many of their own most expert, most wise and most learned mathematicians of the whole Christian world (as Busaeus, the Jesuit of Mainz [Johannes Busaeus], boastfully reports in thesis 170 of his Disputatio) — or (if only Pope Gregory xij. [Gregory XIII] speaks the truth in the Bull) out of these...

...the most expert men in these matters, whom the Pope himself had long before chosen out of the leading nations of the Christian world, and who devoted much time and care to that labour of correcting the Calendar — not one of them comes forward to explain the reasoning of the new Calendar and argue its case in earnest. Both the rest of them and those very men whom I called out in that writing of mine, whether obliquely or by name, keep silent. Indeed, I have it from trustworthy men that even that Mathematician whom I touched on page 2 of my Examen has been beaten by the truth and has come over to my opinion. I hear that some others are doing the same: bound though they are to the papal religion, they nevertheless admit openly that the demonstrations of that writing of mine cannot be refuted by anyone at all, however great a Mathematician he may think himself. Let me add this too. I have likewise been informed by trustworthy men that a certain person has scraped together some things or other[?] more against my person than against my writing, but that they have been suppressed by the authority of his Superiors as worthless and utterly unfit for publication.

THEREFORE the demonstrations of that Examen of mine still stand unmoved, and do not lose their force under the abuse of these men. The new Calendar, by contrast, remains in every one of its parts wholly imperfect, faulty, defective. That being so, out of what love of novelty — or rather, bewitched or driven by what sting of madness — do the papists, mathematicians and others alike, keep commending that utterly defective Calendar of theirs to the whole world so grandly, under the wholly false title of a most exact and most perfect Reformation, and pressing it and forcing it upon them? Is this not a deliberate mockery of the whole Christian world, a tyrannical subjugation of it like a herd of slaves, and its utter ruin?

DOES this braggart soldier not seem, delighted at a victory already won, to be singing his own triumph? I am astonished, and astonished in the extreme, that he can be so puffed up that — I will not say he despises every Mathematician in the whole world by comparison with himself — he actually believes no one is to be found who could meet him on equal terms. One of two things must be true: either he is so swollen with the spirit of pride that he refuses to look at truth itself, or

else — and this is what his Examen shows — he is entirely ignorant of, and a stranger to, the ecclesiastical ceremonies by which Easter has been celebrated throughout the whole Christian world down to the present time. Blinded by his craving to contradict, he does not see how absurd the objections are that he brings against the new Calendar. But perhaps I shall bring it about that he opens his eyes at last to recognize his own errors — or at any rate that those who can see nothing in this business for themselves will not follow a blind guide.

[Margin: The new Calendar is rightly called Perpetual, and it is not a cesspool of all the errors that can be found in any Calendar, as Maestlin would have it.]

For in this Apologia of mine I have shown plainly why the new Gregorian Calendar is called Perpetual and liable to no change whatever, and that it deserves that name, however much he may rage in the meantime. If he wants to understand this — and that he has entirely failed to understand it is proclaimed both by his Examen and by this pamphlet of his — let him read Caput 5. lib. 1. and caput 4. lib. 2. of this Apologia. As for his reproach that the new Calendar is a cesspool of all the errors that can befall any Calendar, who does not see that he said this out of hatred for all Catholics, and above all for the Roman Pontiff, the Vicar of Christ? Had he charged the new Calendar with one error or two, someone might perhaps have suspected that not quite all errors had been removed from it. But now that he proclaims everything in it faulty, who will believe he spoke with a sincere and candid mind? So let us compare the new Calendar with the old, so that no one can fail to see that Maestlin attacks the Gregorian Calendar, and calls it the cesspool of all errors — as though the errors of all Calendars flowed together into it in troops, as into a bilge (his own word) — not out of love of truth, but bewitched or driven by that sting of madness which he charges against us. What if we show that all its errors have been removed, so far as the Cycle allowed?

[Margin: The errors of the old Calendar, which have been removed in the new one so far as the cycle allows.]

In the old Calendar the equinox was continually abandoning the place appointed for it and moving forward toward the beginning of the month, so that in the years immediately before the correction it had drawn a full ten days away from its own seat. Nor did it halt its advance there: its increments grew larger every day, and there was no hope at all that it would ever return of its own accord to its proper place. In the new Calendar, by contrast, the equinox falls on 21 March, the seat assigned to it by the ancients. And if it happens that the equinox sometimes withdraws from that day, on account of the instability of the true motions, that

withdrawal cannot grow to 10 days, as it did in the old Calendar, but at most to two or three; and of its own accord, with no other remedy applied, it returns to the 21st day, even after 20000 years, as we showed in Book 1. Next, in the old Calendar the golden number presented the Paschal Lunæ XIII much later than the facts warranted, so that the opposition according to the Cycle — that is, Luna XV — usually followed the mean opposition by four days, whereas Luna XIII never fell upon the mean opposition itself, still less ran one day ahead of it, which is what a correct arrangement of the Cycle in a Calendar requires. The new Calendar has corrected this intolerable error so that the Paschal Luna XIII almost always runs one day ahead of the mean opposition, or coincides with it, or at worst falls not long after it. What greater accuracy could be looked for in any Cycle? From the two errors of the old Calendar that I have recounted, and that we have removed in the new Calendar, two further errors followed, and very grave ones. First: in those years in which Luna XIII according to the golden number fell on 11 March, or on the 20th, or on any day lying between the two — which happened whenever one of the golden numbers 3. 6. 8. 11. 14. 19. was running, that is, six times in every nineteen-year span — Easter was always thrown out of the first month into the second.

[Margin: When Easter was celebrated in the old Calendar either in the second month, or after Luna xxi, contrary to the decrees of the Fathers.]

Second: whenever the Luna XIII of the golden number fell on a Sunday, or on a Monday, Tuesday or Wednesday, Easter was celebrated in the fourth week — that is, on Luna xxij, or xxij, or xxij, or xxv — because the Luna XIII of the old Calendar was in the sky nearly Luna xvij; and so, whenever Easter was four days or more away from that Luna XIII, it necessarily fell on Luna xxij or later. Since all these errors have been removed from the new Calendar, so far as the Cycle allowed — as I have demonstrated in this Apologia — what impudence and recklessness is this in Maestlin, that, sunk himself in the cesspool and bilge of every error, he is not afraid to call the new Calendar the Cesspool of all errors? He himself has certainly not been able to convict it of a single error — however grandly he boasts of having done so — unless we choose to call it an error that the calculation of the new Calendar does not agree in every respect with the true motion of the Sun and of the equinox. Apart from this he proves absolutely nothing else in his whole Examen.

[Margin: What does Maestlin prove in his Examen?]

But that this agreement is not necessary — indeed, that it is not even possible for any Calendar in which popular rules have to be set out and a Cycle laid down to

answer to the true motions — can be seen abundantly, and more than abundantly, from what we have demonstrated in the two preceding books. It would therefore be truer to call his Examen, and this Defensio published against Possevino, not merely a cesspool of errors but a workshop of every lie with which the new Gregorian Calendar can be assailed and attacked.

[Margin: Maestlin's writings against the Calendar are a cesspool of all errors and a workshop of every lie.]

MY OPPONENT then goes on with his victory and his triumph, and tells us that his Examen came as a complete surprise to us: for we do indeed threaten him with a reply, yet none of us has published one so far.

He promises himself victory as confidently as though he had overturned the new Calendar by some solid argument — when in fact all the weapons he brings forward in his Examen establish only this (as I said a little earlier): that the equinox, once the equation of the new Calendar is applied, does not correspond exactly to the true equinox. And that no one has ever denied. Nor can any even and uniform equation be devised that agrees precisely with the true motions, as we demonstrated at length in Book 1. If he happens to maintain that such an equation can be found, let Maestlin construct it himself, with that laborious cleverness of his, so that we may see he had good reason to censure the new Calendar. But if he admits that it cannot be done at all, then let him admit as well that on this ground he has attacked the new Calendar rashly and ranked it below the old.

[Margin: Maestlin proves only that the new Calendar does not agree exactly with the true motions — which is beside the point, and is denied by no one.]

For consider: was the old Calendar, which you praise so highly, Maestlin, and prefer to this new one on every count, so shaped to the true motion that it never diverged from it? Certainly, if the deadly hatred you bear the Roman Church allowed you to admit the truth, you would never deny that the new Calendar comes closer to the true motion than the old. For in the old Calendar the equinox had so far abandoned 21 March, the day appointed for it, that it could not possibly return there unless 10 days were subtracted from the year. In the new one, although the equinox strays from that day for a while, it nevertheless returns to it of its own accord after some centuries have passed, with no other remedy applied. I say nothing of the lunations around the time of the correction, which in the old Calendar differed from the true new moons by a full four days and more — something that cannot be said of the lunations of the new Calendar.

[Margin: The old Calendar diverges from the true motions more than the new one does.]

As for your claim that many, Catholics among them, have come over to your opinion, on the ground that by their silence they testify that, convicted in their own conscience, they cannot resist the truth — that troubles me little. You may see for yourself how true it is. For my part, I set out at the beginning of this *Apologia* the reason why no one has yet answered your *Examen*; and you can now see well enough that the reason was a true one and not invented, since you see that windy *Examen* of yours foiled by this *Apologia* of ours, such as it is. And indeed I do not doubt that our reply has come as a complete surprise to you — just as you say your own *Examen* did to us — the reply that you call, falsely and wittily (as you do everything), an elephantine birth. What can you do about it? So great an animal as the elephant cannot give birth quickly. The elephant is slow to give birth, I grant, but what it bears is an elephant; whereas you, when you give birth, bear a gnat. For what is there in your writings, Mathematician of Tübingen, beyond the sting of slander and the trumpet of self-advertisement? Yet I am not afraid that this elephantine birth of ours will look to you late rather than early: if you are waiting for it as eagerly as you say, you now have what you were waiting for. See to it, then, that you do not change your mind and decide there was after all no reason to wait for it so keenly. But let us pass on to other matters, and weigh the chief remaining heads of Maestlin's *Defensio*.

[Margin: Maestlin gives birth to a gnat.]

[Margin: Three things above all in Possevino's writing stung Maestlin.]

THREE things above all in that writing of Possevino's stung Maestlin extraordinarily. First, that Possevino called him a heretic. Second, that he asserted the boastful title of Maestlin's *Examen* shows well enough what a windy mind the man has, and that consequently there is far less in the body of his writing than its front promises, and that most of it is rotten stuff. Third, that he maintained the new Calendar is built up by Maestlin rather than pulled down, confirmed rather than weakened: for in the *Examen* Maestlin demonstrated that the equinox withdraws from 21 March in both directions, and thus that the 21st itself, the day the Gregorian Calendar assigned to the equinox, is in a sense the midpoint between the 19th and the 24th, the limits within which the equinox can wander. That all three of these things are said by Possevino with perfect truth we shall show with the utmost clarity and with no trouble at all.

[Margin: That Maestlin is a heretic.]

FIRST, then, that Maestlin is a heretic no one who knows him will deny — unless he happens to be a heretic himself. I pass over what most people in Germany know, that he was driven out of Heidelberg for being a Ubiquitarian [Vbiquetarius]. The profession of faith that Maestlin employs in this Defensio of his, in order to escape the name of heretic, is in fact such that, even if we had no other evidence at all, we could cut his throat with his own confession. For he rejects the traditions of the Fathers, he despises the patronage of the Saints, and he assigns justification and blessedness to faith alone; and finally he professes himself a Ubiquitarian — if not in word, then in substance. With what face, then, does he refuse the name of heretic, when he takes up so eagerly heresies so many and so open?

[Margin: What Maestlin undertook to prove in his Examen against the new Calendar.]

[Margin: Maestlin brings nothing new against the Calendar in his Defensio.]

SECOND, the attentive reader will easily recognize from what follows how truly Possevino asserted that the boastful title of Maestlin's Examen shows well enough what a windy mind the man has, that there is consequently far less in the body of his writing than its front promises, and that most of it is rotten. Maestlin had undertaken to demonstrate in his Examen — and in this very Defensio he emptily boasts of having demonstrated — that everything in the new Gregorian Calendar is so faulty and corrupt that it ought more truly to be called the Cesspool of all the errors that can befall any Calendar than a restoration. Then, coming down to particulars, he says: that the equinox has not been correctly restored to 21 March by the removal of 10 days; that it cannot be kept at the 21st if the equation prescribed in the new Calendar is applied; that the Epacts do not properly perform their office of indicating the new moons and the Paschal termini, both because they are arranged faultily in the Calendar and because their equation has been wrongly set up; and finally that the ancient Solar Cycle, or Cycle of Dominical letters, has not been perfectly equated so as to indicate the Dominical letters as they stood at the time of the Council of Nicaea. But how much of all this he actually proved in that wordy Examen can be gathered clearly from what we have written against him in this Apologia. For in it we have amply refuted every one of his quibbles, which he boastfully repeats in this Defensio; so that nothing seems worth adding here, especially since he has himself brought forward nothing new against the Gregorian Calendar in this Defensio of his. I will add only this, which we showed above as well: if his whole Examen is examined more carefully, we shall find that nothing is proved in it except that the retention of the

equinox on 21 March by the equation of the new Calendar does not agree with the true equinox.

[Margin: There is far less in the body of Maestlin's Examen than its front promises, since he proves only that the equinox of the new Calendar does not agree with the true equinox — and yet he had undertaken to prove far more.]

But both the author of the Calendar and we ourselves, who were summoned to the restoration of the year, foresaw this before the Calendar was published by GREGORY XIII, Supreme Pontiff — as can be established with perfect clarity from the Compendium that was sent to the Christian Princes a full five years before the correction of the Calendar. For why else would these words have been added near the end of it, as we also said in Cap. 4. of this book?

[Margin: The authors of the Calendar foresaw that the equation of the solar year would not answer to the true motion in every respect; so Maestlin attacks it in vain.]

Once the vernal equinox has been restored to the place from which it had fallen away, and this Cycle of Epacts — which can be adapted to any length of year — has been set beside the Calendar, and the scheme of intercalation we have described has been adopted along with the equation of that Cycle, the years and months will hereafter agree with the reckoning of the Sun and Moon so well that no variation or discrepancy will be able to arise thereafter; and if any ever should arise, this same method shows that it can be beautifully restored to its proper state.

Why, I ask, would this have been added if we had thought — as Maestlin slanderously charges us with thinking — that our equation could never diverge from the true motion of the equinox? And why, if we had likewise supposed that the Alphonsine year, which is midway between the greatest and the least, would answer to the true equinox in perpetuity, so that it would never need any equation other than the one we prescribed — why then, I ask you, would these further words have been added by us at the end of the same Compendium?

But if to anyone the Alphonsine calculations should seem too uncertain to be trusted, and he judges it better to hold to more recent ones, he will certainly see that the arrangement and ordering of this ingenious Cycle, and of the table of Epacts devised by Lilius [Aloysius Lilius], is such that it can be fitted without any trouble to the calculations of Copernicus, or of anyone else at all, provided that a small equation-table drawn up from them is substituted for the one we have written in the margin — as, for example, the table we have set down here, which does not depart much from Copernicus's reckoning.

Do we seem to you, Maestlin, to have meant by these words that the new Calendar is called Perpetual because the equinox clings to 21 March so firmly that our equation cannot shift it from that day? You are quite mistaken if you think so. How could we have thought that, when we left it open for the equation to be set up either to the Alphonsine year, or to Copernicus's year, or to anyone else's? We called the Calendar Perpetual for this reason: that, with no change made to its Cycle, the equation can be set up for any length of year whatever, and easily corrected if it is found to stray too far from the true motion — as we explained more fully in Capite 4. libri 2.

[Margin: Why the new Calendar was called perpetual by its authors.]

Since this is so, are you not ashamed to throw at us the very thing we freely concede and admit? Why do you keep charging us so shamelessly with promising, in our New Calendar, the restoration of the vernal equinox to 21 March with such careful provision that it can never in all perpetuity withdraw from that day as from its own fixed seat — when you cannot show that we said this anywhere, except in the sense we have set out concerning the Calendar's perpetuity? You are beating a stone, Maestlin, as the proverb has it: first because you waste your effort, since you accomplish nothing against us, and second because you injure yourself rather than us, since everyone can see from this that you are looking for a knot in a bulrush, as the saying goes, and maliciously attacking the new Calendar by slander. Is this not a case of there being far less in the body of your Examen than its front promises? And is it not rotten, next, that you find fault in the new Calendar with the very thing the Church has always devoutly observed in the celebration of Easter, on the authority of the Decrees of the Fathers and of the Councils? I mean when you say that Easter is not to be celebrated at the full moon next after the equinox — although this custom has always prevailed in the Church, and Easter cannot be celebrated more fittingly at any other time, as I proved above both from the most ancient practice of the Church and from the weightiest writers who have written on the correct celebration of Easter. In this matter you betray your ignorance all too plainly.

[Margin: Many things in Maestlin's Examen are rotten.]

Is it not rotten that you should quibble that we restored the Calendar toward the end of the year 1582 rather than near its beginning, so that the Easter which — as you prattle — had been lawfully celebrated in the old Calendar should not be improperly celebrated in the new? You certainly show how well versed you are in this business, since you are, as the saying goes, wrong by the whole sky. For that year's Easter would have been lawful, by the prescription of the Council of

Nicaea, if 10 days had been removed at the beginning of the year; whereas in the old Calendar it was celebrated improperly, in the fourth week, contrary to the Decrees of the Fathers and of that same Council, as we demonstrated in Cap. 3. lib. 1. Yet you are so pleased with this rotten doctrine of yours that you are not ashamed to boast, in that Defensio of yours, that the truth — recognized both about the other errors of the new Calendar and especially about this one, allegedly committed in the new Calendar at the Easter of 1582 — is a stake in our eyes. But take care that this very reply of mine, not to say the whole Apologia, in which I have plainly convicted you of ignorance in these matters, does not turn out to be a beam in your own eyes.

[Margin: This reply is a beam in Maestlin's eyes.]

Is it not utterly rotten that you should think Luna XIII does not differ from the full moon, when this runs counter to the teaching of all the Fathers and of the Councils? Is it not rotten to teach, against the whole school of Mathematicians, that the true æquiuoetium [recte: æquinoctium] can be a full four days distant from the mean, and thus that the mean claims 23 March for itself while the true one will slip to the 27th after some centuries have passed — when a calculation of this matter extended over 20000 years flatly contradicts it? And finally, is it not rotten to attack the equation of the Epacts so boldly when you have entirely failed to grasp its foundation and root, as is clear from what we wrote in cap. 7. lib. 2.? I pass over in silence the fact that you attack neither the equation of the Epacts nor that of the Solar Cycle from their own proper principles, as the philosophers put it — for you understand perfectly well that neither of them could have been set up more suitably. The one thing you do establish is that the equation of the equinox does not agree exactly with the true equinox of past years; and that tells nothing against us, as we showed above in cap. 7. lib. 1. Certainly, to overturn both equations you would have to show that neither of them answers to years to come; and this you have not done, nor ever will. In the Solar Cycle you did not even attempt it; and how successfully the matter turned out for you in the Epacts will be judged by those who read Cap. 7. lib. 2. of my Apologia attentively.

[Margin: When Maestlin proves that the equinox recedes from 21 March now to the 19th, now to the 24th, he confirms the equation of the equinox in the new Calendar.]

LASTLY, that Possevino affirms truly and rightly that Maestlin — unwilling and unwitting though he is — has done more to confirm the Gregorian correction than to weaken it appears plainly from what we wrote in lib. 1. cap. 5. 6. & 7. For Maestlin shows that the equinox of the new Calendar wanders from the 21st

appointed for it, now to the 19th, now to the 24th — his claim that it can fall away as far as the 27th being, as we established in that same place, a slander and altogether false — so that the 21st holds a kind of middle position between the extreme days of the withdrawal. Who, then, will doubt that the equation of the equinox has been most aptly devised, since it keeps the equinox at the midpoint of the withdrawal in either direction, so that even after 20000 years it still returns to the 21st day of its own accord? Anyone who wants more on this should read those same cap. 5. 6. & 7. lib. 1. of this Apologia.

I HAVE NO intention of working through the remaining chapters of this Maestlinian Defensio, since in them he merely repeats the arguments he had already put forward in the Examen — with countless insults and mockeries added, boasting more than once, as he heaps abuse on us, that none of us will dare to answer him, indeed that none of us can. Such is the presumption of that swollen Tübingen Mathematician. Those arguments I believe I have answered fully and abundantly in the two preceding books. From his abuse and insults, moreover, with which all his pages — I might say all his sentences — are crammed, it will be easy to infer in what spirit Maestlin has attacked the new Gregorian Calendar with such angry and uncontrolled feeling: whether out of zeal and love of the truth, or rather out of hatred for the Roman Pontiff and for the whole Catholic and Orthodox Church.

[Margin: Why no reply is made to the remaining chapters of Maestlin's Defensio.]

For my part I hold the view that he would have harried the Calendar with the same fury even if the true motions had been fully considered and observed in it, or however else it had been restored — for this reason alone, that it was issued by the Roman Pontiff and proposed by him to the whole Christian world for acceptance. Then indeed he would have cried out — and not without cause — that we are impostors and disturbers of the public Peace in the Holy Roman Empire, on the ground that we were violently thrusting out the civil years, which ought to be equal and adapted to the common people's grasp, and which the whole Church, Eastern as well as Western, has always used from almost the very beginning down to our own age, and

[Margin: That Maestlin insidiously urges us to construct perfected tables, so that our Calendar may be able to be Perpetual.]

— and force unequal years upon them in their place, years that must inevitably throw trade and human contracts into extraordinary confusion. That he would certainly have done this cannot be doubted. For if he calls us impostors now,

when we have kept in the Calendar the equal year which, because of its immemorial use, is the best known of all to everyone, what, I ask, would he have done had we brought into the Church a new year — and an unstable and highly unequal one at that?

Let him stop, then, giving us treacherous advice and harping on the claim that we ought first to have built, from new observations, new tables — utterly perfect ones — before correcting the Calendar, so that (as he himself puts it) we might have boasted more confidently of the perpetuity of our Calendar. In fact this would have given him a greater opening to insult us: as men who had abandoned the observations of the most excellent astronomers and applied their own instead, confirmed as yet by no experience, to a matter as grave as the restoration of the Calendar. Add to this that the Calendar would then have been perpetual on no reckoning at all.

[Margin: That the Calendar could not be Perpetual if it rested on certain particular astronomical tables.]

For a Calendar cannot be perpetual if it is bound and tied to any astronomical tables so tightly that it never departs from them in any respect. No tables composed down to this day, even by the most expert astronomers — nor any that can be composed — permit us to promise much for their durability, because the periods of the celestial motions have not yet been fully grasped, as we showed in Cap. 4. lib. 1. A Calendar will be perpetual only when the cycle set out in it fills all the days of the whole year, so that, with the due equation applied at its proper times, it can be adapted to every length of the year without any change whatever being made in it. That this is exactly what the new Gregorian Calendar is has been shown plainly in the two preceding books.

SO THERE you have it, Maestlin: someone has at last answered your absurdities — and why should I not call them absurdities, since all your arguments proceed from sheer ignorance of what the Fathers and the Councils decreed about the right celebration of Easter, and so are pure trifles? You had thoroughly persuaded yourself that no one would do it, and for that reason you kept jeering at this reply in your *Defensio*, calling it an elephant's birth. And I have answered — one man out of all those who took part in that splendid work of correction — not because I feel that I have more talent than the others, but because so it seemed good to those whom I think it wrong to disobey. What is more, the goodness of the cause and the love of truth roused me to enter this contest, such as it is, the more willingly: so that anyone at all, provided he is not wholly ignorant of astronomy and has even a middling command of the ecclesiastical computus, may be able to

defend and protect the new Calendar against your currish barking with no trouble whatever.

[Margin: Why this Apologia does not refrain entirely from harsher words.]

And in this reply I would gladly have refrained from those words that sting and prick you now and then, had not your own garrulous and utterly shameless abuse forced me to it — abuse in which you leave out no insult, no contemptuous word that you do not spew out against the Supreme Pontiff or against us who restored the Calendar at his command — forced me, a man otherwise wholly alien to this kind of speech both by nature and by the rule of my order.

[Margin: If Maestlin had attacked the Calendar modestly, a modest reply would have been made to him.]

Certainly, had you set out modestly whatever difficulty you had, like a man who wants nothing more than to be instructed in matters he does not know, we too would have answered most modestly. But now that you have overstepped the bars and bounds of modesty and decency, and, like some braggart soldier, have paraded a triumph over us through six hundred insults and reproaches, as though the victory were already won, we could not do otherwise than take that boldness and arrogance of yours as it deserves. We do not compete with you in abuse — everyone is easily outdone by you there — but we merely blunt your intolerable audacity with the weight of our words, and even so we remain always mindful of Christian modesty.

[Margin: That in attacking the Calendar Maestlin sets himself against the whole Christian world.]

AND WHO, after all, are you, sunk in a corner of the earth and in the obscurity of Tübingen, to set yourself so insolently against the whole Christian world and to try to overturn what the Roman Emperor, all the Kings and Christian Princes who are true sons of the Catholic Church, all the Republics and the most famous Universities urged the Roman Pontiff with one consent to complete as soon as possible? Be ashamed — if any shame is left in you — of that notable impudence of yours, by which you have betrayed your ignorance, not to say your folly, to the whole world. Would it not have been better to accept and embrace the new Calendar in silence together with the whole Christian world, rather than to appear to despise all mortals in comparison with yourself, as though you alone were wise? — especially since the new Calendar is in no respect opposed to your false Religion, in which you obstinately persist and for whose sake you have taken up so great a war against the new Calendar.

But you will say that this Calendar is stuffed with countless errors and utterly contradicts astronomical truth, and that this was not to be borne. Which errors, then? These, I suppose, the ones we have mentioned more than once.

[Margin: Four errors of the new Calendar which can in no way be avoided, however the Calendar is set up.]

First, the equinox is not kept, by the equation prescribed in the Calendar, on 21 March, to which it was brought back; instead it wanders freely away from that day in both directions as far as the 19th and the 24th, although it returns to the 21st in the meantime. Second, the new moons are shown by the epacts later than they should be, and so it can happen — though rarely — that Easter is thrown into the fourth week of the lunar month. Third, Easter is sometimes transferred from the first month into the second, or into the twelfth, although this too happens rarely: namely when the Paschal Moon XIII falls before 21 March but comes after the day on which the equinox occurred, or falls on that same day, should the true equinox happen before the 21st; or again when the equinox follows 21 March while the Paschal Moon XIII comes before that same equinox, provided it is not found before the 12th. Fourth, Easter day will sometimes be kept — though very seldom indeed — on Moon XIII itself, before the full moon, that is, before Moon XV.

[Margin: That apart from those 4 errors, which cannot be avoided, Maestlin has convicted the Calendar of no error.]

To these four errors may be reduced all the objections that are truly brought against the new Calendar by you, or that can be brought by anyone else; nor will you ever convict it of any other fault, even if you bring every engine to bear. But these four errors — if they are to be called errors, when they must sometimes be admitted not carelessly but of necessity — cannot be avoided in any Calendar that is established by cycles and rules which are easy to grasp and uniform, as is only right. As to the first: if the equinox must be fixed to some definite day so that the Paschal terms may be settled and determined in advance — which is absolutely necessary in the civil and political year — who is there who does not see that the true equinox, because of its unequal and irregular motion, can now come before the day appointed for the equinox and now after it? Indeed, even if the motion of the equinox were always equal and uniform, this inconvenience still could not be avoided by any means, on account of common and bissextile years, as we demonstrated above. And this error is necessarily accompanied by the third, as is plain. The second error, then, must be admitted altogether

in every Calendar in which the lunar cycle is rightly arranged, lest it should sometimes happen that the new moons of the cycle run ahead of the conjunctions of the luminaries actually made in the heavens, and thereby the fourth error be incurred more often. Even so we cannot escape, in our own Calendar, the fact that our Easter sometimes falls on Moon XIII — though far more rarely than in the old Calendar around the time of the Council of Nicaea. Would you not, then, have acted far more prudently had you passed over these necessary errors — and others too, if any had crept in — along with the whole Christian world? For you tolerated, together with the Church, errors in the old Calendar that were far greater and more conspicuous, and yet no disturbance followed from that in the Empire or in any commonwealth. But you, like a bawling pettifogger, stir up tragedies over trifles, so as to seem to be doing and saying something.

SINCE THIS is so, who — apart from you alone, Maestlin — will be of such reckless audacity as to dare carp at the new Calendar because things have not been avoided in it which cannot be avoided in any way? And I do not doubt that, with your inborn arrogance, you will attack the new Calendar once again after this answer of mine, so as not to seem beaten and to have lost your case — although you claim, falsely and hypocritically, that the authority of truth counts for so much with you that you would yield to it most gladly if anyone were to teach you otherwise from the sources of this business. But contrive everything you like, try however you will to pour darkness over the truth on every side: you will accomplish nothing, you will achieve nothing. The light of truth will of itself shake off all darkness in the end — and yet why do I say this? All that earlier fog which you had cast over men's minds has been so thoroughly dispelled that there is no room left now for new fog: day has broken, all lies open, everything is plainly seen. You will be able to do no harm at all, even if, like the Caecias wind, you draw the clouds after you.

[Margin: What Maestlin must prove if he is to overturn the new Calendar.]

But if you really do want to attack and overturn the Gregorian Calendar again, you will have to show either that other errors besides the four just enumerated are to be found in it, since those four cannot be got round; or that the Church runs into them more often in the new Calendar than in the old; or else, if you can achieve neither of these — as I am fully convinced you cannot — you will have to produce a Calendar of your own that is entirely free of every flaw, provided that the civil year is used in it (that is the main point) and that the cycles customary in the Church are employed: which we expect you to do at the Greek Kalends. Be of stout heart, then, and set your hand to so splendid an exploit.

HIC RHODVS, HIC SALTVS. [Here is Rhodes; here make your jump.]

FINIS.

APPENDIX TO THE *DEFENCE OF THE NEW ROMAN CALENDAR*

Divisional title page of the volume's third part. Transcribed verbatim first, then translated. The typographic distinctions of the original are preserved: italic for the word APPENDIX and for Continens and the privilege line; small capitals for the opening word of each item in the list and for the proper names; the line-end hyphens fall where the compositor set them.

Verbatim transcription:

MOGVNTIÆ, Sumptibus Antonii Hierat apud viduam Reinhardi Eltz.
Cum gratia & priuilegio sacræ Cæsar. Maiest. ————— Anno
M. DC. XII.

Translation:

APPENDIX

TO THE DEFENCE OF THE NEW ROMAN CALENDAR

Containing

Joseph Scaliger's [Joseph Justus Scaliger] *Refutation and Correction of the Gregorian Calendar*, itself corrected by Christoph Clavius;

A *Reply* to the abuse and slanders of the same Joseph Scaliger against the Gregorian Calendar, by the same author — to which is added a *Refutation of Scaliger's Cyclometry*;

A *Confutation* of the Calendar of Georg Germann [Georgius Germanus], by the same author;

The *Admonition* of Theodosius Rubeus on behalf of Christoph Clavius, against François Viète's [François Viète] complaint;

The *Reply* of Laurentius Castellanus to François Viète's complaint against Christoph Clavius.

MAINZ [Moguntiaë], at the expense of Antonius Hierat [Anton Hierat], at the press of the widow of Reinhard Eltz. By the grace and privilege of His Sacred Imperial Majesty. ————— In the year 1612 [M. DC. XII.]

Diagram. The Jesuit printer's device, set between the list of contents and the imprint. A rectangular woodcut: at the centre, an upright oval cartouche enclosing the IHS monogram, surmounted by a budded (trefoil-ended) cross rising from the crossbar of the H, with three nails arranged in a fan below it; the monogram sits within a flaming/rayed glory. Around the oval runs a beaded frame bearing a lettered legend, read clockwise from the upper left. The cartouche is enclosed in strapwork scrollwork, with a winged cherub's head at the top centre, two winged angel figures playing wind instruments in the upper corners, and two winged putti in the lower corners; foliage and fruit fill the border, and a small basin-like ornament finishes the foot.

- Legend, lower left arc (reading upward): LAVDA
- Legend, upper left arc: BILE
- Legend, upper right arc: NOMEN
- Legend, lower right arc (reading downward): DOMINI
- Central monogram: IHS

The four segments are the single motto **LAVDABILE NOMEN DOMINI** ("Praiseworthy is the name of the Lord", Ps. 112:3), broken across the four turns of the beaded band. Every letter is inked and legible; nothing is occluded, and the word LAVDA is not divided from BILE by anything but the band's turn.

IOSEPHI SCALIGERI ELENCHVS

Joseph Scaliger's Refutation

and Correction of the Gregorian Calendar

CORRECTED

by CHRISTOPH CLAVIUS of Bamberg, of the Society of Jesus

PROOEMIUM OF CLAVIUS

Louis Chasteigner of La Roche-Posay [Loysius Castagnerus Rupipozæus], Baron of Abain — a man both of the noblest birth and of the deepest learning — was serving as ambassador of the King of France to Gregory XIII, Supreme Pontiff, and out of the long-standing friendship between us he recently sent me a little book of Joseph Scaliger's on the Paschal canon of Bishop Hippolytus, together with some extracts (as he calls them) from the Greek computus of Isaac Argyrus on the correction of Easter. To these Scaliger had added his *Refutation and Correction of the Gregorian year* [*anni Gregoriani Elenchum & castigationem*].

Captivated by the name and reputation of so great a man, I seized on the book eagerly, in high hope that it would offer something worthy of himself and worthy of his father. My hope was not altogether disappointed. I found much in it ingeniously worked out, sharply said, and fully explained — enough for you to recognize the son of Julius Caesar Scaliger. And yet, as I read (I say this with all respect for him), I came upon a number of things that seemed to have been written with less care than a man of his stature warranted. And so, passing over everything else, I had noted in the margin only those points on which he criticizes the Gregorian calendar mistakenly; and in the end, urged on by men of the greatest weight, I was brought to publish those notes, so that Scaliger's authority should not stand in the way of readers who see less clearly in this business — and at the same time so that he himself might in future wish better provision made for his own reputation, which I favour.

But I beg and implore Scaliger that, just as he judged himself free to correct and amend the Gregorian calendar, which almost the whole Christian world has approved, so he should allow others the same freedom to correct his own correction — not out of a wish to disparage, but out of a wish to admonish; and that he should take it with an even mind that this little book of his reaches men's hands in the most thoroughly corrected state possible, which is exactly what he

seems to want for the Gregorian calendar. Indeed the remarkable restraint he displays in the very preface to his *Castigatio* bids me be of good cheer. I need have no fear about his letting Clavius admonish him as a friend, since he himself professes *that he would have thought more of being criticized by Clavius than praised by many*; nor need I fear that he will acknowledge grudgingly whatever errors there may be in this little book, since he admits *that, being human, he could have gone wrong*. And all the more so because, in a matter of this kind, if he has gone wrong he has gone wrong not against himself but against the commonwealth — and this on his own verdict, since he says that our error is *a public one* and *leads the field*. Now if an error is detected in the very point on which he charges us with error, it will surely have to be reckoned the graver in proportion as the man errs more grievously who, caught in error himself, mocks those who travel the straight high road. We shall do it the more gladly, so as to bring a man eager to track down the truth back onto the road once he has been shown his own error. So then, having set out Isaac Argyrus's method, he proceeds to correct the Lilian — or rather the Gregorian — calendar as follows.

SCALIGER.

THE REFUTATION AND CORRECTION OF THE LILIAN YEAR

So the concern to correct the observance of Easter is nothing new: it has been under discussion for more than two hundred and fifty years. When the matter was taken up again within our grandfathers' memory and entrusted by the Supreme Pontiff to that most learned man Johannes Regiomontanus [Regiomontanus], it could not be brought to a conclusion, both because of his death and because of other disturbances that intervened. In recent years, however, Gregory XIII proposed a new correction of the year and won the approval of the greater part of Europe for it, so that this new form, received with warm consent, has entirely erased the old Julian one from the minds of ordinary people. ^a Since, then, it is in the public interest that the calendar be kept as free from error as possible, while it contains things that could be improved — indeed things that must be corrected outright — I judge that if I set out my own view on the matter, better minds and better judgements will be roused to do the same.

[Margin: a]

CLAVIUS.

^a There is in fact nothing we desire more than that the Gregorian calendar should both be, and be reckoned, as good and as free from error as possible. That was

also the reason why, by order of Gregory himself, Supreme Pontiff, it was put before virtually all the mathematicians of the Christian world for examination, and was not published until, everyone's opinions having been carefully gathered, it was established to be sufficiently corrected. Nor would Joseph Scaliger have been passed over on that occasion — a man no more distinguished by his father's learning than by his own — if he had had as great a name among mathematicians as he has among men of letters and learning. But since he has now entered the ranks of the mathematicians and demands a hearing from us, let him certainly be heard, if that is what he wants — now that the business is finished, seeing that he could not be heard while it was still whole.

SCALIGER.

I am well aware how hard a thing it is to touch this sore, since at the end of my books *On the Emendation of Time* [*De Emendatione temporum*] I spoke of this business only briefly and sparingly; and yet for all that restraint I could not escape the hatred and the abuse of men who think they are being wronged if we do not swear by their words and suppose that they themselves can never be mistaken. ^b And so, as I hear, the task was assigned to the most learned mathematician Christoph Clavius of writing against me; and, so that I should not be in doubt about it, Antonio Possevino [Antonius Posseuinus], in that lukewarm *Apology* of his against Chytraeus [David Chytraeus], threatens me with trouble from Clavius.

[Margin: b]

CLAVIUS.

^b No task was ever assigned to me of writing against Scaliger; it was to break Maestlin's [Michael Mästlin's] intolerable effrontery, which is what we tried to accomplish in the *Apology for the Gregorian Calendar*. In that book we plainly and clearly refuted everything that this most reckless man had blurted out against the new calendar. Nor does Possevino *threaten* Scaliger with any *trouble from Clavius*; he merely gives notice of that *Apology* of ours, which we have mentioned, to the calendar's assailants. If only Scaliger had examined it out of a desire to learn the truth rather than to contradict! He would certainly have turned his mind from *Correcting* the calendar to defending it, and with a better reputation for prudence, or for talent.

SCALIGER.

I waited for that book most eagerly and for a long time, ^c and many people either told me or wrote to me that they had actually seen it in Clavius's hands.

[Margin: c]

CLAVIUS.

^c The whole thing is a fabrication. Those men must have been dreaming, the ones who *either told or wrote* that they had seen it *in my hands* — which never happened. Even so, I am glad that Scaliger brings that eagerness of his, that hunger still unappeased, to this admonition of ours, so that in future he may become both more modest and more careful.

SCALIGER.

[?] For my part, since *I would have set more store by being criticized by Clavius than praised by many*, I cannot make out what occasion, or what material, he could have found for writing against me, since I have said nothing that could offend the feelings of any decent man. For if there are errors in my books — and why should I not admit that, being human, I could have gone wrong? — men of such stature ought not to divert their thoughts from better occupations to refuting my trifles. I release them from that care. Let them not waste their effort: I shall correct my own errors better, and more willingly, than they can point them out. What I have done wrong, I have done wrong to myself, not to the commonwealth. *Their* error is a public one, and it leads the field. And so I urge them — with all ambition and ill will cut away, as men of liberal education ought to behave — not to love their own work so much, or hate us so much, that they give up hope that something better may one day be got from us.

CLAVIUS.

^a There is no need of urging. You will be taking this error from us with our full goodwill, if you prove that it is an error; and you will find us not only fair-minded but grateful as well. Meanwhile I await what these things finally are that you suppose can be supplied better by you — since you are confident that you alone have seen more than everyone else.

SCALIGER.

^c[?] Just as Possevino [Antonio Possevino] did — who in his *Apologia* attacks our method for the solar cycle of the Lilian year with the utmost self-assurance,

though no better and no shorter method can be devised. And it is astonishing that a man who leaves nothing undone to persuade everyone that he alone is learned and wise should have taken so little thought for his own reputation. But both in that *Apologia* and in the *Bibliotheca* that has recently appeared he shows plainly that he has not read my work, or has not understood it — as when he says that I reject the decrees of the Fathers of Nicaea, or something else of that sort, φορτικὸν [Greek: *phortikon*, "burdensome," "offensive"] and uncivil. Let that censor of morals and critic of books show me where he read this anywhere in my whole work.

Are we to believe it? Or do those who hate invent dreams for themselves?

Will there ever be an end to writing, if anyone chooses to go hunting through his *Bibliotheca*?

Will anyone think it worth wasting his leisure on such concerns?

Has any work ever come out that was more open to criticism, fair and unfair alike, than his *Bibliotheca*? Who ever saw self-assurance more secure about another man's judgment? But let me return to the point. So far as he himself knows, I have never criticized the plan of correcting the year or Easter, and everyone who reads my writings will admit that I was of no other mind. What I do criticize in this new scheme, and what needs correcting altogether, I shall set out — once I have first said something about the design of the author of the year.

CLAVIVS.

☞[?] You attack Possevino far too angrily, my dear Scaliger — not to say intemperately — a man learned, moderate, and devout. What word is there about you in his *Apologia* that is not full of modesty, courtesy, and respect? Or was this what galled you, that he disapproved of your method? But criticisms made by men who disagree with one another are not to be blamed, provided they keep clear of abuse and insult. Debate about doubtful matters is the exercise of talent and the parent of truth. Besides, why should he not have been permitted to disapprove of your method, when you were permitted to disapprove of the Lilian method, approved by papal authority? Consider, please, whether — if anyone compares the modesty of that *Apologia* with this anger of yours, to put it as gently as possible — he may not apply that old line to you:

He has hay on his horn: keep well clear. [Horace, *Satires* I.4.34]

But remember: nothing is done rightly in anger, and nothing done rightly is judged rightly in anger. Now as for the *Bibliotheca*: grant that Possevino may

perhaps be charged with some fault of human error, since he chose to pass judgment on nearly all the distinguished writers, knowing that so many judges would afterwards be passing judgment on his judgment — even so, he deserves not merely pardon but perhaps praise as well. For, to say nothing of Cicero and Jerome, he did the same thing your father did, that most learned man; he did the same thing you do every day. I do not see why he should be forbidden what you reckon everyone concedes to be lawful for you — unless of course you take this liberty of judging other men's books, and this confident security about another's judgment, to be your family's private property. "But there is much in that *Bibliotheca* that you do not approve of." Granted. There will certainly be much that others both approve of and profit by. That everything you write should win everyone's approval is more to be wished for than hoped for. Moreover, since you harry that *Bibliotheca* so contemptuously, I am afraid that to those who have read it you will yourself seem to be indulging in that very φορτικὸν and uncivil behaviour which you censure in Possevino without cause.

SCALIGER.

DE CYCLO SOLIS IN PERIODO Liliana.

[On the solar cycle within the Lilian period]

From the Alphonsine measure of the tropical year — than which no better has so far been found — experts observed long ago that in 134 Julian years one bissextile day is superfluous, and in 402 years, three. But leaving the two years out of account, they thought that 400 years could safely be taken as the proper period, since 400 is a multiple of four and therefore better suited to the reckoning of the bissextile day; over that interval only 97 bissextile days are to be used, and when the period comes round — that is, in the four-hundred-and-first year — the Kalends of January fall again on the same dominical letter. For when 400 Egyptian years are divided by seven, one is left over, and this combined with the 97 bissextile days makes 98, a multiple of seven. So if, for example, the Kalends of January of the first year fell on a Sunday, the last day of December of the four-hundredth year will fall on a Saturday, and accordingly the Kalends of the four-hundred-and-first year will be brought round to a Sunday, as in the first year. This, then, will be the proper period of the tropical year.

Since the experts had settled this long ago, a hundred years back or more, Lilius [Aloysius Lilius] embraced this period and set about the correction of the year, ten days being removed from the calendar so that in place of the xi of March, that is, the xxi should be reckoned. Since, then, three bissextile days must be suppressed in four hundred years, he takes them away from the end of the first,

the second, and the third century, but allows the end of the fourth century to be bissextile — so that, for example, February of the years of Christ 1700, 1800, 1900 will not be of twenty-nine days but of twenty-eight, whereas February of the year 2000 will be of twenty-nine. The Lilian Tetracosiiëteris [*Tetracosiieteris* — the four-hundred-year period], therefore, consists of four centuries, each century of three solar cycles together with sixteen years of a fourth cycle begun, so that in the first, second, and third centuries one bissextile letter is omitted in year xvi of the fourth solar cycle. This is just as you have it in the table [*Laterculus*] set out below, in which, under the centuries 0, 100, 200, opposite year 16 of the cycle, you have a doubled letter, one capital and one small — Cb, Ed, Gf — and both run on in the years 16, 44, 72. But in year 100 — that is, in year 16 of the fourth cycle — the small letter begins the cycle of the following century, as you see in the table. We assume, then, that the equinox has always fallen on xxi March from the beginning of the epoch of Christ. So, casting away all the 400s from the years of Christ, there remain —

— the years of the current Tetracosiiëteris. In these you must consider which century it is, and which year of the solar cycle within the century; and from the table you will have the Lilian dominical letter. Suppose I want to know the dominical letter of the present year 1594. Casting away all the 400s, there remain 394 years of the running century-count, of which three centuries have already elapsed, while year 94 of the fourth century is now running. In the table, among the expanded years, opposite year 94 under 300 — that is, under the third century elapsed — you have in the common corner the letter B, the dominical letter of this year 1594. Again, suppose I want to know the dominical letter of the year 1800. Casting away all the 400s, there remains the hundredth year of the second century. Under 100 — that is, with the first century elapsed — opposite year 100 you have in the common corner Ed. And because it is the hundredth year of the century, the letter d will not make a bissextile day but will simply run on, as in a common year. But in the years 1744 and 1772 both letters will be taken, because the bissextile day is reckoned there. Again, from the years of Christ 1600, casting away 400, there remains the hundredth year of the fourth century. Under 300, opposite 100, there occurs in the common corner the doubled letter B A — both, note, capitals. By this it is marked that A is always taken for the bissextile day; that is, that both letters have their place in that year, the first from January to the position of the bissextile day, the second from the position of the bissextile day to the end of the year. ^a This method is extremely quick, and none better can be had — none, at least, that is to be learned from a written table.

But a method that can be held in memory is far quicker, if you keep hold of the four initial letters of the four centuries — G, B, D, F. For these, take four words from that very well-worn mnemonic verse — *Gratis, Bonus, Dei, Filius*:

Filius esto Dei, Cælum Bonus accipe Gratis.

[Be the Son of God; good man, receive Heaven freely.]

For the old cycle is interrupted four times. And so, at the beginning of the first century, the solar cycle, starting from GRATIS, sets that word at the base of the index finger [*index*]; FILIVS at the base of the middle finger [*medius*]; ESTO at the base of the ring finger [*medicus*]; DEI at the base of the little finger [*auricularis*]; and so on in turn, as is usual in the common method of the solar cycle. At the beginning of the second century take BONVS at the base of the index finger, ACCIPE at the base of the middle finger, and so on, as is clear from the formula set out below:

| III | | III | | II | | I |
|--------|------|-----|-------|-------|--------|--------|
| Filius | Efto | Dei | Cælum | Bonus | Accipe | Gratis |

In this, GRATIS has I, for the first century; BONVS II, for the second; DEI III, for the third; FILIVS IIII, for the fourth. From this you also gather that the break in the weekly reckoning comes about by the omission of a single letter: the break from GRATIS to BONVS, that is, from the first century to the second, comes about by omitting the word ACCIPE;

and the break from BONVS to DEI by omitting the word CÆLVM; and so with the rest. Anyone who wants to disparage so quick a method must be either malicious or ignorant of these matters. And yet this is the very method Possevino condemns.

But if anyone wishes to handle this by the Julian solar cycle, he can do it as follows. Let him take the year of Christ from the table, out of the collected years of Christ, if it is found there exactly; if not, the next lower one. The character of the solar cycle taken opposite it, and then counted out in the formula of the solar cycle up to the current year of the solar cycle, will show the Lilian letter. An example. I want to know the dominical letter of the year 1601. The year is found exactly among the collected years of Christ. The character opposite it is XXI; in the formula of the solar cycle this will be the first year of the solar cycle. And so, since in the said year 1601 the year of the solar cycle is the fourteenth, that number counted from XXI will end in the formula at VI, beside which the letter G is the dominical letter of the year proposed, 1601. Again, I want to know the Lilian dominical letter for the year 1741 — a number that is not found exactly among the collected years. The character of the next lower number, 1701, is IX; and 1741 is the fourteenth year of the Julian solar cycle. In the formula, fourteen counted from IX will end at XXII, and therefore at the letter A, which is the Lilian dominical letter of the year proposed, 1741. You will find this true by the other method as well, opposite the expanded year 41 under 100, with the first century elapsed: there stands the same letter A. And as for this method too — although it is the same as the Lilian one — how much quicker it is than the Lilian itself, I leave to be judged by a modest man who is expert in these matters, and not by Possevino.

CLAVIVS.

^a It is indeed so, as the proverb says: everyone finds his own beautiful — you delight in your method, I in mine. To others the method we proposed in the *Apology* seems both better and quicker, the one by which the dominical letter is found without the solar cycle (as we showed in Book 3 of the *Apology*) — and found from memory at that, so that neither Scaliger nor anyone else should miss that feature in it. But I do not in fact reject this method of Scaliger's for the time after the correction of the calendar: I see that it can be of use. It does, however, have this defect, that it holds only for time to come and not for the past as well. For if it is carried back into earlier years it will show a false dominical letter, even if you assume, as he wishes, that the equinox falls on 21 March. To take an example: in the year 325 — that is, at the time of the Council of Nicaea — the

equinox had its true, not its fictitious, seat on 21 March; yet Scaliger's method offers the dominical letter D, when in fact it was C.

SCALIGER.

DE EPACTIS LILIANIS.

[On the Lilian epacts]

Hipparchus was the first of all to discover that in 304 Egyptian years and 75 days a complete ἀποκατάστασις [Greek: *apokatastasin*, accusative of ἀποκατάστασις, "restitution" — the Moon's full return to the same position; printed with the στ ligature sort] of the Moon is accomplished, so that nothing is left over in the lunar reckoning [*epilogismus lunaris*]. But 304 years with 75 days fall short of 304 Julian years by one day, since 76 bissextile days belong to 304 Julian years.^a Therefore the Julian epacts in the calendar will run one day ahead after 304 years.

[Margin: a]

CLAVIVS.

This rests on authority rather than on truth; examined more carefully it totters, and the whole of Scaliger's edifice, raised as it is on this substructure, collapses along with it. For if the Moon ran ahead of its seat by one day — that is, by 24 hours — in 304 years, it would anticipate by 1½ hours in a single nineteen-year cycle. That is false, and against all the astronomers. For as I showed in Book 2, chapter 1, of the *Apology*, from Ptolemy, Alfonso [Alfonso X — the Alphonsine Tables], and the Prutenic Tables [Reinhold, *Tabulae Prutenicae*], in one cycle it anticipates only 1 hour, 27 minutes, 31 seconds, 55 thirds, so that in 312½ years it anticipates roughly one day. But not to go over ground already covered: anyone who wants more on the subject should read through chapter 1 of Book 2 of the *Apology*. Yet I really cannot wonder enough why Scaliger — than whom, for all I know, no one has been more practised at sifting and harrying other men's discoveries — should in this matter have shown himself so unlike himself; and why he did not seek genuine credit by refuting what is false, when he often seeks fame for his name by harrying what is true. And this especially, since that very Isaac Argyrus [Isaac Argyros], whom he embraces so warmly, could easily have warned him of the point. For Argyrus (as can be gathered even from him, in the excerpt on the correction of Easter) taught in express words that the Moon does not run exactly one day ahead in 304 years.

SCALIGER.

Suppose the new moon, or the first day of the lunar month, falls on the third of December in the Julian calendar in this year 1594, in which the epact is XVIII — which, by the old practice of the computists, begins from March. So, since December is the tenth month from March, with the epact 18 the first day of the moon falls on III December. But after 304 years — that is, in the year 1898 — the same new moon [*neomenia*] will have run one day ahead, and will no longer be on III December but on II December. Therefore, for indicating the new moon, that old epact 18 will be useless, and epact 19 must be taken in its place. Finally, after another 304 years — that is, in the year 2202 — a new epact XX will displace epact 19. So in the Julian year the epacts both press upward and increase by a unit, in proportion to the decrements of the Hipparchan period. The contrary happens in the tropical year: there the epacts are thrown downward, after 228 or 247 years. So in this year 1594 the new moon falls on 13 December, and the Lilian epact is 8. In the year 1841 the same new moon will come down to the 14th day, and the epact will be 7 — and so always, unless something intervenes to prevent it. The epact, then, increases in the Julian year and decreases in the tropical. Therefore the epact —

— both in the Julian year and in the tropical, rise upward from unity κατὰ μετέμπτωσιν [Greek: *kata metemptōsin*, "by metemptosis" — the shift of the epact that accompanies the solar equation] following the natural series, and sink downward, against the natural series, κατὰ προέμπτωσιν [Greek: *kata proemptōsin*, "by proemptosis" — the anticipation of the lunar reckoning]. If, then, the epact becomes 19 out of 18 in the Julian year, and 9 out of 8 in the tropical, it follows that the epacts run through the whole set of thirty numbers after some thousands of years. A perpetual cycle of epacts will therefore have to be set up from X I to X X X, propagated by always advancing through the number eleven. And since in the calendar the series of increments (or of decrements) is retrograde, no series other than a retrograde one can be entered in the calendar.

^a It is therefore not true, as that most learned mathematician Clavius writes at the beginning of Chapter I I I of the second book of the *Apologia*, that the epacts can descend downward from one to thirty according to the natural series. Nor do I see what defence he can muster for his own view. From what we have demonstrated, they must be wholly retrograde, and no other arrangement can be established. Epacts of this kind, running through thirty in retrograde order, we ourselves once saw in two old calendars: one was prefixed to a Roman Missal most elegantly written, the other to a very ancient Psalter.

[Margin: a]

CLAVIVS.

^a But I shall show that it *is* true, and prove it to you personally, most learned Scaliger, if I now explain at greater length what I there touched on only briefly, and make you see what you deny you can see — namely, what defence I can muster for my own view. The epacts in the calendar are indicators of the new moons; so much so that any other signs whatever could be put in their place. Take the present case. Now, when the epact is 13, the new moon falls on 18 March, and in the following year on the 7th, with epact 24 running — the value the table of epacts current in this century gives. In just the same way, if the epacts were arranged in direct order, so that they did not differ from the days, then for epact 13 the table of numbers showing the new moons would offer us the number 18, and so once again the new moon would fall on 18 March. Then in the following year the same table would present us with the number 7 for epact 24 — and that number 7 is of course eleven units *less* than the number 18 of the preceding year, just as epact 24 is eleven units *greater* than epact 13 of the preceding year. Indeed, here at Rome a calendar was submitted to the calendar commission by an experienced mathematician in which the 30 numbers of the epacts were written out in direct order, and they indicated the new moons perfectly correctly — exactly as the epacts themselves do when arranged in retrograde order. But since in those numbers the increase of the epacts by 11 units is not preserved — the movement goes by decrease instead — we preferred the retrograde order, so that the new moons should be indicated in a more natural way; and this we set out in book 2, chapter 3, of the *Apologia*. It is clear, then, that the epacts *can* run in direct order in the calendar, even though in that case they no longer preserve the reckoning proper to epacts, but are merely signs of the new moons. And this is precisely what we meant to convey in the *Apologia*.

SCALIGER.

Once a perpetual cycle of epacts had thus been established, and the epacts entered in the calendar in retrograde order, ^a Lilius saw that the Dionysian Paschal fourteenth in the Julian year had run three days ahead through the whole cycle without any exception, except in years 8 and 19 — that is, when the epacts are 28 and 29. Those two epacts anticipate the Dionysian seat not, like the remaining 17, by three days, but by four. They will therefore anticipate this century's fourteenth by one day. For today, when the epact is 28 in the Julian calendar, the fourteenth falls on X V April. Epact 28, therefore, must be set at 2 April. Again, today's fourteenth, when the epact is 29, falls in the Roman calendar

on 14 April. So epact 29 is due to the Kalends of April. And since the Kalends of March begin from epact 30 (or 0, which is the same thing), the same epact 0 will fall again on the last day of March — given that the Kalends of April claim epact 29.

[Margin: a]

CLAVIVS.

This is to play the soothsayer and to try to divine. Lilius and the founders of the Gregorian calendar never so much as dreamed of that way of placing the epacts in the calendar. The true and genuine account has been explained by us in chapter 3 of book 2 of the *Apologia*, to which we refer the reader.

SCALIGER.

But we are pressed by a difficulty from the other side. The civil lunar months, as everyone knows, are alternately full and hollow — that is, of thirty and of twenty-nine days. Now suppose we set the epacts so that 0 falls on the Kalends, and on the last day of March, and on 30 April, and so on in succession. Then all the lunar months will have been of thirty days, and the lunar year, which is unfolded in 354 days, will consist of a solid 360 — which is absurd. Besides, once this is done, epact X X I I I I remains useless for the method of the Paschal fourteenth. The nearest Paschal limit is 21 March, the furthest 18 April; but epact 24 sets the Paschal fourteenth on X I X April, that is, beyond the furthest limit. The same epact will also place the fourteenth in March on the X X th of the month, short of the nearest limit. Epact X X I I I I, then, will always be useless for Easter — and especially in this century, since with the ten days cut out the old Julian epact I I I I is today X X I I I I, in year X I I I I of the cycle, whose Dionysian fourteenth moon used to stick at X I I April, but today, κατὰ προέμπτωσιν by three days, is at I X April. With the ten days taken away, then, it is found at X I X April in the Lilian calendar, as has already been said. What remedy, then, will be devised for this evil?

The system of epacts was devised chiefly for the sake of the Paschal fourteenth. ^a Now the epacts that show the fourteenth in March must be the same epacts that show the fourteenth in the other months. For example, when the epact is X V I I I, it is epact V that shows the fourteenth moon throughout the whole year. But this cannot happen if epact X X I I I I is set at V I April. For epact X I will show the fourteenth of March; and so, if epact X I is to show the fourteenth in April as well, epact X X I I I I must necessarily stand at V April. There will therefore be two epacts in the same seat.

[Margin: a]

CLAVIVS.

Of course this is not true in every case. Even if it turns out so in the example you bring forward, still, whenever the pairing [*collegium*] of the two epacts 25, 24 — or, as you would have it, of epacts 0, 29 — falls in between, this order is inter-

—rupted. For when the epact is 8, in some months it is epact 24 that shows the fourteenth, in others epact 25. The same epact, then, will not be able to show the fourteenth for the whole year. But perhaps you will say that the fourteenth belonging to epact 8 does not fall in March but in April. Very well — let us take epact 22 in February, whose fourteenth in March is indicated by epact 20. Next, epact 3 indicates the new moon, and epact 19 shows its fourteenth in April. Where, then, is epact 20 hiding, the epact that indicates the fourteenth — which it surely ought to be doing, if Scaliger's reckoning did not limp? But however the matter stands, we took no account of it, since it seemed to have no bearing on our own purpose.

SCALIGER.

^a If this were observed at alternate syzygies, the months would indeed have come out alternately full and hollow, as the reckoning of the civil lunar year requires. But another obstacle is raised. Since the pairing of the two epacts X X V, X X I I I I has been thrown together onto one and the same day, 5 April, then whenever it happens that both epacts are found within the same cycle, the new moon will necessarily fall twice on the same day within a single cycle — which is absurd. From the year 1900 to the year 2199, epact X X V will be at golden number X V I I, and epact X X I I I I at golden number V I. From the year 3100 to 3399, epact X X V will be at golden number xij, and epact xxiiij at the first golden number. In the year 3800, to the year 4099, epact xxv will agree with golden number xv, and xxiiij with the fourth golden number. Finally, from the year 4500 to the year 4699, epact xxv goes with golden number xviiij, and epact xxiiij with golden number vij. So both epacts, xxv and xxiiij, occur within the same cycle.

CLAVIVS.

^a Here the most learned Scaliger argues entirely correctly. And in fact we reasoned no differently in the *Apologia*, book 2, chapter 3. Of course, the reckoning of the new moons requires this.

SCALIGER.

^a The way that seemed good for remedying this drawback was to join the black epact 25 with epact xxvi. That will have its place whenever the golden number is greater than xi; for then that blackened [*atrata*], extraordinary epact 25 will be taken in place of the ordinary red [*miniata*] xxv — because, as we said, from the year 3100 to the year 3399 epact 25 agrees with golden number xij, and there is no smaller golden number to which that epact could ever belong. For the same reason, whenever the golden number is less than xij, the ordinary red epact xxv is the one to be taken.

CLAVIVS.

^a And the author of the calendar did indeed apply this remedy prudently. The proof is that Scaliger himself, who left this remedy aside in that pairing of epacts 0, 29 of his, has by no means escaped the drawback — as we shall show in its proper place.

SCALIGER.

^b We have treated these matters at some length because the most learned Clavius, in his *Apologia* against Maestlin, explained neither why epact xxix was marked at the Kalends of April in place of xxviii, nor why epact xxiiij rather than any other was dislodged from its own place. Anyone who sets these reckonings of ours against his will easily discover which of the two are the truer.

CLAVIVS.

^b How truly all this is said will be easily grasped by anyone who reads through chapter 3 of book 2 of the *Apologia*, where the reason for this arrangement of the epacts in the calendar is set out — and set out so fully and copiously that Scaliger could have spared himself this labour, had he not wished to take on pointless work and to grow great at other men's expense.

SCALIGER.

Again, whenever the epact of the first golden number is one, then epact xix coincides with the last golden number, xix. That is why the black epact 19 was thrown in with x x on the last day of December, so as to have a place whenever the first golden number is one. For then, as has already been said, epact x i x coincides with golden number x i x. One, as we said, is the first golden number in the following year, marked at x x x January. From the Kalends of December to 30

January there are three syzygies. And since epact x i x is the one running when one is the first number, while no epact x i x is marked in the calendar after the Kalends of December down to 30 January, the black epact 19 must therefore be taken in place of x x, so that two syzygies do not pass without an epact. This will not happen except in the years 1595, 1614, 1633, 1652, 1671, 1690. For many thousands of years would have to be waited out before the first golden number is one again.

CLAVIVS.

Truly, if he had placed that black epact 19 which he so despises on the last day of February, he would not have run into such rough going. As it is, he is forced to set up a lunation of 59 days, as we shall show below; and no one fails to see how inept — indeed how monstrous — that is.

SCALIGER.

Once these points had been noted, there remained the table of the equation of the epacts, which records the changes of the epacts according to their μετέμπτώσεις [Greek: *metemptōseis*, "metemptoses" — the successive shifts of the epact; the print appears to carry accents on both ε and ω, the standard form being μετεμπτώσεις] in the centuries of the years of Christ. The starting point was taken from golden number iij, which in the times of the Council of Nicaea was to be en

—tered at the Kalends of January. And so, whenever the current golden number has to be carried across from the table of the equation into the table of the perpetual cycle of the epacts, one must go back to the third cell from the cell indicated, so as to have the first golden number current in the year proposed. ^a We, however, shall add a more expeditious method of the epacts than the Lilian one — one which shows the first number immediately, without that going-back. In the appended table of the equation of the epacts, from the first year of Christ to 320 (which is the century of the Council of Nicaea), the epact of the first golden number will be 7.

[Margin: a]

| | j | | | | | | | | |

CLAVIVS.

^a This is really excellent — that Scaliger, a man of the greatest ingenuity, should press our own work on us as his! For this method of the epacts is ours as well, and it is set out lucidly in book 2, chapter 4, of the *Apologia*, where the reason is also given why we put that other method ahead of this one. We preferred to begin from golden number *ijj* rather than from *j*, so that it should be plain that the little table of the perpetual cycle of the epacts was excerpted from the expanded table, and so that the characters set above the epacts in the perpetual cycle should indicate the age of the moon in the Martyrology.

SCALIGER.

Since in the Julian year the change of the epacts, as we have shown, ^a takes place after 304 years — but Lilius, disregarding the 4, supposed that the change in the Julian epact occurs every 300 years.

[Margin: a]

CLAVIVS.

^a But we showed above that it takes place after 312 $\frac{1}{2}$ years. And Lilius does not disregard those 12 $\frac{1}{2}$ years that go beyond the three centuries: he calls them back into the reckoning once they have filled out a new century, at which point we direct that 400 years be observed in place of 300. We followed this method as being the more accessible and the further removed from error, as we taught in chapter 4 of book 2 of the *Apologia*. The whole matter will be demonstrated more plainly by the calculation we shall append shortly.

SCALIGER.

From 320 to 500, then, the change will occur — after 300 years, that is. And because from 320 to 500 there are fewer than 300 years, it will be carried on as far as 800, from which another change will begin. And because from 320 to 800 there are more than twice 300 years, and yet only two changes have been made, the 8th and the 9th, this will be made good in the year 1100. And so on thereafter, until in the year 1400 the epact of the first golden number will be xi. It stays so until the year 1582, in which, with 10 days removed, in place of epact xi there will be epact 1 — which holds today and will hold until the year 1700, in which, after 300 years, the epact ought to have increased in the Julian year; but because of the omission of the leap day in the year 1700 it will be 0 instead of 1. It will be the same in the years that follow.

Suppose, then, I want to know the epact of a year of Christ after the removal of the 10 days. Take from the little table of equation the year of Christ proposed, if it is found there exactly; otherwise take the next lower year. The number placed under it will be the character of the first golden number; and if that character is counted out in the perpetual cycle of the epacts and the count ends at the number of the current year of the cycle, it will show the epact of the year proposed.

Suppose I want to know the epact of the year of Christ 1700. Since that year is found exactly in the table of equation, the character 0 set beneath it will be the first number of that year 1700. And since the golden number is x, then in the

perpetual cycle, if you count ten onward starting from epact 0, you will end at ix, which is the epact of the proposed year 1700.

Again, suppose I want to know the epact of the year 1914. Since that number is not found exactly in the little table of equation, the character 29, under the next lower year 1900, will be the first golden number of the proposed year 1914. And since golden number xv is running, in the cycle, counting fifteen from xxix, the count ends at iij, which is the epact of the proposed year 1914.^a This method is better than Lilius's — however ignorantly some Possevinus may be able to carp at it.

[Margin: a]

CLAVIVS.

^a As if this method too were not Lilius's! And as if we had not, for definite reasons, put it second to that other one, as we showed above. So there is no need to drag Possevinus in. He is a devout man and learned enough, and I do not know why Scaliger should have singled him out to run at so often in sport and mockery.

SCALIGER.

^b For what is the point of that stepping back to the third cell, if the work can be done more briefly? This is the scheme of Lilius, the author of this form; this is the method of that Year of his. Now I shall say what there is in it that the commonwealth has an interest in correcting.

[Margin: b]

CLAVIVS.

That stepping back is neither useless nor laborious, as we showed in book 2, chapter 4 of the *Apologia*, and indicated a little earlier.

SCALIGER.

OECONOMIAE EXEMPTILIVM bissextorum elenchus & castigatio.

[An examination and correction of the arrangement of the removable leap days.]

^a A flaw of no small size affects the four-hundred-year period [*periodus tetracosietERICA*] in the arrangement of the three leap days to be rejected, in that the rejection is hurried on before its proper time. For although the leap day ought to be taken away at the end of 132 years, it is taken away at the end of 100; and what was to be done in 400 years is anticipated at 300.

[Margin: a]

CLAVIVS.

^a There is no flaw at all, provided the omission of the leap days is fixed at the centesimal years, as we prescribe. On this plan the equinox is in fact kept in its own place more accurately than if the intercalary day were dropped now in the 132nd year, now in the 136th, as Scaliger would have it. All of this we set out at length in book 1, chapter 5 of the *Apologia* — which is why I am so astonished that a man of such ingenuity should be so forgetful as to sell off as his own this method of intercalating now at year 132, now at 136, along with a great many other things we ourselves presented in that same *Apologia*.

SCALIGER.

^b Again: what is done in a hundred years must wait two hundred years to be done again. For in the year of Christ 1900 the leap day is to be omitted; but in the year 2000 it is kept; in 2100 it is omitted once more. From 1900, the year of the earlier omission, to 2100, the year of the later one, is 200 years. And since an omission is to be made in 1800 as well, in one stretch of two hundred years there are two omissions, and in another two hundred only one.

[Margin: b]

CLAVIVS.

^b Reason compels it to be so, as is explained in that same chapter 5 of book 1 of the *Apologia*. The point is this: since three leap days have to be omitted within a span of 400 years, and these have already been passed over in the preceding 300 years, no further day ought to be omitted in the 400th year. The leap day must therefore be kept at that point, so as to compensate for what was taken away in excess during the 300 years. And that is restored precisely by removing no day in the 400th year.

SCALIGER.

^b What sort of inequality is this? In one century the leap day is omitted, in another it is kept. The learned Clavius has wanted to excuse this, and yet he has convinced no one — no one, at least, who sees anything at all in the matter.

[Margin: b]

CLAVIVS.

^b Consider instead whether it is not fairness, since a compensation is made in the way described — and indeed we have so persuaded everyone else of this

that no one, so far as we know at least, has as yet dared to disapprove of it apart from Scaliger. And in fact no one will be able to disapprove of it who does not wish both to be, and to be reckoned, an unjust judge of things.

SCALIGER.

^c Is there any reason at all, then, why we should not correct this?

CLAVIVS.

^c None — supposing it is fair to castigate and correct what is right. But let us see what this correction of yours finally comes to.

SCALIGER.

^d In 400 years there are twice 132 and once 136. Therefore let the leap day be omitted in the years 132, 264, 400. In that way no absurdity or inequality will be incurred — the sort that cannot be avoided when the leap day is rushed forward.

CLAVIVS.

^d But look how unfair this correction of yours is, and how you spoil the very thing you mean to correct. The inequality we introduce is an equitable one: it lets the equinox retreat from 21 March as little as possible. Our plan never allows the equinox to be a whole day away from its own place — a point about which the most exacting Scaliger gives himself no trouble. Add to this that even if that omission at the centesimal years were less accurate, it would still seem preferable to his, because it is far better suited to the ordinary person's grasp and memory. All of this we explained more fully in the *Apologia*, book 1, chapter 5.

SCALIGER.

In 132 years there are three complete solar cycles together with twenty years of an unfinished fourth; in 136 there are the same number of complete solar cycles together with 24 years of a fourth begun.^a Therefore the ancient solar cycle, which is broken four times in the Lilian form, will be broken only three times in this one. For the dominical letter of the first year of the period will be G, the letter of the year 133 D, the letter of the year 265 A. It will therefore be easier to keep three letters, G, D, A, than four, G, B, D, F. So, since in the year of Christ 1601 the solar cycle ought to begin from the letter G, in the year 1733 it will begin from the letter D, and in the year 1865 from the letter A. Hence, when the period comes round again, in the year 2001 the cycle will start from the letter G as before, and so on without end. On this plan the omission of the leap day will not be anticipated before its time.

[Margin: a]

CLAVIVS.

^a Your reasoning fails you, my dear Scaliger, while you hug that argument of yours as though it were your own little daughter. Since the solar cycle is never broken except when a leap day is omitted, who does not see that on our equation it is broken only three times, since in 400 years only three days are taken out — exactly as many as are taken out in your own method? You will grasp this more plainly if you look more carefully — not, I say, at our table set in the Gregorian Calendar, but at that very table of yours which you have printed in this little book. For you will see that only these three letters, B, D, F, are to be kept, and not four, G, B, D, F, as you wrongly suppose.

SCALIGER.

^b This flaw in the Lilian method — how many[?] other flaws it can go on to propagate in the reckonings of the equinox and of the Moon! These we leave to others to sift out.

[Margin: b]

CLAVIVS.

^b What you call a flaw in the Lilian method, I have shown to be no flaw at all. I am waiting for you to show what other flaws can be propagated from it. Meanwhile we for our part shall show — and we shall show it some little way further on —

how many flaws lie hidden in Scaliger's method, and how many others can be propagated from it.

SCALIGER.

EPACTARVM PERPETVO PER XI. PROGREDIENTIVM ELENCHVS.

[An examination of the epacts advancing perpetually by 11.]

^c Even moderately learned men know that the epacts, taken by the elevenfold increment, are sometimes greater and sometimes less than the computation [Greek: Ψηφοφορίαν (psēphophorian, "reckoning, computation")] of the mean motion of the Moon warrants. And so, if in this year the current epact indicates the new moons in the Calendar correctly, it may well happen that the epact of the following year does not do so reliably, since it has been arrived at by the perpetual addition of 11. Sometimes, then, the epacts run ahead of the new moons, and sometimes they fail to reach them.

[Margin: c]

CLAVIVS.

^c This is said perfectly truly. But how does it hang together that the very man who shows the epacts to be unequal should then charge the Gregorian Calendar with not always indicating the new moons and the fourteenth days exactly? Plainly, in order to set up a civil year, the Church is obliged to follow some fixed and generally accessible scheme of epacts. It therefore brings in epacts that advance by elezens — except that after golden number 19 it adds 12 rather than 11 to the epact, whatever that epact may be, so that the epact concurring with golden number 1 may be formed. This is set out at greater length in book 2, chapter 4 of the *Apologia*. I am therefore quite astonished that a matter so essential to the reckoning of the new moons could have slipped past the acumen of that most learned man Scaliger.

SCALIGER.

Since, then, the epacts were established of old by the Church chiefly for this purpose, that they should show the paschal full moons,^d it will be no light fault if we follow the ordinary progression of the epacts.

[Margin: d]

CLAVIVS.

^d But see how light the fault is in our scheme of epacts, and how seldom it occurs, even though they advance by elevens, as we have said. In three thousand whole years the fourteenth moon is shown in the Gregorian Calendar earlier than it should be scarcely once or twice. You will grant that this is a fault deserving pardon, since no cycle can avoid every inconvenience — and the more so when I go on to show how gravely and how often the fault is committed on your own scheme.

SCALIGER.

For they often run ahead of the full moon by one day,^c which the Latins call the fourteenth Moon, and the Greek authors of the Computus call now the [Greek: τεσσαρεσκαίδεκάτην (tessareskaidekatēn, "the fourteenth")], now the [Greek: πανσέληνον (panselēnon, "full moon")]. It is astonishing how much confusion the Latin authors make on this point, since they now run the fourteenth together with the full moon and now distinguish the two.

[Margin: c]

CLAVIVS.

^c If you ask why the Latins and the Greeks sometimes call the paschal term the fourteenth Moon and sometimes the full moon, the reason is this: the end of the fourteenth is the beginning of the fifteenth, that is, of the full moon — the day on which Easter is celebrated if it is a Sunday. This holds all the more because on the fourteenth day the Moon looks full, exactly as it does on the fifteenth. Besides, when they are looking for the paschal seat, they count the fourteenth moon from the day of the new moon that the cycle supplies, but in such a way that the day of the new moon is itself counted in. And they are not in the least troubled whether that day falls on the full moon itself, or comes one day before it (which they prefer), or one day after — as we showed abundantly in chapter 6 of book 2 of the *Apologia*.

SCALIGER.

For if the paschal term is the fourteenth Moon, and that is not the full moon: suppose, by way of example, that the fourteenth Moon falls on a Saturday. Then, according to the Canon, the Christian Easter will be celebrated on the Sunday following. But that day is the full moon. Therefore Easter will be celebrated at the

full moon,^a contrary to the Canon — given that the fourteenth is not the full moon. For in that case the fifteenth must be the full moon.

[Margin: a]

CLAVIVS.

^a And what Canon, pray, forbids Easter to be celebrated at the full moon? For my part I can find no such Canon. What I do find is that the Venerable Bede, Paul of Middelburg [Paulus Middelburgensis], and other most learned authors on the ecclesiastical Computus teach that Easter is never more correctly celebrated than at the full moon, that is, on Luna XV — since the remaining days from the full moon to Luna xxj are added on account of the Sunday, which does not always fall on Luna XV. We have discussed this at length in chapter 3 of book 1 of the *Apologia* and in chapter 6 of book 2. It remains, then, for Scaliger to show us where this Canon of his is hiding.

SCALIGER.

Therefore the fourteenth of the Christians is the full moon,^b and for that reason the fourteenth day marked by the epact in the old ecclesiastical Calendar is the paschal full moon. The author of the new year followed the same line: his epacts, as he himself pointed out, mark the new moons one day later, so that the fourteenth reckoned from them falls on the full moon.

[Margin: b]

CLAVIVS.

^b In fact this is not done deliberately; it merely happens by chance that the fourteenth of the Calendar falls on the full moon — the cause being the postponement of the new moons. And that postponement is not pointless: it secures for us that the paschal fourteenth does not run two days ahead of the full moon. That is what the author of the new year was after — not that the fourteenth reckoned from the new moon should fall on the full moon, although that does sometimes happen by chance.

SCALIGER.

^c Therefore the Lilian fourteenth is the fifteenth from the new moon, and so the full moon.

[Margin: c]

CLAVIVS.

^c The Lilian fourteenth can indeed sometimes be the fifteenth from the *true* new moon, as we said just now; but not from the new moon of the cycle, which is the hinge on which the matter turns. And so it will never be the full moon of the cycle.

SCALIGER.

I cannot therefore wonder enough that the most learned mathematician Christoph Clavius ^a not only takes a different view, but even holds that the Christian Easter may lawfully be celebrated at the full moon.

[Margin: a]

CLAVIVS.

^a Let the most learned mathematician Joseph Scaliger [Josephus Justus Scaliger] stop wondering; for I cannot but take a different view,

— sentire, since I have no wish to depart from the Canons and the Decrees of the Fathers, and since I see that *the Christian Easter is not only permitted to be celebrated at the full moon, but is even customarily so celebrated* — which I shall demonstrate not long hereafter.

SCALIGER.

^b WHO would grant him that? The fourteenth, he says, is the one that is counted inclusively from the new moon [Neomenia].

[Margin: b]

CLAVIVS.

^b You ask, my dear Scaliger? The Canons grant it; the Decrees of the Fathers grant it; every author on the computus grants it — for they all regularly count the fourteenth from the new moon of the cycle.

SCALIGER.

^c Why, then, is the Lilian fourteenth a fifteenth — and that on the testimony of Lilius himself, as we touched on a little earlier?

[Margin: c]

CLAVIVS.

^c I have already said that this happens by chance, out of the postponement of the new moons, a device that avoids greater drawbacks. And what Scaliger asserts is not true, namely that the Lilian fourteenth is always a fifteenth.

SCALIGER.

^d Why do the Greeks call the paschal term πανσέληνον [Greek: pansélēnon, "full moon"]?

[Margin: d]

CLAVIVS.

^d Because it stands only a little way from the full moon, as we have said.

SCALIGER.

^e Why is the fourteenth of the old Calendar the full moon that suited the age in which the epacts were devised and set beside the Calendar? Nobody denies that the Dionysian fourteenths, which the Church used down to the year 1583, are the ones that fitted the time of the Council of Nicaea — which Clavius himself also admits.

[Margin: e]

CLAVIVS.

^e You take this up as though it were true and invariable, and not rather accidental and often false. Just how far that is so can be seen from Book 2, chapter 6, of the *Apologia*, page 261. There it is plain enough that, in the old Calendar issued after the Council of Nicaea, from that time down to the year 495 the paschal fourteenth ran ahead of the full moon by nearly two days on ten occasions — as is gathered from the placement of the golden numbers and from the calculation of the full moons — which was not lawful; and that for the most part it ran ahead by a single day, which is what the Canons required. How, then, do you dare to say that the fourteenths of the moon around the time of the Council of Nicaea were full moons? And so that you may see, not merely in your mind but with your own eyes, that you assert this falsely — that the fourteenths of the moon around the time of the Council of Nicaea fell on the full moon — look at these nineteen years in the table set out below. You will find in them that, although they are nearly a hundred years distant from the Council of Nicaea, the fourteenth of the moon

counted from the new moon of the cycle never fell on the full moon, but always ran ahead of it by nearly two whole days — bissextile years excepted, in which the fourteenths of the moon of the cycle run ahead of the full moons by one day only, because in those years the fourteenths of the moon stand further from the new moons in the heavens.

| Anni Domini | 418 | 419 | 420 | 421 | 422 | 423 | 424 |

| Plenil. med. | 1.4 | 21.13 | 9.11 | 29.20 | 16.17 |

Table headings, rendered: *Anni Domini* — Years of the Lord; *Aur. num.* — golden number [aureus numerus]; *Luna xiiij.* — the fourteenth of the moon, with A = April and M = March; *Plenil. med.* — mean full moon [plenilunium medium], set as D. H = day and hour. The third panel's stub-head is printed in the singular, *Anno Domini*, where the first two read *Anni Domini*; its last two column-pairs are ruled but blank.

SCALIGER.

^a THE year of Christ 429 is distant from the Council of Nicaea by a hundred years only, and over that interval there is no anticipation of the moon that the senses could detect. In that year of Christ 429 the paschal term, that is the Dionysian

fourteenth, fell on the fourth of April. Therefore 304 years before that year — that is, in the year 125 — the fourteenth will fall on the fifth of the same month, since in 304 years there occurs one anticipation of the moon [Greek: προέμπτωσις (proémp̄tōsis, "anticipation," the moon's running ahead of the reckoning)]. But in the year of Christ 125, which was the year 872 of Nabonassar, an eclipse of the moon took place on the 17th of Pachon completed — that is, on 4 April, at the 8th hour after midday at Alexandria.

[Margin: a]

CLAVIVS.

^a What is assumed at this point is no truer than the rest. For if you look to the mean motion, which the Church follows rather than the true — as we showed in the *Apologia* — in the year 429 the full moon fell on 5 April, that is, on the 4th day, at hour 13 and somewhat more after midday, as is clear from the table immediately above. Accordingly the fourteenth of the moon, falling on the 4th day, ran ahead of the full moon by nearly a day, as is proper. Again, in the year 125 the mean full moon fell on 6 April — that is, on the 5th day, at hour 12½ after midday. Therefore the fourteenth of the moon, falling on the 5th day, runs ahead of the full moon by nearly a day, which agrees with the Canons. In these years, then, the fourteenth was not the full moon, which is what Scaliger takes for certain.

SCALIGER.

^b LOOK — an eclipse of the moon falling at the beginning of the fourteenth.

[Margin: b]

CLAVIVS.

^b Suppose the eclipse of the moon did fall at the beginning of the fourteenth, that is, at the true full moon. I shall readily grant you what you want, provided you grant me in return what must be so: that the mean full moon then occurred *after* the fourteenth of the moon of the cycle, as we have said. That is enough for us.

SCALIGER.

^c Therefore the fourteenth of the Christians is the full moon.

[Margin: c]

CLAVIVS.

^c How much more correctly you would draw the conclusion this way: therefore the fourteenth of the moon is *sometimes* the full moon. For who would accept this inference — the fourteenth of the moon of the cycle sometimes falls on the full moon, or on the 15th of the moon; therefore the fourteenth is the full moon? What you want would follow only if the fourteenth of the moon always coincided with the full moon; and that has neither been proved nor can be proved.

SCALIGER.

^a AGAIN, in the year of Christ 59 the sun was eclipsed on 30 April, on Pliny's testimony. The paschal term of that year ought to have been on the 14th of April; for 304 years later it fell on the 13th of the same month.

[Margin: a]

CLAVIVS.

^a I say nothing of the fact that nothing at all had yet been settled about the celebration of Easter in the year of Christ 59, since the matter first began to be debated nearly a hundred years later, under Pope Pius. What I do say is this. In the year of Christ 59 the mean full moon — as is clear from the tables we set out in the *Apologia*, Book 2, chapter 6 — fell on 15 April at hour 13½ after midday, which must be assigned to the 16th day. So the paschal term of that year, falling on the 14th day, ran ahead of the full moon by almost two days. Again, in the year 363 — that is, 304 years later — the mean full moon fell on 14 April at hour 14 after midday, which is to say on the 15th day. So the fourteenth of the moon, which in that year fell on the 13th day, once again ran ahead of the full moon by nearly two days. In these years, then, 59 and 363, the fourteenth of the moon did not fall on the full moon, as you maintain, but ran ahead of it by nearly two days.

SCALIGER.

THEREFORE, if the paschal term is the fourteenth of the moon, the full moon fell on 15 April, and from it to the eclipse there are only 14 days — ^b which is absurd.

[Margin: b]

CLAVIVS.

^b See whether it is not more absurd to raise an objection where none holds. If you study the ephemerides more carefully, you will certainly find that it is not at all

rare for 16 days to pass between a new moon and the full moon that follows it, and for the full moon then to stand 14 days from the eclipse, that is, from the new moon that comes next. Nor is that surprising: the reverse often happens as well. Consider — to take an example close at hand — the new moon of February 1596. By the ephemerides of Ioannes Antonius Maginus [Giovanni Antonio Magini] it fell on the 27th day, at hour 15 after midday; the full moon, on the other hand, on 14 March at half an hour before midday. The next new moon after that will be on 28 March, at about hour 8 after midday. Do you not see that the full moon stands nearly 16 days from the new moon before it, but only 14 from the one that follows?

SCALIGER.

^c Therefore the full moon immediately preceding fell towards the end of the fourteenth. The fourteenth of the Christians is the full moon.

[Margin: c]

CLAVIVS.

^c On the contrary, the mean full moon, as was said a little earlier, fell on 15 April at hour 13 after midday. The fourteenth of the moon, therefore, falling on the 14th day, is not the full moon.

SCALIGER.

BUT let it be as Clavius will have it. ^a On this showing there will be no error in the paschal celebration of the year 1598; for, as he himself maintains, the Christian Easter can be celebrated even on the very day of the full moon.

CLAVIVS.

^a I will even help you out. Not only is there no error in the celebration of Easter in the year 1598, since it is celebrated at the mean full moon by the prescription of the Canons: it was Maestlin [Michael Mästlin] and a number of others, who supposed there was an error, who went wrong — as I showed in Book 2, chapter 6, of the *Apologia*.

SCALIGER.

^b WHY, then, does he admit that no remedy can be found for this drawback, because of the uniform series of the epacts, which very often fail to keep pace with the new moons?

[Margin: b]

CLAVIVS.

^b You take this in a different sense from the one in which I said it. I have certainly never said that the Easter of the year 1598 is unlawful. What I did say was that no remedy can be applied without Easter's being celebrated occasionally — though rarely — on the fourteenth of the moon, before the full moon; and that does not apply to the year 1598 at all.

SCALIGER.

FOR if in the year 1598 Easter is to be celebrated at the full moon — and Clavius's new Canon ^c allows that this may be done.

[Margin: c]

CLAVIVS.

^c Say rather that the ancient canon of the Popes, of the Councils, and of those who have written on the right celebration of Easter allows it.

SCALIGER.

^d WHAT need is there, then, to excuse [?] what is perfectly in order?

[Margin: d]

CLAVIVS.

^d Where did I excuse anything? Was it when I demonstrated against Maestlin that it is lawful? But defending is one thing, excusing another.

SCALIGER.

^e CLAVIUS would certainly have served himself better if he had not published the sixth chapter of his second book.

CLAVIVS.

^e Scaliger would certainly have served himself better if he had left that sixth chapter alone, since it contains nothing whatever but the teaching of the Fathers, of the councils, and of the authors on the computus, and besides these the unbroken practice of the Catholic Church in celebrating Easter.

[Margin: e]

SCALIGER.

IN it he has said a great deal ^a that he will convince no one of who has even a little understanding of these matters.

[Margin: a]

CLAVIVS.

^a But I have already convinced of these things every kingdom and province that follows the authority of the Roman Pontiff. Nor has any one of those [recte: *qui*, printed *quæ*] who are versed in the Canons of the Fathers, in the councils, and in the ecclesiastical computus dared to reject any part of them — and Scaliger himself, who brings nothing forward against them, is proof enough of that.

SCALIGER.

THEREFORE, however justly he may have criticized Maestlin on other points, on this one he does him an injustice when he grows angry with him for having supposed that the fourteenth of the Christians is the full moon.

CLAVIVS.

^b Scaliger would not acknowledge this as an injustice were it not that, through their partnership in the error, the criticism of Maestlin reaches him as well. And in this matter I am not so much doing Maestlin an injustice as vindicating the Gregorian Calendar from the injustice he does it. For he, like Scaliger, maintains — against the practice of the Church and the decrees of the Fathers — that the fourteenth of the moon is the full moon, and consequently that Easter cannot be celebrated at the full moon.

SCALIGER.

BUT let us hear Clavius himself, in the fourth chapter of the same book: *The new moons of the golden number, around the year of the Lord 500 [?], fell later than those in the heavens, and will therefore be better suited to the use of the Church.* Therefore, most learned Clavius, the fourteenth counted from the epact was the fifteenth from the new moon, and so the full moon. I take you yourself as judge: whether everything you said in the whole of chapter six is not far from the truth, and whether you have not wrongly accused Maestlin.

CLAVIVS.

^c Turn yourself this way and that as you please, most learned Scaliger: you will never make the fourteenth be the full moon. I have said many times already that we postponed the new moons deliberately, so as to guard against the fourteenth of the moon running two days ahead of the full moon. That is the reason why the fourteenth of the moon sometimes coincides with the full moon, although for the most part it runs ahead of it. What sort of conclusion, then, is this of yours — the new moons have been postponed, therefore the fourteenth of the moon is a fifteenth? For if it ever happens that the fourteenth is a fifteenth, it happens by accident, on account of the epacts or the golden number, and not by design, nor because it has been so ordained. Listen to Bede [Bede], Book 5 of the *Ecclesiastical History of the English People*, chapter 22: *If, then, it could be brought about*, he says, *that the Lord's day always fell on the fifteenth day of the first month — that is, on Luna xv. — we could always celebrate Easter at one and the same time*. Here I take you yourself for arbiter, provided you will show yourself fair: whether everything I said in the whole of chapter 6 is not true, and whether I have not deservedly accused Maestlin — seeing that it all agrees with the Canons and with the writers on the computus, whom Maestlin opposes.

SCALIGER.

[Margin: a]

^a LET every one of the most ancient computus-writers be examined — Greek, Latin, Syriac, Arabic. *In all of them the Paschal term is the full moon.*

CLAVIVS.

^a I have in fact examined every one I could lay hands on, and I find that they all teach this: that Easter is to be celebrated after Luna xiiij. of the lunar cycle, whether that day is the full moon, or immediately precedes or follows it. Their one concern is that it should not be celebrated before the full moon, so far as that can be managed. And if any writers on the computus do report — as they seldom do — that the Paschal term is the full moon, they say so because Luna xiiij. is the beginning of the full moon, even though the fourteenth day is counted from the new moon.

SCALIGER.

[Margin: b]

^b *Argyros [Isaac Argyros] calls the Paschal term τὸ ἰϋδαϊκὸν πάσχα [Greek: to ioudaikon pascha, "the Jewish Passover"; the ou is set as a single ligature sort] κ πανσεληνιακὴν συζυγίαν [Greek: kai panselēniakēn syzygian, "and the full-moon syzygy"; terminal -ην set as a ligature sort. The sort standing before πανσεληνιακὴν is the κ kai-compendium (kappa-body with a descending tail and a trailing raised comma), expansion καί].*

CLAVIVS.

^b *Argyros puts it well enough, provided he has a good interpreter. He calls the Paschal term the full moon because the fourteenth of the moon differs little from the full moon; or else because in his own day (just as in ours, before the Calendar was corrected) Luna xiiij. always came *after* the full moon — for between the Council and his time the moon had run ahead of its place by nearly three days.*

SCALIGER.

[Margin: c]

^c *Christ rose after the full moon, namely on the sixteenth day of Nisan.*

CLAVIVS.

^c *I am surprised this slipped from Scaliger's pen, for it contains an obvious error — though it does not bear on the question. If Christ was crucified at the full moon itself (as Dionysius the Areopagite testifies, and as everyone agrees), that is, on Luna xv., how can it be that, having died on the fifteenth of the moon, he rose on the sixteenth? Unless perhaps Scaliger supposes that Christ rose the day after he died — that is, on the Sabbath.*

SCALIGER.

[Margin: d]

^d *That is why the Sunday after the full moon is prescribed for celebrating πάσχα ἀναστάσιμον [Greek: pascha anastasimon, "the Paschal feast of the Resurrection"; στ set as a ligature sort].*

CLAVIVS.

^d *You take it wrongly, Scaliger. Easter is prescribed to be celebrated on the Sunday after Luna xiiij., not after the full moon. That is plain enough from the decrees of Pius, Victor, and the other Popes, and from those of the councils, and I set it out in the *Apologia*.*

SCALIGER.

[Margin: a]

^a *For the τεσσαρεσκαδεκα[?]ται [Greek: tessareskaideka[?]tai, "Quartodecimans"; the syllable after -δεκα- is set as a single circumflexed ligature sort (apparently τῖ) that I cannot resolve] erred in two ways: both in celebrating at the full moon, and in not celebrating on a Sunday — that is, whenever the full moon fell on another weekday.*

CLAVIVS.

^a The Quartodecimans erred because they celebrated Easter on Luna xiiij., not at the full moon — except when the Luna xiiij. indicated by the cycle happened to coincide with the full moon, which around the time of the Council of Nicaea happened very rarely indeed. Had they celebrated Easter at the full moon, or on Luna xv. as Scaliger will have it, they would have been called πανσέληνῖται [Greek: panselēnitai, "full-mooners"; printed with an acute on the ε and a circumflex on the ι] — that is, *pleniluniani* — or Quintodecimans; yet no such name is found anywhere.

SCALIGER.

[Margin: b]

^b *The Christians' fourteenth, therefore, is the full moon, whatever the learned Clavius may urge against it. It will accordingly be the fifteenth from the new moon — on the testimony of Clavius himself and of Lilius. What I assert is this: that the fifteenth from the new moon which the Church calls the fourteenth is at one time a fifteenth from the new moon and at another a fourteenth; and this because of the even advance of the epacts by xi. — which Clavius too admits in his own Apologia.*

CLAVIVS.

^b He comes round to the same point, but it has been refuted sufficiently above. That the fourteenth of the cycle is sometimes a fifteenth from the true new moon in the heavens happens because the cycle's new moons were postponed — and it does not happen so often, since for the most part the fourteenth runs only one day ahead of the full moon.

SCALIGER.

[Margin: c]

^c *But that fault ought to have been cured — that is, the addition of eleven should not always have been followed in finding the epact.*

CLAVIVS.

^c As though it were not the part of a wise physician to leave a lighter ill alone when it cannot be cured without a graver one! Had we chosen to cure that fault, and not always to follow the addition of eleven in finding the epact, we should have thrown everything into confusion. For by the Church's practice the rules put before the people must be easy and uniform, so that they do not mislead those who have to use them.

SCALIGER.

Let us suppose, as we did in the case of the solar period, that the Lilian form had held good from the beginning of the years of Christ; and, starting from the year of Christ 1577, which is the Jewish year 5337, let us set up a nineteen-year lunar cycle with the Jewish new moons added — those new moons whose full moons do not fall before 21 March Lilian. Against these new moons the weekday is set out in the Jewish manner, and it shifts whenever the hours that follow have reached 18. We have also added the Lilian Dominical letter, to mark the epoch of the new moon in the Calendar, as you have it in the table set out below.

Column headings, translated: *Lineæ Cycli* = lines of the cycle; *Anni Christi* = years of Christ; *Litera Dom. Liliana* = Lilian Dominical letter; *Neomeniæ Iudaicæ* = the Jewish new moon, given as *Feria* (weekday), *Horæ* (hours), and *Scrup. 1080* (scruples, 1080ths of an hour); *Menses Liliani* = the Lilian months; *Epactæ Neomeniarū* = epacts of the new moons.

CLAVIVS.

^a What have the Jews to do with Scaliger? Do not get involved with the Jews, my dear Joseph. They are always devising tricks and deceptions. Believe me, they will

throw dust in your eyes, and those Jewish new moons will drive you into error. You will feel it soon enough, when you see that your table is faulty on that account and falls apart.

SCALIGER.

In this table you have, first, the line of the years of the golden number, from the year of Christ 1577 to the year 1595. Next comes the Lilian Dominical letter. In the fourth place is the Jewish new moon, which is always that of Nisan, except in years 3 and 11, in which Adar is taken for Nisan, because its full moon falls after xx. March Lilian. The first number of the Jewish new moon is the weekday; the second, the hours of the moon's mean motion; the third, the remainder in scruples of 1080. An example. In the first year of the cycle — that is, in the year of Christ 1577 — the new moon was 3. 13. 256. The first number shows that the new moon occurred on the third weekday; and since the Dominical letter is B, the third weekday will be the letter D. Accordingly the new moon of the Jewish Nisan falls on 29 March Lilian, at hour 13. 256 from the beginning of the night that precedes the stated day, the 29th. But when the hours have reached 18 or beyond, the weekday is then increased by one. For example, in the second year of the cycle the new moon was 7. 22. 52. Because the hours ran beyond 17. 1079, Feria 7 must therefore be taken as the first weekday — that is, the letter A instead of G; and so always. In the first year of the cycle we see the truth of Lilius's own warning, that the Dionysian epacts, which he reduced by ten, mark the new moons one day late. For the Dionysian epact xj., which today is 1., indicates the new moon one day late, whereas by the true epact the new moon is ij. And therefore — the point we have already touched on — the full moon falls on the Dionysian, or Lilian, fourteenth.

[Margin: a]

CLAVIVS.

^a On this point, my dear Scaliger, I cannot agree with you, however much I should like to. Luna xiiij. of epact j. always falls on 12 April; and the mean full moon in the year 1577 (supposing, as you wish, that the 10 days had already been removed) fell on 12 April at hour 10 after noon — which is day 13. So our fourteenth will genuinely be a fourteenth, not a fifteenth, as you wrongly maintain. Your own fourteenth, of epact ij., falls on the 11th day; and so, if the Lord's day followed, you would be celebrating Easter *before* the full moon — which is absurd even on your own judgment. And do not tell me that it ought to be celebrated after the fifteenth and not after the fourteenth. That this is false I have shown already, and shall show again later at greater length. Then grant that

it is true: on that reckoning, if the day after Luna xv. — that is, 13 April — were a Sunday, you would be celebrating Easter at the full moon, which is the very thing you refuse. You see, then, that our epacts indicate the new moons more correctly for the Church's use than yours do, and that your table of Jewish new moons agrees neither with itself nor with you.

SCALIGER.

But in the second year the epact of the new moon is the same as the Dionysian, as the table shows. The same verdict applies to the third epact. In both epacts, therefore — xij. as much as xxij. — the fourteenth of the moon will not be the full moon. And if in the second and third years of the cycle it had turned out that the Lord's day fell on 2 April and on 22 March, Easter would have been celebrated at the full moon,^b contrary to the Canons.

CLAVIVS.

[Margin: b]

^b You are stuck in the same mud, my dear Joseph. It has been said many times over that by the Canons Easter can perfectly properly be celebrated at the full moon. Produce a single Canon that forbids Easter to be celebrated at the full moon, and you have won.

SCALIGER.

^c *And that is precisely why Clavius rightly excuses the error of the year 1598. For in that year Easter will be celebrated at the full moon, because the epact of that year marks the new moon, and consequently the fourteenth reckoned from the epact is not the full moon. But here Clavius is making excuses for the uniform epacts, by which the new moons themselves cannot always be marked.*

CLAVIVS.

^c In fact I have never excused the Easter of 1598, since I acknowledge no error in it. What I proved, against Maestlin and the other detractors, is that it will be lawfully celebrated on 22 March. So I wonder what put it into your head to say that I was excusing what you had seen me prove. Were you so short of arguments that you had to scrape these together?

And yet you are not unaware how far real coin stands from lupine-seeds.

[Horace, *Epistles* I.7.23]

SCALIGER.

^a *And in doing so he plainly shows that the Dionysian fourteenth is the full moon — the name by which the Greeks call it, πανσέληνον [Greek: panselēnon, "full moon"].*

CLAVIVS.

^a I have said it many times already; but since you make no end of contradicting, it has to be said more often still. We postponed the new moons not so that the fourteenth should fall on the full moon, but so that it should not run two days ahead of it. That fault occurs very frequently in Scaliger's epacts, as I shall show later on.

SCALIGER.

^b *Why, then, does he censure Maestlin for having said that the Christians' fourteenth is the full moon, and that Easter is celebrated contrary to the Canons whenever it is celebrated at the full moon? For that is certainly the force of it.*

CLAVIVS.

^b Please, Joseph, do not take up Maestlin's defence, or the just censure of the case will fall on his advocate. I have said elsewhere already that I was right to censure Maestlin, because he was trying to overturn the canons.

SCALIGER.

[Margin: c]

^c *It is something new, to deny that Easter is not to be celebrated at the full moon.*

CLAVIVS.

^c Consider rather whether it is not new and rash to deny that Easter may be celebrated at the full moon — when the writers on the computus affirm that this is entirely in accordance with the canons (as I showed in the *Apologia*), and the Church has celebrated it so very often. And so that you may stop pestering me by harping on the same point, and so that everyone may see how strangely you deceive yourself here, setting yourself against the canons, against the decrees of the Popes and of the councils, and against the writers on the ecclesiastical computus, I shall make plain what I have just said.

First, then, St Pius, pope and martyr, the tenth from St Peter, laid down around the year of the Lord 159 — as we have it in *de Conser.[?] distinc. 3. cap.* Nosse [Gratian, *De consecratione*, dist. 3, c. Nosse] — that the Lord's Easter is to be celebrated on a Sunday. And it is clear enough that he meant the Sunday which follows Luna xiiij., since he prescribes this on account of the Asians, who used to celebrate Easter on Luna xiiij. itself, without waiting for the Sunday. St Victor, pope and martyr, the fourteenth from St Peter, laid down the same thing more plainly around the year of the Lord 198. His words, in the letter to Theophilus, bishop of Caesarea, which is found at *de Consecr. distinct. 3. cap.* Celebritatem, are these: *That the feast of the holy Pasch ought to be kept on the Lord's day our predecessors have already laid down, and we command that it be solemnly celebrated on that same day; for it is not fitting that the members should differ from the head, or act otherwise. And let that same festival be celebrated from the fourteenth of the moon of the first month up to the twenty-first of the same month.* Next, the same was confirmed and ratified by various councils, and especially by the first council after the Apostles, which was held at Caesarea in Palestine by a good many bishops at the urging of Pope St Victor, and over which Theophilus, bishop of that city, presided — as we read in Eusebius, *Ecclesiastical History* book 5, chapter 24. For there Theophilus, in the synodal letter, states that it was laid down in that council that Easter should be celebrated from Luna xiiij. up to Luna xxj. The same was afterwards confirmed and renewed by the common consent of all in that most famous Council of Nicaea, by the 318 Fathers. I pass over many other councils, so as not to be long. I come to the testimonies of the holy Fathers. The Venerable Bede teaches the same in several places, as I reported in the *Apologia*. Indeed in book 4, chapter 5 of the *Ecclesiastical History* he records that it was decreed in a certain English council, in the king's presence, that Easter should be celebrated on the Sunday after Luna xiiij. of the first month. And it was not merely decreed then: it was also observed in all the centuries that followed. St Isidore [Isidore of Seville], who flourished around the year of the Lord 630, shows the very same in *de Eccles. off.* book 1, chapter 31. Rabanus [Hrabanus Maurus] too, archbishop of Mainz, who was active around the year 855, in *de Instit. cler.* book 2, chapter 39; and Ru-

Rupert, abbot of Deutz [Rupert of Deutz], who flourished around the year 1124, in *de Diuin. off. cap. 27.* of book 6 — all of them confirming the same thing — enumerate every one of the Paschal terms that we see observed in the Church today, and they assert that Easter is to be celebrated on one of the seven days running from Luna xv. inclusive to xxj. inclusive. Furthermore, Guilielmus Durantus [Guillaume Durand], in the *Rationale Diuinorum officiorum* book 8, chapter 12, carefully sets out all 29 Paschal Lunæ xiiij., teaching more than once

— indeed repeatedly — that the first Paschal Luna xiiij. falls on the twelfth day before the Kalends of April and the last on the fourteenth before the Kalends of May, and that Easter must always be celebrated after them. In book 6, chapter 75 as well he states that by the Lord's command Easter is to be celebrated at the full moon, that is, on one of the seven days of the third week. Finally, John of Sacrobosco teaches the same in plain words in his *Computus Ecclesiasticus*; so does Paul of Middelburg, bishop of Fossombrone, in many places of his *Paulina*; so does Johannes Stoeffler [Johannes Stöffler] in his *Calendarium Romanum*; and a great many others besides. Anyone who cares to may read Marcellus Francolinus in his book *de tempore Horarum Canon.*, who in various passages brings forward a great many testimonies proving the same point.

Now observe how complete the agreement among these writers is. In none of them will you find that Easter is to be celebrated on the Sunday after Luna xv. of the first month — always after Luna xiiij. And will anyone really suppose that Scaliger by himself has seen further than all these men together, who from the first beginnings of the infant Church down to our own day preserved with the utmost care a doctrine on the celebration of Easter handed down, as it were, from the Apostles hand to hand? As for Campanus — the one writer on the computus, out of them all, who calls the Paschal fourteenth the full moon — he does so because the end of Luna xiiij., when the Jews were commanded to eat the lamb, is the beginning of Luna xv., that is, of the full moon. The proof is that he then plainly attests and teaches that Easter is to be celebrated on the Sunday after Luna xiiij. counted from the new moon.

BUT in fact all the authorities I have cited are, quite clearly, to be understood of the Luna xiiij. counted from the new moon of the cycle. This is established from the golden number entered in the calendars by Dionysius the Abbot [Dionysius Exiguus], and from the Paschal terms fixed there, all of which fall on the Luna xiiij. reckoned from the golden number of the year proposed. Thus between the golden number xvj., which was set against the eighth day of March, and the 21st of the same month, on which the fourteenth of that golden number falls, you see that 12 days lie between; and that from the 8th inclusive to the 21st inclusive 14 days are counted. The same holds for the remaining golden numbers. Who, then, most ingenious Joseph, has given you the authority to prescribe — by a new custom and practice, which not even the Pope himself would venture to introduce — that 15 days be counted from the new moon of the cycle to the Paschal term? That this runs against the canons, against the decrees of the Popes, and against the doctrine of the Fathers is proved most manifestly by this: since from the Council of Nicaea down to the present time the first Paschal new moon

has been assigned to the eighth day of March, as the unbroken practice of the Church shows, then if Easter had to be celebrated after the Luna xv. reckoned from the new moon, as you would have it, it could never have been celebrated on 22 March — for that day is the fifteenth from that new moon. Nor can you say that the new moon in question should be placed on 7 March: no one ever asserted this, and no golden number was ever attached to the seventh day so as to mark a new moon there. Again, since the last Paschal new moon in the Church's usage has always fallen on 5 April, if fifteen days were to be counted from it, the Paschal term itself would have to be fixed on 19 April, and consequently, if that were a Sunday, Easter would have to be moved to 26 April — which is unheard of and new.

You see, then, that when Luna xiiij. anticipates the full moon and falls on a Sunday, Easter is celebrated by the Church at the full moon itself; and you will find that this was never forbidden — on the contrary, that it was done very often from the Council of Nicaea down to the Gregorian correction. You could easily have learned this too from the old table of movable feasts. For since that table directs Easter to be celebrated on the Dominical letter next following the golden number that marks Luna xiiij., or the Jews' Passover — who does not see that, if the Dominical letter immediately follows the golden number (which happens not infrequently), Easter is celebrated on Luna xv., that is, at the full moon? And so that not the slightest scruple may remain in anyone's mind, and that the whole matter may be clearer than daylight, I have gathered in a table, which I shall append shortly, 175 years in which Easter was celebrated immediately after the Luna xiiij. counted from the new moon. Among these you will find a number of years in which Easter preceded the full moon, especially around the time of the Council of Nicaea — namely the years 326. 330. 346. 350. 370. 394. 441. 475. 495. — as I also pointed out in the *Apologia* book 2, chapter 6. Nor did the Church trouble herself greatly about errors of this kind, whatever they were, although she saw them. Her one precaution was that the canon of the Council should be observed uniformly the world over, the canon by which Easter is prescribed to be celebrated after Luna xiiij. [so printed], even if now and then — though rarely, on account of the arrangement of the cycle — it was kept before the full moon.

From this it follows that the cycle must be so ordered in the Calendar that, so far as it can be managed, the Paschal Lunæ xiiij. anticipate the full moon by one day only, and never by two, except very rarely (since no cycle can avoid it altogether). This our cycle of epacts achieves with the greatest precision, since under it Easter is celebrated before the mean full moon scarcely once or twice in 3000 years — something your Calendar, as we shall say below, is quite unable to achieve, since

your Paschal Lunæ xiiij. very often run ahead of the full moon by two days, and even by three.

BUT so as not to put off any longer what I promised, here for you are the 175 years in which Easter was celebrated on Luna xv. — so that you may see for yourself how rashly you have attacked, with such violence, the constitution of our Paschal reckoning, which you could not shake; and how groundlessly you have argued that it is contrary to the canons, when it rests on the canons above all. And in case you should have doubts about the reliability of this table, it has been put together out of the great Dionysian cycle of 532 years and out of the old table of movable feasts. I have also set beside those same years the corresponding golden numbers and Dominical letters, so that it may be plain to anyone that Easter was indeed celebrated on Luna xv. in accordance with the Canons.

Further, the letter A stands for April, M for March.

Table of the 175 years in which Easter was celebrated on Luna xv. (continues onto the following page). Column heads as printed: *Anni Dom.* (Years of the Lord) | *Aur. Num.* (Golden Number) | *Litera Dom.* (Dominical Letter) | *Pascha.* (Easter). The page sets two such panels side by side; A = April, M = March, per the note on the preceding page. Rules divide the rows into groups of four.

NOR indeed was this peculiar to the Latin, or Western, Church — that it should celebrate Easter immediately after the Luna xiiij. reckoned from the new moon, whether before the correction of the Calendar or after it, provided the day next following is a Sunday. The Eastern Church has kept, and still keeps, the very same custom in perpetuity. This is clear from the tables for finding the movable feasts that the Easterns use, and which Ignatius, Patriarch of Antioch, recently brought to Rome and submitted for inspection to the commission on the Calendar.

Moreover, that the same was done before the Council of Nicaea I can prove on your own testimony, since on the authority of Bishop Hippolytus you rightly affirm that in the year of Christ 222 — which was the first year of the Emperor Alexander, with cycle of the Sun 7 and Dominical letter F, with golden number 14 — Luna xiiij. fell on 13 April, which was a Saturday, and that Easter was celebrated on the following day, the 14th, that is, at the full moon; for in that year the full moon occurred on the 13th, more than 5 hours after noon, and so had to be assigned to the following day, the 14th. This holds all the more since you yourself admit that all this agrees entirely with the canon. And if that is so, then

Easter is not celebrated at the full moon contrary to the canons, as you assert in this *Elenchus* of yours — or else you are certainly inconsistent with yourself.

What of this, too: that in this very year 1595, in which I am writing, Easter was celebrated at the full moon itself, and will be celebrated in the same way again in the years 1599 and 1609? Will you find fault with these cases as well — which lay right before your eyes, and which you nevertheless left untouched? Come now: who does not see that, if Easter could not be celebrated on a Sunday falling at the full moon, that is, on Luna xv., it would have to be celebrated on Luna xxij.? And indeed that if 19 April were a Sunday falling on the Paschal full moon, Easter would have to be deferred both to Luna xxij. and to 26 April? Yet all this is contrary to the Canons, as is plain from what I have said and as I argued at greater length in the *Apologia*. You are therefore wrong by the whole breadth of the sky when you assert that Easter cannot be celebrated at the full moon.

SCALIGER.

[Margin: a]

AGAIN, in year iiij. of the cycle the Epact of the new moon is v., which in the Dionysian and Lillian form is iiij., one day later. ^aTherefore the Lillian — or Dionysian — fourteenth in year iiij. of the cycle is the full moon, since the full moon is the fifteenth from Epact v. Furthermore, you see here that for finding the next Epact it is sometimes necessary to add only 10 to the preceding Epact, whereas the common Epacts advance by a constant addition of xj.: as in the years 2. 6. 9. 11. 14. 17., whose Epacts were propagated by adding 10 to the preceding Epacts; but in the years 4. 8. 15., by adding xij. to the preceding Epacts.

CLAVIVS.

^a AND YET, if you examine the matter more carefully, you will find that our fourteenth rather *precedes* the mean full moon. For our fourteenth falls on 9 April, whereas the full moon falls on that same 9 April at hour 1½ after noon, which is the 10th of April. And you will find, again, that your own fourteenth, which falls on 8 April, runs ahead of the full moon by nearly two days — which is a very grave fault indeed.

SCALIGER.

[Margin: b]

AS FOR the Epact of year xij. having been created by adding xij. to the preceding one — ^bthat came about because of the bissextile day, whose intervention often

defeats the reliability of uniform Epacts. This much alone is established: that this Epact — that of year xij., namely — is produced in due order and correctly by the addition of xij.

CLAVIVS.

[Margin: b]

^b HE IS plainly wrong. For if we wanted to take account of the bissextile day in placing the Epacts in the Calendar, we would confuse the civil year and the ecclesiastical year in an extraordinary way. That is precisely why not even Scaliger himself admitted this manner of placing the Epacts into his own Calendar.

SCALIGER.

[Margin: c]

SINCE, then, matters stand thus, we see ^chow dangerous the method of uniform Epacts is for the celebration of Easter;

CLAVIVS.

ALL that follows from this is what we freely admit anyway: that no cycle of uniform Epacts can be found for the celebration of Easter which avoids error on every side. One must therefore adopt above all the cycle that contains the fewest errors — and we showed in the *Apologia* that ours is such a cycle, as the calculation that follows will make plain.

SCALIGER.

[Margin: d]

^dAND from it arose that most shameful error of the year 1598., which I cannot think why they so confidently confess and conceal at one and the same time.

CLAVIVS.

THIS really is not to be borne. He calls "most shameful" an error that is no error at all, and he charges us with confessing and dissembling at once in a matter which we maintain was rightly done. I have declared before, and I declare now once again, that the Easter of 1598 will be celebrated correctly and according to the Canons — so that everyone may understand that there is no confession and no dissembling underneath it.

SCALIGER.

BUT not even so will the Epacts always remain as they have been set out in the table. For after a number of cycles some of them will be altered and dislodged from their seats, before the rest have moved beyond their own limits. I put this forward in order to point out [Margin: c] the doubtful reliability of uniform Epacts, ^cnot to condemn their use — since the year we use is civil, not astronomical; and for that very reason the Epacts have to be uniform and not astronomical, because otherwise they cannot be suited to ordinary use.

CLAVIVS.

^c NOW at last you seem to be coming back to yourself, my dear Joseph. But look here: if you do not condemn the use of uniform Epacts, you are wasting your labour in harrying our Epacts so fiercely for being fitted to the civil year.

Quo teneam vultus mutantem Protea nodo? [Horace, *Epistles* I.1.90 — "With what knot am I to hold Proteus as he changes his face?"]

A moment ago you were the assailant of uniform Epacts; now, all at once, as though peace had been made, you come forward as their champion; and presently, changing sides again, you will take the unequal Epacts back into partnership. Admit, then, that when you attacked uniform Epacts with all that Jewish apparatus you laboured in vain, and that now, in defending those same Epacts, you stand on the better side. And admit that when, in order to construct your own table of the exact tropical period, you take up the earlier little table of unequal Epacts, you are serving not the public cause but your own. What sort of consistency is that?

SCALIGER.

[Margin: a]

NOW I shall show how the μετάπτωσις [Greek: metaptōsis, "shifting" — the change-over of the Epacts; printed with a πτ ligature sort] of the Epacts comes about in the tropical year; ^abut first let me clear away another error concerning the Lilian year.

CLAVIVS.

^a WATCH what you are doing, Scaliger. So far you have cleared away no error at all from the Lilian year; on the contrary, in the very place where you tried to correct what you took for a mistake, you yourself made a grave mistake. I greatly

fear that in this other one, which you call an error, you will meet the same fortune — or even a worse one.

SCALIGER.

DE ORDINATIONE EPACTARVM IN CALENDARIO. [On the Arrangement of the Epacts in the Calendar.]

[Margin: b]

^b*JUST AS in the omission of the Bissextiles through three consecutive centuries, so too in the arrangement of the Epacts in the Calendar, the author of the new year has blundered laughably.*

CLAVIVS.

[Margin: b]

^b BUT just as we have shown that, in the omission of the bissextiles through three consecutive centuries, the method we proposed is the most convenient for popular use and not at variance with the truth, so — with God's good help — we shall show that the Epacts could not be better arranged in the Calendar than they have been arranged in the Gregorian Calendar. From this it will also be understood that the author of the new year [printed *noni anni*; recte *noui anni*, as in Scaliger's own line above] did not blunder laughably, as Scaliger says,

as Scaliger says; rather, the man who blunders is the one who prefers an inferior method to it — especially since he brings forward nothing new, but offers up as new the very things that we rejected in the *Apologia* as less suitable and less apt to the matter in hand.

SCALIGER.

^c*THE EPACT □ set alongside continuously through each syzygy — that is, the mark □ taken as a single Epact:*

CLAVIVS.

^c AND YET the order of the new moons required precisely this disposition of the Epacts, as I demonstrated in the *Apologia*, lib.2.cap.3. & 6. What is more, I shall show a little further on that the Epacts have been arranged in the Calendar more correctly in that way than they have been by Scaliger.

SCALIGER.

[Margin: b]

^bAND interruptions were devised, which the Greeks call ἑξαίρεσίμους ἡμέρας [Greek: *exhairetismus hēmeras*, "days taken out," excepted days], so that the months should be full and hollow by turns. And that is what is done when, in place of xxv., he names the Epact xxiiij.

CLAVIVS.

^b AS THOUGH we were the first to devise these interruptions! For consider: Julius Caesar, the Alexandrians, the Council of Nicaea, and all the rest who used the nineteen-year cycle — did they not employ these same interruptions? And what of you yourself, who censure them: do you not employ them? — except that, following the Calendar of the *Compendium*, you have put back 0. 29. in place of the Epacts 25. 24., which we repudiated in the *Apologia*. And the natural order does indeed require that in the Calendar a smaller golden number should follow immediately upon a larger one, and not the reverse, a larger upon a smaller. But this order must necessarily be broken in six places, so that the lunar months may be constituted alternately of 30. and 29. days. For that reason the larger number has to be joined immediately to the smaller — which is exactly what we see done in the old Calendar in six months: February, April, June, August, October, and December. And so I do not see why so learned and so ingenious a man should censure in others what he approves in himself, or why he should palm off on us old material, and our own material, as new and his own. For there can be no doubt whether he has read our *Apologia* right through, given that he has hunted from every quarter for an opportunity of carping at it.

SCALIGER.

^aWHAT could be more ridiculous than that?

CLAVIVS.

IT GRIEVES me that such a man, while he wrongly laughs at others, should have given learned men so large an opportunity of laughing at him. For the two Epacts 25. 24., set against the same day, accomplish exactly what those larger golden numbers accomplished which in six places of the Nicene Calendar came immediately after smaller ones — namely, the correct setting-up of the lunar months. This will readily appear if the Epacts are resolved into the golden numbers of the Council of Nicaea, which is what we did in the *Apologia*,

lib.2.cap.4. How, then, can this be ridiculous, unless the Fathers of the Council of Nicaea, Julius Caesar, and the Alexandrians are to be judged ridiculous as well? And that, assuredly, no one will judge, except a man who plays a second Democritus, laughing at everyone and everything and so offering himself to all as a laughing-stock. Nor is even that true from which you snatch your laugh, when you say that we call the Epact 24. in place of Epact 25. For we do not confuse the Epacts: we call 25. the Epact which is 25., and 24. in the same way. Then, sharp fellow that you are, you throw at us an objection that tells against yourself, since you take the Epacts 0. & 29. into a single partnership [contubernium] in exactly the way that we take 25. & 24.

SCALIGER.

^b*IN THE YEAR 1900. the golden number will be the first, the Lillian Epact xxix., the Lillian Dominical letter G: the Jewish new moon 7.6.651. on 31 March, Lillian. There, then, the Epact xxix. ought to have been placed — where, however, the Epact □ has been set: whereas on the Kalends of April xxix. stands in place of xxviiij.*

CLAVIVS.

^b HERE TOO you thrust our own material on us, doctored by you, and hawk it about. For consider: did we not ourselves place this arrangement in the Calendar of the *Compendium*? Did we not reject it in the *Apologia*? Did we not show why we rejected it? But so that the matter may be understood more plainly, we shall discuss it here too at greater length. That the proper seat of Epact 29. is the first day of April and not the thirty-first of March is taught most aptly by that very year 1900. which you use to fight against us. For since Epact 29., assigned to the first day of April, sets Luna xiiij. on 14. April, while in the year 1900. the mean full moon falls on 14. April at hour 4. after noon, that Luna xiiij. plainly comes immediately before the full moon. What could be done more correctly than this? Whereas if Epact 29. were set in front of the 31st day of March, its Luna xiiij. would fall on 13. April, and consequently, if the following day were a Sunday, Easter would be celebrated before the full moon — which the Canons forbid. Now if Epact 29., written at 31. March, already hurries its own Luna xiiij. forward in that very year 1900., as we have said, how much more awkwardly will Epact 1., placed at 30. March, hurry it forward — which is what your table of the equation appended to this pamphlet gives for the same year — since its Luna xiiij. falls on 12. April and so anticipates the full moon by nearly three days? And so by your table Easter could be celebrated on 13. April, if that day were a Sunday: nearly two days before the full moon. What could be more absurd than that? But next we shall examine that whole equation-table of yours. In compiling it you felt safe

from anyone else's judgement, because you supposed that perhaps no one would undertake the labour of examining it. Now, if you please, let us carry the calculation out to some year very far distant from our own age, so that from this too it may appear plainly that Epact 29. is more correctly assigned by us to 1 April than by you to the last day of March. In the year 20014., then, the golden number will be 8.; and if you consult our equation-table, you will find Epact 29., whose fourteenth falls on 14. April, if it occupies 1 April. Therefore, since the calculation shows the Paschal full moon on 14. April at about hour 13.

after noon, who does not see that Epact 29. has been correctly placed at 1 April, since its fourteenth precedes the full moon by nearly a whole day? Now compare your method with ours: let Epact 29. be placed at the last day of March, as you wish; it will assuredly show the Paschal Luna xiiij. on 13. April — that is, two days before the full moon. Do you see how much more correct and more consistent our method is than yours, even over a long stretch of time?

SCALIGER.

CERTAINLY, if the civil lunar months are to be established full or hollow by turns, then, like it or not, if the Kalends of March have had xxx. or □ (which is the same thing), the thirty-first day of the same month must necessarily have the Epact xxix. in place of that Epact.

CLAVIVS.

^a FOR MY part, I do not see what that necessity is. For the months are constituted full and hollow by turns just as well by the two Epacts 25. 24. taken into a single partnership as by the two 0. 29. which you follow. This one difference remains: that our pair indicates the Paschal Luna xiiij. more correctly than that pair of yours. Read, please, if you have the leisure and the will, the lunations of the thirty cycles of the expanded table of Epacts, which we set out in the *Apologia* lib.2.pag.206. You will see that the lunations are alternately of 30. and 29. days, with a few exceptions, because the nineteen-year cycle and the reckoning of the embolismic months sometimes interrupt this course, on whatever plan it is written out in the Calendar.

SCALIGER.

[Margin: a]

^a*BUT the author of the [new] year guarded against this evil by devising ἑξαίρεσιμδς ἡμέρας after the manner of the Greeks, and by taking the Epacts xxv. xxiiij. into a*

single partnership. Shrewd indeed! This is to κακὸν κακῷ ἰᾶσθαι [Greek: kakon kakō iasthai, "to heal an evil with an evil"; ἰᾶσθαι is set with a single combined σθ sort, whose σ and θ do not letter-separate, and the iota subscript of κακῷ does not resolve on the scan].

CLAVIVS.

^a NO — prudently. For the lunations demanded this, namely that they should be constituted alternately of 30. and 29. days, as was said above. Therefore this is not to κακὸν κακῷ ἰᾶσθαι, as you put it, but to avert an evil by a well-timed remedy — since this equation of the Moon is achieved more correctly through the Epacts 25. 24. than through 0. 29., as we demonstrated more fully in the *Apologia*, and as we showed a little earlier, when we taught that Epact 29. is more correctly placed at the beginning of April than at the end of March with Epact 0. See, then, whether it is not rather *your* taking those two Epacts 0. & 29. into a single partnership, in order to cure this inconvenience, that is κακὸν κακῷ ἰᾶσθαι.

SCALIGER.

[Margin: b]

*IN THE YEAR 1590. the Lilian letter was G: the Lilian Epact xxiiij. The Jewish Paschal new moon 4.23 489. on 5 April, right opposite Epact xxiiij. Correct. * ^bWhat need was there, then, to put xxix. on the Kalends in place of xxviiij.?**

CLAVIVS.

^b THE REASON is ready to hand. For if Epact 29. were moved forward to the last day of March, its Luna xiiij. would run ahead of the full moon by two days, as I explained a little earlier — and this especially, because, since Epacts 24. & 25. are set before that same day, 5 April, on account of the full and hollow months, the proper seat of Epact 29. will be the first day of April.

SCALIGER.

[Margin: c]

FOR IF, as the method required, the Epact xxviiij. had been set on the Kalends, there would have been no need to break open the bars in order to carry the Epact xxiiij. over to 5 April. For the fifth day of April claims the Epact xxiiij. for itself — provided that the Kalends have taken possession of the Epact xxviiij., and not otherwise.

CLAVIVS.

^c YOU ARE mistaken, most learned Scaliger. The method requires that Epact 29. be placed on the Kalends of April, not 28. — precisely so that Epact 29. should not be forced to climb up to the last day of March and to call its Luna xiiij. back to 13. April, with the result that in a number of years it would precede the mean full moon by two days, which is absurd. There is this further point: that if Epact 28. occupied the Kalends of April, its Luna xiiij. would fall on 14. April. So in the year 1851. — to note one case out of many — since the golden number is 9., the Epact 28., and the Paschal full moon falls on 15. April at about hour 15. after noon, that is, on the 16th day, that Luna xiiij. would run ahead of the full moon by nearly two days, contrary to the Canons. This being so, did the method require Epact 28. to be placed on the Kalends, as you wish, or on the second day of April, where it has been placed by us? Nor indeed was there any need to break open the bars, as you say. For Epact 24. did not burst into 5 April by force, as into someone else's property, but came into its own by its own right, as though through an opened door. For the fifth day of April was owed to it by right, on account of the alternating lunations of 30. & 29. days. But I see what you are about: you charge us with the crime that holds good against yourself. It is you who broke the bars open, when you forced Epact 29. into the place of Epact 30. or 0., against the reckoning of the Lunae xiiij., as we demonstrated above.

SCALIGER.

^aFOR NO Praetor can send that Epact into possession of another Epact's [seat], contrary to the deeds.

CLAVIVS.

^a AS THOUGH Epact 24. needed any Praetor's authority to be sent into possession of Epact 25., when for a long time now, by the deeds themselves, it has held that seat by the best right there is! But as for that Epact 29. of yours — what Praetor will ever grant it possession of a seat belonging to another, not merely contrary to the deeds, but contrary to right and religion as well? And this above all when it cannot be done without harm to the commonwealth, since that violence and injury would throw the order and standing of the Lunae xiiij. into confusion.

SCALIGER.

IN THE YEAR 1935. the golden number will be 17., the Lilian Dominical letter F, the new moon [Neomenia] 5.0.580. on 4. April. But the golden number is greater than 11. Therefore, by the Lilian method, the black Epact 25. must be taken. It agrees

correctly, then, with the day proposed, the 4th. Again, in the year 1715. the Dominical letter will be the same, F: the new moon 5.6.667. It will therefore fall on the same day, 4. April. The golden number is vj., which is certainly less than 11. So by the method the red Epact xxv. must be taken. By the method, then, it will fall on 5. April, but by the new moon on the 4th. My question is this: since the new moon both of the year 1935. and of the year 1715. falls on the same weekday, and the Dominical letter is the same, and both agree with the same day — why then have they been given different seats? ^b I would not count it too dear a price — a talent laid against it — to know this mystery. [Margin: b]

CLAVIVS.

^b BUT I will teach you this mystery, most learned Scaliger, for far less — indeed for nothing at all — since you are so eager to know it; for even the springs themselves are thirsty. In the year 1935. the golden number 17. answers to the black Epact 25.; in the year 1715., however, the golden number 6. answers to the red Epact 25. Now the order of the golden numbers in the Calendar requires that the smaller golden number follow immediately after the larger. It is therefore correct to place under the black Epact 25., which answers to the golden number 17., the red Epact 25., which answers to the golden number 6. Otherwise the two golden numbers 17. and 6. would have to be assigned to the same day, 4. April — since the two Epacts would, as you wish, fall on the same day, that is, would have to be taken as one and the same. Who does not see that this is absurd? There you have one explanation of this mystery, and a very good one; now take a second. In the year 1715. the new moon occurred 6. hours later than in the year 1935. What wonder is it, then, if the Epact of the earlier year occupies the higher day and the Epact of the later year the lower? Let me put it more plainly. In the year 1715. the Paschal full moon fell on 18. April at about hour 4. after noon, and hence on the 19th. Now if the red Epact 25. of that year were assigned to 4. April, as you wish, its Luna xiiij. would fall on 17. April, nearly two days before the full moon — which contradicts the Canons. And here is a further way of seeing which of us places and employs the Epacts more correctly. In that very year — to offer one example out of many — you take, by your own method, Epact 26., which you have placed on 3. April; its Luna xiiij. falls on 16. April and runs ahead of the full moon by nearly three days. What could be more inept than that?

SCALIGER.

I KNOW what Clavius has brought forward on this point — things which his own reputation required him either never to have published, or else to have used to remove the error. And in truth he would have done more prudently to correct the

error than to excuse it. "So far is it from being the case," he says, "that the new moons are thrown into confusion, that they are rather restored to their own seats."
[Margin: a]

CLAVIVS.

^a I WOULD much rather that Scaliger — whose reputation I wish well — had said nothing at all about this, so that he might not be convicted of erring twice himself in wrongly marking another man's error. I showed a little earlier that no error is committed in the lunations by reason of the differently coloured Epacts xxv. 25.; on the contrary, that from those very Epacts the Paschal Lunæ xiiiij — which is the main point — are found perfectly correctly. Where, then, does this error lie hidden that Scaliger would have us remove? All this will become much clearer still when we go on to compute a great many full moons against the Scaligerian Epacts.

SCALIGER.

^b *WELL now, what sort of philosophy is this? Two are one, and one is two. One day has been distributed to two Epacts; two Epacts have been gathered into one day.*

CLAVIVS.

^b HERE I cannot help exclaiming: Good God, what is this? A distinguished philosopher and mathematician, one who has stirred not only Flanders and Germany but France as well, declares that he does not understand the very philosophy he himself uses! I beg you, Scaliger, collect yourself and hold back, or you will run onto your own sword-point. Have you not yourself thrown two Epacts, 0. and 29., together into one day? And if you care to scoff, I may scoff at your Epacts in the very same words — for because you assign your Epacts 0. 29. to the same day, you are forced to set beside the preceding day that same black Epact 0. together with Epact 1., whenever the order of the lunations requires it — and I may exclaim along with you: *Well now, what sort of philosophy is this? Two are one, and one is two. One day has been distributed to two Epacts: two Epacts have been gathered into one day.* But we may just as well both laugh at these quibbles together. For the alternation of lunar months of 30. and 29. days necessarily demands that this philosophy be admitted, that two Epacts be brought together into one day, and that one day be distributed to two Epacts of different colour. It remains, since we stand in the same case, to see which of us has made better use of these paired Epacts. For my part, I showed clearly in the *Apologia* lib.2.cap.3. that if we are to follow the authority of the Council of Nicaea, this is

better done by the Epacts 25. 24. than by 0. 29., because in that way the Paschal lunations differ less from the lunations of that Council. It is now your part to show that it is better done by your Epacts 0. 29. — which you will never accomplish.

SCALIGER.

^a *BUT why does an even and continuous arrangement of the Epacts offend them? From the Epacts * 29.28.27.26.25. in March to the like Epacts in April there are 30. days. From Epact 24. and those following in March to the like Epact and those following in April there are only 29. days.*

CLAVIVS.

^a AN even and continuous arrangement of the Epacts does not offend us at all; we rather delight in it. And so we have observed it most carefully in the Calendar, except where the alternation of the lunar months in the Epacts 25. 24. forces it to be done otherwise. And you have done the very same thing — though with less skill — in the Epacts 0. 29.

SCALIGER.

^b *WHY are these in a worse condition than those? Surely all this is trifling.*

CLAVIVS.

^b IN WHAT way "worse"? Is it because the earlier Epacts have lunations of 30. days and the later ones of 29.? On that showing, if they are all to be in equal condition, every lunation will have to be made 30. days long, or else 29. — which no one with even a light tincture of mathematics would think tolerable. But if that is absurd, then it is certainly necessary that one set of Epacts have lunations of 30. days and the other of 29., in alternation. Yet why waste words? If you insist on calling this a fault, you are guilty of the very same fault yourself. Do you deny it? I will proceed against you with your own sealed documents. In your Calendar, from Epact 0. at the beginning of March to the next like Epact there are 30. days; from Epacts 29. 28. 27. and the rest that follow in March to the next like ones there are only 29. days. This shows up still more plainly in the other months: from Epact 29. on the last day of March, and from 28. 27. 26. and the rest that follow in April, to the next like Epacts 29. 28. 27. 26. &c. at the end of April and in May, there are 30. days; whereas from Epact 29. at the end of April, and from 28. 27. 26. and the rest that follow in May, to the next like Epacts 29. 28. 27. 26. &c. in May and June, there are only 29. days. Here I shall cut your throat with your own

sword. For I ask you: *why are these in a worse condition than those? Surely all this is trifling.* But I make your excuses for you: it is not your reckoning of the Epacts that is trifling — it is your speech.

SCALIGER.

^a *THE FAULT in the arrangement of the Epacts in the Calendar is therefore twofold. First, when he placed Epact * on 31. March, but Epact 29. on the Kalends of April, breaking the natural alternation of full and hollow months. Next, when he did not keep even that order, but transferred Epact 24. from the sixth day of the month to the fifth, and shut up two Epacts of the same colour in a single cell, like a pair of [Greek: θεῶς ... ὁμόναος (theous ... homonaous, "gods sharing one and the same shrine") — both words set with the fount's curly ϑ and the 8 (ov) ligature sort; no accent resolves over either ligature, so none is supplied]. And not content with that, he thrust the paired Epacts of different colour, in every month, into the preceding cell.*

CLAVIVS.

^a BUT take care that you do not sin in many ways yourself here too. In neither point is the fault ours. That we assigned Epact 29. to the first day of April, and coupled Epact 24. with Epact 25., we have sufficiently justified above, so that nothing further need be said about it here. For we have kept the natural alternation of full and hollow lunar months perfectly — as is explained at length in the *Apologia* lib.2.cap.3. How manifold, then, is your own fault, when you falsely charge another with a twofold one? And especially when you commit the very thing you censure in us. For you have shut up two Epacts of the same colour, 0. and 29., in a single cell, "like a pair of gods sharing one shrine," to use your own gibe. And in the very point on which you mock us — that we have thrust the paired Epacts of different colour, in every month, into the preceding cell — you bring yourself down.

SCALIGER.

^b *AS FOR why he should have done this, and why that Ethiopian-woman Epact should be preferred to the little red one whenever the golden number is greater than 11. — there was no reason for it, as has been sufficiently shown from what ^b we adduced above.*

CLAVIVS.

^b WE GAVE the fullest possible justification of this matter in the *Apologia* lib.2.cap.3. If you will consider it more attentively, you will certainly not go on asking why I arranged that the black Epact — the one you jokingly call the Ethiopian woman — should be preferred to the little red one whenever the golden number is greater than 11. Because you have rejected that Ethiopian woman, you sometimes find yourself in great straits: for you are forced to crowd two new moons of the same nineteen-year cycle into a single day, namely whenever both Epacts 0. and 29. fall within the same cycle. Truly, had you known the use of this Ethiopian woman, you would have kept her eagerly, and beside Epact 1. you would also have set the black Epact 0. against 30. March, so as to escape by her help the difficulty I have mentioned — a difficulty you will run into in the years 2546. and 2557. For in the year 2546. the golden number will be 1., and by your method, in the table of the true tropical period, the Epact 29.; while in the year 2557. the golden number will be 12., and by that same method of yours the Epact 0. And these two Epacts, 29. and 0., thrown together into the same day, exhibit two new moons of the same cycle on one and the same day. See now from how great a danger that Ethiopian woman, whom you so despise, would rescue you. For if the black Epact 0. were then taken before the red one, this difficulty would be avoided with no trouble at all. You will say: if Epact 1. and the black Epact 0. were then to occupy the same day, we should certainly be stuck in the same mud, and the Ethiopian woman would bring us no help whatever. It is not so. For Epact 1. will never coincide with the black 0. in such a way that both are in use in the same cycle — a point explained more fully with respect to Epact 26. and the black 25. in the *Apologia* lib. 2. cap. 3., and evident in our expanded table, in which no cycle has Epact 1. where Epact * has been placed under a golden number greater than 11. But see how far this error extends — the error into which you have fallen through your contempt for the Ethiopian woman. You will be caught in the same straits in the following years, which I subjoin: 2565. 2576. 2584. 2595. 2603. 2614. 2622. 2633. For taken two by two in order, they are contained within the same nineteen-year cycle; and in the first of each pair golden number 1. coincides with Epact 29., while in the second golden number 12. coincides with Epact 0., by your method. Likewise in these years: 3214. 3225. 3233. 3244. 3252. 3263. 3271. 3282. 3290. 3301. For if they are taken in order two by two, in the first Epact 29. will coincide with golden number 4., and in the second golden number 15. with Epact 0. Likewise in these: 3483. 3494. 3502. 3513. 3521. 3532. 3540. 3551. 3559. 3570. 3578. 3589. For taking them again two by two in order, in the first Epact 29. coincides with golden number 7., and in the second

Epact 0. with golden number 18. Likewise in these years: 4561. 4572. 4580. 4591. 4599. 4610. 4618. 4629. 4637. 4648. 4656. 4667. For in the first, if they are taken in order two by two, Epact 29. will coincide with golden number 2., and in the second Epact 0. with golden number 13. Besides these, in the years 5362. 5373. 5381. 5392. 5400. 5411. 5419. 5430. 5438. 5449. For here again, taking them two by two in order, in the first golden number 5. will coincide with Epact 29., and in the second, with golden number 16., Epact 0. The same, in short, will happen as often as the eight cycles of the ta-

—ble of our expanded table are in use, the ones prefixed with the letters N, G, B, t, q. k, g, d. For in these a golden number greater than 11. always coincides with Epact 0. or *, or 30., and a golden number not greater than 11. with Epact 92. [recte: 29.]; and so you are forced to throw two new moons of the same nineteen-year cycle together into a single day. You would have got yourself out of these rough places easily, with the Ethiopian woman for your guide, had you followed our example and preferred her to the little red one. That it is inept and absurd to assign two new moons of the same cycle to the same day — who does not see it, if he has so much as touched Ecclesiastical Computation with the tip of his lips? For it was precisely with great ingenuity that the nineteen-year cycle was devised, so that in the space of 19. years no new moon should return to the same day. Do you see now what excellent uses that black Epact has? Do you see how often that splendid method of yours collapses once this safeguard is despised? Go now, and mock our Ethiopian woman by comparison with the little red one!

SCALIGER.

^a *THERE remains another difficulty in the arrangement of the Epacts. For the Epacts are Paschal, and were instituted for the sake of Easter; ^a and therefore their beginning ought to have been set in the Paschal month, that is, in March. For March is the first month in the ancient Church. Gregory of Tours calls July the fifth month; Sidonius calls February the twelfth. Since, then, Lilius begins his Epacts not from March but from the Calendar of January, he runs into two drawbacks. The first is that in a bissextile year the new moons after February are thrown into confusion by the intervention of the preceding bissextile day. The second is that from the Kalends of December to 31. January there is no Epact xix. except the one entered on the second of December — even though from the second of December to the last day of January two complete syzygies elapse. Hence it happens that when Epact xix. coincides with golden number 19., no Epact is to be found to mark the second syzygy. It was to meet this drawback that the blackened Epact 19. was contrived, to set its foot in possession of Epact xx. on the last day of December. [Margin: a]*

CLAVIVS.

^a IT COULD indeed have been done as you wish. For the months of January and February have nothing to do with finding Easter, and March is the beginning of the astronomical year. But since the golden number of the new civil and ecclesiastical year begins from January — for the year used in old times always to turn in that month, seeing that in the month of January the golden number indicating the new moon was always greater by one than the golden number which showed the new moon in the preceding December — why should the Epact of the new year not begin along with the golden number? Especially since January and February together contain 59. days, which fill out two lunations, and the lunar months are none the less alternately of 30. and 29. days. As for that disturbance of the new moons by the intervention of the bissextile day, which you dread so greatly, it was always disregarded both by the Council of Nicaea and by the Church — since the golden numbers would disturb the new moons in the same way; if indeed it should be called a disturbance at all, when it can in no way be avoided, whether the year begins from January or from March. But, you say, we have no Epact 19. at the end of December: neither have you one at the end of February. We are therefore on equal terms — except that our reckoning is better than yours in this respect, that whenever golden number 19. coincides with Epact xix. in such a way that in the following year the epact is 1. with golden number 1., you are forced to make a lunation run from 30 January to 29. March, that is, of 59. days, which is ridiculous and monstrous. We, who assign the black Epact 19. to 31. December, are out of that hazard — as has been sufficiently explained in the *Apologia*.

SCALIGER.

^b *LET those foul errors, then, be corrected, and let the Epacts of the Calendar be marked as follows.*

GOOD words, please, my dear Scaliger! I have already shown well enough that there is no error in our Calendar that needs correcting. But if you have a taste for correcting errors, you are welcome to correct your own — of which I have pointed out a fair number, and shall point out more, and serious ones at that; I will not call them foul, so as not to fall myself into the intemperance of language I censure in others. There is one thing, however, that I am eager to learn from you, if it is no trouble: why do you enter the Epacts differently in this Calendar of yours from the way you did in the one you published in your book *De emendatione temporum*? For there you assigned to the same day these two Epacts, 1. and 0., and that in the month of April; but here 0. and 29., in the month of

March. Why are the same Epacts not always set at the beginnings and ends of the months in both Calendars? I ask you, what is the cause of this variation? If you corrected the Epacts rightly there, why do you correct them here again, and differently at that? Have you perhaps corrected the old by the new because, now that we hold up a light in the Calendar of the *Compendium*, you already see more than you saw before? If that is so, I am confident that when you have looked upon the greater light shed by this admonition of ours, these things too will look old to you which are now new.

SEQVITVR CALENDARIVM SCALIGERIANVM.

SCALIGER.

a ...*the CALENDAR having been established in this way.*

CLAVIVS.

a Look hard at what you are doing, my dear Scaliger, and then look again — in case "*one day the flock of birds should come to reclaim its own feathers*" (Horace, *Epistles* I.3.18–19): you know the rest. For you are perfectly well aware that this Calendar of yours is borrowed goods. The whole of it comes from Lilius's Calendar, the one sent to the princes in the *Compendium of the Restitution* — apart from the first two months, which you want to have close the year, and which contribute nothing to finding Easter. Go ahead, then: make your own what belongs to someone else. But have you forgotten that in Book 2 of the *Apologia*, chapter 3, we ourselves pointed out the defects of this Calendar, the very defects for which we thought the less of it?

SCALIGER.

b *No error will follow.*

CLAVIVS.

b What Mercury can guarantee you that? Are you really so sure there is no error? Do you know and have you inspected every recess and byway of that road? We shall show you a great many things you have perhaps never noticed, and from

them you will understand how manifold is the error that follows — especially if your table of the equation is brought into it. Those errors I shall produce later, when I come to examine your tables.

SCALIGER.

c There is no need for that prodigious pairing of two red Epacts, or of as many Epacts of a different colour.

CLAVIVS.

c And how can you prove that, either to anyone else or to yourself? For if there is no need of that "prodigious" (your word) pairing, why have you attached two Epacts, 0. or 30. and 29., to one and the same day? Unless perhaps it fails to be prodigious in your Calendar for this reason, that you adopt the mark 0. for 30. — as if it made any difference which marks you use, when the thing itself is the same. But in truth, most learned Scaliger, if we are willing to look at the light, we shall easily understand that the pairing cannot be avoided, because of the hollow and the full months, and that it is not prodigious but an ingenious device.

SCALIGER.

d Everything will be plain, provided a good starting point is kept — that is, provided the reckoning of the cycles is entered upon according to the lunar μεταπτώσεις [Greek: metaptōseis, "shifts" — the displacements of the Moon].

CLAVIVS.

d Look where you are heading, my dear Scaliger. Come back off the bypath onto the road, and do not let the inviting look of that path deceive you. I tell you in advance and I warn you: it is rough and treacherous, and you will stumble and go astray on it more often than you suppose.

[Margin: a]

SCALIGER.

FOR, as we have already said, in the Julian year the προέμπτωσης [Greek: proemptionsis, the "forward fall" — the advance of the Epacts] of the Epacts occurs ^a after 304 years, which are sixteen complete lunar cycles. In the tropical year, by contrast, the μετέμπτωσης [Greek: metemptionsis, the "backward fall" — the retardation of the Epacts] occurs after 228 or 247 years — that is, alternately after cycles of xij. or xiiij.

CLAVIVS.

a The assumption is false. I showed above that the Moon's anticipation occurs after $312\frac{1}{2}$ years, not after 304.

SCALIGER.

b For these changes cannot occur except by the reckoning of the cycles. Take an example in the Julian year. When the Epact of the first golden number is xi. in the Julian year, as it is today, the new moon falls on 19 March. This will hold for 304 years. Afterwards a προέμπτωσης will take place, and the new moon which fell on 19 March will have moved up to the 18th of the same month; and in the second year of the golden number, when the Epact is 22, the new moon is placed on 7 March; but after 304 years, in the same year of the cycle, that same new moon will have taken its step to the 7th of the month.

CLAVIVS.

b This is not true either. For since the lunations really do run one day ahead in the space of $312\frac{1}{2}$ years — as we said above, and as we taught at length in Book 2 of the *Apologia*, chapter 1 — it is perfectly clear that this anticipation does not fall at the end of a period of cycles. For $312\frac{1}{2}$ years contain sixteen nineteen-year cycles and eight and a half years besides.

SCALIGER.

c From a golden number, then, the change is made to a like golden number — from the first to the first, from the second to the second. Again, in the tropical year, in the first golden number, when the Epact is unity, as it is today, the new moon falls on 30 March. After 228 years [printed anos; recte: annos] that same new moon will have sunk to the 31st of the month, at the point when the Epact of that same golden number will be 0. or *. Since, therefore, the change of the Epacts will take place in the year 1700, after the omission of the bissextile day, and since in that same year 1700 the golden number 10 will be running, the change will accordingly have been made from golden number 10 of the year 1586 to golden number 10 of the year 1700 — and not from the year 1500 to the year 1700.

CLAVIVS.

c I will readily grant you this, provided you take it rightly. For it holds only on this condition: that whenever a change has to be made, the epact assumed with the same golden number is greater or less by one than the preceding epact,

according as the lunations have shifted toward the beginnings or toward the ends of the months. For example, if epact x is running with golden number 8, then epact xj — or ix — must be assumed with that same golden number 8, so that the change is made to a like golden number. You will find that this is always observed in our method. Yet it is not always the same golden number that runs at the beginnings of the changes; your own table of equation shows as much, since different golden numbers correspond to the years in which you decide the change must be made. Still, it cannot be denied that from any golden number to a like one an exact number of cycles has elapsed — or at least one cycle — even though the change does not occur at the beginnings of those cycles, but a little before or a little after. For the change need not occur after a precise number of completed cycles; it is enough that, with the same golden number, an epact greater or less than the preceding one be taken at the time the change has to be made, whether this happens at the beginning of a new cycle or a little after. You will not be able to shake this by any argument.

SCALIGER.

a This, indeed, is ridiculous. For the golden number of the year 1500 is not the same as that of the year 1700.

CLAVIVS.

a You say this as though it were necessary that the golden number be the same at the beginnings of the changes — which I have just shown is not so, and which is no more observed in your method than in ours. For you say that a change is made from the year of Christ 1601 to the year 1733, and yet the golden number in the earlier year is 6 and in the later 5. Again, you want a change to be made from the year 1875 to 2001, and yet the earlier has golden number 4, the later 7. It is therefore not ridiculous that the change should be made from the year 1582 (for which you wrongly put 1500) to 1700, even though the golden number is not the same in both. It is quite enough that around the years in question two epacts differing from one another by a unit should correspond to the same golden number. This, I say, is not ridiculous. What is ridiculous is to carp at another man for the very thing on which, without realizing it, you carp at yourself.

SCALIGER.

b But the learned Clavius says that this change occurs in 312 Julian years — that is, in xvi cycles and one octaeteris. Yet in xvi cycles one whole day is left over from the lunar epilogism. And the octaeteris is greater by one day, 12 hours 41 minutes 33

seconds, than the Julian octaeteris. In this way the compensation would come out. But, as I said, these things do not suit civil use.

CLAVIVS.

b You are not satisfied, learned Scaliger, that the lunations run one day ahead in 312½ years, as we have said repeatedly. Then overturn the calculation on which that advance is built up in the *Apologia*, Book 2, chapter 1. And that you will never manage unless you first show that the Moon anticipates by 1½ hours in the space of 19 years — against the common opinion of all astronomers. Or at least produce some argument for your position worthy of your talent. For the one you did bring forward — that the change must be made from one golden number to a like golden number, to fight against us — you have found to be a leaden dagger.

SCALIGER.

For example: let the Dionysian epact xi of the first golden number mark a new moon on 20 March. At the beginning of the year 313, in which the epact of golden number ix will be x, it will mark — because of the προέμπτωσιν [Greek: proemptōsin, accusative of proemptōsis, "anticipation"] — a new moon on 21 March. ^c So the difference will be two days. So far is it from being true that a proper period of προεμπτῶ[?]εος [Greek: genitive of proemptōsis; one letter at the ink-spread limit] is completed in 312 years. For when the epact of golden number ix is x, then the epact of the first is xij. Thus, as we have already said, the new moon of the year 313 will be two days off from the epoch of the year 305. There was therefore no reason why so great a man should persuade himself that that change occurs in 312 Julian years. For what could he have said more foreign to his own scheme than that in 312 Julian years the new moon falls on 21 March which formerly fell on 19 March — when that is rather a μετέμπτωσις [Greek: metemptōsis, "postponement"] and not a προέμπτωσις? But, as I said, a* προέμπτωσις never occurs in the Julian year, nor a μετέμπτωσις in the tropical, except from one golden number to a like golden number.*

[Margin: [?]] — a single bare siglum letter set in the outer margin beside this paragraph; the glyph does not resolve]

CLAVIVS.

c Well now! What is this sleight of hand? Or is it confidence in your own wit — are you fishing for the applause given to a conjuror? No doubt, if you had not meant to deceive us, you would have argued like this. Whenever epact xi corresponds to golden number 1, epact ix is owed to golden number ix.

Therefore, once $312\frac{1}{2}$ years are completed, because of the anticipation of the lunations (unless it is blocked by the omission of the bissextile), epact xij will correspond to golden number 1, and epact x to golden number ix — and so the lunations will fall one day earlier. That, I say, is how you ought to have argued, in the way I have set out. Where, then, is your difference of two days? Your argument is far too generous, and it can be turned back on yourself. For in the table of the corrected tetracosimeteris, in the year 1865 the golden number is 4 and the epact iiij. Then in the year 2001, in which you want the change downward to be made, the golden number is 7, and so epact iij will correspond to it. But whenever epact iij corresponds to golden number 7, epact 0 is owed to golden number 4. Therefore the new moon which in the year 1865 is marked on 27 March by golden number 4 — or by epact iiij — will fall, after the year 2001 (since the golden number is again 4 and the epact 0), on the last day of March. So the difference will be three days. But it is foolish to let oneself be driven by tricks and quibbles away from things that are perfectly clear in themselves. The right way to argue was this. When epact iiij corresponds to golden number 4, epact vij is owed to golden number 7. Therefore, when the change downward has to be made, epact iij will correspond to golden number 4, and epact vj to golden number 7 — and so the lunations will fall one day later.

SCALIGER.

a But Lilius did not act prudently either, when he says that a προέμπτωση occurs every 300 Julian years. For it happens no more in 300 than in 312: neither number is a nineteen-year number [printed decemnouennalis].

CLAVIVS.

a How prudently Lilius acted in putting forward a method suited to civil use is plain enough from *Apologia* ca.4. lib.2., where this method, advancing by 300 years, is explained. Nor does it matter at all that neither of these numbers, 300 and 312, is a nineteen-year number, as we said above when we showed that the change is not made from one golden number to a like golden number.

SCALIGER.

b Let us then set up a table in which, once the collected years of Christ have been noted at intervals of 132 and 136, the Jewish new moon is also noted according to the intervals of the cycles between the epoch of the years of Christ beginning from the year 1557 and the epoch of the collected years. Then, from the Julian

anticipation, the tropical μετέμπτωσης will easily be detected, according to the bissextiles to be rejected [biffexta reijcula].

CLAVIVS.

b But that Jewish new moon is no less opposed to the true reckoning of the cycles — as far as the fourteenth moons are concerned — than the Jews are to Christians. You will grasp this well enough yourself once you see that by its deception you have got yourself entangled in a great many very serious errors.

SCALIGER.

So that you may take this in more readily, here is the table we have set out below. Its first column contains the years of Christ collected at twice 132 and once 136. The second column contains the Julian solar cycle; the third, the dominical letter corresponding to it; the fourth,

TABVLA ÆQVATIONIS EPACTARVM

In Tetracosiieteride Emendata.

[Table of the equation of the epacts, in the corrected tetracosimeteris.]

Columns 6–8 (*Feria* | *Horæ* | *Scrup.* 1080.) stand under the spanning head *Neomenia Iudaica* ("Jewish new moon").

Anni afteriscis notati sunt ἐκβόλιμα [Greek: *ekbolima*, "intercalary" — literally "thrown in"]. — The years marked with asterisks are intercalary.

- the golden number likewise agreeing with that same year; the fifth, the Jewish new moon; the sixth, the intervals of the cycles — that is, of the golden numbers — between the year proposed and the years of Christ from 1577 to 1595 inclusive, as you have it above in the Table of the cycle. An example. To the year of Christ 1601 there agrees golden number 6. From the year of Christ 1582, in which the same golden number stood, to the year proposed*
- there are 19 years, and therefore one complete cycle. So add 2.16.595 — the amount belonging to one cycle — to the new moon 7.10.822, which is the new moon of that year 1582, and you will have the new moon 3.3.337 for the proposed year 1601. And since the Julian dominical letter is D, the third weekday, which belongs to the new moon, will fall on the letter F, and so on 24 Martij Julian, as you have it in the seventh column. But since 10 days have been struck out of the Julian year — the number recorded in the eighth column — the new moon will accordingly be found on 3 April of the

tropical year, again on the third weekday, since the dominical letter is G. Again, for the year 3465: the interval of cycles from the year of Christ 1584 is exactly 99 cycles. So the character of 99 cycles, namely 7.6.585, added to the new moon 2.4.414 of the year of Christ 1584, will make up the new moon 2.10.999 for the proposed year 3465, on 24 Februarij Julian, on the second weekday, as the Julian dominical letter E notes. And since the 24 days to be rejected present themselves in column 8, that same new moon will fall on the 20th day of tropical Martij, on the letter B — that is, on the second weekday, since the tropical dominical letter of that year will be A; therefore letter B, the second weekday. In the eleventh column stand the epacts of the new moons reckoned from the conjunction Moon itself — the Moon, that is, from which the fifteenth Moon is the paschal term. In the twelfth column is noted the first golden number, which will be in use in that year and thereafter until it is changed again. Finally, the* ἐκβόλιμοι *or rejected lunar months are marked wherever the new moon passes beyond 4 April.* ^a *For, counting from 4 April, the fifteenth day will be the Christians' fourteenth, or the fifteenth of the Jewish Nisan.*

[Margin: a]

CLAVIVS.

a We have refuted this sufficiently above, where we showed that the paschal term is Luna xiiij. counted from the new moon, and not the xv. or the full moon. On this matter there is more in *Apologia* lib.1. cap. 1.& 3., and again lib.2.cap.6.

SCALIGER.

In the year 2133 the new moon has been placed on V. April, and the fifteenth day reckoned from it falls on xix. April — beyond the last paschal term. Instead of the April new moon, therefore, the Martij new moon must be taken, opposite epact xxiiij.; that is, on the seventh of Martij, and the fifteenth day reckoned from it ends on xxi. Martij. Therefore, although a cycle consists of 235 syzygies, whenever an ἐκβόλιμος month falls in it the cycle then has only 234 syzygies. And so from the year of Christ 2114, in which the new moon fell on the iiij. of April, to the proposed year 2133, although 19 years have gone by and hence 235 syzygies, that cycle will nevertheless have only 234 syzygies, because the paschal syzygy falls on 7 Martij and not on v. April. ^a *How much safer — indeed how much truer — this method is for detecting the Moon's metempsychoses in the tropical year than the one that proceeds by 300 or by 3012 [?] years, let Clavius himself be the judge.*

[Margin: *a*]

CLAVIVS.

a We see it otherwise. Whether rightly or not, we shall see a little later, when we compare the two methods and demonstrate so plainly that ours is by far the safer and the truer in marking the fourteenth moons that we shall not refuse even Scaliger himself as judge.

SCALIGER.

b And he, at any rate, will not deny that this table has been carried through with elegant craftsmanship.

CLAVIVS.

b I do not in fact deny that this table has been carried through with elegant craftsmanship; but I am afraid it has more elegance than truth, as anyone will readily see who checks it against the reckoning. Now I put one question to you: what kind of craftsmanship is it that in the year 1733 a day is thrown out — so that the lunations descend by a day in the Calendar, seeing that 304 years have not yet passed since the year 1601 — and yet your method keeps the same epact with golden number 1 as in the year 1601? The same thing happens in practice in the year 1865. It is astonishing how many errors arise from this carelessness in tracking down the fourteenth moons. This will be established from the table of the tropical period, which has been developed with much the same craftsmanship. It is this latter table that we shall sift, rather than the other (though we shall show by several examples that the other is false as well), since you set more store by it than by the first — and especially because you put it before all nations and peoples as a rule and standard of truth, as though it had dropped from heaven, by which the judgments of all in the correction of the Calendar are to be guided. Meanwhile let this serve as a sample of both: each of them not rarely throws the lunations forward toward the ends of the months, so that they occur two days later than they ought. That happens from the year 2533 to the year 2665, and from the year 3733 to the year 3865, in the corrected tetracositeris. Then from the year 2537 to the year 2673, and from the year 294 [?] to the year 3073; likewise from the year 3471 to the year 3609, and from the year 4817 to the year 4949, in the proper tropical period. What could you have said more foreign to your own design? For either the Moon needs an equation, on account of its anticipation in 304 years, or it does not. If it does need one, the new moons will certainly stay as they were, because of the omission of the bissextile

day. For the one day by which the new moons are forced to descend toward the ends of the months — on account of the rejection of the day that the equation of the solar year demands — is restored toward the beginnings of the months by the Moon's anticipation. How, then, will they descend by two days, as you would have it? If on the other hand the Moon does not require an equation, the new moons will descend by one day only, because of the omission of the day in the bissextile year. This error flowed from your not having taken account, as you should have, of the anticipation and postponement of the lunations, but only of the Jewish new moon, to which you fitted your epacts. The result is that they are not fit for tracking down the paschal Lunæ xiiij., as can be understood from the few examples appended here.

Appendix ad Novi Calendarii Romani Apologiam — Joseph Scaliger's *Anni Liliani Elenchus & castigatio*, with Clavius's replies (continued)

The table below carries no printed caption; it is the set of worked examples Clavius announced at the foot of the preceding leaf. Column heads, transcribed verbatim (the four narrow heads are set rotated 90°, reading bottom-to-top), with their English sense:

- Anni Domini — Years of the Lord
- Aureus Numerus. — Golden number
- Epactæ Gregor. — Gregorian epact
- Epactæ Scalig. — Scaliger's epact
- Lun. xiiij. Gregor. — Gregorian Luna xiiij
- Lun. xiiij. Scalig. — Scaliger's Luna xiiij
- Dies exempti Scal. — Days omitted, Scaliger's reckoning
- Dies exempti Greg. — Days omitted, Gregorian reckoning
- Plenil. media Gregoriana. — Gregorian mean full moon
- Plenil. media Scaligeriana. — Scaligerian mean full moon

The last two columns carry the sub-head D.H. (*dies, hora* — day, hour); the trailing A. in the Luna xiiij and full-moon columns is Aprilis (April).

There you have it: in these years your Luna xiiij. anticipates the full moon by two days, or by three — which is against the canons. Our Luna xiiij., by contrast, precedes the mean full moon by one day at most, or else falls on the full moon itself, which agrees with the canons. I could set down six hundred examples of this kind; I knowingly leave them out, because I am saving the more exacting examination for the table of the proper tropical period. So you see that what I said is true: your table of the corrected tetracosimeteris has more elegance in it than truth.

SCALIGER.

[Margin: a]

If the epacts of the cycle-table were always self-consistent from the year of our Lord 1577 onward, ^a the matter would already be settled, since they could safely be taken for the equable and ordinary epacts, which advance by an increment of eleven.

CLAVIVS.

^a The five examples just above show exactly how far the matter would be settled, and how safely we could adopt those epacts; and the examination of the table of the proper tropical period will teach the same thing still more plainly.

SCALIGER.

[Margin: b]

As it is, however, some of them shift, while the rest stay intact in their own place — as anyone who cares to test it can establish. ^b Therefore the epacts drawn from the perpetual cycle of epacts will sometimes have the fourteenth moon as the paschal term and sometimes the fifteenth; and this is not an error of the authors of the new year, but of the equable epacts themselves.

CLAVIVS.

[Margin: b]

^b We have said again and again that this does not happen by design but comes about by chance: it follows from the nature of the cycle that Luna xiiij sometimes falls on Luna xv, that is, on the full moon — as you yourself affirm. The fault, then, if fault it must be called, is committed when the fourteenth day falls on the fifteenth, not when it falls on the fourteenth; the latter is in fact rather what one would wish, as may be gathered from the canons and from the decrees of the Fathers. The proof is this: if the fourteenth falls on the full moon and on a Sunday, Easter has to be transferred to Luna xxij. — and yet that is the very thing the canons order to be avoided so far as it can be. You do the opposite, in making Luna xv. the paschal term.

SCALIGER.

^a *But here is where the authors of the year go wrong: they prescribe that in the year 1598 Easter be kept on 22 March and not on 29 March, though they know that the fault committed there is a shameful one.*

CLAVIVS.

^a Enough! Stop battering us about the Easter of 1598, rashly reproaching us with errors and slandering us. In pressing that objection so often, take care that the fault you commit is not fouler than the fault of the men whose offence there you call shameful. I have said it often enough already — but a man who objects the more often has to be answered the more often: that Easter will be kept correctly, both by the usage of the Church and by the prescriptions of the canons. The grounds for this we set out in the *Apologia* lib.2.cap.6. So how do you dare to say that we know a shameful fault is committed there?

SCALIGER.

[Margin: b]

But they will object that this evil cannot be met, on account of the equability of the epacts. Since they have resolved to preserve that equability, every drawback will be guarded against^b if from the epact they always take the fifteenth day inclusive, and not, as they are used to do, the fourteenth. For occasionally — though very rarely — the full moon will be indicated too late; and the authors themselves admit that this defect is more tolerable than if the full moon is anticipated.

CLAVIVS.

^b Is that really it, my dear Scaliger — do you issue this pronouncement like the Pythia from Phoebus's tripod? For who are you, to take it upon yourself to frame a rule by which the rule of all the Fathers about the paschal terms is overturned? Do you not see where your stubbornness is carrying you, when, to set up those paschal terms of yours, you confound not only human law but divine law as well? But look how shrewd and convenient that rule of yours is going to be, if it is adopted. For from it

Easter would be kept over and over on Luna xxij., against the canons — every time, that is, that Luna x v. fell on a Sunday. How many other faults that rule of yours could go on to breed, we shall show later.

SCALIGER.

^c *So the nearest term of the paschal new moon will be vij. Martij, while the remotest new moon will be iiij. Aprilis: that is, the epact of the nearest term will be xiiij. [?] , and of the remotest xxv.*

CLAVIVS.

^c I beg you, my dear Scaliger: do not let the heat of your own cleverness carry you off and drive you headlong. It is monstrous how much you take upon yourself, when against so many councils, canons, and decrees of the Fathers — and against the teaching of everyone who has written on the right celebration of Easter — you try to overturn the new moons and the paschal terms. For who, since the Council of Nicæa, has ever seen, read, or accepted that the first paschal new moon was 7 March and the last 4 April? Or do you not know that everyone who has handed down rules on this subject prescribes as follows: if the new moon falls, say, on 8 March, the paschal term is set on the 21st of the same month, and not, as you would have it, on the 22nd? By what right, then, do you at this point

postpone the customary paschal term by one day — and do the same with the other paschal terms? Who was there ever — I will not say a Supreme Pontiff, but an emperor, a king, or a tyrant — who gave orders so unrestrainedly as to want to govern the whole world and shape it to his own pleasure, against the settled custom and usage of every nation? How do you suppose the Easterners — to say nothing of the rest — are going to accept this command of yours, when in this business they refuse absolutely to depart from the Council of Nicæa [printed Concilio; recte: Concilio]? So if you set about correcting the Calendar, be careful not to overstep the terms the Fathers laid down; otherwise you will nowhere find fair ears or fair minds to listen.

SCALIGER.

[Margin: a]

^a *In this way nothing further will remain that could either offend fair minds or hand the unfair a handle for criticism. As for those who dream of a ἀναποδισμόν [Greek: ἀναποδισμόν (anapodismon, "retrogression, stepping back"); the initial alpha shows no clearly legible breathing mark at this resolution] of the vernal equinox by three and by four days, and the reverse — they really do show how little they see in these studies. That is a thing which cannot be refuted in a few words.*

CLAVIUS.

^a You are wrong, if I may say so without offence, most learned Scaliger — and grievously wrong. That novel scheme of yours would offend the minds of all the Easterners, who from the Council of Nicæa down to the present have kept the paschal terms together with the Roman Church. It would offend all Catholics, when they saw the canons altered with no weightier cause. And finally, fair-minded and unfair alike would snatch at the handle for criticism, resenting that we should depart from an ancient custom — and one confirmed, at that, by councils and by the decrees of the Popes.

SCALIGER.

^b *But another flaw comes in. Since the difference between the tropical year and the Julian is hor.0. Min.10. Sec.44. Ter.24., in 400 years it mounts up to hor.71. Min.36. — that is, three days less 24 minutes. Now in 2000 years those minutes make 2 hours, and in 24000 a whole day: which, admittedly, is bound to occur only after so many thousands of years.*

CLAVIVS.

^b This flaw did not deceive us in the least, as we set out in lib.1. Apol. cap. 5.; so nothing new is being urged against us. But a flaw of this order, whatever it comes to, is not worth so much that to avoid it one should bring in a harder and less popular scheme of intercalation than the one that proceeds by 400 years. For even if those neglected fractions do introduce an error of one day over a span of about 24000 years (as Scaliger will have it), we have nonetheless prescribed in the *Apologia* lib.1.cap. 5. and lib. 2. cap.4. a method by which our successors, if the world lasts that long, will be able to remedy so slight an error. And what of this — that perhaps before 24000 years are out another form of intercalation will have to be instituted? For it is uncertain whether the present one, which proceeds by 400 years, or alternately by 132 and 136, will keep the equinox on 2[?]. Martij through many thousands of years, since we do not yet hold the true length of the year sufficiently well examined.

SCALIGER.

[Margin: a]

^a *Even so, it was in the interest not only of posterity to use as accurate a year as possible, but also of the authors of the year to put forward one as accurate as possible — which does not happen if we keep the tetracosimeteris as the solar period. For the tetracosimeteris that will follow after 20000 years will have to be docked not of three bissextile days, as the rest are, but of four. And besides, after 12000 years that flaw will already begin to be felt and perceived in the new moons and the equinoxes, on account of the half-day — which will tug the ear of the correctors of the year who will be alive in that age, and will cry out plainly that the oncoming disorder must be met.*

CLAVIVS.

^a I do not deny it, supposing we could "play to the stage and the crowd," as the phrase goes. But matters of this kind ought to be weighed not on a goldsmith's balance but on the common scales, especially since the length of the year is not yet, as we said, well enough known and understood. That is why it was sufficient to have put forward a mean year — the Alphonsine, that is — which you too approve, and rightly approve: because up to now, given the weakness of human wit and the obscurity of the subject, no more accurate mean year has been able to be found. Indeed, if we consider the matter more attentively, we shall find—

—we shall find (given the length of the year that we use) that after 2 0000. years the equinox still holds close to 21. Martij, since in the year 20005 it occurs on the 20th day, after midnight, as we gathered in the *Apologia* lib.1.cap. 6.; and that the Lunæ xiiij. agree with the canons, since, as we said above, in the year 20014 the golden number is 8 and the epact xxix., and its fourteenth day is 14 April, while the mean full moon falls on the 14th day at about the 13th hour after noon. And so at that time the tetracosimeteris will not have to be docked of four bissextile days, nor need anyone fear that the flaw you prophesy for 12000 years from now will begin to be felt and noticed in the new moons and the equinoxes on account of the halved day. That day will by no means — whatever you falsely proclaim — tug the ear of the correctors of the year who will live in that age, nor will it cry out that an oncoming disorder must be met; for no disorder at all will come.

SCALIGER.

[Margin: b]

So let the tetracosimeteris be rejected, and let bissextile days be taken out at alternating intervals of 132. and 136. years, until, when this has been done fourteen times, the solar cycle comes round again to its starting point. For in 134. one bissextile day is lost, and in 268. two bissextile days are done away with — that is, in the years 132. and 136. For in this way a number divisible by four will result, which cannot be had in 134. years. If, then, seven times 268. years are taken, or (what comes to the same thing) 132.136. are alternated fourteen times, a period of 1876. years will result. ^b And the common people will certainly grow used to this alternation more easily than to the centuries of the Lilian period.

CLAVIVS.

^b Do you really claim that in the end the common people will grow used to that alternation of yours more easily than to the centuries of the Lilian period? How do you know? Is it because you suppose the crowd will favour Scaliger more than Lilius, and so put the Scaligerian scheme ahead of the Lilian? The thing speaks for itself: a form of intercalation that advances evenly by centuries of years, and is in every way like the customary intercalation applied every fourth year, is more popular than yours, which limps along unevenly through an alternation of 132. and 136. years. But if you do persuade the common people of this — the thing you are trying to persuade us of — you will be a great Apollo in my eyes.

SCALIGER.

^c *For who does not see this, and who would not rather be astonished that Clavius prefers the removal of bissextile days across three consecutive centuries to this method?*

CLAVIVS.

^c Nobody sees it but you. So either you alone see and all the rest are blind, or else, if the rest see, you alone are dreaming. For at the assembly on the correction of the Calendar that even scheme of intercalation was judged by everyone's vote to be the easier and the more popular, while yours was rejected for its unevenness — so that I can only wonder that you, trusting your own wit, have taken up the defence of a case already throttled by the verdicts of so many most learned men.

SCALIGER.

^d *And Clavius, to be sure, would not have done this, nor would the other authors of the new form, if they had noticed this point beforehand, before the year was published. We have appended a table made up of two periods, whose construction, form, and method are the same as those of the one above, so that it needs no separate explanation. The Dominical letters with which the solar cycle begins, throughout all the metempsychoses [metempsychosibus], are contained in this distich:*

Gaude digne coli. gaude fax clara bonorum. Felix esto bonis, ades & deuotus amicis.

[Rejoice, you who deserve to be honoured; rejoice, bright torch of good men. / Be kind to the good; be present, and devoted to your friends. — the mnemonic works from the initial letters of the words, which give the Dominical letters in order.]

SEQVITVRTABVLÆQVATIONIS

Epactarum in iusta periodo tropica.

[HERE FOLLOWS THE TABLE OF THE EQUATION of the Epacts in the proper tropical period.]

in iusta periodo tropica.

Scaliger's table, printed in full. The first (unlabelled) column carries the intercalary mark; an asterisk there marks an intercalary year, not an epact of 30 (see the note printed beneath the table). The tenth column, "Dies Neomeniæ in mense Iuliana," holds a day-number at the left of the cell and the month abbreviation (M = Martij, Feb. = Februarij) at the right; both are given here in one cell. A / M in the "Dies Neomeniæ in anno tropico" column are Aprilis / Martij.

Anni asteriscis notati sunt ἐκβόλιμοι. [The years marked with asterisks are ἐκβόλιμοι (ekbolimoi, "intercalary").]

CLAVIVS.

^d Do you really claim that we, before the calendar year was published, had failed to notice that the form of intercalation could be set up by alternating periods of 132 and 136 years? I am astonished that it should have occurred to you to announce such a thing — which you certainly would not have done if, before publishing this castigation of yours, you had noticed what we set out in the *Apologia*. Read book 1, chapter 5 of the *Apologia*, if you please: you will find that we teach in explicit words that the omission of the bissextile days can indeed be managed in this way, but that we judged the arrangement by centuries of years preferable, as being easier, better suited to the ordinary man's grasp, and — the main point — safer. There you have the crime; there you have the reason why

Saliger [Scaliger], otherwise a most learned man, single-handedly indicts the Gregorian Calendar, which the whole world has approved by consensus. Indicts, do I say? No: without even stating the charge, he chastises it bitterly and savagely — so that it is only fair that so equitable a judge should himself, in the old Roman fashion, be prosecuted for extortion.

Come then: since we have answered his charges sufficiently, let us say a few words about our emender and corrector himself, so that it may appear more plainly whether what he promises so confidently really is an improvement. Let us therefore look a little more closely at the Scaligerian tables, which he himself extols to the skies. First, then, as concerns the table above for the 19 years of one cycle, from 1577 to 1595: I miss your consistency, most learned Scaliger. For I find that it agrees neither with your own perpetual cycle of epacts nor with your doctrine. In the table for the proper tropical period you want epact 1 to answer to golden number 1 from the year 1601 onward; so tell me, please, why in 1577 — which is only 24 years earlier, so that no change in the Moon can have taken place in the interval — you assign epact ij to that same golden number 1? Or, if you allot epact ij to golden number 1 in 1577, why do you not assign that same epact ij to the same golden number 1 in 1601? Reason would certainly demand it. Or do you hold that epact ij must be assigned to golden number 1 in 1577 in order to keep to the Jewish new moon, which you fixed on 29 March? If you accept that, the error will creep further, for you will see that most of the epacts of the remaining 18 years of that table turn out to be faulty. For whenever epact ij answers to golden number 1, then, by your own perpetual cycle, the other golden numbers will — for as long as that same nineteen-year cycle lasts — take the epacts of the table we insert here; and a great many of those epacts differ completely from the ones you entered in that table of yours.

The epacts of the perpetual cycle (Ep. cyc. perp.) set against Scaliger's epacts (Epact. Scal.) for each golden number (Aur. num.). The printed table is broken into two halves, golden numbers 1–10 and 11–19; the last cell of the second half is blank.

| Aur.num. | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------------|----|-----|--------|---|-----|-------|-------|-----|------|----|
| Ep. cyc. perp. | ij | xij | xxiiij | v | xvj | xxvij | viiij | xix | o | x |
| Epact. Scal. | ij | xij | xxiiij | v | xvj | xxvij | vij | xix | xxix | x |

| Aur.num. | 11 | 12 | 13 | 14 | 1
5 | 16 | 17 | 1
8 | 1
9 |

x | x
x |
| Epact. Scal. | xxj | iiij | xiiij | xxiiij | v
j | xvij | xxviiij | i
x | x
x |

Look: only ten of the epacts of this table agree with yours, namely at years 1, 4, 5, 8, 10, 13, 15, 17, 18, 19 of the cycle. In the rest they diverge. And if epact 1 were assigned to golden number 1 in 1577, just as it is from 1601 onward — as is right, since in that year, no day yet having been rejected apart from the 10, the Moon needs no equation — a far greater discrepancy will appear, as this second table shows.

| Aur.num. | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 1
0 |
|----------------|----|-----|--------|------|-----|------|-----|--------|------|--------|
| Ep. cyc. perp. | j | xij | xxiiij | iiij | xv | xxvj | vij | xviiij | xxix | x |

5 | 16 | 17 | 18 | 19 |
|----------------|---------|------|-------|--------|--------|------|---------|-------|---------|
| Ep. cyc. perp. | xx
j | ij | xiiij | xxiiij | v | xvj | xxvij | viiij | xi
x |
| Epact. Scal. | xx
j | iiij | xiiij | xxiiij | v
j | xvij | xxviiij | ix | xx |

Do you see that they agree in only seven places, namely at years 2, 3, 6, 7, 9, 11, 14 of the cycle? And that at golden numbers 12 and 16 the difference amounts to two units — which is utterly absurd, as the calculation will show in a moment? And, besides, that epact iiij of golden number 12 has been generated from the preceding epact by the addition of 13 units — which is altogether monstrous, and entirely alien to the reckoning of the new moons? You will say that this came about through the intervention of the bissextile day. I take the point; but tell me this as well: why did the same not happen in years 4, 8, 16, which are also bissextile? Why should these be in a worse condition (to use your own words) than that one? Certainly the lunations of any given year cannot recede toward the beginnings of the months from the lunations of the immediately preceding year

by more than 11 days — at most 12 in a bissextile year — since the epact of a single year is 10 days, 15 hours, 11 minutes, 22 seconds if the year is common, but 11 days, 15 hours, 11 minutes, 22 seconds if it is bissextile, as we set out in the *Apologia*, book 2, chapter 6. But the lunations marked by your epacts for year 12 stand 13 days away from the lunations of year 11 that the epacts indicate — except in those months which assign the two epacts 0 and xxix to the same day. This is plain in May and April. For from epact xxi in May, which shows the new moon in year 11, to epact iiij, by which you want the new moon of year 12 to be marked in April, 13 days are counted; whereas the calculation gives the difference between these two mean new moons as only 11 days, 15 hours, 11 minutes, 21 seconds — a figure less than twelve days, let alone thirteen. Come, let us consult the calculation. In 1587 the mean new moon of May fell on day 6, hour 23, minute 50, second 31. In 1588, however, the mean new moon in April occurs on day 25, hour 8, minute 39, second 10 — and yet your epact iiij puts it back on day 25, well before the mean new moon, which must be assigned to day 26. Now if we subtract 25 April, hour 8, minute 39, second 10 from 6 May — that is, from 36 April, hour 23, minute 50, second 31 — the stated difference of 11 days, 15 hours, 11 minutes, 21 seconds remains. Where, pray, is the difference of 13 days here? But I suppose this holds only for the mean new moons of the years in question, not for the true ones as well. On the contrary, it holds no less of the true than of the mean: for the true new moons of those same two years and months are not a full 12 days apart from one another either, as is clear from the *Ephemerides* of Io. Antonius Maginus [Giovanni Antonio Magini]. Do you see what snares the Jewish new moons have led you into, snares you can never get yourself out of? — namely that you anticipate the new moons in the heavens, and set one further apart from the other than the reckoning demands, which is nothing else than to confound and disorder the whole theory of the new moons.

But let us also compare some of your fourteenth moons for those same years with ours, and with the mean full moons, so that we may see which of us has ordered the epacts in the Calendar more correctly for the Church's use, and which chooses the epacts better for indicating the ecclesiastical new moons. From this too it will appear that the new moons have not been correctly marked by you, and that you interrupted the even progression of the epacts by elevens without cause, so as to arrange the new moons otherwise. For this is the only reason you can plead on your own behalf for the epacts of those 19 years differing from the epacts of the perpetual cycle and not advancing evenly by 11. For since the new moons must be established in such a way (as I taught in the *Apologia*, book 2, chapter 6) that the fourteenth moons do not run two days ahead of the full moons — lest, if the following fourteenth day were a Sunday, Easter should be celebrated before the

full moon — we shall find from the calculation that you have very rarely kept to this. Here is the table, with the epacts,

the fourteenth moons and the mean full moons.

Column heads as printed: Anni Domini | Aur. numerus | Epacta Greg. | Epacta Scal. | Lun.xiiij. Gregor. | Lun.xiiij. Scalig. | Plenilunia media. | Dies, quibus xiiij. Scal. præueniunt plenil. (the days by which Scaliger's fourteenth moons anticipate the full moons). In the moon-date columns A = Aprilis, M = Martij; in the Plenilunia media column H. is the hour.

| Anni Domini | Aur. numerus | Epacta Greg. | Epacta Scal. | Lun.xiiij. Gregor. | Lun.xiiij. Scalig. | Plenilunia media. | Dies, quibus xiiij. Scal. præueniunt plenil. |

We assign a full moon that falls after midday to the following day, on the doctrine of everyone who has written on the computus — a doctrine you yourself will not deny, since you attribute to the following day a new moon that comes 18 hours after the preceding sunset. Therefore, when your fourteenth moon precedes the full moon by two days, be aware that you are offending against the Canons. For if your fifteenth moon were a Sunday, you would celebrate Easter before the full moon, that is, on the true fourteenth moon — which the canons do not permit. And when your fourteenth moon runs almost three days ahead of the full moon, as happens in 1589, Easter would be celebrated two days before the full moon, on

the thirteenth moon, before the Jews' Passover — which is even more absurd. But perhaps you will say: does your own fourteenth moon [printed Luna *iiiij.*; recte: *xiiiij.*] not anticipate at all in that year? It does anticipate somewhat, but still by a whole day less than yours — which is in fact a consequence of the nature of the cycle. For no cycle, however arranged in the Calendar, can avoid every drawback. The one thing we must take the greatest pains over is that it be so arranged as to contain the fewest possible errors; and this we are confident we have achieved in the Gregorian Calendar, since far fewer errors are found in it than in yours — as appears partly from the table of 19 years given above, and partly, and much more clearly, in the examination of your table of the equation of the proper tropical period. Moreover, in these 9 years of the table above, even if not your fifteenth moon but your sixteenth were a Sunday, Easter would still be celebrated after the fifteenth moon (as you have wrongly, and against the Canons, decreed it must be) — on the full moon itself, which you nevertheless flatly deny to be permissible. And so you put on the very thing you feared. Therefore, whether Easter is celebrated next after the fourteenth moon or after the fifteenth, it is settled that your Jewish new moons are false in those 9 years. Indeed — and this is even more intolerable, and against all the writers on the computus — in those same 9 years you place the epacts on the very days on which the mean new moons fall. So there you have it, my dear Joseph: how false and deceptive that table of yours for 19 years is — the very table you make the foundation of your table of the equation of the proper tropical period. And so that table, resting on so weak a foundation, is bound to be utterly ruinous, as will be clear in a moment from its examination.

To begin with, then, I observe that in changing the epacts that answer to golden number 1 you took account neither of the anticipation of the new moons, which you claim occurs in 304 years, nor of the days removed, each one of which requires the current epact to be changed into the next lower one. This is indeed the greatest error, and it is the parent of the rest. For before 304 years have elapsed from the epoch, or root, the current epact must be changed into the lower one as many times as days have been removed. But as often as 304 years have elapsed, that many units must be subtracted from the number of rejected days, so that the remainder shows by how many units a smaller — that is, a lower — epact is to be taken. This you did not observe; instead you put your trust solely in the Jewish new moons of the table of 19 years above, which, as we said earlier, drove you into error. Go on now, believe the Jews, and take the reward of your credulity! But look at the error into which the Jewish new moons have brought you. From 1581 to 1733 the 304 years have not yet elapsed, and so the Moon needs no equation. Therefore, since one day is removed in 1733, the epact 2

running with golden number 1 (given that epact xvj answers to golden number 5 in 1581) must be changed into the lower one, 1 — which you did, and rightly. Next, from 1584 to 1869 there are likewise not 304 years. Therefore, since another day is removed in 1869, so that at that point two days will have been rejected since the correction, the epact to be taken would be xvij, two units smaller than epact xix, which runs with golden number 8 in 1584. Consequently golden number 1 ought to have epact 0, or *, answering to it, and not epact 1, as you have it in the table. Again, from 1583 to 2001 three days will have been taken away, and the 304 years are counted once: therefore the epact to be assumed would be v, smaller by two than epact vij, which on your own authority answers to golden number 7 in 1583; that is, the epact of golden number 1 ought to be 29, not 0 as you would have it. Next, from 1587 to 2537 the 304 years are contained three times. So, subtracting three from the 7 days that will then have been removed, 4 remain; and the epact to be taken would be smaller by that many units than 21, which answers to golden number 11 in 1587 — that is, epact 17. And therefore epact 27 must be assigned to golden number 1, whereas you assign epact 29. Furthermore, from 1595 to 3609 the 304 years are reckoned six times. So if you subtract six from the 15 days that will then have been removed, 9 remain. Therefore 9 must be taken from epact 20, which answers to golden number 19 in 1595, so that epact xi remains as the one answering to that same golden number 19 in the year 3609; and so epact 23 will be due to golden number 1 — and yet you assign epact 21 to golden number 1. Do you see how great and how grave the collapses are? Finally, if we care to examine the other years of the table of the proper tropical period in the same way, taking from your table of 19 years the year that has the same golden number as the year assumed in the table of the proper period, we shall find that you very rarely assign to golden number 1 the epact that the reckoning of the Moon's anticipation and retardation requires. And what other cause is there of an error so great, and spread so far and wide, except that you tied the epacts to the Jewish new moons alone? From this it must follow that intolerable errors arise in the new moons and in the fourteenth moons, as the appended table of 50 years shows. In it we have set down, in the first place, the years of the Lord; then the golden

Table of fifty years (the *tabula 50 annorum* announced at the end of the preceding leaf: "as the appended table of 50 years shows"). The table occupies the whole page; the description of its twelve columns follows on the next page.

Calendar; the eighth, those same full moons according to Scaliger's intercalation. The ninth comprises the Dominical letters by the method of the Gregorian Calendar; the tenth offers the same letters by Scaliger's method. In the eleventh we have noted the days rejected according to the equation of the Gregorian Calendar, and in the twelfth, finally, the days removed according to Scaliger's equation. Now whenever your fourteenth moons run two days ahead of the mean oppositions, you must admit that you determine the epacts wrongly and set them out incorrectly in the Calendar — as was said above in the examination of the table of 19 years, from the year 1577 to the year 1595 [printed annum] — since it is falsely that the fourteenth moons are found by them. Furthermore, a full moon that falls on some day after noon must be assigned to the following day, as we also pointed out above. The calculation of the mean oppositions has been set up here, as elsewhere, by means of the tables of epacts that we compiled in the *Apologia*, lib. 2, cap. 6 (Clavius, *Apologia* II.6); and the calculation made by the new moons of 76 years, which Paul of Middelburg [Paulus Middelburgensis] presents, does not differ from it by much. We have amassed so many examples in this table and in those that follow, not so much to set the errors of the Scaligerian epacts before your eyes as to teach that the Gregorian epacts indicate the Paschal fourteenth moons correctly, as the Canons prescribe. This will be plainly evident if the Gregorian fourteenth moons are compared with the Gregorian mean full moons, and the Scaligerian fourteenth moons with the Scaligerian mean full moons.

In all these years — and I have passed over a good many more in which the same thing happens, for either there are examples enough, or I do not know what "enough" means — your fourteenth moons always run two days ahead of ours, and they fall very nearly the same number of days before the full moons, sometimes even three days before them (as in the years 2575, 2594, 2595). From this it follows that, if the next following day were a Sunday, Easter would have to be kept — on your epacts, and by the Church's prescription, since she always celebrates that festival on the first Sunday after the fourteenth moon, as we have shown more than once — one day before the full moon, and sometimes even two days before it. And not even you deny that this is contrary to the Canons and the decrees of the Fathers, since you ...

(The sentence breaks off at the foot of the text block; the two tables follow, and the argument resumes beyond this leaf.)

Second table (the first of the "tabellæ" just announced; it continues on the following page).

Column heads as printed: Anni Domini. | Aureus numerus. | Epactæ Gregorian. | Epactæ Scaligeria. | Lunæ xiiij. Greg. | Lunæ xiiij. Scali. | Plenilunia media secundum intercalationē Gregor. (sub-heads H. M.) | Plenilunia media secundum intercalationē Scalig. (sub-heads H. M.) | Litera Dom.Greg. | Litera Dom.Scalig. | Dies exempti Greg. | Dies exempti Scalig.

you do at least permit it to be celebrated on the full moon itself. Indeed, even if Easter had to be celebrated after Luna xv. — the position you cling to tenaciously along with Mæstlino — it could still be celebrated on the full moon itself, which you refuse to allow, or even, against the Canons, before the full moon. It is clear, then, that your epacts are neither correctly arranged in the Calendar nor correctly traced from your table, since their fourteenth days run ahead of the mean oppositions by more than they should. This error is admittedly corrected in most cases by the current Dominical letter, which very often follows the fourteenth day by more than two days; but that does not mean the epacts are not to be judged faulty in themselves. What is more, if we used your Calendar, we should in actual fact more than once celebrate Easter after Luna xiiij. — which is the Church's ancient practice — and yet before the full moon. This would happen in the years 1737. 1791 1859.1957.2575.2995.3195.3266. For in all of these the proper Dominical letter immediately follows your Luna xiiij., whereas the mean opposition does not immediately follow it; and in the year 2575. Easter would run

two days ahead of the mean opposition. And if you argue that Easter must be celebrated after Luna xv. so that it does not fall on the full moon — a claim for which you cannot produce a single authority with any competence in this business — you will be unable to escape presenting Easter for celebration on the full moon itself in the years 1734. 1802.2238.2519.3033.3138.3209. The same will happen even if Easter is celebrated after Luna xiiij., as reason requires, because in these years the Dominical letter follows Luna xiiij. by two days, on the full moon itself. But with us this is no offence, since we know that by the Canons Easter may be celebrated on the full moon; it is an offence on your side, since you deny that it may be done. Furthermore, in those eight years listed above — 1737. 1791.1859.1957.2575.2995.3195. 3266. — unless you rule that Easter is to be celebrated on Luna xv., as the Canons and the decrees of the Fathers prescribe, you will defer it to Luna xxij., against every writer on the computus, against the councils, and against the canons.

But here are another 80. years for you, in which greater errors are committed, since in them your Lunæ xiiij. anticipate ours by three days, and sometimes even four.

In all of these years — and I have passed over many more in which the same thing happens, so as not to seem bent on burying you under a multitude of examples — your Lunæ xiiij. always run three days ahead of ours, and they fall before the mean oppositions by very nearly the same number of days, sometimes even by four (as in the years 2546.2565.2603.2611.2622.2945.2983.3214.3233.3271.3290.), and only rarely by no more than two. So if the next day — that is, your Luna xv. — happens to be a Sunday, then by your epacts, and by the Canons and the practice of the Church, Easter will be celebrated one or two days, and sometimes even three, before the mean full moon. That is utterly absurd, and unheard of. And if it could not be celebrated on the full moon, as you wrongly suppose, but only after Luna xv., then even so, if the day following Luna xv. were a Sunday, it would be celebrated either on the full moon itself — which you will not have — or one day, or even two days, before the full moon, against the Canons. You see, then, how wrongly your epacts are placed in the Calendar, epact 29. having been moved from 1 April to 31. March, and so on; and how falsely your table of the true period supplies them. You see this whole structure of yours shaken and collapsing of its own accord. Nor does the matter stop there. Your epacts not only fail in themselves to give us a legitimate Easter; they very often actually force upon us an Easter kept against the Canons and the decrees of the Fathers. For if Easter is to be kept after Luna xiiij. of the cycle, as is right and as the Canons direct, then in the year 2565.

it will be kept three days before the mean opposition; in the year 2650. one day; likewise in the year 2670.; and in the years 2606.2907.3059.4778. two days. What could be more inept? And if, as you wrongly hold, Easter had to be kept after Luna xv., then in those same years it would be deferred to Luna xxij. of the cycle — which the Canons forbid. Next, in the years 2231.2603.2630.2643.2647.2667.2945.2975.3002.3290. Easter will run one day ahead of the mean opposition, and that after Luna xv. of the cycle; while in the years 2610.2613.2617.2637.2661.2671.2918.3070.4721. it will be celebrated on the full moon itself, and indeed on Luna xv. of your own epacts — something you shudder at without cause. Further — see how far I am willing to go — in the year 2619., in which your epact is xxv., there will be no legitimate Easter at all. Why so? Because in March this epact is not the Paschal one, since it occupies 6 March; it is Paschal in April, setting its fourteenth day on 17 April. Now since by your equation the mean opposition falls on 19 April at hour 17. — that is, on the 20th day — it will not be the Paschal opposition, since it comes after the 19th; rather the March opposition, falling on the 21st day at hour 4. — that is, on the 22nd day — will be the Paschal one. So Scaliger will be forced that year to keep Easter in the second month, and wrongly at that, since his Luna xiiij., falling on 17 April, runs three days ahead of the opposition. That is faulty, because on its own terms Easter, coming after Luna xiiij., could be kept on the 18th if that day were a Sunday — two days before the full moon; or, as his own opinion has it, after Luna xv. on the 19th if that were a Sunday — one day before the full moon. How much more correctly, then, does our epact XXII. for that year, setting its XIV. on 22 March, present Easter in the first month, since by our equation the March opposition occurs on 22 March at hour 4., that is, after the equinox? What could be more correct? And this error will not attend your table only once: precisely the same thing will happen in the year 2638. For again your epact will be XXV., whose Paschal XIV. holds 17 April; and yet the April opposition, falling on the 19th at hour 10., is not the right one, since it must be assigned to the 20th, after the 19th — and your XIV. precedes it by three days. How much better, then, does our epact XXII. for that year set out Easter, placing Luna XIV. on 22 March, since by our equation the opposition occurs on 22 March, after the equinox, and so belongs to the first month? In the year 2646., however, your epact will be 2 4., and, as you would have it, the Paschal one in March. Now since the March full moon then occurs on the 2 2nd at hour 9. — that is, on the 2 3rd — your XV. will fall on 21 March, running two days ahead of the full moon. That will not serve, if Easter is not to be liable to be celebrated before the full moon. But our epact that year will be XXI., whose XIV. is marked on 23 March, one day before the full moon, which for us falls on the 2 3rd day at hour 9. What could be more accurate? Do you see

how much more happily matters stand with our epacts and our equation? Nor does the error of your table stop here; it creeps further. You make epact 24. the Paschal one in March, which is an outright novelty, since not one of the writers, nor of the Fathers, has ever brought 7 March — the day set opposite epact 24. — within the limits of the Paschal new moons that are traced by the numbers of the cycle. How much more correctly does our table put the same epact [?] back in April! Let us consider, if you please, the following 16. years, in which each of us employs epact XXIV.

Do you not see that you keep Easter in the 12. month, while we keep it in the first? For your full moons in March all come before 22 March, and so the true Lunæ xiiij. fall before the day of the equinox; whereas ours in April do not go past 19 April, and so the true Lunæ xiiij. do not pass beyond the 18th. Now it is agreed among writers on the computus that the Paschal full moons are contained within one or another of the 29. days counted from 22 March inclusive to 19 April inclusive. From this it follows that those which come before 22 March belong to the last

[printed page number 46]

Table of the sixteen years in which both parties use epact XXIV (the *sequentes 16. annos* announced at the end of the preceding leaf). The table stands at the head of the page; the prose resumes beneath it.

month, and those which pass beyond 19 April belong to the second. Do you see, then, most learned Scaliger, what a forest of errors in the Paschal new moons emerges in this table of ours out of your epacts and that new Canon of yours? I come now to another kind of error, and no light one.

In the tables above, the Lunæ xiiij. of the Scaligerian method always run ahead of the Lunæ xiiij. of the Gregorian Calendar by two or three days, sometimes even by four. Let us now see, if you please, most learned Scaliger, whether your table for the true tropical period ever also offers us Lunæ xiiij. that fall later than the Gregorian ones. For if that happens, your equation will be caught out as faulty and false on every side. So let us consider the following 58. years, in which the Scaligerian epacts are two less than the Gregorian and therefore mark the new moons and the fourteenth days in the Calendar two days later — unless the epact concerned is one of these five, 25.26.27.28.29., for these show them only one day later, since in your Calendar they have been moved up by one day.

Here, first of all, I am utterly astonished: what came into your mind, most learned Scaliger, to push the new moons a full two days toward the ends of the months from the year 3609. as far as the year 3745., when only one day was rejected from the year 3608.? For on account of one day removed the new moons are compelled to descend by one day in the Calendar, not by two — unless you are willing to say that those same new moons from the year 2477. to the year 3609., which its epacts marked two days earlier, were false. I do not believe you will say that, for fear your table of the true tropical period should collapse from the foundations. And no less remarkable does it seem to me that in the next 132. years following — that is, from the year 3745. to the year 3877. — you drive those same new moons back again by two days toward the beginnings of the months. For on account of the

day taken away from the year 3744., if the Moon needs no equation the new moons ought to descend by one day and not to ascend by two; while if it does need an equation, they ought to stay on the same day, as the theory of the new moons requires and as we have written more fully in the *Apologia*, book 2, chapter 4 (*Apologia* II.4). And if in these 132. years the new moons are correctly marked, it must follow that in the preceding 136. years the same new moons were wrongly indicated two days late. But I see that in placing the new moons you took no account of the equation of the solar and of the lunar year, but only of the Jewish new moons [Neomeniæ Iudaicæ] — and that has been the cause of all your troubles, as I have partly shown already and shall shortly show further. Let us therefore examine your Lunæ XIV. — for these must be weighed more carefully than the new moons, because of the solemnity of Easter, and on your own authority at that — and let us compare them with the fourteenth days of the Gregorian Calendar, so that the attentive reader may recognize how much more correctly and aptly the epacts are placed in the Gregorian Calendar, and their equation established, than in the Scaligerian. This is precisely what we have done in the preceding table. There it is plainly to be seen that the Lunæ XIV. of the Gregorian Calendar always run one day ahead of the mean oppositions, just as in the tables above. What could be devised more exactly right in this business? And that Scaliger's Lunæ XIV. almost always follow the mean oppositions by two days. What could be brought forward more foreign to a correct celebration of Easter? The result is that in every year of the next table Easter is kept duly and lawfully according to the prescription of the Gregorian Calendar — that is, on the Sunday next after Luna XIV., as the Canons direct — whereas by Scaliger's method it usually falls in the fourth week, namely on Luna XXII., XXIII., and XXIV., which the Canons in no way allow. For example: in the year 3609. the Gregorian Calendar sets Easter on 5 April, that is, on the Sunday next after Luna XIV. But the Scaligerian Easter is thrown forward to 12. April, that is, to the Sunday next after its own Luna XV., and so onto Luna XXIV. — and further still, since Luna XV., or the opposition, occurs on about the 3rd day. Likewise in the year 3612. the Gregorian Easter will fall on the first day of April, but the Scaligerian on 8 April — Luna XXIV. And the same must be said of very many other years in the same table.

Table of the fifty-eight years in which the Scaligerian epacts are two less than the Gregorian (the *insequentes 58. annos* announced on the preceding leaf: A.D. 3609–3699). The table fills the whole page; no prose accompanies it.

D E I N D E — next, in the years 3613. 3621. 3632. 3640. 3678. 3697., Scaliger's method will put Easter in the last month, since in those years the mean full moon falls not after the equinox but almost always before it, as the table set out below shows. That certainly cannot be excused, and must be judged a very grave error.

But perhaps you will say: What? Does your method avoid every error? I admit that in the years 3621. 3678. 3697. the mean April oppositions, on our scheme of intercalation, fall on the 19th a little after midday, as the table above establishes, so that they appear to belong to the second month rather than the first. Yet since the mean oppositions in the month of March come before the equinox, and therefore cannot belong to the first month, the Gregorian Calendar more correctly takes for its Paschal oppositions the ones that occur in the month of April. The reason is that it is a lesser fault to celebrate Easter in the second month than in the last, since the latter is expressly forbidden while the former is allowed. And this error — if it should be called an error at all, when it cannot be avoided — does not arise from any defect in the cycle. It arises because in the years just named no mean opposition falls on any of the 29. days from 22. March inclusive to 19. April inclusive, which are the only days assigned to the Paschal full moons; so that neither the March nor the April opposition turns out to be Paschal, the first belonging to the last month and the second to the second month. Since, then, one of the two must be taken if we wish to celebrate Easter in those years, it will be better, as we have said, to choose the opposition in April than the one in March. You see, then, most learned Scaliger, that your celebrated method of the Jewish new moons lies undone by this defect. And if that does not move you to hate it, you are welcome to love it — with no rival.

T R I A — three things, I think, are plainly established by what has been said. First, that Scaliger — an extraordinary thing in so gifted a man — has in this

critique of his brought no objection against us that is in any way new, has produced practically nothing that we had not foreseen long beforehand in the commission on the reform of the Calendar, and nothing, in short, that we had not ourselves rejected on the soundest of grounds. Second, that the Calendar proposed by Scaliger, together with his table of the equation *in iusta periodo tropica* [i.e. his *Tabula Æquationis Epactarum in iusta periodo tropica*, "Table of the Equation of the Epacts in the correct tropical period" — the table whose display head stands at printed 38; the terminal vowel of *iust-* does not resolve cleanly here, *iusta/iustæ* [?]], contains not one fault but very many, and those not trivial. Finally, that the Gregorian Calendar is criticized unjustly by Scaliger and by others: for in it the equation of the solar year as well as of the lunar, together with the distribution of the epacts, is so arranged that everything answers very neatly to the mean motions — which is not what one sees in Scaliger's Calendar. The tables above prove it. In them the mean Paschal oppositions have been computed over many thousands of years, and they agree remarkably with the fourteenth moons of the Gregorian Calendar, while they diverge in many ways from those which Scaliger's Calendar sets out. The reason is that his fourteenth days either run ahead of the mean oppositions or lag behind them by more than they should, whereas our fourteenth days almost always precede the mean full moons by one day — which agrees wonderfully with the Canons and with the writers on computus. There is no reason, then, for Scaliger to boast so extravagantly of his Calendar, or to offer it to the whole Christian world as a kind of divine rule and heavenly gift. All the same, we both give him and feel enormous gratitude, since his critique afforded us the occasion of illuminating the Gregorian Calendar by astronomical calculation over a great many years. The result will be that everyone understands that everything in it is rightly arranged, and that in nothing (so far as the nature of a cycle permits) does it disagree with what the councils, the Fathers, the Canons and the writers on computus have decreed. Moreover, this critique of Scaliger's — so careful, and by a man at once so acute and so learned — gives us great hope that no one hereafter will shake the Gregorian Calendar in any part, or bring forward anything better; for so great a man could not do it, and he was virtually the one man of all who seemed able to. But enough of this; let us come to Scaliger's peroration.

SCALIGER.

a Let us then embrace this thoroughly corrected form: let the bissextile days be removed evenly, at alternating intervals of 132. and 136. years; let the epacts be placed in the Calendar in their own order, and that beginning from the Calends of March, not from the Calends of January, as the specimen Calendar we have given

shows; let no two epacts, whether of the same colour or of different colours, be crowded into a single cell; let epact xxix. not be entered in place of epact xxviii. at the Calends of April; and let epact ☐ not be set immediately beneath a single epact in every month, since this is to be done only at alternate syzygies. If this is done properly and in order, as we have said, then not only will there be no censure at all, but the highest praise will accrue to the authors of the year.

CLAVIVS.

a Where on earth does this θεὸς ἐκ μηχανῆς ἐπιφανείς [Greek: *theos ek mēchanēs epiphaneis*, "a god appearing from the machine" — the *deus ex machina*; the print sets a circumflex over the eta of *μηχανῆς*, not the classical *μηχανῆς*] come from, who unties by his own authority what is like the insoluble knot of a tragedy? Truly, if he had known what we demonstrated a little earlier, he would judge very differently. For we have made it plain both that this form is thoroughly faulty — I say it with the author's leave — and that the bissextile years are removed not only more easily but also more correctly

[printed page number 49]

by centuries of years in the Calendar; that the epacts cannot be placed better than they stand in the Gregorian Calendar, and that with the start made from January and not from March; and finally that two epacts, whether of the same colour or of different colours, are on occasion crowded into a single cell not without good reason. Therefore, since everything has been done properly and in order, from this critique of Scaliger's there has accrued to the authors of the Calendar not only no censure at all but even the highest praise.

SCALIGER.

b Away with the faults, then. Let us have done with all childish skirmishing and get on with the business in hand. Everyone must put his shoulder to this, for it is everyone's concern. As long as the received form contains things you may criticize — and they are far too many — those who do not yet use it will always be able to plead why they ought not to. But if it is put forward corrected, there is no reason why it should not be accepted by everyone, since the Julian, which still clings on in many parts of Europe, is not free of fault.

CLAVIVS.

b What would you do, my dear Scaliger, or what would you say, if you had detected in our Calendar faults as many and as great as those we have noted in

your critique? All the same, your advice is sound: away with the faults — which certainly cannot be removed unless the method you have invented is removed. By all means let us have done with all childish skirmishing — which we shall assuredly never do unless your critique has done with it. And finally, let us do *what is in hand*, namely follow the Gregorian Calendar, approved by the consent of the whole world. Undoubtedly everyone must put his shoulder to this, for it is everyone's concern, as you rightly advise. Indeed, since it is now settled that there is nothing whatever in the received form that can justly be criticized, those who still do not use it will not hereafter be able to plead why they ought not to. For since what is put forward has been corrected more than sufficiently, there is no reason why it should not be accepted by everyone — seeing that the Julian, which still clings on in many parts of Europe, is not free of fault, while it is plain enough that the form put forward by that most learned and most gifted man Joseph Scaliger is not free of many great faults. Even so, what held back the Saxons, the English, the Danes and a number of other peoples from accepting the Gregorian Calendar was certainly not any belief that it was defective, but heresy and hatred of the Roman Pontiff. The Calendar pleases them; its author does not. And I have no doubt they would have received it most gladly if it had had the Emperor for its author instead of the Pope. I have myself seen a certain writing of the heresiarch Kemnicius [Martin Chemnitz] to the Landgrave of Hesse, a man outstandingly accomplished in mathematics, in which he commends the calendar quite openly and says that it would deserve to be adopted, were it not that it came from the Roman Pontiff. I pity men of that sort. The very thing they ought most to approve on account of its author, they reject — approved though it is on its own merits — solely on account of its author; and like defiant sons who hate the best of fathers, they would rather go without their father's gifts than enjoy them. And so, taking harm with their eyes open and of their own will where they might have drawn benefit along with everyone else, they earn the price of their own folly and obstinacy, even by their own judgment.

SCALIGER.

a But let this form which we propose be the most elegant, the most thoroughly corrected, the safest, and the most readily workable.

CLAVIUS.

a Are we to believe it? Or do lovers dream up their own dreams? [Virgil, *Eclogues* VIII: *credimus? an, qui amant, ipsi sibi somnia fingunt?* — set in italic as a quotation inside Clavius's roman] For I do not see how that scheme of yours can be *most elegant*, when a disordered equation of the solar or the lunar year

disfigures it; or *most thoroughly corrected*, when, as we have shown, it is heaped with faults; or *safest*, when it leads into inextricable pitfalls; or, finally, *most readily workable*, when it labours under countless difficulties because of the inconsistency of the tables it relies on. The form we have put forward, by contrast, is certainly such that I have no doubt at all that by now it appears to you too, as it does to everyone else, the most elegant, the most thoroughly corrected, the safest and the most readily workable. And if the shape of your own method still delights you, you may love it alone: you will certainly not have me — or anyone with sense — for a rival.

SCALIGER.

b I therefore beg those whose business this correction is: let them lay aside all hatred and all complaint, and either admit this form or devise a better one.

CLAVIVS.

b Stop begging, my dear Scaliger. We have laid aside all hatred and all unjust complaint, and even so we can in no way admit that form of yours once it has been examined more carefully. We do not deny that we could have erred, for we are men. But if anything in human affairs is certain, we are confident that in this matter we have not erred. For it is more likely that one man should be misled and deceived in his own cause than that many men, no less capable judges, should be so in another's. Indeed we find the Lilian method to be the best, precisely by comparison with this form of yours; so that there is no point in devising a better one — which, in my judgment, cannot be done.

SCALIGER.

[siglum: a small solid mark, apparently a worn superscript letter [?]] For we are not hawking our own work. This one thing we demand, urge, and beg again and again: that the faults be removed.

[printed page number 50]

CLAVIVS.

c Nor, for that matter, are we hawking our own work. Before it was published to the world at large we submitted it for examination to all the distinguished mathematicians of the Christian world, as the *Compendium of the Calendar* [*Compendium Calendarii*], sent out to princes and to republics, attests. And Gregory, Supreme Pontiff, sanctioned the new Calendar on their verdict and by the common consent of them all. This one thing we demand — that discord be

removed, since the faults have been removed — this we urge (to use your own words), and beg again and again.

This is what I had to write: not so much against this *Elenchus*, or critique of the Gregorian Calendar, as on behalf of the Gregorian Calendar and of the truth. I ask and implore Scaliger, a man outstanding in talent and in learning, not to take what I have said in any sense other than the one in which I said it. For my own part I have said nothing whatever with the intention of detracting from his reputation, which I wish to see safeguarded. My purpose was rather to warn a man no less industrious than gifted — and to warn him as a friend, as I said at the outset — not to think that other men must be mere hay by comparison with himself, and not to let himself be carried headlong in reliance on the talent in which his strength chiefly lies, but rather to turn those splendid resources of nature and learning to the defence of what is true and right. The truth has at times made me somewhat freer in my speech; I do not deny it. Literary studies and disputations are of this kind: they cannot be handled as they deserve without some heat of spirit and a certain sharpness, especially when the task undertaken is the defence of truth against slanders. Had my purpose been to refute the man rather than to protect the truth, I should have gone about this business very differently. But since he himself professed that in this *Elenchus* he was seeking the truth alone, I too have been content to refute and demolish the fallacious arguments brought against the truth. For I have no fear that a man of such quality and such standing, once the fog of error has been dispelled, will prove more eager for controversy than for truth — especially since to err is human, while to acknowledge and correct an error belongs to the wise man. Nor in fact has Scaliger won no credit for his talent by this effort of his — in my judgment at any rate, except that I find modesty wanting in it — whether because *in great undertakings even to have willed it is enough* [Propertius II.10.6, quoted in italic: *in magnis & voluisse fat est*], or because in attacking the cause of the Gregorian Calendar he has made it more illustrious, and better.

F I N I S.

RESPONSIO AD CONVICIA, ET CALVMNIAS IO- SEPHI SCALIGERI, IN
CALENDARIVM GREGO- RIANVM.

Autore

CHRISTOPHORO CLAVIO BAMBER- GENSI, E SOCIETATE IESV.

A REPLY TO THE ABUSE AND SLANDERS OF JOSEPH SCALIGER AGAINST THE GREGORIAN CALENDAR.

By

Christoph Clavius of Bamberg [Christoph Clavius], of the Society of Jesus.

[Global PDF p. 818 — printed 52]

RESPONSIO CHRISTOPHORI CLAVII BAMBERGEN- SIS E SOCIETATE IESV,

Ad conuicia, & calumnias Iosephi Scaligeri, in Calendarium Gregorianum.

THE REPLY OF CHRISTOPH CLAVIUS OF BAMBERG, OF THE SOCIETY OF JESUS

To the abuse and slanders of Joseph Scaliger against the Gregorian Calendar.

I would have borne your intemperate language against me, Joseph Scaliger, and the unbridled licence you allowed yourself for every kind of dishonest carping in the work you recently published on Eusebius's *Chronicle* — that treasury of chronology — in the spirit I would have judged proper to a Christian, to a man in religious life, and to a man of this age. But at the same time you showed yourself an enemy of decency and a foe of the truth. And since my silence and my self-restraint would have brought a great deal of harm and no advantage at all, whether against your shamelessness or against your lies, I shall now heap upon you charges which — if they cannot deter you from the recklessness of slander (and I should be a fool to think they could) — will at any rate, as I hope, vindicate me and my writings before posterity against a thoroughly unjust calumny. And so that my silence may not tell against me in the eyes of less sophisticated readers — I have no fear of the sharper sort, who see perfectly well what I am proving and what you fling out at random — I shall deal with you in a well-meaning spirit, though in rather hard words, and far more by the weight of arguments. On this one point above all I shall part company with you as widely as I can: you, whenever you say anything, care nothing at all — shameless man — for whether you say it aptly, fittingly, consistently, or truly. Indeed, if I had any hope that you would change the mind and heart you have so far armed for every kind of folly, falsehood, and insolent speech, and recall them to better and saner counsels, I would warn you as a friend, make my suggestions in private, urge you gently, and

exhort you mildly. But you have long since returned, as if by right of postliminium, to your natural bent, convicted though you were by the force of a truth thoroughly known to you — a truth which, if you care to remember, you once professed yourself. And so I shall take up with you the method that the most learned Fathers and the holiest of men, of whom we have abundant examples, took up with the assailants of truth. I shall imitate Augustine, Jerome, Origen, and Tertullian, to say nothing of six hundred others. When they found that they could not correct men by sweetness of speech and the charm of kindly persuasion — by the gentler remedies, as it were — they applied fire, the knife, the opening of veins, the harshness of the steel: that is to say, they cured them by a sharper chastisement in words. I would rather, then, that truth should breed in you this hatred of me that has followed so far, than that base compliance should win me your goodwill.

And it is not in me alone that you have stirred up this reaction — I, to whom your character has long been an open book: shifty, underhand, many-sided; that crafty audacity, that insolent self-assurance, that shameless and brazen effrontery. You have stirred up in everyone an astonishment that passes all belief: astonishment, that is, that at your broken age, full of years (whether full of judgement I do not know), you should have turned your mind to trifles as childish as these, which could bring you no advantage, much expense, a great deal of disgrace, and the stain of folly and stupidity. Come, tell me: if you hated Clavius out of hatred for the truth, what reason was there to relapse again and again into the same ravings, and to set yourself against the decrees of the Popes, the judgements of the Fathers, the enactments of the Councils, and the most solid arguments of learned men? What reason was there — out of hatred of Clavius, or rather, to put it better, of piety — to desert the common consensus of the Church like a traitor, and to conclude that you had to wage open war against her? Did that papal bull so turn your stomach that you thought every drop of your malignant venom had to be vomited out on me? That was what stung you — precisely that. For you saw that if you did not want to look impious, you would have to think as the bull thinks; and that if you kept silent, your unbridled appetite for carping would be badly served, and you would never get the chance to pour out insolently in speeches that full wineskin of yours, crammed with abuse of every kind. I know what caused you pain: my thoroughly just rebuke of that thoroughly unjust rebuke of yours has upset you. But look here, my good man, what is it in that rebuke that you object to? This one thing, plainly: that I spoke of you more respectfully than your ignorance deserved. In what word, even the lightest, did I offend you? Was it that I dismissed your arguments so temperately that a good many people judged *me* the one to be blamed for treating you so kindly? But I

could not — I would not, and indeed I had no right to — subscribe to utterly false opinions for your sake, with truth thrown aside. Whom did you take yourself to be dealing with, Scaliger? Or for whom were you writing, when in the *Canones Isagogici* to Eusebius's *Chronicle* you exhaled so many insults, without bringing forward even the slightest argument, in the most disgraceful fashion, straight from the stables and the vilest taverns? For those men, perhaps, who do not know your character? I am not lying, Scaliger — so help me God — when I say that while I was working my way through those writings of yours, so full of shamelessness and squalor, I judged that Tertullian's remark against Hermogenes fitted you quite superbly: *Hermogenis doctrina tam nouella est, denique ad hodiernum diem homo in* — "Hermogenes's teaching is so novel that, in short, down to the present day he is a man in the [world...]"

[Global PDF p. 819 — printed 53]

seculo & natura quoque hæreticus, etiam turbulentus, qui loquacitatem facundiam existimet: & impudentiam constantiam deputet, & maledicere singulis officium bonæ conscientiae iudicet.

[The Tertullian quotation, carried over from the foot of the preceding page, completes:] "...a man in the world, and by nature a heretic as well, and a troublemaker into the bargain — one who takes garrulity for eloquence, reckons shamelessness to be firmness of principle, and judges the abuse of every individual to be the duty of a good conscience." (Tertullian, *Adversus Hermogenem* 1)

Sed non replenda est curia verbis, Quæ tuto tibi magna volant.

But the court is not to be filled up with words — the grand words that fly safely for you.

One must deal with the learned and the erudite, Joseph. And in fact I do not believe you meant it when you assign me to the mathematicians not on the strength of native talent but by practice and by the long persistence of my labours — since in that critique of the Gregorian Calendar you had spoken of me honourably, and said you would rather be criticized by Clavius than praised by many. But I shall now say nothing about my own talent; such as it is, I acknowledge that it comes wholly from God, best and greatest, in whose service my industry has always sweated. And even if it were of the highest order, it would not go canvassing for a vote of praise on my own recommendation. On this score you deserve heavy censure: you praise that wretched mediocrity of talent of yours — for I do not, as most people do, take you for a blockhead or a lump of

lead — in such a way that nothing could look more distasteful or more absurd. I think I have aptly transferred to you what Jerome said against Jovinian: *Totus tumet: Totus iacet, attollit se per singula, & quasi debilitatus coluber in ipso conatu frangitur: Non est contentus nostro, id est, humano more loqui: altius quiddam aggreditur.* — "He is all swollen and all collapsed at once. He rears himself up at every point, and like an enfeebled snake he breaks in the very effort. He is not content to speak in our fashion, that is, in human fashion: he attempts something loftier." (Jerome, *Adversus Iovinianum* I.1)

Parturient montes, nascetur ridiculus mus.

The mountains will go into labour, and a ridiculous mouse will be born.
(Horace, *Ars poetica* 139)

That this is not the work of a sane man, Orestes out of his mind would swear. A few words must now be said about your talent; the discussion of it is to be framed to fit you — and not to run long, as your writings do.

Piperis & thuris iam iam factura cucullos.

Destined all too soon to make wrappers for pepper and incense.

But, in view of your deserts, briefer than one might expect. And since —

Nequam bestiam; & damnificam imitaris, quam non amabo.

You are imitating a worthless and destructive beast, one I shall not love.

— I shall use arguments of my own, not those of my colleagues, whose virtue and integrity of character you find hateful, and whose learning, endorsed in every branch of study by the public consensus of all scholars, is no cheap thing. And yet you have chosen, as usual, to detract from the reputation of *Benedictus Pererius* [Benito Pereira], a man of the greatest learning and erudition. In complaining that his writings lack a chronological method — a method which is in fact exactly present in his books — you reveal what it really is that you resent: that they shed lustre on the Church, defend the judgements of the Fathers, and weigh the considerations of sincere piety and doctrine; in a word, that being sacred and pious, they support the Catholic religion. It is with my own pen, my own, that I shall prick you; you will be wounded by my arguments, not by re-stitched and randomly clever patchwork — if I may call it that — of grammatical phrases, of the kind those *Prolegomena* of yours are made of. In them, good God, what is there that you do not repeat a thousand times over, swapping actives for passives, until you have rolled right back to the starting-points of your own stupidity? How much better off you would have been had you never come up out

of grammar's hovel to look upon a light of learning broader than your mind's edge could take — above all the light of mathematics, whose most dazzling brilliance so dazed your dull and blunted mind that, half-blind, you have blundered this way and that, baffled and unsure, against every kind of stumbling-block of error. Now attend.

Eheu quam miseros tramite devio Abducit ignorantia.

Alas, how wretched are those whom ignorance leads astray by a byway!

[Margin: Boet. lib.3. Metro. 8.] — Boethius, *Consolatio Philosophiae* III, metrum 8.

And this has certainly been the lot of all those men who in this age of ours have believed the highest credit of their talents lay in openly opposing every one of Ours, and in attacking them besides with every kind of abuse, where it was allowed and where it was not. Pindar puts it splendidly:

[Margin: Ode 8. Nem.] — Pindar, *Nemean* 8.

Ὅψον δὲ λόγοι φθονεροῖς.

Inuidis sermones obsonij sunt loco.

For the envious, words serve in place of a relish.

[Greek: the printed text has the breathing-plus-acute set as a separate sort before the capital omicron; the received Pindaric text reads φθονεροῖσιν, but the print shows the shorter ending — transcribed as printed.]

And that other poet, quoted in Stobaeus:

[Margin: Serm. 37.]

Τοῖς ὅδ' ἐν ὅσιν, ὅδ' ἐεῖς ὅλως φθονεῖ; Αἰεὶ τὰ σεμνὰ πάντα κέκτηται φθόνον,
Ἄπαν τὸ λίαν συνετὸν, ἔστ' ὅτι [?] φθόνον.

*Iis qui nihil sunt, inuidet nemo certe; At splendidis invidia rebus est comes,
Hanc magna comitem habet prudentia.*

No one at all envies those who are nothing; but envy is the companion of splendid things, and great intelligence has envy for its companion.

[Greek: 8 is the printed ou-ligature sort, i.e. οὐδὲν / οὐδὲ / ὅσιν (= οὗσιν). The verb before ὅτι in the third line is set with the στ ligature sort (ς), i.e. ἔς = ἔστ', expanded here in the block's convention; the span between it and the final φθόνον remains unresolved and is flagged [?]. The Latin rendering above is the source's own.]

Tell me, Scaliger: if you thought you knew something, why did you not put forward your objections against me in a friendly spirit, in a human manner — certainly not a bestial one — so that, even if others recognized your ignorance, they would have no ground at all for blaming your intention? As things stand, by what means will you escape the judgement of Posterity, seeing that in its verdict it concedes nothing whatever to favour for the dead, when it will find you not merely raw and unskilled in the subject you handle, but malicious as well?

Come now, use whatever talent you have. Apply your mind, lend your ears — not unfair ears, as is your habit, but fair ones; that is how a learner must be disposed. Have done with quarrels and insults: for if you are a grammarian, you know that line of Euripides in the *Bacchae*:

Ἀχαλίνων ζομάτων ἀνόμδ τ' ἀφροσύνας τὸ τέλ(ος) δυσυχία.

Infraēnis oris, (vt tuum est) ac illegitimæ stultitiæ finis est infortunium.

The end of an unbridled mouth (such as yours is) and of lawless folly is misfortune.

[Greek: the print sets the στ ligature sort (ς) in ζομάτων and δυσυχία, the ου ligature (υ) in ἀνόμδ, and a single terminal ος-ligature sort in τέλ(ος) — i.e. Ἀχαλίνων στομάτων ἀνόμου τ' ἀφροσύνας / τὸ τέλος δυστυχία (Euripides, *Bacchae* 386–388).]

Lay aside your hatred for a while. Put on a temper that is not ungenerous (as it mostly is), nor stubborn (as it often is), nor obstinately fixed (as it always is), but readier to learn. Take this little work of mine, painful though it may be, as a drug and a remedy for curing that sickness of your soul — for by no other word can it, or should it, be more correctly named. And convince yourself that you will win a greater reputation for talent and integrity among all men if you frankly acknowledge, without any malicious pretence, that in your errors you are a man, and at last give truth your hand, than if for the sake of consistency — or rather of obstinacy — you choose to persist in your opinion. For my part, I shall lead you, straying and wandering as you are, through the labyrinths, so to call them, of your ignorance, by truth's Ariadne-thread, so that if you have any soundness of mind, so as to be willing, and any talent, so as to be able, you may easily find your way out of ignorance's windings. And so that you may be guided more easily, and as if by the hand, to weighing the force of the arguments, I shall sort out everything you have scattered about in confusion and disorder here and there, and shall arrange each item as precisely as can be done in its proper place.

And first, to make my beginning here: that book of mine fell under your eye, the one which...

[printed page number 54]

contains the exposition of the [?] Calendar — the book which you, with stupid audacity, call in your Pedagogic commentary a *Giant mass* and a *Gigantic Apologetic*. You would like to patch up your own ruin with the ruins of that mass! Poor wretch: you apparently do not see what foundations it rests on, or with what defences it is equipped, so that it holds every threat and every siege-engine in contempt. In this Gigantic work of mine you call me *raving*, *a babe*, *a raw recruit*. Raving, because I put you into my books, and judged that importunate, shrill crow worth a rebuke from me? A babe, because I handled you courteously and kindly, when you deserved to be pricked with every sting that speech has? A raw recruit, because up to now I have endured your audacity, your self-assurance, and that excessive boasting of yours, more nauseating than nausea itself? Just so — indeed. But you will find out from my arguments that I have now changed my policy. Perhaps you will say that you called my Calendar a giant mass because it carried the Pope's bull at the front, and that you assail the Pope's authority so fiercely because you are the Church's declared enemy. So that is the source of those tears; that is the source of poor little Scaliger's bellowing and complaints. But do put some limit at last on your shouting. What more is there to say? We cannot oblige you. We are sons of the Church, and we follow the papal authority, which is the rule and standard of truth. As long as you are good, we keep you in the place of a brother; but as long as you choose to be what you are, we keep you in the place of a heathen and a tax-collector. Have you got me? You have, I think.

O R D O Y O U call it a *Gigantic Apologetic* because in it the table of movable feasts, together with the epacts and the mean full moons, is continued and extended right up to the year five thousand? Then I have hit the nail on the head. For the reason you call the book a giant mass is precisely that the table struck you as immense — the very table which (and this is what pains you) plainly demonstrates that the equation of the epacts in the new Calendar has been rightly established, since by means of it the movable feasts are celebrated, for all those years, in accordance with the Decrees of the Councils and of the Popes; a very few years excepted, in which, because of the imperfection of the cycle (for no cycle can avoid every inconvenience, as I taught in the exposition of the Calendar), matters stand a little differently. This you cannot bear with an even temper — precisely because the thing refutes your own equation in the clearest way. For your equation does not present Easter as celebrated according to the

Church's prescription even for the nine years after the year 1600, as I showed at great length in my correction of your *Elenchus* and in the book of the exposition of the new Calendar, where the mean full moons of a great many years were computed in order to demonstrate this. There you have 50 years in which your Lunæ XIII always run two days ahead of ours — which are the true ones, as I showed — and all the computists teach that this is faulty. Then another 80 years are added, in which your Lunæ XIII, which you fabricate at your own discretion, get ahead of ours by a full three days; and that is a graver fault still. Again, 16 years are to be seen in which you carry out the solemnity of Easter in the twelfth month, and so force two Easters upon us in one year — and none at all in the year immediately following. What could be more absurd than that? I pass over your other errors, which are noted in the places I have mentioned.

S I N C E T H I S is so, are you not ashamed to charge the Gregorian Calendar so often in your book, slanderously, with having its epacts wrongly arranged and equated? For if right up to the year 5000 they lawfully indicate the Easter to be celebrated [*Pascha cele-brati*, so printed; sense requires *celebrandum*], how do you dare to assert that they are utterly false and erroneous? Consult our tables published in the exposition of the Calendar — but do it attentively; otherwise you will understand nothing, for from what you say I gather that this is exactly what has happened to you so far. And if you do not find the matter to stand as I say, let me be a liar. There you have the reason why our exposition of the Calendar displeases you so much, and why you have neither borne the truth with an even mind nor acknowledged it.

N E X T, in the same Prolegomena, and in the three books of the Canons, you repeat your errors to the point of nausea — errors which I refuted long ago in my correction of your *Elenchus* (which you most shamelessly call a *strawy little pamphlet*, to say nothing of the other, filthier names you dress it up in). Why, I ask, do you make no answer to my criticisms, or fail to make good your own inventions? You really are a ridiculous man, Scaliger — a babbler, rather — since you have failed to grasp that one must proceed by argument, not do battle with insults. In my exposition of the Calendar, if you have looked at it, I bring forward the strongest of arguments; and I do not merely take the force out of your objections — I dissolve them in the plainest possible way, throw them out, and shatter them utterly. Why do you not learn from me? You ought first to have refuted my arguments, and then to have shored up your own and confirmed them — if you had had any. But how could you have any, when truth itself is one? And if you are willing, you will see that truth quite transparently in my arguments. I find nothing solid in your Canons; all I see is a hodge-podge of

tables, useless for this business, stitched together partly out of your own opinion, partly out of the opinion of the Jews, the Arabs, the Egyptians, the Chaldeans, the Saracens, the Armenians, the Damascenes and other men of that sort — tables which teach absolutely nothing to the purpose. Your object, of course, is to catch the popular breeze by a vain [?] display of your hollow learning, which only those admire who see and understand nothing in this business. Good God, how often do you show off your "method" gloriously! How offensively you praise it! How often do you exult in your discoveries (and what are they?) so much that you scarcely seem to be in possession of yourself! If you had earned any credit at all with the rest of the world from your writings — and be assured you have earned none — you would nevertheless have ruined it completely by that sycophantic boasting. Do you really commend discoveries of your own in which ignorance is lavish with words and full of tedium?

O, H O W O F T E N do you throw it at us mockingly that the principles of the new Calendar are a *divine discovery* — when in truth they are a divine discovery (and that is what stings you most), since in it the Canons and the Decrees of the Fathers and the usage of the Catholic Church are observed to the letter. The same cannot be said of your own *strawy* Calendar (to use your own word), as is clear from my refutation: for in the celebration of Easter you stray from the Church's practice by the whole width of heaven, so that it can truly be asserted that you are entirely ignorant not only of what is required for the right celebration of Easter, but that you do not even understand what the word itself means. The Paschal tables which I constructed according to your Calendar demonstrate that clearly enough. But let us now look over a few of the quibbles you have spewed out against me and against the new Calendar, so that everyone may understand that in them you conduct yourself not sincerely and openly, but slyly and maliciously. Listen, Grammarian: *Nothing is, Antipho* —

Quin male narrando possit deprauier.

but that it can be spoiled in the telling.

A N D it really is remarkable that you say nothing new, but simply repeat the very same things and force upon us, like cabbage warmed up again, what I refuted long ago — so that the poet's line fits you with perfect justice:

[Margin: Georg. 1.]

Et veterem in limo rana cecinere querelam.

And in the mud the frog[s] croaked their old complaint.

B U T if you happen to be held by so strong a desire to hear those same criticisms of mine over again, I shall comply with your wish. Perhaps what you did not take in before you will take in now that it has been repeated so many times — that is how it goes with duller minds. Yet I shall do this not of my own accord

[printed page number 55]

and gladly, but under compulsion and provoked by you — above all to satisfy many friends who have urged me to it more than once, even though not a few of them have judged your trifles to deserve no rebuke at all.

Præbe ergo aures iniquæ mentis Aselle.

Lend your ears, then, you donkey of an unfair mind.

Y O U A T T A C K, before anything else, in the Prolegomena to the Canons and in the Canons themselves, what I demonstrated both in the *Apologia* against *Mæstlinum* [Michael Mästlin] and in the exposition of the Calendar — namely, that the Moon anticipates one day in $312\frac{1}{2}$ years. You reject that anticipation and insist instead that it takes place in 304 years, following Hipparchus in this (of whom I shall speak a little further on) and the common run of computists.

L E T U S P R O V E our own equation first, and then refute yours — since, as you say in the Prolegomena, you are eager to learn from me on what grounds I concluded that a προήγησιν [Greek: προήγησιν (proēgēsīn, accusative of προήγησις, "running-ahead, anticipation"); the initial pi is set with the curly π sort] of one day comes about in $312\frac{1}{2}$ years. So hear the proof of it — a proof for which no other astronomy and no other arithmetic is needed (whatever you chatter). The lunar month, taken according to the mean motion, comprises 29 days, 31 minutes of days, 50 seconds, 7 thirds, 57 fourths — that is, 29 days, 12 hours, 44 minutes, 3 seconds, 10 thirds, 48 fourths. Therefore 235 lunar months will make up 6939 days, 16 hours, 32 minutes, 27 seconds, 18 thirds, 0 fourths. And since 19 solar years consist of 6939 days and 18 hours, the 235 lunar months will fall short of 19 solar years by 1 hour, 27 minutes, 32 seconds, 42 thirds. It is by this interval of time that the Moon anticipates its own places in 19 years. And when the calculation is carried through, in $312\frac{1}{2}$ years it runs ahead of its places by 23 hours, 59 minutes, 53 seconds, 5 thirds, which fall short of a whole day by only 0 hours, 0 minutes, 6 seconds, 55 thirds. So we can rightly say that the Moon runs ahead of its places by one day in $312\frac{1}{2}$ years, since only 0 hours, 0 minutes, 6 seconds and 55 thirds are wanting to complete the day.

S U P P O S E the size of the lunar month to be the same — 29 days, 12 hours, 44 minutes, 3 seconds, 10 thirds, 48 fourths — as the Prutenic Tables [Reinhold,

Tabulae Prutenicae] would have it, which are held to be the more reliable. Then, working out the same calculation, you will find that in 304 years the Moon anticipates its places by only 23 hours, 20 minutes, 43 seconds, 12 thirds; and these fall short of a whole day — that is, of 24 hours — by 0 hours, 39 minutes, 16 seconds, 48 thirds. For those to be anticipated as well, a further 8 years and more are needed. So it is truer that the anticipation of one day occurs in $312\frac{1}{2}$ years, as we say, than in 304, as you will have it. If you have some other arithmetic and some other astronomy, share it with us, and answer this calculation of ours if you can.

O N T H E C O N T R A R Y, the Moon cannot anticipate a whole day in 304 years unless we say that in a single enneadecaeteris [*enneadecaeteris* — the nineteen-year cycle] it runs ahead of the Sun by $1\frac{1}{2}$ hours. And that in turn is impossible unless you lay down that one lunar month comprises no more than 29 days, 12 hours, 44 minutes; and consequently the common lunar year 354 days, 8 hours, 48 minutes; and the epacts of one year 10 days, 15 hours, 12 minutes. All of this is thoroughly ridiculous and discordant — indeed it contradicts every astronomer, since they all make the lunar month and the lunar year larger, and the epact of one year smaller. As for the drawbacks that follow from these false lunar periods, anyone who uses them to compute the mean new and full moons over a great many years will find them out easily enough. Since this is so, a judicious reader will readily see how inept, childish and ἰδιωτικὸν [Greek: ἰδιωτικόν (*idiōtikon*, "amateurish" — the mark of an untrained layman)] it is to suppose that the anticipation of one day takes place in 304 years and not rather in $312\frac{1}{2}$.

B U T what shall we say of Hipparchus, who was the first to lay down that this anticipation takes place in 304 years? Did he too go wrong? Not in the least. He simply followed the common practice of astronomers, who, so as to put forward what they call round numbers, are not much troubled about certain small fractions. So we see them make the year 365 days and 6 whole hours, although according to the Alphonsine Tables it comes to only 365 days, 5 hours, 49 minutes and 16 seconds. Again, we see the same men set the epact of one year as comprising 11 whole days, although it contains only 10 days, 15 hours, 11 minutes and 22 seconds. In the same way they say that the new moons return to the same days of the months after 19 years, although in fact they come back sooner by 1 hour, 27 minutes, 32 seconds and 41 thirds. Yet they leave the care of these small fractions to posterity, to add or subtract them after many years, so that both the year may be corrected and the new moons may be found more surely by means of the epacts. It is on this principle that, in order to correct the year, the period of 400 years was instituted, in which three bissextiles are cancelled. And in order to

correct the lunations, tables of the true epacts have been drawn up — as we did in the exposition of the new Calendar, and as Erasmus Reinhold, *Antonio Magino* [Giovanni Antonio Magini] and others have done. Finally, so that the nineteen-year cycle should not lead us into error, Hipparchus devised the period of 304 years, which the crowd of computists follows; whereas we have set up the more accurate period of $312\frac{1}{2}$ years. Observing, then, in this way that 304 years contain 16 nineteen-year cycles, and 323 years 17 of them, Hipparchus chose the round period of 304 years as being nearer to the $312\frac{1}{2}$ years in which the anticipation of one day more truly occurs — because, that is, over many centuries no error of a whole day arises in tracking the new moons. But we must not suppose that he thought the anticipation of one day happened exactly in those 304 years, unless we are prepared to say that he understood the calculation of the new moons no better than you do — and that is not to be said of so great a man. Although, to judge by your ignorance, I have put it too mildly: you would think that nothing should be granted to Hipparchus — nor even to Archimedes, nor to all the mathematicians, if they hold an opinion against you. But that point about the round number the acute mathematician Scaliger did not notice, or at any rate pretended not to notice, so that he might have freer scope (though no cause) for finding fault with our anticipation, which we say takes place in $312\frac{1}{2}$ years. For what is it you are criticizing here, Scaliger? That, dropping the round number of 304 years, we propose the truer number of $312\frac{1}{2}$, even though the nineteen-year cycle is not contained in it an exact number of times, as it is in the other? If that is so, you will certainly be criticizing all astronomers — and this is the mark of the utmost (shall I say ignorance, or shamelessness?) — for asserting that the year contains 365 days, 5 hours, 49 minutes, 16 seconds, on the ground that the common crowd makes it 365 days and 6 hours. On the same principle you will reckon worthy of blame those who define the epact of one year as comprising 10 days, 15 hours, 11 minutes and 22 seconds rather than 11 whole days with the common run of computists. And finally you will not leave unblamed those who assert that the new moons return to the same days of the months after 6939 days, 16 hours, 32 minutes, 27 seconds, 18 thirds — on the ground that this number of days does not fill out the 19 years, which is 6939 days and 18 hours. What could be more absurd than that? See, then, how honourably you conduct yourself in those quibbles of yours. See what monsters, what prodigies you admit in mathematics — you who have not grasped that you have declared war not only on the mathematicians, whom you reckon to have seen nothing whatever, but on the common judgment of all men and on truth itself. But where are those outcries of yours? Where the shouting? Where the mob-scenes? Where those schoolmasterly exclamations which you poured out against Clavius — not

because you meant them, but so that you might look as though you had thumbed through Priscian? Where are those ravings, that notable babyishness, and the raw-recruit's apprenticeship in

[printed page number 56]

these matters, which you say you can see in my book — although you see nothing there at all? That you are certainly a raw recruit in these matters, indeed a babe, and for the most part raving, no one will be able to doubt who considers the sheer number of insults that keep dropping out of the hedge of your teeth, and who sets my solid doctrine, drawn from practised astronomers, beside your own chimeras and dreams. Immortal God! In order to assail our equation and defend your own, what has not dropped from you that is unworthy of a mathematician — you, a mathematician (if indeed you are a mathematician, and not rather a *κακομαθηματικός* [Greek: *κακομαθηματικός* (*kakomathēmatikos*, "a bad mathematician," one who has learned his mathematics badly); the print sets the curly ϑ sort], as your *Cyclometrica* abundantly testify)? You say: if the Moon in $312\frac{1}{2}$ years runs one day ahead of its place, then a new moon which — to take your example — has fallen in March must, after $312\frac{1}{2}$ years, anticipate one day in September; and you add: who could hear that without laughing? What raw recruit, let alone what mathematician, has ever let slip so gross an absurdity? But look here: who could hear without laughing what has slipped out of you in this passage? As though that new moon of March were also the new moon of September! Compare two March new moons with each other, or two September ones — but of the same golden number — and you will see that the later of the two by $312\frac{1}{2}$ years has anticipated one day. Not, however, in the year that is later by $312\frac{1}{2}$ years, since that year does not have the same golden number as the year which precedes it by $312\frac{1}{2}$ years, but in another year after it which does have the same golden number. For example: in the year 323, with golden number 1, the mean new moon of March fell on the 23rd day; but in the year 646, which is 323 years later, with the same golden number 1, it fell on the 22nd. There you see that the Moon has anticipated one day. Again — to use your own example — in the year 1292, with golden number 1, the new moon of March occurred about the 20th day of March, and in the year 1615, with the same golden number 1, on the 19th of March. For in order to observe the anticipation of one day, one must not take two years of different golden numbers, as you maliciously and fraudulently do, even if the one is $312\frac{1}{2}$ years or more distant from the other. Of that kind are your two years 1292 and 1604, which are 312 years apart from each other, and of which the earlier has golden number 1, the later 9. In this matter you trifle so childishly and so like a sycophant that you deserve to be hissed off the stage.

Whom did you imagine you had to deal with, you Momus? With some ignoramus or blockhead who would not recognize your slanders? Do you not know that two different golden numbers within one and the same enneadecaeteris, even though they are next to each other, place the new moons on different days — while the Moon can neither anticipate its own places nor put them off (for who is such a blockhead as to say that in one year the Moon anticipates or postpones a whole day)? For instance: if the golden number VIII indicates that the new moon of March falls on the 13th day, as happens in this century, does not the golden number IX in the following year throw it onto the second day, while the golden number VII in the preceding year sets the same new moon on the 24th day — so that the one comes eleven days earlier and the other eleven days later? Would you accept this line of argument if someone were to argue against you in that way? In the year 1292 the new moon fell, for example, on the 20th day of March; in the year 1597, which is 305 years distant from it, on the 8th; and in the year 1595, which is 303 years later than it, on the 31st. Therefore the Moon does not anticipate one day in 304 years — seeing that the new moon of the year 1597 precedes that of the year 1292 by 12 days, while the new moon of the year 1595 follows it by just as many days. Certainly I think you would not accept it, and rightly so. For if it anticipates one day in 304 years, it cannot but anticipate one day in 303 and in 305 years as well, provided the same golden number is taken which was in use 304 years earlier or *circiter* [thereabouts]. Take it, then, that in the same way, if the Moon anticipates one day in $312\frac{1}{2}$ years, as I have proved, it cannot be that after 323 years from the year 1292 — that is, in the year 1615 — it should not likewise anticipate one day, since in both years the golden number is 1. So stop throwing the year 1604 at us, since in it the golden number is not 1, as in the year 1292, but ix. For since in the Calendar the golden number ix has its seat under golden number 1, but not immediately under it, as we said in the exposition of the new Calendar, chapter 9, the result is that the new moon of the one falls two days below the new moon of the other. Likewise, because the golden number XII is placed immediately above golden number 1, it comes about that the new moon of the former falls on the day which precedes by one day the day of the new moon of golden number 1. For my part I cannot wonder enough at your ignorance — or your malice — so remarkable is it. For if the Moon anticipates one day in 304 years, as you suppose, how can it be that a few years later or earlier it does not also anticipate one day, provided one and the same golden number is taken? Or has it escaped you that all astronomers and computists teach that the new moons do not return to the same days except from one golden number to its like after 19 years have elapsed? But to hold that the anticipation of one day takes place from one year of an enneadecaeteris to the

like year, so that the span of time in which one day is anticipated contains an exact number of enneadecaeterides — that is sheer soothsaying and prophecy. Who are you, to dare prescribe a law to the Moon, that it must anticipate one day in just so many years? And yet why should you not dare, when you so regulate its course as to bring a new populace of stars into the heaven and to invent new lunar revolutions? For if the Moon in a single enneadecaeteris does not anticipate one and a half hours, as I showed above, how can it anticipate one whole day in 304 years? You ought to be ashamed of such ignorance, and of such incompetence in arithmetic, that you cannot work out this calculation, or do not understand it. And let this be enough on the anticipation of the Moon in $312\frac{1}{2}$ years. If it does not satisfy Scaliger — what is that to me? I care not a straw. But if he is willing to learn and to correct his own follies and falsehoods, let him consult the tables placed at the end of my correction of his book. Those tables abundantly demonstrate that the anticipation more truly occurs in $312\frac{1}{2}$ years than in 304, since the Lunæ XIII reckoned by the equation that advances over $312\frac{1}{2}$ years agree better with the Canons and with the decrees of the Councils than those reckoned by the equation that advances over 304 years. And so I cannot wonder enough why Scaliger is willing to persist so stubbornly in his error.

T H E S E C O N D head in the new Calendar which Scaliger's stomach cannot digest concerns the fixing of the equinox at the 21st day of March. In this matter he betrays his own stupidity in mathematical questions, and his remarkable shamelessness, quite wonderfully. For it is not against me alone, but against all the astronomers of our own time as well — all who have written about the restitution of the equinox and its retention at the 21st of March — that he rages and raves most absurdly. In the exposition of the new Calendar we wrote as follows. Since in 400 years the equinox runs three days ahead of its place, we restore it to its own place by the omission of three bissextiles in 400 years. And so that this omission may be easier, and better suited to the grasp of ordinary people, we laid down that in the first centesimal year, which will be 1700, the bissextile day is to be omitted, so that that year has only 365 days, whereas otherwise it would contain 366. The same is to be done in the second and third centesimal years, namely in the year 1800 and 1900; but in the fourth cen-

[printed page number 57]

tesimal year — say in the year 2000 — a day is to be intercalated in the customary way, so that that year comprises 366 days. On this plan, in any span of 400 years the first three centesimal years are to be common years (2100, 2200, 2300), and the fourth, 2400, bissextile; and so on in turn. This rule of intercalation will be

very easily kept in the memory, since it closely resembles the familiar intercalation every fourth year, in which the first three years are common and the fourth bissextile.

And what does Scaliger — that most acute mathematician, if you please, and the most sharp-sighted of all men — say to this? He does not approve this method of intercalation. Why? Because (as he trifles) on Clavius's view three would be four and four three. What intolerable impudence! Where did you find that I ever said this in my writings? Is it because I removed three days from three centesimal years, days which accumulate over four centesimal years? Where did you learn this stupid brand of logic? Is this that famous keenness of intellect you are forever parading? Are these perhaps those admirable discoveries of yours? And to help you grasp the matter better, I shall put it to you by an example fitted to your capacity. Suppose someone has to pay three gold pieces over four years, and, to oblige his creditor, pays all of them in the first three years, so that in the fourth there is nothing left to pay: will three now be four for you, and four three? Listen, my dear Scaliger — take my word for it, you will draw a sounder and less absurd conclusion from that case. So the stick is in the corner, ready to give you a sound beating for your inept raving. What an unheard-of, stupid, frivolous and childish way of arguing! Who could receive it without laughter, without an explosion of catcalls and hissing? Indeed, when I read such flippancy and absurdity in your writings,

Obstupui, steteruntque comæ, & vox faucibus hæsit.

I was struck dumb; my hair stood on end, and my voice stuck in my throat. [Virgil, *Aeneid* II.774]

I would never have believed that so much stupidity could be found in a man of sound mind.

F O R as to your saying that I was struck dumb when I learned from your *Elenchus* that the first day must be omitted in 132 years, the second in 136, and the third in 132 — you are dreaming outright. Why should I be struck dumb, except at your incompetence, at the fatuous dullness of your mind, and at your remarkable stupidity in every department, seeing that I have heard nothing new from you, nor learned anything? Have you not read in my *Castigatio* of your *Elenchus* that, before your *Elenchus* was published, we in the commission on the correction of the Calendar had already rejected this method of intercalation (which you falsely make out to be your own) as less convenient — precisely because it cannot be retained in the memory so easily — and that we preferred our own, which proceeds by centuries of years, for many reasons? For ours is

both easier and keeps the equinox more correctly in its place, and it closely resembles the customary intercalation applied every fourth year. Attend, if you please, to what we wrote in the exposition of the Calendar, chapter 5, Num. 18, 19 and 20. There I demonstrated most clearly that if the equation proceeding by centuries of years is used, the equinox cannot recede so far from its place as it can if the equation is set up by intervals of 132, 134 and 136 years. In the former case it recedes at most by 18 hours — that is, in the first century; for in the second it stands only twelve hours from its original place, and in the third only six. But on that other equation of yours it recedes by a full day three times in every span of 400 years. Let the prudent reader now judge which is the greater fault: to force the equinox to recede from its place by 6, or 12, or at most 18 hours, or by a full 24.

Why, then, does Scaliger shout and bellow that we are rushing the intercalation ahead of time? We do not rush the intercalation at all; rather we force it, so to speak, always to keep the middle road between rushing and delaying the intercalation. Nor is Scaliger right in asserting that intercalation is to be made only when the hours and minutes have made up a whole day. Do you not notice, Scaliger, that you are fighting against the whole company of astronomers and against every nation? Do you not see that everyone applies the intercalation every fourth year at about the beginning of the fourth (that is, the bissextile) year — near the end of February, in other words (as was done in this bissextile year 1608 as well) — when the equinox has slipped from its place towards the end of the month by only 18 hours, and not at about the end of that same year, when the equinox will by then have receded from its place by 24 hours? Have you not observed that the Arabs follow very nearly the same method of intercalation in their equation of the lunar year? For they never wait until a whole day accumulates from the omitted hours; rather, whenever a number greater than 12 is made up out of those hours, they institute an intercalary year, adding one day to the lunar year of 354 days — a year they call *embolismic*. Campanus is a witness to this in his *Computus maior*, and Paulus Middelburgensis [Paul of Middelburg], book 2 of his *Paulina*. Certainly, if you do not know these things, you do not deserve to be trusted in this business of the Calendar.

I will bring forward one man from among the recent writers who also undertook to correct the Gregorian Calendar: Franciscus Vieta [François Viète] — in mathematical matters you could not so much as be his pupil — who did not dare to find fault with our equation of the equinox, but embraced it as thoroughly accurate. Nor did he fear that utterly empty argument of yours, *therefore four are*

three, and three are four, which is judged wholly unworthy of a serious man who has serious matters at heart.

T H E O T H E R heads of the correction of the Calendar which displease Scaliger have been confirmed by us both in the *Apologia* against Maestlin and in the *Castigatio* of Scaliger, and finally in the exposition of the new Calendar — so that it is truly astonishing that he should lay aside all shame and repeat the same things so impudently, when he neither refutes my arguments nor even appears to have taken them in. He thought he had done enough for himself and his own party if he could rave against me insolently and abusively, less than sober. Immortal God, how magnificently he brags about his own Calendar, and proclaims that there is no way at all — none whatever — by which the Calendar can be corrected except the one he himself has taught! What a man: not merely frivolous, but (what is worse) deceitful and dishonest, courting a reputation for cleverness from nothing but the malicious foulness of his language and the barren wickedness of his opinions. How true this is, my *Castigatio*, published long since against his own *Castigatio*, shows: its chief heads we have repeated at the end of the exposition of the Calendar. There I showed most fully that his Calendar teems with countless errors — which is what happens to those who desert the truth — and that by it Easter is almost always celebrated unlawfully, so that it is plainly empty and futile, and the credit for glory which Scaliger arrogantly claims for himself is inglorious and false.

N E X T he attacks our arrangement of the epacts in the Calendar bitterly and abusively, and reproaches us sharply for having assigned epact xxx, or *, to the first day of March, when — as he would have it — we ought to have entered xxix. In this he not only errs disgracefully, since the lunations, on our arrangement of the epacts, alternate at 30 and 29 days as reason requires; he even contradicts himself, since he

[printed page number 58]

himself, in the Calendar of his own *Elenchus*, likewise set against the first day of March the epact xxx, which in his own system the mark o signifies. So he is wrong either here or there. Our excellent helmsman could neither slip past Scylla nor avoid Charybdis. This at any rate makes it clear that he arranges the epacts not on any settled view of the matter but at random, at his own whim. Did he not see that he was contradicting himself? He really ought to have observed the old proverb:

mendacem esse memorem.

that a liar must have a good memory.

There is this to add as well. Since the epacts are the indicators of the new moons, any epact whatever can be assigned to the first day of the month, provided the equation of the epacts is then properly set up. Indeed the epacts can be entered in the Calendar in forward order rather than in retrograde order — as I showed in my *Castigatio* of Scaliger's *Elenchus* — even though on that arrangement they would not then preserve the true reckoning of the epacts. Scaliger therefore labours in vain to prove that the epact xxix, and not xxx, must be attached to the first day of March; all the more so because our own ordering of the epacts indicates the new moons more correctly, according to the usage of the Church, than it would if xxix occupied the place of the first day of March. That is evident from that great table of Movable Feasts set out in the exposition of the Calendar — the table he cannot bring himself to look at with a kindly and untroubled eye.

I N T H E end he repeats the same old refrain about the two epacts xxiiii and xxv, in red, prefixed to the same day in six months; and likewise about the epact xxvi in red and 25 in black, which also occupy the same day above those two. Each of these pairs he calls a monstrous partnership of two epacts. Who could fail to marvel at the man's stupidity here, seeing that he does not understand that this has to be done because of the alternating lunations of 30 and 29 days? For unless it is done, all the lunations will contain 30 days, as I set out at length in the exposition of the Calendar. Did you not notice, Scaliger, that in the placing of the golden numbers in the Calendar the smaller numbers are always set immediately below the larger ones, with six places excepted? What, I ask you, is the reason for that variation? Is it not so that the lunations may be constituted alternately of 30 and 29 days? Since, then, the two associated epacts achieve exactly the same result, they cannot be faulted without the arrangement of the golden numbers being faulted too — and what could be said that is more absurd than that? Weigh a little more attentively and carefully, if you please, the thirty Calendars of the golden numbers in chapter 15 of the exposition of the Calendar, where I taught how the golden numbers are extracted from the epacts. If you do that, I have no doubt you will shake off this gross ignorance of yours. The thing is plainer than a man of sound mind could deny.

B U T what am I doing? I am teaching Scaliger why two epacts are paired in the Calendar for six months, as though he did not know it himself. Did he not himself also, in the Calendar he constructed in the *Elenchus*, set two epacts, o and xxix, against the same day in six months? And quite prudently so: for otherwise all the lunations would comprise 30 days. Nor can he say that o is not an epact on the

ground that it is not a number, since it is equivalent to the number 30, so that in place of the sign o the epact xxx could be written. Let the kindly reader see, then, how candidly Scaliger conducts himself, when he censures in others what he could not avoid himself. Yet in this respect his arrangement of the epacts is worse than ours: although he threw these two epacts, o and xxix, onto a single day in six months, so that the lunations should be constituted alternately of 30 and 29 days, he nevertheless did not place above them the epact o in the other colour, beside the epact i, in the way that we placed the epact xxv, in a different colour, beside the epact xxvi.

For it is out of ignorance of this point — and in truth the exceedingly acute mind of Scaliger was not very quick to grasp the reason for it — that he is very often driven to throw two new moons together onto the same day within one and the same nineteen-year cycle, which is utterly absurd and contrary to all the computists. And this happens to him whenever the character of the epact is one of these: XII, XXIII, IV, XV, XXVI, VII, XVIII, XXIX. For then both epacts, o and xxix, have to be taken within the same nineteen-year cycle. Had he written the epact o in a different colour beside the epact i, he would have avoided this drawback: for with a golden number greater than xi, the epact o in the different colour would have to be taken — just as we prescribe that with a golden number greater than xi the epact 25 in black is to be used. Behold the acuteness of Scaliger, who failed to understand a thing so necessary, and without which the new moons cannot be regulated!

And so anyone at all would approve those two partnerships of epacts, the one of unlike colour and the other of like colour, if only he had any grasp of this excellent doctrine. Nor do we shift the Paschal limits of the Council of Nicaea from their place by means of our epacts, as he falsely and slanderously charges against us; we preserve them most scrupulously, as is right. Our great table of the movable feasts bears witness to this. Where, in that table, has Scaliger found Easter celebrated at any time after 25 April? Let him point out a single instance, and he will be my great Apollo. For with the golden number III current and the epact xxiii in this century, the Paschal Luna xiv does not fall on 19 April, as he falsely asserts (it is his native gift to be ready to deceive), but on 21 March. Let me add one point here. Scaliger holds that the Paschal limit is the full moon, that is, Luna xv. Since, then, the last limit falls on 18 April, who does not see that if that day should be a Sunday, Easter would then be celebrated on Luna xxii — which, on his own testimony too, is against the ordinances of the Church? Let him now chatter and bellow:

Quis concolorium Epactarum, quis discolorium paria sine risu aspicere potest? Consulat Clavius Calendarium nostrum, nulla portenta in illa reperiet, non paria Epactarum, non Epactas nigras, non illam vltimam atram, & nefastam 19. in fine anni, quam sine stomacho neque videre, neque cogitare possumus.

Who can look without laughing at these pairs of epacts of like colour, and of unlike colour? Let Clavius consult our Calendar: he will find no monstrosities in it, no pairs of epacts, no black epacts, none of that last dark and accursed 19 at the end of the year, which we can neither look at nor think of without disgust.

If your own pair of epacts of like colour can be looked at without laughter, why does our pair of like colour offend you? I have consulted your Calendar. Good God, how many monstrosities I detected in it! First I looked at the reckless arrangement of the epacts, since on it Easter is not correctly celebrated in a great many years, as I showed in my examination of the *Elenchus*; so there is no need to repeat the same errors here. Next, I see that you very often force two new moons onto the same day, against all the computists and against the reckoning of the Moon, as I said a little earlier. And I see that, because the dark epact xix is neglected at the end of the year, you set up a single lunation of 59 days whenever the golden number XIX coincides with the epact xix, as has happened in this century. For from 30 January inclusive to 30 March exclusive — where the new moon is indicated by the epact i, which is then to be taken — 59 days are counted. What more absurd or more monstrous thing could be devised? You will certainly not meet with this monstrosity in our Calendar.

C O M E now, let us look into whether, in that Calendar of his which he has celebrated with so many eulogies, a lunation of 31 days in a bissextile year is avoided — the lunation which he himself wrongly calls a monstrosity. For a thing cannot be called a monstrosity when it can in no way be avoided and when all the computists necessarily admit it, a matter on which I have written at greater length against Franciscus Vieta in the exposition of the Calendar, chapter 24. But if it must be called a monstrosity, then it

[printed page number 59]

must, then this monstrous Scaliger cannot escape a just reprimand, since he most openly admits that very same thing so often in his own Calendar. For the epact xxiii on 26 January, together with the epacts that follow as far as the epact xxiiii on 24 February, makes a lunation of 31 days in a bissextile year: because from 26 January inclusive to 25 February exclusive 30 days are counted, and with the

intercalary day, 31. In the same way, from 18 February inclusive — where the epact is o — to 20 March exclusive, where the epact of the following year is xi, there are 30 days, and with the intercalary day 31; and so with the rest. There, then, you see how truly you exalt your Calendar to the skies with all that praise! Are you not ashamed of such vaunting and such false boasting? You are plainly blind if you do not see so many monsters and monstrosities in your own Calendar. So why do you shout,

quis vnquam legit, vidit, audiuit, mensem Lunarem esse 31. dierum?

whoever read, saw, or heard that a lunar month is one of 31 days?

— and call this an asinine error? Then you are the ass, since you commit it so often.

A N D besides, these absurdities and slanders which I have refuted are contained in the *Prolegomena*. He then repeats them, to the point of nausea, in the *Canons*, with a thousand insults and abusive terms, so that it wearies me to hammer at them here again. In the whole book he shouts and bellows nothing else but *Clavius, & Calendarij reformatores hoc ignorarunt* — *Clavius and the reformers of the Calendar were ignorant of this* — while producing nothing solid, of the kind he contends we are ignorant of, from which the true reckoning of the Calendar might be gathered. His own Calendar, crammed with so many errors, is the proof of that. For if those matters of which he reproaches us with ignorance really are to the purpose, how does it come about that he himself could not, from them, put together a Calendar without error? I pass over the fact that he fastens a great many things on me by slander — among the rest, that I deny the Moon's mean motion is to be taken as the standard for the epacts. That this is utterly false is proclaimed by that great table of ours of the movable feasts, in which I always directed the Lunæ xiiii to the mean full moons, as I did in most other places too. Pass the same judgement on the other slanders with which he assails me. The prudent reader will have no difficulty in recognizing that what I have said here is true, if he attentively considers what I have taught in the exposition of the Calendar, and sets it in some order alongside the errors that gush out of Scaliger's Calendar — errors which I catalogued both in my *Castigatio* of the *Elenchus* and at the end of the Calendar.

B U T so that I may at last gather up the wreckage of your shipwreck, Joseph Scaliger, this is the warning I want to give you: a plank still remains by which, since you cannot save the cargo, you may at least save your shipwrecked and storm-tossed body. And truly, if there is any mind or judgement in you, you will reflect that you are already rehearsing for death; that a judgement greater than

any human one is hanging over you, from which your talkativeness will never free you. And if my salutary warnings do not touch you, at least, in God's name, see this much: that not long from now you will pay the penalty for all your crimes; that all the powers below have already conspired for your ruin, and are waiting for that last hour in which you spew out your guilty and rotting spirit. Tear yourself away from so great a plague. Assent to the Church; do not spurn the decrees of the Popes; do not turn away from Catholics; subscribe to the truth. I want Clavius to have no part in moving you: let the silent outcry of conscience move you, the mind of the faithful, the authority of the Doctors, the judgement of Posterity. If you do not approve my advice, then test my arguments and weigh their force. Reckon it over quietly with yourself, with no onlookers by, and still more with none of those disturbances of feeling that blind the mind's edge — reckon over the inconsistency, the frivolity, the falsity of your own statements. For here is the fruit not so much of this *Apologia* as of a just complaint: the salvation of your soul; namely, that at long last, freed from those hellish excesses, you should put off the counterfeit mask of the wise man which you would like to be seen wearing, and reveal yourself openly to everyone as you really are. For my own part, since you have ruined both your reputation and the health of your soul, my dearest wish would be that — since you cannot look to your reputation, or can do so only with difficulty — you should at least be willing to keep your soul safe from the eternal punishments that threaten it.

Listen to Augustine; and let this be my last warning. *Rise up, man, against yourself, before the tribunal of your own mind; and when judgement has been set up in your heart, let thought be there as prosecutor, conscience as witness, fear as executioner.* And if in fact you do this, and, as Ambrose advises, make good in this brief span of life the punishments of hell that are to come, you will free yourself from the eternal judgement. [Margin: Lib. ad Virg.cap. 18.] For the loss of your name in this mortal life would be a small thing, and no harm at all, provided you were willing to think with the Church and — freed from the hands of those most cruel enemies who revel in your destruction — to subscribe to the ordinances of the Fathers and to the propositions of the true faith.

FINIS.

REFVTATIO CYCLOMETRIÆ IOSEPHI SCALIGERI

Refutation of the Cyclometry of Joseph Scaliger

REFVTATIO CYCLOMETRIÆ IOSEPHI SCA- LIGERI,

Auctore

CHRISTOPHORO CLAVIO BAMBERGENSI, E SOCIE- TATE IESV.

Refutation of the Cyclometry of Joseph Scaliger [Joseph Justus Scaliger], by Christoph Clavius of Bamberg, of the Society of Jesus.

REFVTATIO CYCLO-METRIÆ IOSEPHI SCALIGERI, *Auctore*
CHRISTOPHORO CLAVIO BAMBERGENSI, E SOCIE-TATE IESV.

Refutation of the Cyclometry of Joseph Scaliger, by Christoph Clavius of Bamberg, of the Society of Jesus.

Joseph Scaliger's *Cyclometrica Elementa* are of such a quality that they are altogether unworthy of a mathematician. He was quite capable, to be sure, of fooling the eyes of the unskilled — with big drawings of figures, the kind one sees traced in the mathematicians' sand, and by scattering through the whole book the alphabetic letters that mark the steps of a demonstration, letters he painted in red chalk and vermilion so that you should miss nothing of Suffenus — until they took him for a mathematician, since his works so ostentatiously wore what looked like the face of mathematical work. But it will not do at all: *if a sow prints the letter A on the ground with her snout* — as the man says (if you remember him, Scaliger) — *no one in his senses will on that account suspect that the Andromache of Ennius could be written out by her.* [Margin: Cic. 1. de Diuinat. — Cicero, *De Divinatione* I.] Nor, if you — no little cleverer than a sow — draw both A and B, indeed all the Greek letters together, and the Latin ones too, in vermilion and in every pigment there is, will it immediately follow that you can persuade me, or any mathematician, that you are able to write Archimedes' *Equiponderantia* [On Plane Equilibriums], or that work of his you tear at so savagely, the *Measurement of the Circle*. And in truth Scaliger's *Cyclometrica* is so full — I will not say of geometrical errors, but, in all honesty, of outrages — that apart from the title, which he drew from the Greek so as not to look unlearned to the general run of men of letters, he has produced nothing that smells of mathematics.

For nearly ten years now I have often laughed at these outrages, yet I would never have exposed them publicly. Partly because I think it only right to encourage a gifted man — which is what I judged Scaliger to be — even in his

bare attempts; and partly because in this matter he did no injury to the commonwealth, as he did before when he impudently attacked the Roman, that is, the Ecclesiastical, Calendar. Here he wronged only himself, or a handful of mathematicians. But in a book he lately cobbled together this ungovernable man showed such arrogance toward all good men — arrogance that did not spare even the saints who reign with Christ — and such impudence of tongue toward me in particular, though I had done nothing to deserve it, that by slandering every decent thing he has now wrung from me the very rebuke of his many faults that he could not wring from me by thinking ill of mathematicians: a plain rebuke, and one that suits not only my temperament but my toothless years as well. But look, reader, I beg you, at the reason Scaliger fell upon me: it is because I defended a calendar that is Roman, papal — indeed, whether Scaliger likes it or not, genuinely mathematical. What is one to do with such a man? By my way of life I am papal, by religion Roman, and by inclination — if not by knowledge — a mathematician. If Scaliger shudders at the first two, the third he professes himself. On that count at least he should have made allowance for my study. And if he would not, he should at least have brought against my work not merely a licence to abuse, but even some new argument that I had not already demolished long ago in the *Elenchus*. But in fact he chose to attack not my work but me; whether wisely, whether rightly, posterity will judge. Meanwhile I shall not let him find in Clavius the imitator of himself that he deserved. Scaliger's mistakes I shall run through with a mathematician's pen, which is easy enough to do; Scaliger himself — though that would be little harder — I shall leave untouched. Perhaps he will learn either to know more or to write less; he will learn not to think himself the only human being alive; and unless he is utterly incapable of learning it, he will learn that contests in literary matters can be fought even by a man who is no gladiator.

Since it would take too long to recount and refute everything he has got wrong in geometry, I have judged it worth the trouble to expose, in selected passages only, the chief and truly childish outrages of so great a mathematician. From these the discerning reader will easily form a judgement about the rest — especially since most of this man's absurdities have already been learnedly refuted by *Franciscus Vieta* [François Viète] the Frenchman and *Adrianus Romanus* [Adriaan van Roomen] the Netherlander, both outstanding mathematicians, and by others elsewhere too.

And so that in this correction of a slippery man there may be no room left for shuffling and escape, I shall set the whole business out as follows: first Scaliger's own words, with a note of the passages they are taken from; then, placed beneath

Scaliger's words, my own verdict on what he says. Many know that I did just this, and not without profit to my readers, when I corrected the same man's insufferable *Elenchus*. Let us begin, then, with the dedicatory letter.

SCALIGER.

In epistola dedicatoria ad ordines Hollandiæ, &c. [In the dedicatory letter to the Estates of Holland, etc.]

I hold that this concerns not only my own standing, but that of my ancestors as well — their greatness and their glory: that I, very nearly the last of our most ancient and most illustrious family, should not go without the testimonials of such great men, testimonials which my ancestors themselves never lacked, on account of their services and their brilliant achievements.

CLAVIVS.

How much you boast about yourself in this letter, Joseph Scaliger — and how vaingloriously, how pompously! And, I suppose, in order to prove yourself no bad panegyrist, you began from the cradle. But believe me, that effort was unnecessary. It is well known that spewing out a panegyric on oneself and Philipppics — or something still more caustic — against others takes one and the same talent, and one and the same kind of man. And so you stirred the bile of a man who is not unlearned, Gaspar Scioppius [Kaspar Schoppe], who traced the origins of that most illustrious and most ancient family of yours — you know where he traced them to. How truly, I cannot say: I am a man with no expertise in history or genealogy, least of all obscure genealogy. He certainly won applause from the literary theatre, in which that line of yours has by now been chanted by your family so many times —

————— *& mi genus ab Ioue summo.* [and my line too is from Jove most high.]

— that it had stirred up who knows how much resentment against players who were far from bad.

SCALIGER *ibid.*

It is my task, therefore, to show not only how gladly I allowed myself to be persuaded, but also to take pains that whoever reads my works hereafter may say boldly that the fruit he gathers from your judgements is no empty one.

CLAVIVS.

On the contrary, it is my task — and every mathematician's — to show that you have persuaded no one of any of the things you urge, and how freely everyone may admit that even wise men's judgement of another man's ability is sometimes empty.

SCALIGER *ibid.*

The credit of this science is so sure that a man who does not abuse it never wastes his labour, whereas a man who uses it forcibly — which is what those ancients Antipho, Bryso, and Hippocrates of Chios did in this matter, and, to my unending astonishment, the great Archimedes as well — gets nothing out of his demonstrations except to look as though he had meant to go wrong demonstratively.

CLAVIVS.

Did I not point out that it belongs to one and the same dog to fawn on itself and to bark at others or tear them apart? That you have not wasted your labour, because you do not abuse the science of mathematics, is as empty a piece of self-flattery as your mauling of the greatest of men, Archimedes — to say nothing of the rest — for having used that science forcibly is unjust. But of course, if your own light requires Archimedes' darkness, then I prophesy this for you, Joseph Scaliger, and I am no bad prophet:

————— *In æternam* ————— [Into everlasting (night) —————]

[Margin: *Æneid.* 12.]

You know the rest.

SCALIGER *ibid.*

But we fall as far short of those ancients in knowledge as we do in natural ability.

CLAVIVS.

Welcome to good sense and a sound mind: my congratulations. If only it would last.

SCALIGER *ibid.*

This much we can promise with certainty: that up to now they are surpassed by us, because we have demonstrated everything not παραλογισικῶς [Greek: paralogistikōs, "fallaciously," by way of a paralogism] as they did, but κατὰ τὸν

ἐπιστημονικὸν λόγον [Greek: *kata ton epistēmonikon logon*, "according to strictly scientific reasoning"].

CLAVIVS.

Hah — back to your old self so quickly, my Scaliger? So they argued fallaciously, and you alone according to strictly scientific reasoning? So may God grant you a sounder mind, as surely as there is nothing sound in you and everything is sound in Archimedes. And you will not deny it — if you understand what I write — noble as is the spirit you draw from that most illustrious and most ancient family. But let me for once raise a question about wording. I have never met anyone more Greek than you, Joseph Scaliger: the title of the whole book is Greek; the headings of the propositions and problems are Greek; the letter itself is half-Greek from beginning to end. I am not finding fault; I am asking the reason. Some suggest the temper of a man fishing for praise among the lowest rabble. Others, a taste for showing off. Most think they have said it all when they say: frivolity. For my part, I pronounce no verdict — but I do give this warning: your work will stand no higher with geometers if it circulates half in Greek than if it circulates in Latin.

SCALIGER *ibid.*

And so with confident modesty we declare that in the discovery of the thing itself, too, they are surpassed by us by a long interval — the thing which, after it had eluded them for so long, we at last set before your eyes after so many centuries, and now dedicate for the first time to your name.

CLAVIVS.

Do you call this modesty, Joseph? Then what counts with you as arrogance? What as impudence? Whom, I ask you, out of the whole number of learned men, have you heard, seen, or read setting himself above everyone with modesty of this sort? — unless perhaps someone from among the Scali-

gers. But the most illustrious progeny of that most ancient family of yours gives you spirits that are more than confident. Perhaps you are afraid of the old line:

————— *Degeneres animos timor arguit.* [Fear betrays a degenerate spirit.]

Away with you, I beg: take that "confidence" of yours out of the world of letters at last — it is not, as you call it, "confident modesty." And what is it you offer? Will you display before our eyes something that eluded Archimedes, that eluded so many centuries of learned men? You are mistaken. What you will display is not

what eluded Archimedes, but what Archimedes successfully steered clear of as though it were a reef: monstrosities and prodigies of faulty argumentation. Do not suppose, reader, that I say this as an exaggeration. Were it worth the trouble, I could swear the most solemn oath that in this whole abortion of Scaliger's there is not one piece of reasoning that does not lie; and if I am wrong, I do not refuse to stand as a liar in your eyes, reader.

SCALIGER *ibid.*

Receive, then, most noble and most eminent gentlemen, a work greater than the ill-disposed expect.

CLAVIVS.

You have prophesied truly. Anyone who wishes you ill, Scaliger, would never — if I judge rightly — have expected from you so much material, not for correcting you, but for laughing at you. I shall not do that. You will find in me no ill-wisher, but a friendly monitor and a pointer-out of your mistakes, careful and painstaking, as befits a man of my years and calling — however you may in the end have deserved of me. Let us pass on, then, to the Prolegomena.

SCALIGER *in Prolegomenis.* [in the Prolegomena]

About the straight line equal to the perimeter they took little trouble — indeed they took no interest in it at all. For carters too may observe that line every day, since the wheel cuts it off from any track it makes when it has revolved round to the same point on itself from which it first began to move.

CLAVIVS.

You will have gained nothing worth the effort, Scaliger, by lying so openly. Who has ever heard the name of mathematicians without also hearing that a great many of them, and the foremost of them in knowledge, laboured at the search for a straight line equal to the perimeter of a circle? And what else is Archimedes about in the book on Spirals, Proposition 18? For Dinostratus, in devising the quadratrix with such great labour, wasted his effort unless he was seeking a line equal to the perimeter of the circle. Nor did they do this without reason: once a straight line equal to the circle's perimeter has been found, the circle is squared at once, as Archimedes demonstrated with the greatest acuteness in the little book on the measurement of the circle, Proposition 1. But you flatly deny it. What has that to do with the case? If, in your zeal to contradict everybody, you were to assert that the sun does not shine, I should not conclude that the sun lacked light, but that you lacked either eyes or something better than eyes.

But what am I to say about that splendid piece of mathematics — that carters can observe every day a straight line equal to the circumference of a circle in the track which the wheel cuts off in a single revolution? What a delightful mathematician, one to whom there is no access except through carters and cab-drivers, just as once there was no access to Plato except through mathematicians! So a carter, by the chance revolution of a wheel in mud and filth, will teach what Archimedes and Dinostratus could not teach with the impressions of a precise stylus in learned dust: namely, which straight line is equal to the perimeter of a circle. You are afraid, I suppose — born and bred as you are for glory — of being hissed off the stage for so foul a disgrace. I will free you from that fear, if I make it plain that not even you assent to so great an absurdity. Come, then: these are your own words, in the Prolegomena itself, if you acknowledge them. *For if I find with a compass that one magnitude is equal to another magnitude, it does not immediately follow that it is equal to that magnitude; indeed I shall refuse to believe it true, if it cannot be demonstrated ἐπιστημονικῶς* [Greek: *epistēmonikōs*, "scientifically," by strict demonstration]. By the same reasoning, then, granted that I find from a single revolution of a wheel a straight line equal to the circumference, it does not immediately follow that it is equal to it, unless a demonstration proves it — since one can go wrong in that revolution in many ways, as even a man who has had nothing demonstrated to him scientifically knows almost more than scientifically.

S C A L I G E R in *Prolegomenis*.

This the divine Archimedes does pursue — though unsuccessfully, and with the grossest errors — in the third demonstration of his Cyclometricum, where he attempts to express that length in numbers.

C L A V I V S.

In what, then, is he divine, if he is so unsuccessful and so full of error? No: he is divine in mathematics through and through; as for you, I do not know whether you are unsuccessful, but you are certainly most full of error. Learn, rather, what that divine genius set out to do in the demonstration, and how successfully he achieved it. His aim was to show which ratio in numbers does not fall far short of the ratio of the circumference to the diameter — not which straight line is equal to the circumference; and that he accomplished with complete success. For he demonstrated that the ratio of the circumference to the diameter is a little less than three and one-seventh [tripla sesquiseptima], that is, three and ten seventieths [tripla superdecupartiente septuagesimas], but greater than three and ten seventy-firsts [superdecupartiente septuagesimas primas]. I

demonstrated this in the *Geometria practica*, book 4, chapter 6 — although you most erroneously declare that the ratio is greater than three and one-seventh, contrary to the judgement of all mathematicians, taken in by a worthless argument drawn from the dregs of carters, because you have entirely failed to understand Archimedes' demonstration.

SCALIGER in *Prolegomenis*.

*For there is no kinship between τῷ ἐμβαδῷ [Greek: τοῦ ἐμβαδοῦ, *tou embadou*, "the area" — both words printed with the ou-ligature sort] and the rectilinear figure contained by the semidiameter and the perimeter.*

CLAVIUS.

The kinship is so close that this rectilinear figure is wholly equal to the circle, as Archimedes demonstrated — whatever you may bark to the contrarium [recte: contrarium, "to the contrary"].

SCALIGER in *Prolegomenis*.

*which he himself wrongly called the τετραγωνίζουσα [Greek: τετραγωνίζουσαν, *tetragōnizousan*, "the squaring line," the quadratrix], since it contributes nothing to τετραγωνισμόν [Greek: *tetragōnismōn*, "quadrature"], as we have shown elsewhere.*

CLAVIUS.

All of this is false. Dinostratus did rightly call that line the quadratrix, since by means of it the circle is squared, as I demonstrated in my commentary on Euclid, book 6. You, on the other hand, will demonstrate that it contributes nothing to the quadrature on the Greek Kalends.

SCALIGER in *Prolegomenis*.

We, then, have achieved more than Dinostratus himself and more than Sporus. For we have shown both what it is and how it can be described; and besides, we have not only detected the point itself, but have also taught what it is.

CLAVIUS.

Good heavens, how magnificently you boast and parade yourself! I will say how things really stand. At my present age, and being a man of anything but a frivolous temper, I never meet with silly boasting of this sort without laughing from the heart. For into my mind come the Thrasos and braggart soldiers whom I have long — from boyhood, that is — heard on the stage, and never without

laughter. What else is that line of yours: "We, then, have achieved more than Dinostratus himself and more than Sporus"? Exactly so:

Cum quo bellator Mars haud ausit dicere Neque æquiparare suas virtutes ad tuas.

[The man with whom warrior Mars would not dare to speak, nor match his own prowess against yours.]

Have done, Scaliger, I beg you. This boasting of yours is your enemy. Look at who you are and at the men you are being carried against; consider not what you can promise but what you can deliver. So you have described the quadratrix (to talk Greek along with you); you have not only detected the point but have also taught what it is. Where, pray? Certainly nowhere in this book — as I shall show, clearer than daylight, in the proper place.

SCALIGER in *Prolegomenis*.

For just as the famous Bryson used to say that an equal can be found if a greater and a less are established, so Archimedes supposed that if the circle proposed were neither greater nor less than the triangle proposed, then it was equal — which is plainly faulty, as we have demonstrated elsewhere.

CLAVIUS.

Archimedes' inference is not faulty, as you slanderously claim, since Euclid used the same kind of argument more than once. Nor do you refute that inference correctly in your *Diatriba*; you commit a thoroughly gross paralogism instead, as I showed in the *Geometria practica*, book 4, chapter 6. And are you not ashamed — you who profess to be a mathematician — to deny that a magnitude is equal to a magnitude than which it is neither greater nor less? For if it is not equal, it will certainly be unequal, and therefore either greater or less. Do you see where your own paralogism has driven you — the paralogism by which you suppose you have overthrown Archimedes' argument? But no more of this here. I refer you to that scholium of mine in book 4 of the *Geometria practica*. There you will learn, if you are willing and able, that you must not in future be a laughing-stock to mathematicians.

SCALIGER in *Prolegomenis*.

He dared to pronounce a thoroughly absurd thing: namely, that the perimeter of a circle falls short, beyond the triple, by a seventh part of the length of the diameter.

CLAVIUS.

On the contrary, it is you — for why should I not be allowed to say of you, on the side of truth, what you were allowed to say of Archimedes against the truth? — it is you, I say, who pronounce most absurdly, when you pronounce that Archimedes said something thoroughly absurd about the ratio of a circle's circumference to that circle's diameter. But perhaps, as commonly happens with perverse minds, sound and true mathematical demonstrations count with you as thoroughly absurd — such as the demonstration by which Archimedes proved that ratio to be less than three and one-seventh. That demonstration you will not shake, however many engines of abuse you bring up against it.

SCALIGER in *Prolegomenis*.

If anyone is an admirer and a student of Archimedes' divine genius, I am he. But let young men beware of the reefs of his τῶν εἰς ἀδύνατον ἀπαγωγῶν [Greek: tōn eis adynaton apagōgōn, "reductions to the impossible"]. For he is suspect, and we have in fact detected not a few utterly absurd errors of his — which can be spoken of at a more convenient time and place.

CLAVIUS.

A fine admirer of Archimedes you are, to be sure, when you proclaim that you have detected utterly absurd errors in him and warn young men to beware of his reefs and of his reductions to the impossible. Meanwhile — scrupulously Latin here, ready Greekling though you are — you have steered clear of the reef of the word *Impossibilis* more successfully than you have steered clear of the reef of empty talk, or of ignorance in mathematics. For what is sharper than Archimedes' reductions to the impossible? What is better fitted to knock a man off his footing and send a shameless fellow like you headlong? And if that is not so, come, great geometer: bring out one of these utter absurdities where we can all see it. But you have brought out some already — and you will bring them out at a far more convenient place and time. Very well: at that same place and time I shall refute them. For the present, what you have brought out amounts, if I remember rightly, to these two: one concerning the area of the circle, and one concerning the ratio of the circum-

— the ratio of the circumference to the diameter; and then a third, *propos.* 19, on the power of the circle, in the area of the parabola. Against these I need nothing more, for now, than a word to check your scolding: Archimedes committed no fault in these matters, you a great many childish ones. That this is not said idly you will learn below. So let young men beware of the reefs, the quicksands and the Scyllas of your παραλογισμῶν [Greek: *paralogismōn*, "fallacious inferences" —

set with the παρ-ligature sort]. In Archimedes there is nothing to beware of: everything in him is deep, certainly, but safe — calm water.

SCALIGER in *Prolegomenis*.

And so, when we accept magnitudes of this kind as true because we cannot demonstrate them (but detect them with the compasses alone), we bankrupt our own good name and brazen it out, extricating ourselves smartly by some shameless reduction to the impossible. Archimedes resorts to this so constantly that he seems not to hold a kingship in geometry but to run a tyranny. And so, as we have warned so many times, not a few of his conclusions are falsely drawn.

CLAVIVS.

It is your own name, Scaliger, that you have bankrupted. Our Janus here — the exchange where geometers and astronomers keep their accounts — has you posted as a defaulter. Go and settle accounts with the geometers: if you find a single one who will trust you with a farthing, call me a liar. And you charge *Archimedes* with shamelessness? *Archimedes* with tyranny? This, to be sure, is what it means to have brazened it out in earnest, and by the most shameless abuse to run a filthy tyranny over men of talent. But it will not last long, believe me. I see Brutuses standing ready — men who, seeing that patience gains nothing against that iron face of yours, have resolved to settle the matter with a sharpened stylus and toothed paper.

SCALIGER in *Prolegomenis*.

It is enough for me that the thing itself, which I have accomplished by the kindness of Almighty God, clears me of every suspicion of ἀλαζονείας [Greek: alazoneias, "imposture, boastful pretension"].

CLAVIVS.

Do you really claim to have accomplished *the thing itself* — that is, the quadrature? I refute nothing. Your own fallacy-ridden little book refutes you. Carry on; you will learn.

SCALIGER in *Prolegomenis*.

In the Cyclodynamicum, which I made the second part of the Cyclometricum, the squaring both of the circle itself and of its segments is carried out γεωμετρικῶς [Greek: geōmetrikōs, "geometrically"] at any rate, and καὶ κατὰ [printed with the abbreviated κ-with-stroke sort] τὸν ἐπισημονικὸν λόγον [Greek: epistēmonikon logon, "the demonstrative/scientific account" — set with the ς (στ) contraction

sort], not τυραννικῶς [Greek: *tyrannikōs*, "tyrannically"], as Archimedes does. For arithmetic has no place here.

CLAVIVS.

It is you who run a tyranny in a matter of this kind, not Archimedes, since you demonstrate nothing solid. Archimedes never asserted that the circle can truly be squared by numbers; he only showed how little a square found by numbers falls short of the circle's area. So much for the things you wrote in the Prolegomena, whether over-arrogantly and boastfully or simply falsely. Now let us look, step by step, at some of your fallacies, so that everyone may understand that you are altogether inexperienced in geometry, and ignorant of it.

SCALIGER in *Prolegomenis*.

About the circle IB, whose centre is G, let the square FA be described; and in the same circle let the square IB be inscribed. Again, let the square HE be obtained about the same centre G, its side EK being equal to the rectangle contained by BM, AL — that is, by the sides of the inscribed and of the circumscribing squares. With the diameter FA drawn, let the straight lines NB, OE, produced, meet the side LA; likewise let the straight lines KE, MB, produced, meet the side AP. By VI.24 the rectangles BA, BE and EA are all squares. Let the straight line CD be joined. The angles BCD, BDC will be half right angles, while the angle CRE is a right angle. Therefore the angle REC is half a right angle, by I.32. Hence, by 6 of the same book, the straight lines RC, RE are equal. In the same way it will be shown that the straight lines QE, QD are equal. Therefore the parallelograms CE, ED are squares, and equal to the squares BE, EA. Indeed all four squares BE, EA, CE, ED are equal to one another, by the first common notion. Therefore the diagonals BE, EA are equal as well. The square HE, then, is equally distant from the squares FA and IB; and for that reason it is a mean both in position, as has been demonstrated, and in power, from the construction. For the mean proportional was taken between the sides IM, FL, etc.

Diagram. A single woodcut set into the left half of the page, beside Scaliger's lemma. It shows a large upright square, a circle inscribed in it touching all four sides, an upright square inscribed in that circle, a third upright square concentric with them and intermediate in size, the diagonal of the outer square drawn from its lower-left to its upper-right corner, and — crowded into the lower-left corner of the outer square — a small group of short straight lines forming two small squares with their diagonals. The lines of the two smaller squares are carried out

to the left-hand and bottom sides of the outer square. All seventeen letters below are read directly off the block; no letter is supplied from the accompanying text.

- L (outside the block, above the outer square's upper-left corner): outer square's upper-left corner
- F (outside the block, above the outer square's upper-right corner): outer square's upper-right corner
- A (outside, below the outer square's lower-left corner): outer square's lower-left corner
- P (outside, below the outer square's lower-right corner): outer square's lower-right corner
- K (inside, on the left-hand vertical of the intermediate square, at its top): upper-left corner of the intermediate square
- H (inside, at the top right, just below F): upper-right corner of the intermediate square
- O (inside, at the lower right, below H): lower-right corner of the intermediate square
- M (inside, upper left, below and right of K): upper-left corner of the square inscribed in the circle
- I (inside, upper right, below H): upper-right corner of the square inscribed in the circle
- N (inside, lower right): lower-right corner of the square inscribed in the circle
- B (inside, on the drawn diagonal, below and left of centre): lower-left corner of the square inscribed in the circle
- G (at the centre of the circle, on the drawn diagonal): centre
- C (at the left, on the outer square's left-hand side, low down): endpoint of the lower horizontal carried to side LA
- D (at the bottom, on the outer square's bottom side): endpoint of the vertical carried down to side AP
- R (just right of C, inside): vertex in the small corner construction
- E (below R, inside): lower-left corner of the intermediate square
- Q (just right of and below E, inside): vertex in the small corner construction

The corner construction at A is the densest part of the block: the individual short strokes there cross at very small scale, and while the seventeen letters are legible, the exact set of line-endings inside that corner cannot be resolved cell-by-cell at native resolution [?].

CLAVIVS.

I take you up at this very entrance, Scaliger: see that you do not miss the door. I truly cannot wonder enough how a mathematician — which is what you proclaim yourself to be, however falsely — could blunder so childishly in his very first demonstration. You say you have demonstrated that the square HE is equally distant from the squares FA and IB. That is entirely false, and false on your own construction: for you make the side EK the mean proportional between the sides AL and BM. From this it follows that the side AL exceeds the side EK by a greater excess than that by which the side BM falls short of the side EK — as I said in the fourth property of the three proportionalities, among the definitions of Euclid Book 5, and as is plain in these three numbers in continued proportion, 18. 12. 8., where the excess of the greater numbers is 6 and that of the smaller is 4. But

so that you may at long last begin to learn something, I will uncover the very head of your error. It is this: you supposed that the diagonal CD passes through E, the intersection of the sides EK, EO. That is not true, except when the three sides AL, EK, BM are in arithmetic proportion — which is contrary to your own construction. Therefore, since the side EK is the mean proportional between the sides AL and BM, it is impossible for the diagonal CD to pass through the angle E; it must pass below it. In other words, that mean-proportional side will cut the diagonal BA above the diagonal CD. So your reasoning is a parallogism.

SCALIGER *in propos. 1.*

About a given finite straight line, to describe a dislocated volute [voluta luxata — Scaliger's own term]: that is, the Helix of Archimedes.

About the given finite straight line BD, bisected at E, let the circle ABCD be described. When the quadrants of its circumference have each been divided into four, the whole circumference ABCD will be divided into 16 parts, such as DF, FH, HK, and so on. When straight lines have been drawn from the centre E to the marks of those divisions, the whole circle will be divided into 16 scalpra, etc.**

And a little further on.

Let d be equal to ED, divided into 16 equal parts, by VI.9. From the straight line EF, then, let GF be taken away — that is, one sixteenth of the line d — by I.3. In the same way let IH, two sixteenths, be taken from EH, and so on, decreasing.

And a little further on.

Taking the interval GD, then, as a base, let an isosceles triangle be conceived as standing upon that base, one leg of which is equal to fifteen sixteenths of the line d — namely, to EG itself. Then with the vertex of that isosceles triangle as centre, and with the interval EG, let the arc GD be described. In the same way, when an isosceles triangle has been set up on the base IG whose side is equal to 14 sixteenths taken from the line d — that is, equal to the line EI — with the vertex of that triangle as centre and with the interval EI let the arc IG be described; and so on, until the centre E has been reached.

Diagram. A woodcut set into the right half of the upper part of the page. It shows a circle with a horizontal diameter drawn across it and sixteen straight lines radiating from the centre to the circumference. Inside the circle a second, smaller curve winds inward from the right-hand end of the diameter toward the centre, crossing the radii. Below the circle, and about as wide as it, runs a straight horizontal line closed at both ends and divided by short cross-ticks into a series of equal parts; it is lettered at its left end. Every letter listed is read directly off the block.

- A (at the top of the circle, on the circumference): top point
- K (on the circumference, upper right, between A and H): division point
- L (inside, just below and left of K, on the winding curve): point on the inner curve
- H (on the circumference, right, below K): division point
- I (inside, just below H, on the winding curve): point on the inner curve
- F (on the circumference, right, below H): division point
- G (inside, just below F, on the winding curve): point on the inner curve
- D (at the right-hand end of the horizontal diameter): endpoint of the diameter
- B (at the left-hand end of the horizontal diameter): endpoint of the diameter
- E (at the centre, where all the radii meet): centre
- M (on the circumference, lower right, above the right-hand part of the divided line): point on the circumference
- d (at the left end of the divided horizontal line beneath the circle, set as a minuscule with an ascender): the divided line
- [?] (at the very bottom of the circle, directly below E): a single letter whose sort prints reversed and does not resolve at native resolution. The accompanying text names the circle *ABCD*, so this is the position C would occupy, but the glyph itself is not legible and is not committed.

CLAVIVS.

What a delightful mathematician! If the schoolboys do not greet him with the whip, they do badly by so fine a teacher. I am amazed that you can conceive of a helix being put together out of circular arcs, when a helix made that way cannot have a uniform curvature, precisely because the arcs are different — and every two of them always form curvilinear angles at their ends, since they cut one another there if they are produced. Next, who will grant you that the arcs of those circles have to be described through the sixteenth-parts of the circumference ABCD — that is, through the lines that divide the whole circumference into 16 equal parts? Certainly, if the same circumference were divided into more equal parts, a different helix would be described, made up of smaller arcs, and it would differ from yours entirely: for these smaller arcs would both cut one another and also cut your larger arcs, at the points D, G, I, etc. So within one and the same circle different helices, unlike one another, would be described — which is utterly absurd and utterly inept.

Worse still: if the arc DG were a portion of a helix, then, if the radius of that arc were drawn from D and a perpendicular were erected to it at D, that perpendicular would ^a touch the helix at D. It would therefore cut off, from the straight line EA produced, a straight line equal to the circumference ABCD, by *propos. 18* of Archimedes *De heliciis*. And if that is granted, why should mathematicians torment themselves any further in searching out the quadrature [*tetragonismus*]? Would not the rectangle contained by half of that cut-off line and the radius ED be equal to the circle, by *propos. 1* of Archimedes *De circuli dimensione*?

[Margin a: 16. tertij.]

There is this too. Since the arcs GD and GI have different centres, if two radii were drawn from G to those centres (and they will be quite different from one another), and perpendiculars were erected to them at G (and these too would be different), ^b both would touch the helix at the point G — and so at one and the same point two different lines could be drawn touching the helix. Which is inept. Have we done enough to establish that you are a most delightful mathematician? Which was to be demonstrated.

[Margin b: 16. tertij.]

SCALIGER in *propos. 2*.

About a given finite straight line, to describe the dislocated volute of Dinostratus.

About the given straight line MN, with the semicircle MQN described and the rectangle MO set up on the same line, MQ and bO will be squares, since bM, bQ, bN are equal, by the definition of the circle. Let the quadrant of the circle MbQ be divided into four, and let the straight lines bg, bh, bI be joined from the centre. Let bM and QP likewise be divided into four, and lines erected cutting the straight lines bg, bh, bi at the points R, S, T. Let the same be done in the square bO; the volute is to be described through the points R, S, T, etc. Then, just as before in the ordered helix, let an isosceles triangle be set up on the base MR, one leg of which is equal to the radius bM; with the vertex of that triangle as centre and with the interval of the line bM, let the arc MR be described. And in the same way let the remaining arcs be continued with the same

Diagram. A woodcut set at the right-hand side of the foot of the page, beside Scaliger's second lemma. It shows a rectangle standing on a long horizontal base, ruled across its interior by a series of vertical lines and one horizontal line, with a quarter-circle arc and a second, flatter curve drawn inside it and radial lines running from the middle of the base out to the arc. A short vertical stroke descends from the middle of the base below the rectangle. Both capitals and minuscules occur on this block; the minuscules b, g, h, i are unambiguous against the capitals (the g carries a full descender, the b and h full ascenders).

- P (outside, at the upper-left corner of the rectangle): corner
- Q (outside, above the mid-point of the rectangle's top side): top point of the arc
- O (outside, at the upper-right corner of the rectangle): corner
- M (outside, at the lower-left corner of the rectangle): corner
- N (outside, at the lower-right corner of the rectangle): corner
- b (below the mid-point of the rectangle's bottom side): centre
- i (inside, upper left, close under the top side): point on the arc
- h (inside, below and left of i, on the arc): point on the arc
- g (inside, at the left, on the arc, set with a descender): point on the arc
- T (inside, left of centre, on the flatter curve): point on the inner curve
- S (inside, below and left of T): point on the inner curve
- R (inside, at the lower left): point on the inner curve
- V (inside, right of centre, above): point on the inner curve
- X (inside, right of V, lower): point on the inner curve
- Y (inside, right of X, lower): point on the inner curve
- Z (inside, at the lower right): point on the inner curve

- f (immediately below b, at the foot of the short vertical stroke descending from the base, set as a minuscule): the point the continuation of this lemma on the next page names as lying on the produced radius

interval upon the bases XY, YZ, ZN. Hence it will necessarily follow that the vertex of the isosceles triangle set up on the base TX lies on the produced radius at the point f — so that the circumference TVX is to be continued not from the mark T to the mark V and from V to X, but from T to X through the point V. Therefore V is the end of the volute of Dinostratus MRSTV, or of the volute NZYXV.

CLAVIVS.

The same fault is committed here as in the description of the helix. This dislocated volute, which has a uniform curvature, cannot be assembled out of circular arcs — as I said above, and it can be shown in the same way. For since all these arcs are described with the interval of one and the same radius bM but from different centres, they will necessarily cut one another at the points R, S, T, etc. And the more equal parts the quadrant MQ and the straight lines Mb, PQ are cut into, the more intersecting arcs will make up the volute; and so more volutes will be described inside the quadrant MQ. What could be more inept than that, or more absurd?

SCALIGER in *scholio proposit. 2.*

The way, then, is now secured for us to detect the end of the Dinostratean volute — a thing Sporus of Nicaea denied could be done.

And in the scholium to prop. 1 in the Appendix.

And indeed this is that most celebrated Dinostratean γραμμὴ [Greek: grammē, "line" — set with a γρ ligature], wrongly called by him, and by posterity, τετραγωνίζουσα [Greek: tetragōnizousa, "the squaring line" (the quadratrix) — set with the 8 (ov) contraction sort]. For Dinostratus persuaded everybody that, once its end — the point V, that is — had been detected, the two supreme things vainly sought by the ancients had been detected: namely the quadrant of the circle's circumference, and the power of the circle. The quadrant, because it is the third proportional to the segment BV and the radius bQ — which is truer than truth. The power of the circle, because it is equal to the rectangle conceived under the radius and the semicircumference of the circle. And that is utterly false; and so it is faultily called τετραγωνίζουσα. For it squares nothing; it only investigates the quadrant of the circumference. And so it would more truly be called quadrantaria than quadrataria. If, therefore, the opinion of Dinostratus and of the other

mathematicians were true, we should have no further labour before us; on the contrary, we could already boast, without any ill-will or suspicion of arrogance, that we had found the τετραγωνισμὸν [Greek: tetragōnismōn, "the squaring, quadrature"] so long harassed by everyone — we who have detected the true point V, the end of the volute itself.

CLAVIVS.

There is no reason for you to boast that you have secured the way to detecting the end of the volute, because the point V cannot be the end. For since no portion of the volute can be an arc of a circle, as has been said, it is impossible that the arc TV should indicate the extreme point. And so, although what Dinostratus and Archimedes demonstrate about the rectangle contained by the radius of the circle and the semicircumference is truer than truth (whatever you may chatter to the contrary), the circle is still not squared, since to this very day the extreme point of the volute has not been found. Your own discovery is thoroughly childish and unworthy of a mathematician. And let this stand as my reply to your abuse of Dinostratus and of the whole posterity of mathematicians — whatever your grammarians may finally decide about those newly coined words of yours, *quadrantaria* and *quadrataria*.

SCALIGER in *propos. 3.*

Of a radius divided by the limit of a dislocated volute, the smaller segment is an irrational line, which is called an Apotome.

Let the radius BG, in the semicircle AGE, be divided unequally at the point C by the end of the hamstrung volute, from the preceding scholium, and let CG be the smaller segment. I say that the segment CG itself is an irrational line, which is called an Apotome. When the rectangle EH has been completed, AG will be a square. Let the diagonal BH be drawn. With the radius GB produced toward the side of F, let BF be equal to two fifths taken from BG, by VI.9. From the line BA let BR be cut off, equal to the mean proportional between BF, BG, by VI.13. Now the lines BF, BG are commensurable in length, by the construction. Therefore the line BR is commensurable with them, seeing that it is ῥητὴ [Greek: rhētē, "expressible, rational"] in power, by X.20. But since, as the length BF is to the length BG, so the power of BF is to the power of BR, and the power of BR to the power of BG — that is, of BA — by the corollary of VI.20. And BF is to BG as 2 to 5, by the construction; that is, as a non-square number to a non-square number. Therefore the square of BF to the square of BR, and the square of BR to the square of BG — that is, of BA — have the ratio that a non-square number has to a non-square number. Therefore, by

the last part of X.9, the sides of those squares, BF, BR, BA, are incommensurable in length with one another, and commensurable only in power. Since, then, BA is a ῥητὴ length (for it is 5 of the parts set out, as has just been said), while BR has been shown to be incommensurable in length with that same BA and commensurable with it only in power, AR will be an Apotome, by X.74. From the marks C, R let the lines CQ, RY be drawn parallel to the lines AB, AH, meeting the lines HA, HG at the points Q, Y, and cutting one another at the point D. Therefore CD, BR; likewise BC, RD, will be equal, from the construction, with the help of I.33 and I.34. But the angle CBD, in the triangle DCB, is half a right angle, because of the diagonal BH in the square AHGB, by I.34. Likewise the angle C is a right angle, from the construction. Therefore the remaining angle CDB is half a right angle, by I.32; and by 6 of the same book the sides CD, CB are equal. But CD was already equal to BR. Therefore the two lines CB, BR are equal to the same CD. So they will be equal to one another, by the first postulate. And consequently the rectangle BD is a square about the diagonal BH in the square ABGH. Therefore DH also will be a square about the same diagonal, by VI.24. But BR cuts off from BA — that is, from BG — the Apotome AR. Therefore CG, being equal to it, will be an Apotome. Which was to be demonstrated.

Diagram. A woodcut set into the left half of the page, beside Scaliger's third lemma. It shows a wide rectangle standing on a long horizontal base, with a large arc springing from the lower-left corner, rising to the top side about half-way along, and descending to the lower-right corner. The interior is ruled by several vertical lines and two horizontal lines, and a diagonal is drawn from the upper-left corner down toward the base; two short diagonal strokes cross near the left. A short vertical stroke descends from the middle of the base below the rectangle. Small leader-dashes point to two of the interior letters. Every letter listed is read directly off the block; those the lemma does not name are given by position only.

- H (outside, at the upper-left corner of the rectangle): corner
- Y (on the top side, a little to the right of H): point on the top side
- G (on the top side, at the summit of the arc): top of the arc
- A (outside, at the lower-left corner): corner
- E (outside, at the lower-right corner): corner
- B (on the bottom side, at its middle): centre
- R (on the bottom side, left of centre): point on the bottom side
- O (on the bottom side, between R and B): point on the bottom side
- Q (outside, at the left, on the left-hand side of the rectangle): point on the left side

- I (inside, upper left, with a leader-dash): interior point
- D (inside, below I, at the left): interior point
- K (inside, below D, with a leader-dash): interior point
- L (inside, upper left, on the arc): point on the arc
- M (inside, at the middle left): interior point
- C (inside, at the centre, above N): interior point
- N (inside, at the centre, below C): interior point
- F (below B, outside the rectangle, at the foot of the short vertical stroke): point on the produced radius

CLAVIVS.

You will have done something great, Joseph Scaliger, if you can carry this off as a demonstration before a mathematician. For my part, I shall convict it of being remote from all truth before a judge not a little fairer to you than to the truth — namely yourself. (See how far I trust the fairness of my case!) I therefore pronounce this proposition false, and pronounce that in demonstrating it you reason fallaciously, you, the mathematician so much greater than Archimedes. I demonstrate both points briefly, as follows. The paralogism consists in this: you assume that the lines CQ and RY, if BR is taken as the mean proportional between BG and its two fifths BF,

as BF — intersect one another on the diagonal BH, namely at the point D. That you do not prove; nor can you prove it, as I shall show below. For if they do intersect at D, it follows very nicely that BR and BC are equal, and likewise the remaining lines RA and CG; and therefore, since RA is an apotome, as you rightly proved, CG will be an apotome too. But suppose they intersect above the diagonal BH, at I. Then BR will not be equal to BC. For BR and RD are equal, because the angles at B and D are half right angles; whereas BC is greater than RD, since BC — if CQ passes through I — is equal to RI, and therefore greater than RD, that is, than RB. From this it follows that the remainder CG is smaller than the apotome RA. And if CQ and RY intersect below the diagonal, at K, the contrary follows: CG is greater than the apotome RA. You see, then, that you prove nothing unless it is granted you that the lines CQ and RY intersect one another on the diagonal, at the point D.

A N O T H E R fault lies in this demonstration of yours. You assume BR to be the mean proportional between BG and BF, two fifths of BG, and yet you make no attempt to prove from that assumption that the lines CQ and RY intersect on the diagonal BH. Geometers count this a fault, for they always bring the parts of the

construction to bear in the demonstration. Why do you take BR as the mean proportional between BG and two fifths of it rather than between BG and three fifths of it, or one fifth? Or, for that matter, between BG and two sevenths of it, or three, or four, or one? On any of these your sophistical demonstration proceeds equally well. For by the last part of proposition 9 of the tenth book, the lines BA and BR are rational and commensurable in square only; and therefore, by proposition 74 of the tenth book, RA is an apotome, just as before. Do not conclude from this, however, that CQ and RY cut one another on the diagonal. That BA and BR are rational and commensurable in square only is taught by the last part of proposition 9 of the tenth book. For the ratio of BF to BG is as 3 to 5, or 1 to 5, or 2 to 7, or 3, or 4, or 1 to 7 — that is, as one non-square number to another non-square number, and so forth. Learn your geometry better, then, so that you may know what it is you have to demonstrate.

N O W that your proposition is false — that is, that BC, the line between the centre B and C, the end of the volute, is *not* the mean proportional between BG and BF, two fifths of it, as you would have it (since of course you suppose BC equal to BR), but is greater than the mean proportional — has been demonstrated by *Adrianus Romanus* [Adriaan van Roomen] and *Franciscus Vieta* [François Viète]. I shall set their demonstrations below, so that you may at last feel some shame at being so little versed in geometry and yet reckoning everyone else — indeed Archimedes himself (which is intolerable — as worth nothing beside yourself).

Van Roomen's demonstration runs roughly as follows. Let the whole sine BG, or BA, be set at 100000; BF will accordingly be 40000, that is, $\frac{2}{5}$ of BG or BA. From 40000 into 100000 there arises the number 4000000000, ^a which is equal to the square of the line BR, the mean proportional between BG and BF. Its square root, taken less than the true one — that is, BR — is 63245; taken greater than the true one, 63246.

[Margin: a — 17. sexti. (Euclid VI.17)]

Next, let us take the arc GL to be a twelfth part of the quadrant, that is, to contain $7\frac{1}{2}$ degrees, and the arc LA to be $82\frac{1}{2}$ degrees. Let BO likewise be conceived as a twelfth part of the radius BA. So, with the whole sine BA set at 100000, BO will be its twelfth, $\frac{100000}{12}$. Then, when the radius BL and the perpendicular OM have been drawn, the point M will lie on the volute, as I showed at the end of Book VI of Euclid. And when MN too has been drawn perpendicular to BG, ^b BN will be equal to OM.

[Margin: b — 34. pri. (Euclid I.34)]

Now since OM is greater than 63246, as I shall show, BN will likewise be greater than 63246 — that is, than BR — and so BC will be greater still by far. For when the whole sine BO is set at 100000, OM is the tangent of the angle ABL, as I said in my treatment of the sines: the tangent, I mean, of $82\frac{1}{2}$ degrees, namely 759575. If, then, we set it out thus — as BO, the whole sine 100000, is to 759575, the tangent OM, so BO, $\frac{100000}{12}$, is to a fourth term — OM will be found greater than 63297. Therefore BC will be far greater. Since, then, BR has been found greater than 63246, the line BC between the centre and the end of the volute will be greater than BR, the mean proportional between BG and BF, two fifths of it. And consequently CG will be smaller than the apotome RA. Nor will you ever demonstrate that CG is an apotome unless you first show that BC and BG are rational and commensurable in square only — which you will manage on the Greek Kalends.

F R A N C I S C V S Vieta, for his part, demonstrates as follows that the line BC is greater than the mean proportional between BG and two fifths of it. From what we demonstrated out of Pappus at the end of Book VI of Euclid, the radius BA, or BG, is the mean proportional between the quadrant AG and the line BC. And since, when the diameter is 7, the circumference is less than 22, as Archimedes demonstrated — and when the diameter is 14, the circumference is less than 44 — it follows that if the radius BA is set at 7, the semicircumference will be less than 22, and the quadrant AG less than 11. Therefore if the radius BA is set at 35, the quadrant AG will be less than 55. Now the rectangle contained by BC and the quadrant ^c is equal to the square on BA, that is, to the number 1225. Dividing this by the quadrant AG, which is less than 55, we shall find BC greater than $22\frac{3}{11}$. For if the quadrant were exactly 55, BC would be $22\frac{3}{11}$. And it is plain that if the number 1225 is divided by a number smaller than 55 — namely by the quadrant AG — the quotient comes out greater than $22\frac{3}{11}$. Again, of the parts of which BA, or BG, is 35, BF is 14. So, since 14 into 35 makes the number 490, whose square root is less than $22\frac{3}{22}$, the mean proportional between BG and BF will be less than $22\frac{3}{22}$. Therefore, since BC has been shown to be greater than $22\frac{3}{11}$, BC will be greater than that mean proportional. And so, if from BA and CQ two lines are cut off equal to the mean proportional between BG and BF, their end points will fall short of RD — since BR and CD are equal to BC, on account of the square CR — and not fall short of it by less.

[Margin: c — 17. sexti. (Euclid VI.17)]

S C A L I G E R *in propos. 5.*

THE PERIMETER of a dodecagon to be inscribed in a circle is greater in power than the circumference of the circle. And the more sides the polygon to be inscribed in the circle has, the more will the perimeter of the polygon exceed in power the circumference of the circle.

Let there be a circle ABG about the centre F, whose diameter is AG. Let AB be the side of a hexagon, AD the side of a dodecagon, and AC the side of a 24-sided figure. Let the lines FB, FD and FC be drawn; then AB and AD will be bisected at H and E by our proposition 4, ^a and therefore also cut at right angles. Now since, when the diameter AG is put at 16, if we set out "as 7 is to 22, so is 16 to another term," the circumference will be found to be a little less than $50 \frac{2}{7}$ — let us then take it not to exceed 51. And since the side FA is in power sesquitertian [4 : 3] to the perpendicular FH, of the parts of which the square of the radius FA — that is, the side of the equilateral triangle FAB — is 64, the square of the perpendicular FA [?: FH expected] will be 48, and its side will be about $6 \frac{12}{13}$. If this be subtracted from the length

[Margin: a — 3. tertij. (Euclid III.3)]

Diagram. A large circular arc drawn about the centre F. A straight vertical line runs down the left of the figure from A at the top, through F, to G at the bottom, so that AG is the diameter. From A the arc sweeps to the right and downward through C, D and B, and then curves back down to G. Three straight lines are drawn from the centre F out to the arc, meeting it at C, D and B; three chords are drawn from A to the same three points. E is marked on the chord from A that meets D; H is marked lower down, on the chord AB. Labels read directly off the block:

- A (top left, upper end of the vertical diameter): A
- C (on the arc, first point right of A): C
- D (on the arc, below and right of C): D
- E (on the chord from A, between C and D): E
- H (on the chord AB, below E): H
- B (on the arc, at the right, where the chords and the radius meet it): B
- F (left, centre of the circle, where the three radii spring): F
- G (bottom left, lower end of the vertical diameter): G

No further lettering is visible on the block. The points named in the accompanying text but not lettered on the woodcut are none — every point cited (A, B, C, D, E, F, G, H) appears.

of FD, there will remain the length of the line HD, about $1 \frac{1}{13}$.^a Since, then, the square on DA is equal to the squares on DH and HA, and DA is the side of the dodecagon, the perimeter of the dodecagon will be greater in power than twelve times HA — that is, than three times the diameter AG — by twelve times the square of $1 \frac{1}{13}$, that is, by about 13 whole units of power, whose side is far greater than 3. And this, compounded with three times the length of the diameter, will be greater than 51. The perimeter of the dodecagon is therefore greater than 51, and for that reason far greater than the circumference ACDBG.

[Margin: a — 47. pri. (Euclid I.47)]

CLAVIUS.

W H A T am I to wonder at first here — that in a matter so perfectly plain you should be blind so busily and so persistently, or that, blundering so foully, you should still lay claim to the name of mathematician with such assurance? That the perimeter of a dodecagon inscribed in a circle is greater than the circumference of the circle is what that most expert craftsman Joseph Scaliger asserts. Asserts, did I say? He goes further, and with no hesitation at all professes that he has demonstrated it. But granting that reason has failed you, are we to believe that you have been robbed of the light of your eyes as well? For I shall not argue with you by mathematical reasoning but by plain facts that the eye can take in, so that you may have no way of slipping off. Where did you ever see an arc smaller than its own chord? Come now: take twelve arcs, and subtend each arc with its own chord. Will you not admit that the circumference of the circle, made up of the twelve arcs, is greater than the perimeter of the dodecagon, which twelve straight lines make up? And if in the end you dare to deny it, who is to forgive you? But see how much thought I give to your reputation. For my part I shall never bring myself to believe that this was really what you thought. Rather, not being thoroughly schooled in the geometrical arts, you were so hemmed in on every side by numbers, so entangled and enmeshed in them, that — provided you might at last tear yourself free of that maze — you would break out at whatever opening presented itself. I have heard from one of your intimates that, when a great many people from France and Germany had in friendly fashion urged you to change this opinion, wholly unworthy of a geometer, and when you had at last recognized the way by which they hoped to lead you out of the fog, your reply was this: that the proposition belonged to a man whose body was then gravely ill, and whose mind too had been infected by the body's contagion. I should indeed have congratulated Scaliger here on singing the recantation of this proposition — had he not, like the filthiest of dogs, swallowed down again, and more foully than

before, what he had once in disgust thrown up. For not long afterwards, as though he repented of that recantation, this most acute man, in no way the most ignorant in the geometrical arts, went back over his own work, inspected it again and again, and applied himself wholly and diligently to examining it. Then at last, as a wholly upright judge, he boldly repeated those same condemned errors and paralogisms of his which he had been unable to see scattered through his own proposition. He openly professed that he had demonstrated by numbers that the perimeter of the dodecagon is greater than the circumference of the circle, and sternly announced that with that demonstration he meant to transfix the eyes of every mathematician there is anywhere. And since there is no one who does not see that this is false, he was astonished that a demonstration by numbers had brought him to maintain such a falsehood, and did not hesitate to declare that demonstrations by numbers even in Archimedes — such as the one on the ratio of the circumference to the diameter — are wholly deceptive. But I shall now make plain how much he wraps up in his demonstration, and how false it is, through ignorance of numbers. Let this be our business now: since Scaliger has not seen the paralogisms of this demonstration of the fifth proposition, let us expose them — not for his sake, which would be labour wasted, but so that they may become plain even to less practised readers.

A N D here at the outset I pass over — though it richly deserves a schoolboy's whipping — that he does not even know the terms the more skilled use. What sort of expression is this? *If the diameter is 16 of the parts set out, one seventh will be less than $\frac{3}{16}$. Accordingly three times the length of the diameter together with $\frac{3}{16}$ — that is, $\frac{51}{16}$ of the length of the diameter — will be greater than the perimeter of the circle.* Had he consulted the geometers, he would surely have put it thus: one seventh of a diameter of 16 parts is less than 3, since $\frac{1}{7}$ comes to no more than $2\frac{2}{7}$; and therefore three times the length of the diameter, that is 48, together with 3, namely 51, will be greater than the perimeter of the circle. It was for this reason that in setting out his demonstration we wrote that the circumference does not exceed 51 if the diameter is 16, and not that it does not exceed $\frac{51}{16}$ of the length of the diameter, as he has it; for if one expresses the circumference by the number $\frac{51}{16}$, it would come out smaller than the diameter 16 — which is the height of absurdity. But let us come now to the demonstration itself, in which two conspicuous blunders stand out above the rest, blunders by which you may recognize Scaliger.

A F T E R he has demonstrated, then, that the line HD is $1\frac{1}{13}$ — or rather a little less, since FD is 8 and the number $6\frac{12}{13}$ is a little less than FH — and likewise that the square on AD is equal to the squares on AH and HD, he infers that the

perimeter of the dodecagon, which is twelve times the side AD, is greater in power than twelve times HA (that is, than three times the diameter AG) by twelve times the square of $1\frac{1}{13}$; and accordingly, since the square of the number $1\frac{1}{13}$ is $196/169$ and twelve times that is $2352/169$, that the square of the dodecagon's perimeter exceeds the square of three times the diameter AG by the number $2352/169$ — that is, by $13\frac{155}{169}$ — whose root is far greater than 3, since it is very nearly $3\frac{921}{1261}$ [?]. For the approximate root of the numerator 2352 is $48\frac{48}{97}$, or $4704/97$, just as the root of the denominator 169 is 13; and these two roots make up a fraction whose numerator is $4704/97$ and whose denominator is 13, as may be seen in this display. Dividing the numerator by the denominator yields the approximate root $3\frac{921}{1261}$ [?].

[Printed display, set within a ruled frame:]

$$\begin{array}{r} 4704 \\ \hline 97 \\ \hline 13 \end{array}$$

And here he has made his first disgraceful slip. For if the square of the dodecagon's perimeter were twelve times the square on AD, and the square on the line that is three times the diameter (or twelve times the line AH) were twelve times the square on AH, then the square of the dodecagon's perimeter would exceed the square on the line that is three times the diameter by twelve times the square on HD, that is, by the number $13\frac{155}{169}$ — just as, since the square 9 exceeds the square 4 by the number 5, so the number 108, which is twelve times the square 9, will exceed the number 48, which is twelve times the square 4, by the number 60, which is twelve times the excess 5. This indeed follows from proposition 7 of the *Sines*, and this excess 60 is produced by multiplying the excess 5 by 12. But the case is not so. For since the perimeter of the dodecagon is twelve times the side AD, just as three times the diameter is twelve times the line AH, ^b the square of the dodecagon's perimeter will have to the square on the side AD the ratio of 144 to 1 — that is, the ratio duplicate of the sides. And by the same reasoning the square on three times the diameter will have to the square on the side AH the ratio of 144 to 1. Therefore the square of the dodecagon's perimeter will exceed the square on three times the diameter by one hundred and forty-four times the square on HD, which was $196/169$, or $1\frac{27}{169}$; so that the excess of these squares is about 167, which arises from multiplying the square on HD, that is $1\frac{27}{169}$, by 144, as follows from the same proposition 7 of the *Sines*. And the square root of this excess 167 is nearly 13, since it comes very close to $12\frac{23}{25}$.

The excess between the square of the dodecagon's perimeter and the square on three times the diameter is therefore not about 13 — or, more exactly, $13\frac{155}{169}$, whose root is $3\frac{921}{1261}$ [?], and so greater than 3 — as Scaliger will have it.

[Margin: b — 20. sexti. (Euclid VI.20)]

B U T even if it be granted to Scaliger that this root is greater than 3, what he goes on to infer from it is still not sound. Therefore this root

is 3, and something more; added to three times the diameter, that is, to 48, it makes the root of the square of the dodecagon's perimeter — *hæc est*, makes the perimeter of the dodecagon greater than 51, and therefore greater than the circumference of the circle. For it is not the case that, if one square exceeds another, the side will exceed the side by the root of the excess; it exceeds it by a smaller number. The square 100 exceeds the square 64 by the square 36, and yet the side 10 does not exceed the side 8 by the root of the excess, which is 6, but by the number 2, which is less than 6. Again, the square 4225, whose side is 65, exceeds the square 3969, whose side is 63, by the square 256, whose side is 16; and yet the side 65 exceeds the side 63 only by the number 2, and not by 256 [as printed] with the side 16. The reason why the greater side always exceeds the lesser by a number smaller than the root of the number by which the greater square exceeds the lesser is this. Since, by proposition 7 of Book 6 of Jordanus [Jordanus de Nemore], the difference of the sides multiplied into their sum produces the difference of the squares, the root of that difference will be the mean proportional between the difference of the sides and their sum; and therefore the difference of the sides will be smaller than the root of the difference of the squares. So even if the square of the dodecagon's perimeter did exceed the square on three times the diameter by the number $13\frac{155}{169}$, it would not follow that the perimeter of the dodecagon exceeds three times the diameter by the root of the square number $13\frac{155}{169}$, which is greater than 3; it would exceed it by a smaller number, one which, added to 48, will make a number less than 51.

I have shown, I think, where Scaliger's "demonstration" — as he himself calls it, though the wise judge it a piece of schoolboy reasoning — goes wrong. For in the first place he supposes that the square of the dodecagon's perimeter exceeds the square on three times the diameter by twelve times the square of the number HD, $1\frac{1}{13}$, whereas it exceeds it by one hundred and forty-four times that square. This is so gross that I should have thought it could have been noticed not merely by the less skilled but even by Scaliger himself — if, like a bat, being a creature of the night, he could have borne the light of day. Then again he errs in thinking that the root of the square of the dodecagon's perimeter exceeds the root of the

square described on three times the diameter by the root of the excess of the squares. And even if in this he thinks himself entitled to the fullest confidence, he ought at least to have put some confidence in Jordanus, who plainly demonstrates the opposite in Book 6, proposition 7, as I have reported.

S O you would have commended yourself to us better, my dear Scaliger, if you had preferred to draw the conclusion I am about to state. Since HD is about $1\frac{1}{13}$, as has been shown, its square will be $1\frac{27}{169}$; and this, added to 16, the square on AH, makes $17\frac{27}{169}$, the square on AD, that is, $\frac{2900}{169}$, whose root AD is about $4\frac{198}{1391}$. For the approximate root of the numerator 2900 is $53\frac{91}{107}$, and the root of the denominator 169 is 13. These two roots make up a fraction whose numerator is $53\frac{91}{107}$, or $\frac{5762}{107}$, and whose denominator is 13, as appears in this display. And when the numerator $\frac{5762}{107}$ is divided by the denominator 13, the quotient comes out $4\frac{198}{1391}$ as the approximate root AD; and this, taken twelve times, will give the perimeter of the dodecagon as $49\frac{985}{1391}$, which is less than the circumference of the circle, since by Archimedes the latter is $50\frac{2}{7}$ — that is, three times the diameter 16 together with $\frac{2}{7}$ [?]. And yet this perimeter of the dodecagon is greater than the true one, because the square on DH, $1\frac{27}{169}$, is greater than the true value, seeing that the line DH is a little less than $1\frac{1}{13}$, as was said above. By Archimedes' lower limit the circumference of the circle is less than the true value at $50\frac{18}{71}$, and the perimeter of the dodecagon is smaller still than that, even though it is greater than the true value.

[Printed display, set within a ruled frame:]

$$\begin{array}{r} 5762 \text{ [?]} \\ \hline 107 \\ \hline 13 \end{array}$$

SCALIGER in *eadem* propos. 5.

A G A I N, the square of the side $1\frac{1}{13}$, the line HD, is $\frac{196}{169}$; and this, put together with the square on HA, will make the square on DA, $17\frac{47}{169}$, by I.47, since the angle DHA is right, as has already been shown. The square on EA, therefore, is $\frac{730}{169}$ (namely the fourth part of the square on DA, which is double EA). But the square on the line CA is greater in power than the square on EA by the square on EC, by the same I.47; for the triangle CEA is right-angled. But the square on EA is $\frac{730}{169}$, whose side is a little greater than $2\frac{7}{13}$. Hence twenty-four times more than $2\frac{7}{13}$. They will be more than — or at any rate not less than — $\frac{61}{16}$:

the perimeter, that is, of the [Greek: τὸ τεσσαρεσκαίκοσι(?)γώνον (τοῦ τεσσαρεσκαίκοσι...γώνου, "of the four-and-twenty-angled figure," i.e. the 24-gon; set with the 8 (ου) contraction sort. One medial cluster, which reads as δεκα, does not fit the sense and is left flagged)], is in any case greater than the perimeter of the circumscribing circle, which had been set at only 51/16. And the more sides the polygon has, the far greater will the perimeter of the inscribed polygon be found by numbers than the perimeter of the circumscribing circle. Which was to be demonstrated.

CLAVIUS.

BUT hey there, hey! What is this, and where does so great a monstrosity come from, my good man? Until now I supposed I was dealing with nothing worse than a non-geometer [Ageometra]; now you show yourself utterly untaught in arithmetic as well. For where, with all your splendid learning, did you learn that the square on HD, 196/169, together with the square on AH, 16, makes the square on DA 17 47/169? Anyone who has so much as touched arithmetic notices at once that it makes 17 27/169. Next, neither do I see why the side EA of the square 730/169 — the fourth part of your false square 17 47/169 on the line AD — should be set down as a little greater than 2 7/13. For I find it only a little greater than 2 55/702. The nearest root of the numerator 730, taken greater, is 27 1/54; and the root of the denominator 169 is 13; and these two roots make up a fraction whose numerator is 1459/54 and whose denominator is 13, as you see in the display set out. And when the numerator is divided by the denominator, the quotient comes out 2 55/702 — a little more, that is, than the side EA. Since, then, you have set the square on HA [?] greater than it should be, and accordingly have made its fourth part 730/169 and the side of that 2 7/13, which is likewise greater than it should be, what wonder is it that from these false assumptions you have found the perimeter of the 24-sided figure to be about 61, greater than the circumference of the circle, 51? And here too you blunder splendidly, in taking EA for the side of the 24-sided figure, when CA is that figure's side.

[Printed display, set within a ruled frame:]

$$\begin{array}{r} 1459 \\ \hline 54 \\ \hline 13 \end{array}$$

IF the reckoning is done correctly, the perimeter of the figure will be found smaller than the circumference of the circle, though still greater, as it ought to be,

than the perimeter of the dodecagon. For since the square on HD, $196/169$, together with the square on AH, 16 , makes $17\frac{27}{169}$, the square on DA, whose fourth part is $725/169$ — that is, the square on the line EA — and since this, taken away from 64 , the square on AF, leaves as remainder the square on FE, $10091/169$, whose nearest root taken less than the true one is $7\frac{1900}{2613}$. For the nearest root of the numerator, taken less, is $20191/201$; and this, with the nearest lesser root of the denominator, that is, with 13 , makes up a fraction whose numerator is $20191/201$ and whose denominator is 13 ; and dividing the numerator by the denominator gives the quotient $7\frac{1900}{2613}$. If, then, FE, $7\frac{1900}{2613}$, is subtracted from FC, 8 , the remainder will be EC, $713/2613$, which is greater than the true value; and its square, $508369/6827769$, likewise greater than the true value, added to $725/169$, the square on the line EA, will make the square on the line AC, [numeral: ?], greater than the true value, whose approximate root is [numeral: ?] — since the root of the numerator, taken next less, [numeral: ?], with 33969 , the root of the denominator, makes

makes this fraction; and when the numerator is divided by the denominator, the quotient is $10072062450/48212201971$ [?].) Multiplied by 24 , this gives the perimeter of the 24-sided figure, $241720408800/4821220170$ [?] — that is, $50\frac{668400300}{48212201700}$ [?] — which is less than the circumference of the circle. Where now, I ask you, is that perimeter of the polygon greater than the circumference of the circle? Speak up: let us hear from your own mouth, with willing ears, a thing never before heard by me or by anyone else. Or better still, consult someone who has studied arithmetic, who can help you find the perimeter of the polygon and teach you arithmetic more plainly.

[Margin: the fraction just referred to, set in a ruled frame in the outer margin:]

SCALIGER in *scholio eiusdem propos. 5.*

Since, then, as has now been shown, the more sides the inscribed polygon has, the greater its perimeter is found by the numbers to be than the circumference of the circumscribing circle, Archimedes tried in vain to investigate the circumference of a circle by numbers in a polygon of very many sides circumscribing the circle. For the circumscribing polygon is beyond doubt far larger than the similar inscribed polygon — and that inscribed polygon has been shown by the numbers

to have a greater perimeter than the circumscribing circle. The circumscribing polygon, therefore, will have a greater perimeter still, and so his error is the wider.

This is a notable paradox in geometry, and one that Archimedes himself, as we have already remarked, did not notice. In any other way there is no doubt that an arc is greater than the chord that subtends it; but by the numbers it will be found otherwise.

CLAVIVS.

Would anyone mutter that you are not "Most Illustrious"? or suspect that you do not draw your descent from an ancient and noble family? On the contrary: this paralogism of yours is so distinguished in its nobility that it could have conferred its own nobility on you. But listen, whoever you are, for whose sake Scaliger has at last, after so long an expectation, composed this book of his; listen to the verdict of a man of the utmost expertise in geometry and arithmetic, and from it recognize the lion by his claw, as the saying goes. What he teaches is no trifle, nothing commonplace. For he thinks he has demonstrated a remarkable paradox: that a polygon of 12 sides, or of more, has a perimeter greater than the circumference of the circle circumscribing it. Do you still not see, Scaliger, how many lies you fabricate inside a single lie? How many faults are to be caught in this thoroughly inept demonstration of yours (to call it by your own name for it) was shown just above. This point, however, is the decisive one, and it convicts you not of ignorance only, but of rashness and impudence as well. For who could bear with an even temper to see you do Archimedes so gross an injustice? Archimedes investigates the perimeter of the circle by numbers ἐπιστημονικῶς [Greek: epistēmōnikōs, "scientifically," i.e. by strict demonstration], and proves that the circumference of a circle has to its diameter a ratio less than triple-and-ten-seventieths [tripla superdecupartiente septuagesimas, i.e. $3 \frac{10}{70}$], but greater than triple-and-ten-seventy-firsts [tripla superdecupartiente septuagesimas primas, i.e. $3 \frac{10}{71}$]. And you will never, however much you contrive everything that your passion for contradicting suggests to you, be able to break his demonstration or shake it.

SCALIGER *in propos. 6.*

The square on the circumference of a circle is ten times the square on the diameter.

Let the circle NO cut off from the infinite line Q T the straight line AB, beginning to move along that line from the point on it at which it touches, until it comes

round to the same point again, by the first postulate of this work. The straight line AB, then, is equal to the perimeter of the given circle NO. On the straight line AB let the semicircle AEFB be described, and let there be fitted into it a length EB triple the length NO, by the first proposition of the fourth book; and let the straight line EA be joined. Next from the point E let the straight line EC be dropped perpendicular to AB, by 12. of the first book. Again from the same straight line AB let the tenth part DB be cut off, by 9. of the sixth book. Lastly from the point D let DF be erected perpendicular to AB, by 11. of the first book, and let the straight lines FA, FB be drawn. By the corollary to 8. of the sixth book, the straight line BF is a mean proportional between AB and BD. Therefore by the corollary to 20. of the sixth book, as the length AB is to the length BD, so is the square on AB to the square on BF; but the length AB is ten times the length BD, by construction. Therefore the square on AB is ten times the square on BF. Hence by 47. of the first book the square on AF is nine times the square on BF — that is, the length AF is triple the length FB, by 9. of the tenth book. This being demonstrated, let AR and BP be erected perpendicular to AB; they will therefore be parallel to the straight lines CE and DF. And so the angle RAE will be equal to the angle AEC, and the angle PBF to the angle BFD, since they are alternate angles. Likewise the angles EHA, FHB are equal by 15. of the first book; and in the triangles EAH, FBH the angles AEH, BFH are equal, being right angles, by 31. of the third book. Therefore the remaining angle EAH is equal to the remaining angle FBH; and when these are taken away from the equal angles RAB, PBA, there remain RAE — that is, AEC — and FAB; likewise PBF — that is, BFD — and EBA, equal. But the angles AEC, ABE are equal, and likewise BFD, FAB, because the triangles AEC, AEB, and likewise BFD, BFA, are equiangular, by 8. of the sixth book. Hence FAB, EBA are equal, just as the angles AEB, BFA are also equal in the triangles ABE, BAF. Therefore the remaining angle EAB is equal to the remaining angle FAB, and the one triangle is equiangular with the other. Since, then, both triangles ABE, BAF have the side AB in common, opposite equal angles AEB, BFA, and the same side adjacent to the equal angles EAB, FBA, therefore by 26. of the first book the remaining sides AF, FB are equal to the remaining sides BE, EA. But the length AF is triple the length FB, by construction. Consequently BE will be triple the length EA. But that same BE is triple the length NO, by construction. Therefore by 9. of the fifth book AE and NO are equal. And so the square on AB — that is, the square on the circumference of the circle NO — is ten times the square on the diameter NO, which was to be demonstrated.

Diagram. At the left of the block stands a small circle with a vertical diameter drawn through it, its centre marked by a dot; the top of that diameter is lettered N and the foot O. To the right of the circle runs a long horizontal straight line,

lettered T at its far left end and Q at its far right end, with B and D marked on it toward the left and C and A toward the right. From B a vertical line rises to P; from A a vertical line rises to R. Between B and A a large arc is drawn over the base line. The point F sits low on the arc, immediately above and slightly right of B, and is joined by short lines down to B and down to D, and by a long line running right to A. The point E sits high on the arc toward the right, and is joined by a line down to C, by a line to A, and by a long line running left and down to B; the lines from F to A and from E to B cross each other beneath the arc.

- N (top of the small circle at the far left): N
- O (foot of the small circle): O
- T (far left end of the horizontal base line): T
- P (top of the vertical erected at B): P
- F (on the arc, just above and right of B): F
- B (on the base line, foot of the vertical to P): B
- D (on the base line, immediately right of B): D
- R (top of the vertical erected at A): R
- E (on the arc, upper right): E
- C (on the base line, left of A): C
- A (on the base line, foot of the vertical to R): A
- Q (far right end of the horizontal base line; an italic swash capital): Q

The point H, which Scaliger's proof repeatedly names (angles EHA, FHB; triangles EAH, FBH), is **not lettered on the woodcut** — the block shows the crossing of AF and BE but leaves it unlettered.

CLAVIVS.

Since this proposition — which is wholly the Arabs' — is stuffed full of fallacies on every side (for the ratio of the square described on the circumference to the square on the diameter is less than tenfold, as is clear from what Archimedes demonstrated in his little book *On the Measurement of the Circle*: for if the diameter is set at 7, the circumference is a little less than 22, and the square of the diameter will be 49 and that of the circumference a little less than 484, which has to 49 a ratio less than tenfold, since it is 490 that stands to 49 in a tenfold ratio) — since, I say, it has nothing of truth in it, I shall take pains to point out only those things which have cast darkness over our geometer Scaliger...

cast darkness over him. Now that he has demonstrated that the angles EAH, FBH are equal, the inference is correct: that if these angles are taken away from the

right angles RAB, PBA, the two remaining angles RAE, FAB — that is, AEC, FAB — taken together are equal to the two other remaining angles PBF, EBA — that is, to BFD, FAB taken together. Likewise that AEC is equal to the angle EBA, and BFD to FAB, by 8. of the sixth book. But it will never be gathered from this that FAB, EBA are equal, or AEC, BFD. And so Scaliger's demonstration collapses of its own weight; nor, strain as he may, will it ever prove that the straight lines AF, FB are equal to the straight lines BE, EA, and therefore that the straight line AE is equal to the diameter NO, or that BE is triple EA.

Since this labour could seem to Scaliger to have turned out well enough and just as he wished, he was carried away by his happy success and wanted to be borne higher still. So the very same proposition 6. — already secure enough, in his own judgment, on the strength of the first demonstration — he now tries to establish by yet another demonstration, one that might outdo the first (if we are pleased to grant Scaliger any credit). For Scaliger brings this second one alone to bear in proposition 3. of the Appendix to his *Cyclometrica*, as though it could take up the fight on behalf of all the rest and win the day single-handed. But he achieves nothing, because this second demonstration assumes the very thing he thinks he demonstrated in proposition 3.: that the greater segment of the semidiameter [*semidiametri*, so printed] which the displaced volute [*voluta luxata*] cuts off is a mean proportional between the semidiameter itself and two fifths of it. Since that is faulty, as was shown above, this later demonstration too cannot fail to be utterly false.

SCALIGER in *coroll. propos. 6.*

From these things it is established that the ratio which the length of the circumference of a circle has to the length of the diameter is greater than triple-and-a-seventh.

For if, say [V.G.], the length of the diameter is 7 parts, then in those parts in which the square of the diameter is 49 [recte: 49], the square of the perimeter will be 490 — which is indeed greater than 484, and 484 is only in the triple-and-a-seventh ratio.

CLAVIS.

But who would deny it — anyone, that is, to whom you have made good only that brilliant paralogism of yours, by which you tried to show that the square on the perimeter is ten times the square on the diameter, or anyone who has never seen the demonstrations of Archimedes and the rest? Archimedes certainly gives us grounds for believing that any such thing has been demonstrated by more expert

men, or ever could be demonstrated, only on the strength of your paralogism — since he demonstrates the exact opposite and contrary, however perversely you struggle against it.

SCALIGER in coroll. 2. propos. 6.

If a straight line cutting a certain angle of a triangle cuts the base as well, and the squares on the sides containing the cut angle stand to one another just as the segments of the base do, then that cutting line is perpendicular to the base, and the cut angle is right.

In the previous figure, in the triangle AFB (let the triangle AFB be considered bare, without the other things that are in the figure), let the straight line FD, cutting the angle F, cut the base AB also, in D, and let the squares on the sides FB, FA containing the angle F be to one another as the segments DA, DB of the base AB. I say that the straight line DF is indeed perpendicular to the base AB, and that the angle F is right. Erect the straight lines AR, BP at right angles to the base AB, and let us imagine drawn from the point F, the vertex of the angle AFB, to imaginary points q, m taken on the straight lines AR, BP, two straight lines Eq, Fm, both parallel and equal to DA, DB, and so on.

CLAVIS.

I could well wish that I were sometimes allowed either to censure nothing at all, or at least not everything, and not to mark it all with the censor's nail, as they say. But what am I to do, a man as devoted to truth as I am incapable of putting up with falsehood? This whole proposition of yours, the whole of it, is falsehood; the whole of it, demonstration and all, is error and darkness. And although it contributes nothing to cyclometry, I shall examine it all the same, so that every age may admire, as far as it can, Scaliger's plainly divine acuteness in geometrical demonstration. I shall set out its falsity once I have first pointed out the paralogisms sown through the demonstration. When, therefore, he directs us to draw from the point F, to the perpendiculars AR, BP, two straight lines both parallel and equal to DA, DB, he is openly begging the question. For how can this be done unless FD is perpendicular to AB — which is the very thing set out to be proved? For unless FD is granted to be perpendicular to AB, FD and BP will not be parallel; and consequently the perpendiculars drawn from F to BP, and DB, cannot be equal,^a however parallel they may be. For only parallels between parallels^b are equal, on account of the parallelogram formed out of those parallels. You feel, I suppose, Scaliger, what a ruin your ruinous demonstration drags down with it — or else I give up thinking well of you. But let us now turn

our eyes and our mind to the falsity of the proposition itself. I say, then, that it is possible for a straight line cutting a certain angle of a triangle to cut the base as well, and for the squares on the sides containing the cut angle to stand to one another just as the segments of the base do, and yet for the cutting line not to be perpendicular to the base, and for the cut angle not to be right.

[Margin: ^a 28. pri.]

[Margin: ^b 34. pri.]

For let there be a triangle ABC having the angle A right, and from A let the perpendicular AD be dropped to the base BC. Then, by Scaliger's preceding corollary 2., the square on AB will be to the square on AC as BD is to DC. With the arc CF described from A at the distance of the greater side AC, let the straight line BE be drawn making the angle ABE obtuse and cutting the arc in E. Let the straight line AE be joined; let DF be drawn parallel to the joined straight line CE; and lastly let the straight line AF be dropped from A to F. Since, then, AE is equal to AC,^c the square on AB will be to the square on AE as it is to the square on AC — that is, as BD to DC, by hypothesis, that is, as BE to FE. In the triangle ABE, therefore, the straight line AF has been dropped from the angle A, cutting the base in F, and the square on AB is to the square on AE as the segment BF to the segment FE, as we have shown; and yet AF is not perpendicular [*perpendicularis*, so printed] to BE, since the angle AFB is less than the obtuse angle ABE; nor is the angle BAE right, being part of the right angle BAC. You now have in full view, candid reader, the outstanding and singular acuteness of so great a man as Scaliger boasts himself to be, and in matters geometrical you may admire either the height of his skill or his rashness. For with what a voice, with what spirit, did he insist that he was proving the straight line AF perpendicular to BE, and the angle BAE right?

[Margin: ^c 7. quin.]

Diagram. A triangle standing on a long, nearly horizontal base, with its apex A at the top. B lies at the left end of the base and C at the right end; from A the sides run down to B and down to C. On the base, at D, the short line AD falls from the apex. Below and left of D lies F, joined to A by a line from the apex and to D by a short line, so that a narrow spike A–F sits inside the triangle. From B a long line runs down and to the right to E, which lies low on the right; A is joined to E, and C is joined to E. A wide arc, convex downward, sweeps from below F across to the right, passing through E and running on toward C.

- A (apex, top centre): A

- B (left end of the base): B
- D (on the base, right of B, foot of the line from A): D
- F (below the base line, inside the figure, under and left of D): F
- E (low on the right, on the arc): E
- C (right end of the base): C

No other letters are cut on the block; in particular the letters q and m named in Scaliger's own corollary belong to his earlier figure, not to this one.

SCALIGER *in scholio propos. 6.*

But Archimedes tries to demonstrate, by a reduction to the impossible, that the length of the perimeter is a little greater above the diameter than triple-and-a-seventh — that is, that the square of the perimeter is less than 484, when of course the square of the diameter is 49.

That error the demonstration above sufficiently refutes. But why he persuaded himself of it, and posterity too, has been set out in the Prolegomena. A similar absurdity occurs in 18. & 19. of Archimedes' *περὶ ἑλικῶν* [Greek: the first word is set with the standard *περ-* abbreviation ligature sort rather than spelled out; *peri helikōn*, "On Spirals"].

CLAVIVS.

I could never have supposed that your enmity toward Archimedes ran so deep that one or two charges against him — false though they were — could not satisfy you. The suspicion now steals over me that, exactly as he has taken up the contest for truth against you, so you have taken up the contest for falsehood against Archimedes; and that this is how all the hatred that ordinarily holds between truth and lying has migrated wholesale into the pair of you. For what do you fling at him except your own errors and paralogisms? And what does he set against you except the truth? For with as much truth as he demonstrated, in his book *On the Measurement of the Circle*, that the ratio of the circumference to the diameter is less than triple-and-a-seventh, and so on — with just so much falsehood do you shamefully oppose him.

In the five propositions that follow — namely 7. 8. 9. 10. & 11. — Scaliger tries to find a straight line equal to the circumference of a given circle, and conversely to find a circumference equal to a given straight line; likewise to take a prescribed part away from a given circumference; and finally to take a prescribed part away from a given angle. But since in every one of these he either assumes that the square on the circumference is ten times the square on the diameter — which we

refuted above — or else describes the spiral by means of circular arcs, which is likewise inept and absurd, the constructions of those propositions will be false through and through; so that it is not worth spending time on refuting them.

S C A L I G E R in propos. 12.

If, from two diameters cutting one another at right angles in a circle, the sides of the hexagon and of the pentagon to be inscribed in the same circle are thrown out from the end of the one to the other produced, then the remaining part of the diameter so thrown out — the part lying between the produced side of the hexagon and the side of the square to be inscribed in the same circle — is bisected by the side of the pentagon.

In the circle ABCD let the diameter BD, which cuts the diameter AC at right angles, be produced without limit toward the side of G; and let the straight line AG, equal to the diameter AC, meet it so produced. Next let the straight line BG be bisected in F. And it is evident that CG is equal to GA, and that the whole triangle AGC is equilateral, and that the squares on AG and on EG are as 4 and 3, as we have now said so many times, and are therefore commensurable with one another in square only. But EB, being half of AG, is commensurable in length with AG, and therefore commensurable with EG in square only. BG, then, will be an ἀποτομή [Greek: apotomē, "apotome" — an irrational straight line of Euclid X], an ἄλογος line [Greek: alogos, "irrational"; printed with the terminal -ος contraction sort]. I say that if a straight line is dropped onto that ἀποτομήν BG from the end A to the point of bisection F, the line so dropped is the side of the pentagon to be inscribed in the circle ABCD — that is, that the side of the pentagon to be inscribed in the circle ABCD, when produced, meets the mark F. Let the straight line AF then be joined, cutting the circumference ALB in the point M. I say that AM is the side of the pentagon to be inscribed in the circle ABCD, and so on.

Diagram. A circle with A at the top, C at the bottom, B at the left and D at the right, the two diameters AC and BD crossing at the centre E. The horizontal diameter is produced to the left well beyond the circle, to G; F is marked on that produced line between G and B. On the arc between A and B lie L (higher) and M (lower). From A a set of straight lines fans down and to the left, meeting the arc at L and at M and running on outside the circle to G. A dotted line runs from M across to E, and a second dotted line runs from M down and to the right to C; a broken (dashed) line runs from G down and to the right to C, and another from G up and to the right toward A, so that the triangle AGC appears in broken rule.

- A (top of the circle): A

- L (on the arc, upper left): L
- M (on the arc, below L): M
- G (far left, on the produced horizontal): G
- F (on the produced horizontal, between G and B): F
- B (left end of the horizontal diameter): B
- E (centre of the circle): E
- D (right end of the horizontal diameter): D
- C (bottom of the circle): C

CLAVVS.

I should have thought you deserved pardon — a man by no means on the friendliest terms with truth — if you merely put forward falsehoods as truths. But that you should labour with so much effort to demonstrate this lying proposition of yours, partly by murky circumlocutions fetched from every quarter, partly (as your habit is) by perpetually begging the question, and often bringing in matter foreign both to the truth and to the question at hand — who would pardon that in a learned man, which is what you wish to be? Take, for example, the claim that BG is an apotome, and so on. The falsity of the proposition consists in this. Since the triangle AGC is equilateral by construction, the angle GAC will be a third part of two right angles, that is, 60 degrees. Next, since AM is the side of the pentagon, draw the straight line ME: the angle AEM will be 72 degrees,^a which is double the angle AGM, and so the angle AGM will be 36 degrees, and its complement CAM 54 degrees. And finally the angle BAE is 45 degrees. Now with the whole sine AE set at 10000000: EG is the tangent of the angle GAE of 60 degrees, namely 17320508; EF is the tangent of the angle FAE of 54 degrees, namely 13763820; and EB is the tangent of the angle BAE of 45 degrees, namely 10000000. These tangents do not exceed one another by equal amounts. The excess GF is 3556688, whereas FB is 3763820. Therefore the sides of the hexagon, of the pentagon and of the square do not cut off equal segments on the diameter DB produced. Do you not then acknowledge, Scaliger, that your proposition is faulty and false? Do you now want to recognize with me where in the end it goes wrong? I will show you. Bring your whole mind to bear on this.

[Margin: ^a 20. tertij.]

The five values stand in a ruled frame in the left margin of this passage:

| | |
|-----|----------|
| EF, | 13763820 |
| EB, | 10000000 |
| GE, | 3556688 |
| FB, | 3763820 |

S C A L I G E R in eadem propos. 12.

Let another circle ABCD be described, whose diameter AC, cutting the diameter BD, is produced toward the parts M, or G. Let DM be joined, equal to the diameter BD. AM being bisected in F, let FD, FB be joined. And so, as you see, here MD holds the place of the straight line AG in the other circle, and AM is the apotome holding the place of BG. What has to be shown is that the triangle BFD is one of the five triangles into which the pentagon is resolved. For by the same procedure it will be shown that DF — that is, AF (in the other circle) — is the side of the pentagon. With centre F and radius FD, or FB, let the circle GBID be described. Let the equal straight lines BI, BK be joined, and from IB produced indefinitely to N let BH be cut off equal to FB. Let the straight line HF be joined, cutting the circumference GKBID in K. Then from HI let HL be cut off equal to HK, and so on.

Diagram. Two overlapping circles. The lower, smaller circle has A at the top, C at the bottom, B at the left and D at the right, its two diameters crossing at the centre E. The larger circle, drawn about the point F as centre, has G at its top and passes through B on the left, D on the right, and I at the bottom (I lying inside the smaller circle, on the vertical line below E). One straight vertical line runs down through the whole figure, carrying in order from the top G, M, F, A, E, I, C; the horizontal line B–E–D crosses it at E. From F straight lines run down-left to B and down-right to D, and a long straight line runs from F down and to the left through K to H, cutting the larger circle at K. To the left of the figure, a second straight line comes in from N at the upper left, passes through H, then through L, and continues down and to the right to B and on to I; K is joined to B by a short line.

- G (top of the larger circle): G
- M (on the vertical line, below G): M
- F (on the vertical line, centre of the larger circle): F
- A (on the vertical line, top of the smaller circle): A
- E (centre of the smaller circle, on the horizontal): E
- B (left, on both circles): B
- D (right, on both circles): D

- I (on the vertical line below E, on the lower arc of the larger circle): I
- C (bottom of the smaller circle): C
- K (on the larger circle, at the left): K
- L (below and left of K): L
- H (further left, on the line from N): H
- N (far upper left, the end of the produced line): N

CLAVIVS.

On whose authority, in the end — on whose agreed concession — is it granted you that the straight line FH passes through K? What if your opponent denies it, and maintains that it falls a little above K, or below? Will you prop up on your own shoulders a demonstration collapsing along with you? Take care, rather, that it does not crush and grind you as well in its fall. For you will not even have the triangles HKL, FKB — and yet you use them in what you go on to add. Unless, then, you want all your labour to be lost, you will first have to prove that the straight line FH passes through K, if BK has been taken equal to IB and BH equal to BF.

Here at last you are true to form, in that you present yourself infected with the same flaw in the following proposition, in the finding of the sides of the heptagon, the enneagon, and the other figures with an odd number of sides. For here is what you have in the demonstration of the following proposition 13.

SCALIGER *in propos. 13.*

If on the same straight line the isosceles triangles into which the equilateral polygons to be inscribed in a circle are divided have been set up, then the angles at the vertex of the polygons having an odd number of sides bisect the interval lying between the two nearest sides of the polygons having an even number of sides.

In the circle ABCD let the diameter AC, produced infinitely, cut the diameter BD at right angles, and let it be cut at S, as if the straight line SD, equal to the straight line AC, had been joined from the limit D and had made the equilateral semi-triangle [isopleuron] DSE, as was shown above. Again let the interval AG be cut off, equal to the side of the square to be inscribed in the circle ABCD. If then the straight line DG were joined, the angle EGD would be the half-angle of one of the 8 triangles into which the octagon to be inscribed in the circle whose semidiameter is GD is resolved, by 20. of the third book. Lastly let the interval AS be bisected at R. If DR were joined, it would be the half-angle of one of the five triangles into which the pentagon is resolved, as was shown above. Therefore let the interval RI be made

equal to the straight line DR that is to be joined. Again, if the straight line DI were joined, IDE would be one of the ten semi-triangles into which the decagon is resolved, by the same 20. of the third book. Let the intervals SG, GI be bisected at the points F, H. Let the straight line DF be joined, cutting the circle ABCD at V. It has to be shown that DV is the side of the heptagon to be inscribed in the circle ABCD. With centre F and radius FB, or FD, let the periphery PBON be described. Let the straight line PB be joined, and let BO, ON be joined equal to it. And so the peripheries subtended by them are equal, by 29. of the third book. Let P B be produced toward Q, infinitely, and let it be met by the straight line from the limit F which joins N, the end of the periphery O N, and runs on until it meets the infinite line P Q at the point M. Let the straight lines FB, FL be joined, and from the straight line PM let the straight line ML be cut off equal to MN. Let NL be joined. Since the angles NOF, BOF are equal by construction, then, the common side FL being produced, the angles below the base NOL, BOL will be equal, by 5. of the first book; and by 4. of the same the bases LN, LB will be equal in the triangles NLO, BLO, and the angle ONL equal to the angle OBL. But the angles FNO, FBO are equal by construction. Therefore the whole angle LNF is equal to the whole angle LBF. Again FNL, MNL together on the straight line MF are equal to the angles FBM, FBP together on the straight line PM, by 13. of the first book; and when the equals FNL, FBM have been taken away, there remain equal FBP, MNL. Therefore the angles MNL, MLN are equal to the angles FBP — that is, FNO — and so on.

Diagram. The block occupies the upper right of the page, the italic demonstration running down its left side. A long straight line runs vertically down the right-hand edge of the figure; along its upper stretch short cross-ticks mark a series of lettered points, reading downward: I, H, G, F. Below F the same line carries three further lettered points before it reaches the circle. From F a sheaf of straight lines radiates down and to the left. Low in the figure a circle is drawn, its vertical diameter lying along that same straight line (the topmost of the three points just named sits where the line meets the top of the circle) and its horizontal diameter running from B at the left to D at the right; E is lettered at the centre, and below E, still on the vertical, stands P, then the lowest point of the circle. A second, larger curve passes through B and swings round to the right and down, cutting the vertical line below the centre; V is lettered where a line from the upper part of the figure meets the circle on its upper right, and X is lettered just to the left of the vertical, above the horizontal diameter. To the left of the circle, N stands high and L directly below it, joined by a short vertical segment; O lies between them and B, on a line running from the upper right down to L. Two long straight lines run far out to the left, converging at a point lettered M, with an italic swash Q lettered

just beyond it at the extreme left: the upper of the two comes down from F by way of N, the lower comes from B by way of L.

- I (top of the vertical line, uppermost tick): I
- H (next tick below I): H
- G (next tick below H): G
- F (next tick below G; the point from which the sheaf of lines radiates): F
- K [?] (first lettered point below F on the vertical; the glyph reads as a capital K, but no K occurs anywhere in Scaliger's proposition 13 or its demonstration): K
- S [?] (second lettered point below F on the vertical; the glyph reads as a capital S): S
- R (third lettered point below F on the vertical, immediately above the circle): R
- A (on the vertical, at the top of the circle): A
- X (just left of the vertical, above the horizontal diameter, on a curve): X
- V (on the circle, upper right, where a line from above meets it): V
- E (centre of the circle, at the crossing of the two diameters): E
- D (right-hand end of the horizontal diameter): D
- B (left-hand end of the horizontal diameter): B
- P (on the vertical, below E): P
- [?] (the lowest point of the circle, on the vertical; the bold glyph images with a crossbar and so reads as G, but this is the position of the fourth point of circle ABCD — the letter is not resolvable with confidence at native resolution): [?]
- N (upper left, joined downward to L and rightward toward F): N
- L (directly below N): L
- O (between N/L and B, on the line running down to L): O
- M (far left, where the two long lines converge): M
- Q (extreme left, an italic swash capital, beyond M): Q

CLAVIUS.

Truly, you are never anything but exactly like yourself, never anything but the same. Look at your own propositions: you will see that they come back round to the same thing over and over. For consider — when you order the straight line FOL to be joined, and the straight line ML, equal to MN, to be cut off from the straight line PM: even granting that you do not press the truth all that far, can you

still deny, you pseudo-geometer, that you are begging the question? For suppose someone argues that the straight line cut off from MP equal to MN ends either short of L or beyond it: with what a crash will everything you infer from it in that feeble demonstration of yours come down on your own head!

SCALIGER *in eadem propos. 13.*

But it must always be observed that the last line, such as LF, being equal to LM, and FM equal to PM, cuts the limit of the last periphery precisely; otherwise there is an error.

CLAVIUS.

What a ridiculous caution — ridiculous even to Scaliger himself! For if you think you have proved from your premises that the straight line LF will always be equal to LM, and FM to PM, what need was there of any caution at all? Could anyone keep from laughing if Euclid, where he teaches in proposition 11 of the first book how to erect a perpendicular to a straight line from a given point on that line, had gone on to warn that it must be drawn in such a way as not to make one angle greater than the other? Anyone could see from his construction that the two angles come out equal, so that nobody has any need of such a warning. Add the laughter that same Euclid would have raised when in proposition 16 of the third book he proves that the perpendicular drawn at the end of a diameter falls wholly outside the circle, touching it there — if he had issued the warning that everyone had already noticed, namely that this perpendicular must be drawn so as not to cut the circle. For by the very fact that it is proved to be perpendicular, it is proved that it does not cut the circle. No less laughter is owed to you, who direct that the lines LF, FM be drawn so as to be equal to the lines LM, PM, when you suppose yourself to be proving that they are equal in any case. And yet I have not taken you on for mockery in such a way as not to see some reason why you should after all want us warned of this: it is, of course, because you could not prove that LF, LM and FM, PM are equal — or that, if LM is taken equal to MN, the straight line FL must necessarily pass through O, which is nevertheless absolutely necessary for the rest of the demonstration.

The hidden shoals [*syrtes*] of your demonstration — or its sins, if you prefer that word — I have now, I think, laid open to you sufficiently; your ...

learn from me that your proposition is false: namely, that the side of the heptagon DV, when produced, does not bisect the segment SG between the points S and G, on which the sides of the hexagon and the octagon would fall; nor does the side of the enneagon bisect the interval GI between the points G and I, on

which the sides of the octagon and the dodecagon would fall. This we shall carry through by means of the tangents, just as we showed above that the intervals AR, RS are not equal, supposing the sides of the square, the pentagon, and the hexagon were to fall on the points A, R, S.

For set the whole sine DE at 10000000. The angle SDE will then be 60 degrees, as was said above, and its tangent ES 17320508. The angle FDE, half the angle of the heptagon, will be $64 \frac{2}{7}$ degrees — that is, 64 degrees 17 $\frac{1}{7}$ minutes. (For since one angle of the heptagon is 1 [numeral: ?]/7 of a right angle, its half will be 5/7. Say, then: if one right angle gives 90 degrees, what will 5/7 give? and you will find $64 \frac{2}{7}$ degrees. Next: if 1 degree gives 60 minutes, what will $\frac{2}{7}$ give? you will find 17 $\frac{1}{7}$ minutes.) Its tangent EF is 20765212. For the tangent of 64 degrees 17 minutes is 20763004, and to one seventh of a minute there correspond 2208 parts, which together with 20763004 make up 20765212. For if one minute, between the tangent of 17 minutes and that of 18, calls for a difference of 15459, one seventh of a minute will call for a difference of 2208, and so on. Lastly the angle GDE, half the angle of the octagon, will be $67 \frac{1}{2}$ degrees, since one whole angle contains 135 degrees. And the tangent EG will be 24142137. These three tangents do not exceed one another by equal amounts: GF is 3376925, whereas FS is 3444704. In just the same way we shall find that the excesses IH, HG are unequal — and so for the other figures. And if you admit that all this is exactly as I have said (as, unless you have lost every sense of shame, you cannot deny), then admit this too: that your proposition 13 has nothing true in it.

[Inset display: two ruled frames — each a closed box, with rules above, below and on both sides, and no internal column rules — are set into the text column itself, flush with its left-hand edge, beginning immediately under the line *SDE, grad. 60. vt supra dictum est*, and together running about nine lines deep; for that whole depth the text is turned around them on the right in a short measure. The upper frame holds the three rule-of-three lines of the calculation above, each closing with the question mark that stands for the fourth term:]

1 90 [numeral: ?]/7 ?
 1 60 $\frac{2}{7}$?
 1 15459 $\frac{1}{7}$?

[Inset display: the lower ruled frame, set directly beneath the upper one in the same inset position, listing the three tangents and the two differences, the differences ruled off beneath:]

 EB [?], 17320508

SCALIGER *in propos. 14.*

On a given finite straight line to construct an isosceles triangle, one or other of whose base angles shall have a given ratio to the remaining one.

CLAVIVS.

In this proposition, my dear Geometer, you commit a paralogism. Do you not see what you have laid down earlier? That you had correctly found the sides of the polygons, of course — and that is false. What wonder, then, if from badly laid premises you draw bad conclusions? You go wrong at the very door.

SCALIGER *in Propos. 15.*

To inscribe in a given circle an equilateral figure with an odd number of angles.

CLAVIVS.

But you are consistent: you commit your paralogisms in the same key, so as not, presumably, to fall out with yourself. Very well: you assumed that you had constructed an isosceles triangle one or other of whose base angles has a given ratio to the remaining one. And since that is as false as you are a false mathematician, you can see — unless you are altogether blind — what follows from this false assumption.

SCALIGER *in propos. 16.*

Given four unequal straight lines, to find a circle such that a quadrilateral composed of the four given lines can be inscribed in it.

CLAVIVS.

What a thoughtless mathematician, to set a problem that is impossible! For unless any three of the four lines taken together are greater than the remaining one, no quadrilateral can be constructed from them, since in every quadrilateral any three sides taken together are greater than the remaining one — or (what comes to the same thing) any one side is less than the other three. In the figure immediately preceding, take the quadrilateral FOBD, in which the diagonal FB has been drawn. I say that the side, FO for example, is less than the three OB, BD, DF. [Margin: a 20. primi.] For since FO is less than the two OB, BF, and BF is less

than the two BD, DF, it is clear that FO is less than the three OB, BD, DF. Why, then, did you not learn from Euclid that this condition had to be added — that any three of the lines taken together must be greater than the fourth? — just as he himself, in proposition 22 of the first book, when he wanted to construct a triangle out of three lines, attached this condition: *But two of them, taken in every combination, must be greater than the remaining one*, since in every triangle two sides taken in every combination are greater than the remaining one. Or was it perhaps your own sharp insight that three sides of a quadrilateral are always greater than the remaining one, and that you therefore supposed a quadrilateral could be constructed out of any four lines whatever?

Furthermore, in the demonstration of this proposition 16 you go wrong so often and in so many things that you seem to call not for a refutation from me — by now I am weary of it, and ashamed to spend such labour so badly — but for a boy's whipping; and all the more so since it has no more to do with the squaring of the circle than an ox has to do with the Pillars of Hercules.

SCALIGER in propos. 17.

To inscribe a segment of a hexagon in the complement of the hexagon's hatchet-figure [securicula].

It is to be considered whether a segment of a hexagon — or (what comes to the same thing) two half-segments of a hexagon — can be inscribed in the complement of the hexagon's hatchet-figure. To the straight line CED, of unlimited magnitude, let the straight line EV, infinite, be perpendicular. Let any equal intervals EC, ED be cut off. Then with centres C, D, and with radii CE, DE, let the peripheries EG, EH be described. Again with the same radius, but with E as centre, let the periphery GFH be described; and let the straight line EF, cut off from the infinite line EV — namely the semidiameter of the peripheries — bisect it at F. The peripheries ENG, EH, GFH are therefore equal, by definition 1 of the third element, because the straight line GH that joins them is equal to the semidiameters EF, CE, DE. Therefore by definition 1 of this book the figure ENG, FHE is the hatchet-figure of the hexagon, and the straight line RF is an apotome, as has been demonstrated elsewhere. Let RK be cut off equal to it, and let the segment GRHMKLG be made equal to the segment GRHFG. Each of them, therefore, will be a segment of the hexagon; and consequently the figure ENKGHE is the complement of the hatchet-figure, by definition 2 of this book. Now the apotome RF is at the least a little greater than one eighth of the semidiameter EF, as was demonstrated in 5 of this book; and therefore the whole FK is a little greater than two eighths of the semidiameter. And so the remainder KE falls a little short of six eighths of the semidiameter. It will therefore be greater than RG by a

little less than two eighths of the semidiameter EF , as is shown in the same 5 of this book. In the straight line EK , then, the height of the half-segment can be found, since the peripheries ENG , EH touch one another only at the point E , by 13. of the third book. From the point K let an infinite straight line be drawn parallel to CD , by 13. of the first book; from it let KB be cut off equal to the semidiameter DE , or to EC ; and from the same line again let the apotome BO be cut off, equal, that is, to the apotomes RF , RK . With centre O and radius OL — which is to be equal to BK , or to DE — let the periphery VLI be described. From the equals OL , BK let the common part OK be taken away: there will remain BO , KL equal. And so KL is an apotome; and therefore the periphery VLI is a segment of the hexagon, equal, of course, to the segment $GFHRG$. And KI will be equal to RG ; and $LIKL$...

... and $LIKL$, equal to $RFGR$. In the same way let AK be cut off equal to BK , and AQ equal to BO ; and with a radius equal to AK , or BK , or OL , let the periphery IMV be described. Thus there will be completed two half-segments IKL , IKM , equal to the half-segments GFR , GKR . Let the straight line CO be joined, cutting the periphery ENG at the point N . CN , then, is the semidiameter of the periphery ENG , by the definition of a circle; and consequently the remainder NO will lie wholly outside that periphery ENG . Now the straight lines ON , OL , and likewise the straight lines CN , CE , are equal by the definition of a circle. But OL , CE are equal by construction. Therefore ON , CN , diameters meeting one another at the point N , make one continuous straight line CNO — indeed CNO is continuous by construction; and consequently their peripheries will touch one another at that same point N . Nor will they anywhere else either touch or cut one another, by 13. of the third book. In the same way we shall prove that EH , IM touch one another in a single point, if the straight line DQ is drawn. Therefore a segment of the hexagon has been inscribed in the complement of the hatchet-figure — or (what comes to the same thing) two half-segments, which touch the two equal lateral segments at one point only. Accordingly there is left over besides a scrap of space out of the complement, and let it be called the remainder of the segment.

Diagram. The block sits at the top right of the page. A long horizontal straight line runs across the top, tick-terminated at both ends: C at the far left, E at its middle, D at the far right. A second horizontal line runs lower down, likewise tick-terminated: A at the far left with Q immediately to its right, and at the far right O with B immediately beyond it; this lower line passes through the points L , K , M in the middle of the figure. From C a long straight line slants down and to the right, crossing the upper arcs at N and running on to the right-hand end of the lower line. A vertical line descends from E through I , K , R and F to V , and continues a little below V . Between E at the top and V at the bottom two pairs of

arcs are drawn, forming a tall pointed oval crossed by a second, narrower one; N lies on the left-hand arc high up, and I on the vertical just below E. A third horizontal line, shorter than the others, runs from G at the left to H at the right, lower than the A–B line, and broad arcs sweep from G and from H up toward E and down toward V. The minuscule letters a and b stand just below L and just below M respectively, inside the figure (they are clearly small letters, contrasting with the capitals L, K, M immediately above them).

- C (left end of the upper horizontal line): C
- E (middle of the upper horizontal line, apex of the pointed oval): E
- D (right end of the upper horizontal line): D
- I (on the vertical, just below E): I
- N (high on the left-hand arc, where the slanting line from C crosses it): N
- L (on the lower horizontal line, left of centre): L
- K (on the lower horizontal line, at the vertical): K
- M (on the lower horizontal line, right of K): M
- a (minuscule; just below L): a
- b (minuscule; just below M): b
- G (left end of the short horizontal line): G
- H (right end of the short horizontal line): H
- R (on the vertical, below K): R
- F (on the vertical, below R): F
- V (on the vertical, at the lower point of the oval): V
- A (left end of the lower horizontal line): A
- Q (immediately right of A on the lower horizontal line): Q
- O (on the lower horizontal line toward the right): O
- B (right end of the lower horizontal line, beyond O): B

CLAVIVS.

Do you really suppose, Scaliger, that you have inscribed two half-segments of a hexagon in the complement of the hatchet-figure? For my part I doubt it; indeed I am certain you have not brought it off. For I detect two faults in your description. First, that without any proof you assume CN to be equal to ON. That will never be granted you unless you prove CD and CO to be equal. Your opponent will therefore say that the arc VLI does not pass through N, but either beyond it or short of it, and consequently that the half-segment LI is not inscribed in the complement of the hatchet-figure. The second fault is this. Even if it were granted

you that the arcs EG, IL touch one another at N, it would still be false that the figure inscribed in the complement of the hatchet-figure contains two half-segments. For since the straight line AB touches the arc GKH at K, and therefore cuts the arcs ILV, IMV at L, M above the arc GKH, the figure LIM will be equal to one segment, being composed, that is, of two half-segments. Hence, once the mixed triangles aLK, bMK are added, the inscribed figure will be greater than one segment. From which it follows that the next two demonstrations, which hang on this inscription, collapse altogether. I pass over the fact that it is superfluous, when you say that RF is an apotome, since this does nothing toward the demonstration.

S C A L I G E R in lemmate ante propos. 5. Appendicis.

If from two commensurable magnitudes two commensurable magnitudes are subtracted, the remainders will be commensurable.

From the two commensurable magnitudes AC, DF let two commensurable magnitudes BC, EF be taken away. I say that the remainders AB, DE are commensurable. For since AC, DF are by hypothesis commensurable, they will have to one another the ratio of a number to a number, by 5. of the tenth book; and in the same way BC, EF will have the ratio of a number to a number. The numbers BC, EF, therefore, subtracted from the numbers AC, DF, will leave the numbers AB, DE. And so the magnitudes AB, DE will have the ratio of a number to a number. Therefore by 6. of the same the two magnitudes AB, DE are commensurable.

Diagram. Two horizontal straight lines set one above the other in the outer part of the text block, each terminated by an upright tick at either end and divided by a further tick within. The upper line is lettered A at its left end, B at the interior division, and C at its right end. The lower line is lettered D at its left end, E at the interior division, and F at its right end.

- A (left end of the upper line): A
- B (interior division of the upper line): B
- C (right end of the upper line): C
- D (left end of the lower line): D
- E (interior division of the lower line): E
- F (right end of the lower line): F

CLAVIVS.

This lemma, although as a first principle it may look self-evident by the very light of nature, is not true — except when BC, taken away from the whole AC, is commensurable with it, or when the ratio of the whole AC to the whole DF is the same as the ratio of the part removed, BC, to the part removed, EF. For (to offer a parallel example of the kind you use in proposition 5 of the Appendix) let there be two magnitudes AB, CD, equal and therefore commensurable; and let the magnitudes taken away, AE, CF, stand in subquadruple ratio [*proportione subquadrupla* — AE one fourth of CF], and be for that reason commensurable as well. But let AE be incommensurable with AB. I say that the remainders EB, FD are incommensurable. For since the whole AB is posited incommensurable with the part AE, a [Margin: a 17. deci.] AE, EB will be incommensurable. Since, then, EB is incommensurable with AE, and — taking AG equal to CF, so that EG is triple AE, seeing that the whole AG is quadruple that same AE — GE is commensurable with AE, b [Margin: b 13. deci.] EB, EG will be incommensurable; c [Margin: c 17. deci.] EG, GB will be incommensurable too; d [Margin: d 17, deci.] and consequently the whole EB is incommensurable with the part GB, and therefore also with FD (which is equal to GB by construction). Which was to be shown.

But if AE is commensurable with AB, then and only then will the remainders EB, FD be commensurable. For since the whole AB is posited commensurable with the part AE, e [Margin: e 16. tertij.] AE, EB will be commensurable. Since, then, EB is commensurable with AE, and GE is commensurable with that same AE, f [Margin: f 12. deci.] EB, GE will be commensurable too. And since the whole EB is commensurable with the part GE, g [Margin: g 16. deci.] GE, GB will also be commensurable. h [Margin: h 16. deci.] And consequently the whole EB will be commensurable with the part GB, and therefore with FD as well, which is equal to GB by construction.

Diagram. Two more horizontal straight lines set one above the other at the outer edge of the text block, each terminated by an upright tick at either end and subdivided by interior ticks. On the upper line A stands at the left end, E immediately to its right at the first interior tick, then two further interior ticks, then G, and B at the right end. On the lower line C stands at the left end, followed by a row of interior ticks, then F, with D at the right end.

- A (left end of the upper line): A
- E (first interior tick of the upper line, close to A): E
- G (interior tick of the upper line, close to its right end): G

- B (right end of the upper line): B
- C (left end of the lower line): C
- F (interior tick of the lower line, close to its right end): F
- D (right end of the lower line): D

You do not, then, infer correctly in proposition 5 of the Appendix when you say: the sector GDE is commensurable with the sector GEF, because it is equal to it; and the segment DE in the former sector is commensurable with the four segments in the latter sector; therefore the remaining hexagon-triangle in the former sector, made up of the five triangles LOP, is commensurable with the remaining segment in the latter sector. You do not, I say, infer correctly, because it is not established whether the hexagon's segment is commensurable with the sector or not. And if it is incommensurable — as is likely — you conclude nothing whatever. See, then, how well versed you are in geometry, you who propound a universal lemma that is not true except in certain cases.

But let us demonstrate the falsity of the lemma by further examples. Let the magnitude AB be triple the magnitude CD, and AE double CF; and let AE be incommensurable with AB. I say that the remainder EB is incommensurable with the remainder FD.

For let it be made that as AB is to CD, so EB is to GD. And since AB is posited triple CD, EB too will be triple GD. [Margin: a 19. quin.] The remainder AE, therefore, will also be triple the remainder CG. Now since AE is posited double CF, CG will be less than CF; and so the point G does not coincide with the point F.

Diagram. Two bare labelled straight-line diagrams set into the text block, one above the other, belonging to the first demonstration.

- Upper rule: a long horizontal line with a vertical terminal bar at each end. A (bold capital, left, above the left terminal); E (bold capital, above an interior tick set well to the left of centre); B (bold capital, right, above the right terminal). Besides the tick under E the rule carries further short interior ticks; their exact number does not resolve at this resolution [?]. No other letters appear on this rule — in particular the block shows no F, G, C or D.
- Lower rule: a short horizontal line with a vertical terminal bar at each end, carrying, left to right, C (above the left terminal), G and F (bold capitals, above two closely-set interior ticks), D (above the right terminal).

Since, then, AE and CF are commensurable — for they stand in the double ratio — while AE is incommensurable with AB, [Margin: b 14. deci.] CF too will be incommensurable with that same AB. But AB is commensurable with CD; [Margin: c 13. deci.] therefore CF and CD will be incommensurable. And since as AB is to CD, so EB is to GD, and AB is commensurable with CD, [Margin: d 10. deci.] EB too will be commensurable with GD. Again, since as the whole AB is to the whole CD, so the part taken away, EB, is to the part taken away, GD, the remainder AE will be to the remainder CG as the whole AB is to the whole CD. Since, then, AB is commensurable with CD, [Margin: e 10. deci.] AE too will be commensurable with CG. But CF is likewise posited commensurable with that same AE. [Margin: f 12. deci.] Therefore CG and CF are commensurable as well; [Margin: g 16. deci.] and consequently CG and GF will also be commensurable. But AE was shown commensurable with that same CG; [Margin: h 12. deci.] therefore AE and GF too will be commensurable. [Margin: i 17. deci.] Yet AE is incommensurable with EB, because the whole AB is by hypothesis incommensurable with its part AE. [Margin: k 14. deci.] Therefore GF too is incommensurable with that same EB. Since, then, EB and GD have been shown commensurable, while EB is incommensurable with GF, [Margin: l 14. deci.] GD too will be incommensurable with that same GF; [Margin: m 17. deci.] and consequently GF and FD will be incommensurable; [Margin: n 17. deci.] and therefore GD and FD will be incommensurable also. Since, then, EB has been shown commensurable with GD, and GD is commensurable [recte: incommensurable — the step immediately preceding proves GD and FD incommensurable] with FD, [Margin: o 14. deci.] EB too will be incommensurable with that same FD. Which was the thing proposed.

ANOTHER WAY, in lines alone. Let the whole AB be rational (that is, commensurable with the assigned rational line) and commensurable with the whole CD — specifically, let AB be triple CD. Then let AE be cut off equal to CD, and let AF be the side of the square whose diagonal is AE, and let it be double CG, so that the cut-off segments AF and CG are commensurable as well.

Diagram. A second pair of bare labelled straight-line diagrams, set one above the other, belonging to the "Aliter" demonstration.

- Upper rule: a long horizontal line with vertical terminal bars. A (bold capital, above the left terminal); then, close together toward the left, H, F, E (bold capitals, each above its own interior tick), in that order; then a long undivided stretch to B (bold capital, above the right terminal).

- Lower rule: a horizontal line with vertical terminal bars. c (above the left terminal); then, close together toward the left, ı and 6 (bold capitals, each above its own interior tick), in that order; then a stretch to d (above the right terminal).
- No other letters appear in either block.

I say that the remainder FB is incommensurable with the remainder GD. For suppose, if it can be done, that it is commensurable. Since AF is commensurable in square with AE, and AB is commensurable in length with that same AE (which is equal to CD), [Margin: p 12. deci.] AF and AB will be commensurable — not indeed in length (for otherwise, as I showed on X.12, since AB is commensurable in length with AE, that is, with CD, AF too would be commensurable in length with that same AE, which is contrary to the hypothesis) — but in square only. [Margin: q 74. deci.] Therefore FB is an apotome. [Margin: r 104. deci.] Therefore GD too, being commensurable with FB, is an apotome. And if it be made that as FB is to GD, so AF is to IG, then, as Euclid demonstrated in proposition 104 of Book X, IG will be the annex [congruens] of the apotome GD, so that IG and ID are rational and commensurable in square only. [Margin: s 12. quin.] For the whole AB will be to the whole ID as FB is to GD. Since, then, FB and GD are commensurable in length (on my opponent's own supposition), AB and ID too will be commensurable in length, and so likewise AF and IG. And since AB and AF are rational, ID and IG, being commensurable with them, will be rational too. But AB and AF are commensurable in square only. Therefore, as we showed on X.10, ID and IG will be commensurable in square only. Since, then, they are rational, [Margin: t 74. deci.] GD will be an apotome and IG its annex.)

But IG will not be the same as CG. For if FB were to GD as AF is to CG, [Margin: u 12. quin.] then AB would also be to CD as (AF) is to CG [the print sets no second term here: "esset quoque AB, ad CD, vt ad CG"] — which is false, since AB is by hypothesis triple CD, whereas AF is by construction double CG.

Again — AF being bisected at H — since AF and AH are commensurable in length, while AF is incommensurable in length with AE, [Margin: x 14. deci.] AH too will be incommensurable in length with AE. [Margin: y 12. deci.] Since, then, AH and AE are incommensurable, each of them being commensurable with AF — the former in length, the latter in square only — it follows that AH, that is, CG which is equal to it, is commensurable in square only with AE, that is, with CD; [Margin: z 74. deci.] and consequently GD is an apotome, whose annex is CG. Therefore the apotome GD has two annexes, IG and CG. [Margin: a 80. deci.] Which is absurd. Therefore FB and GD are not commensurable. Which was the thing proposed.

I have been somewhat long-winded in demonstrating the falsity of Scaliger's lemma, partly so that its falsity may be convicted more evidently, and partly because several other mathematicians use it too, as though it were true, to prove that the circumference of a circle is commensurable in length with the diameter — a matter in which they too have gone astray.

SCALIGER, in propos. 2. secundæ partis Cyclometriæ, & in propos. 6. Appendicis.

THE CIRCLE amounts to [potest] thirty-six segments of the hexagon inscribed in that same circle.

CLAVIUS.

Do you really assert, Scaliger, that you have inscribed a segment of the hexagon in the complement of the hatchet [securicula]? But where did you inscribe it? Outside the margin, I suppose — for I myself have never seen it. The earlier inscription of yours, the only one I have seen, is a paralogism. Since, then, this dictum of yours cannot be traced, nor this position of yours either, this proposition of yours is left undemonstrated, and the fault is your own. But what wonder that you could not demonstrate it, when it is false altogether? This I show as follows, from what Archimedes has genuinely demonstrated — and not by paralogism, as you slanderously allege.

If the circle were equal to 36 segments of the hexagon, the hexagon would be equal to 30 segments, and a single chisel [scalprum] (your name for a sector) to six segments. The segment, then, would be a fifth part of the triangle at the centre. All of which is false on Archimedes' showing. For with the diameter put at 70, the circumference of the circle will be 220 — greater than the true one; and the area accordingly 3850, greater than the true one. A sixth part of this, $641 \frac{2}{3}$, will give a single sector, likewise greater than the true one; and a sixth part of that, $106 \frac{17}{18}$, will on your account be a little greater than a single segment. Taken five times, therefore, it will yield you a triangle of $534 \frac{13}{18}$ — which is not true, since by what we demonstrated in Book 4, chapter 2, number 5 of the *Geometria practica*, the hexagon's triangle (one side being put at 35) is only $530 \frac{5}{6}$. Subtract this from the sector, which we found to be $641 \frac{2}{3}$, and it will leave a single segment of $150 \frac{5}{6}$ [numeral: ?] — far greater than the $106 \frac{17}{18}$ found at first; greater, I say, than a sixth part of the sector. The hexagon's segment, then, is not a sixth part of the sector, as you would have it, but greater.

Again, with the diameter put at 70, the circumference will be $219 \frac{51}{71}$ [numeral: ?] — less than the true one; and therefore the area less than the true one, $3847 \frac{76}{142}$. A sixth part of it, that is, a single sector, is $641 \frac{218}{852}$.

Therefore, on Scaliger's account, a sixth part of this will give a single segment of the hexagon as $106\frac{478}{5112}$ [numeral: ?]. But if from the sector just found, $641\frac{218}{852}$, one takes away the hexagon's triangle found a little earlier, $530\frac{5}{6}$, the remainder will make a single segment of about $110\frac{2160}{5112}$ — which is much greater than the $106\frac{478}{5112}$ found before. And so, whether you take the circumference greater than the true one on Archimedes' showing or less, you plainly see

that you are demonstrating a falsehood. For the segment of the hexagon is neither $\frac{1}{36}$ of the whole circle, nor $\frac{1}{6}$ of the sector, nor $\frac{1}{5}$ of the triangle at the centre, as you falsely supposed.

But so that you may see your own shameful ignorance most clearly, as in a mirror, and recoil from the sight of yourself as from a rabid dog, weigh what I am about to say. The segment of the hexagon, found by Archimedes' solid demonstration according to the lower limit, is $110\frac{2160}{5112}$; and this, multiplied by 36, produces the number $3975\frac{1080}{5112}$ — far greater than the area of the circle, 3850, which is itself greater than the true area. Are you not ashamed, then, to lie so conspicuously as to say that the circle is equal to 36 segments of the hexagon?

All your chimeras collapse under this, the chimeras with which you try to square the circle; so it is not worth the trouble to waste time refuting them, since they contain nothing true. I shall raise only one objection against your quadrature in the corollary and scholium of proposition 3 of the second part of the *Cyclometria*.

SCALIGER, in coroll. & scholio propos. 3. secundæ partis Cyclometriæ.

From this it is clear that the area of a circle is equal to the rectangle contained by the side of the equilateral triangle inscribed in that very circle and by nine tenths of the diameter.

CLAVIVS.

And so, on your view, if the diameter of the circle is 16, the area of the circle will be greater than 199 but less than 200 — which is entirely false on the strength of what Archimedes has demonstrated. For this area of yours is less than the area reckoned according to Archimedes, less even than the one that is smaller than the true area. For with the diameter put at 16, the area smaller than the true one is found to be $201\frac{1}{71}$, while the area greater than the true one is $201\frac{1}{7}$; so that the true area lies between $201\frac{1}{71}$ and $201\frac{1}{7}$, whereas on your account it lies between 199 and 200, each of which is less than the true area.

But look at your ineptitude — better, your ignorance — in squaring the circle: for if your method of squaring is true, it follows that the part is greater than the whole. Do you deny it? Then attend. With the diameter put at 20000000, the side of the equilateral triangle described in the circle will be 17320508 75/1000 — that is, the root of the square which is triple the square of the semidiameter, [Margin: a 12. tertijdec.] since the triangle's side is in square triple the semidiameter. We searched out this root by appending 000000, so as to find the approximation in thousandth parts, as we set out in proposition 20 of Book 6 of the *Geometria practica*. If, then, this side is multiplied by 9/10 of the diameter, that is, by 18000000, there will be produced, on your reckoning, the area of the circle as 311769145350000.

But with the same diameter of 20000000 put down, the area of the figure of 36 equal sides described inside the circle is 312566567093244. For one side of the said figure is 1743114 — double the sine of 5 degrees, of course — and hence the semi-perimeter is 31376052; and this, multiplied by 9961947 (the perpendicular dropped from the centre onto the side, which the sine of the complement of 5 degrees gives, the semidiameter being put at 10000000), produces the area 312566567093244, which is greater than your area of the circle, 311769145350000. And that is more absurd than any absurdity. Let the reader see, then, what a distinguished squarer of the circle Scaliger is, and let him compare Scaliger's quadrature with Archimedes' quadrature of the circle, which exhibits the area of that same circle as greater than 31408450742253 [numeral: ?] (since this area is less than the true one) — and that area is indeed greater than the area of the 36-sided figure given above, as is only proper.

Go now, ranter [Blatero], and boast in the scholium of proposition 6 of the Appendix that you have demonstrated the circle to be less than the rectangle contained by the semidiameter and by a length three and one-seventh times the length of the diameter (you ought to have said: *and by half of* the length three and one-seventh times the length of the diameter) — against Archimedes. Brag that you have produced a rectilinear figure equal to the circle, and have done what no one ancient or modern has done. Shout it out in the scholium of theorem 10 of the Appendix: Where, then, are those men who conceive the circle as contained by the semidiameter and the semi-perimeter? How false is their opinion! How false the all-but-divine Archimedes himself, for whom such a circle is 201 1/7! The circle, therefore, is in square less than the rectangle contained by the semidiameter and half of the straight line which as a whole is less than three and one-seventh times the diameter. Proclaim in the scholium of theorem 12 of the Appendix how far from the truth those men are who make the circle whose

diameter is 16 greater than 200. For all these outcries of yours are empty and contain nothing solid; and they are most evidently refuted by what Archimedes demonstrated.

It irks me to waste time refuting the 13 propositions that follow, since they are all false — deriving their whole force, as they do, from your quadrature, which does not square with the truth in the least.

Finally, I have not leisure enough to refute the last proposition of the *Cyclometrica elementa*, by which you try to overturn Archimedes' quadrature of the parabola; for you appear neither to understand what a parabola is nor to penetrate Archimedes' most subtle reasonings (which indeed exceed the grasp of your understanding). But, to have regard for Archimedes' name and standing, I shall expose your incompetence in geometry in this place too.

SCALIGER in propos. 19. secundæ partis Cyclometriæ.

TO EXHIBIT a parabola which has, to the triangle set up on the same base and with the same height as the parabola, a ratio less than sesquitertian [sesquitertia — 4:3].

Let there be a cone KBC whose base is the circle KBNC, cut normally by the diameters KN, BC. Since the straight lines KB, KC are sides of the square inscribed in the circle, and the angle K is right, the cone KBC will be right-angled [orthogonius], by definition 18 of Element 11. With the side KB bisected at L, and DL joined, the angle DLK will be right, by III.3. The angle K too is right. Therefore the straight lines DL, CK are parallel, by I.28. Hence the cone KBC, cut through DL, will make a parabola. Let it make the parabola BLEMC — the straight line DE, that is, being cut off, which is equal to DL, and which therefore is the height of the parabola, whose base is equal to the diameter of the conic base and is therefore the greatest of all parabolic bases in the section of a right-angled cone; and the whole of it is inscribed in the triangle KBC, that is, not cut by the triangle KBC — that triangle being made by a plane cutting the cone through the vertex and the axis, by Apollonius, Conics I.3. Let the triangle EBC be inscribed in the same parabola. Let us show that the parabola BLEMC has, to the inscribed triangle (that is, to the triangle on the same base and of the same height), a ratio less than sesquitertian, etc.

Diagram. A circle drawn in heavy line, set in the outer right of the text block beside Scaliger's italic lemma, with a straight-line construction inside it and one label above it.

- A (bold capital) at the very top, above the circle, at the apex of two straight lines that run down to the left and to the right.

- κ (small capital, immediately below A) on the circumference at the top of the vertical diameter.
- A vertical straight line runs from A down through κ and the centre to the bottom of the circle.
- β (bold capital) at the left end of the horizontal diameter, on the circumference; γ (bold capital) at the right end, on the circumference.
- δ (bold capital) at the centre, where the two diameters cross.
- η (bold capital) at the bottom, below the circle, at the foot of the vertical line.
- A short horizontal line high inside the circle carries a run of small labels. Left to right: ζ , then line-work which may or may not be a further letter [?], then ϵ ; then ϵ on the vertical axis; then η , then a glyph resembling a β or β which I cannot resolve [?], then ι .
- λ (small capital) just below the ζ/ϵ cluster on the left; μ (small capital) just below the η/ι cluster on the right.
- Fans of straight lines converge on β from the labelled points on the upper part of the figure, and likewise on γ ; further lines join β to γ , β to A, and γ to A.
- Note: the figure shows no arc distinguishable as a drawn parabola at this resolution, and it carries the letters A, ζ , ϵ , η , ι , which the lemma's text never names; conversely the lemma names the parabola BLEMC whose letters λ , ϵ , μ are all present.

CLAVVS.

There is no way anyone could bear with an even mind that impudence of yours, by which the little book of Archimedes on the quadrature

of the parabola — a book all learned men rightly look up to — you dare to attack. Let us see, then, how splendidly you demonstrate that the parabola BLEMC is less than four thirds [sesquitertia] of the triangle BEC.

First, then, without any demonstration you assume that the parabola is enclosed within the triangle KBC. That this is false I show from Apollonius as follows. Since DE and EA are equal by your own construction, [Margin: a 33. primi Apollon.] the straight lines AB, AC touch the parabola at B and at C. [Margin: b 32. primi Apoll.] Therefore the straight lines BK, CK will cut the parabola, and consequently the parabola will not be enclosed within the triangle KBC.

Next, from GE and IE you cut off the third parts GF, IH; and with the straight lines FB, HC drawn you rightly demonstrate that the trapezium FBCH is four thirds of

the triangle EBC. For the triangle EBD is double the triangle BEG. Of such parts, therefore, as the triangle EBD is 6, the triangle BEG will be 3; but BFG is 1 and BEF is 2. Therefore, of such parts as EBD is 6, the trapezium FBCH is 8. And of such parts as EBC is 12, FBCH is 16; and so the trapezium FBCH is four thirds of the triangle EBC.

But when you afterwards go on to infer that the parabola is less than the trapezium FBCH, you go astray by the whole breadth of heaven — because you suppose the parabola to be described inside the trapezium. And that is not true, since the straight lines FB, HC cut the parabola, whether the points F, H lie between α E and β E, as in my figure, or between α G and β I, as in your own figure. Here too you beg the question, assuming without demonstration that the point F always falls between G and α — which in any case does not bear on the matter. And so you prove in no way whatever that the parabola is less than four thirds of the triangle. From this it follows — since Archimedes has truly demonstrated that the parabola is four thirds of the triangle, however much you bark against it — that the parabola is equal to the trapezium FBCH, provided the figure is correctly constructed. Learn the elements of conics first, then, before you set about censuring Archimedes.

SCALIGER, in scholio eiusdem propos. 19.

THEREFORE either not all parabolas, or none at all, have a sesquitertian ratio to the triangle having the same base and the same height as the parabola itself. Yet Archimedes, in the book [Greek: περί τετραγωνισμὸ παραβολῆς (peri tetragōnismou parabolēs, "On the quadrature of the parabola"; the print uses the πε- and πα- ligature sorts and the ὀ (ou) sort)] demonstrates that every parabola is four thirds of the triangle inscribed in it — a demonstration which he fortified with many mechanical epicheiremata. It is truly astonishing that so distinguished a work should be attacked by this one proposition of mine, and I do not see how I am to defend so great a man as Archimedes. Indeed even the parabola that Archimedes himself uses can be attacked in the same way — at which I cannot wonder enough.

CLAVIVS.

Every parabola is four thirds of the triangle inscribed in it, as Archimedes splendidly demonstrated. And it is indeed astonishing that you should have wished to attack the truth with your paralogisms. But what wonder that you do not see how to defend Archimedes, when you do not even understand him? And indeed every parabola can be attacked in the same sophistical way of yours.

SCALIGER in eodem scholio.

If we call in not geometry but our eyes for counsel, who does not see at first glance, with no demonstration going before, that the figure BLEB is less than a third part of the triangle BED? And so that no doubt might be left about the figure of the parabola BLEMC, be assured that we shaped that parabola to the section of a material cone as closely as could be done.

CLAVIVS.

What a splendid pseudo-geometer, fit to be banished to the ends of the earth, who puts more trust in his eyes and in a material parabola than in Archimedes' most subtle demonstrations! Yet you yourself had warned, in your prolegomena, that the compasses are not to be trusted unless demonstration goes with them. How, then, do you say contradictory things? In precisely the same way, in the Prolegomena of the *Cylometrica* [thus printed] and in the Appendix, you call your eyes into counsel, and a material circle rolled along a straight line, in order to persuade us that the circumference of a circle has to the diameter a ratio greater than $3\frac{1}{7}$ — passing over Archimedes' most acute demonstration, which proves the contrary, so that on that account you are not to be listened to. Let Archimedes, then, triumph with his demonstrations, and let Scaliger with his paralogisms vanish utterly and come to nothing.

I will say nothing here of his *Mesolabium*, which likewise swarms with countless errors. Only I cannot pass over in silence his childish blunder in proposition 6, where he teaches that proposition 35 of Book 9 of Euclid can be converted, without any demonstration at all. He could have recognized that error with no trouble in these numbers:

| | | | | | | | | |
|----|----|-----|-----|-----|----|-----|-----|------|
| 2. | 5. | 11. | 29. | vel | 4. | 12. | 50. | 136. |
| | 3. | | 27. | | | 8. | | 132. |

For when the first number is taken away from the second and from the last, the ratio of the remainder of the second to the first is the same as the ratio of the remainder of the last to all the antecedents — and yet the four numbers set down are not proportional. Where, then, is Scaliger's acumen, who failed to notice a thing so obvious?

I have set out, candid Reader, so far as it lay in me, some specimen of Scaliger's learning — or, if you prefer, of his ignorance — in geometry: more briefly, perhaps, and more temperately than either his innumerable outrages demanded or the man's shameless insolence might have seemed to wring from one unwilling. (For he has galled with every abuse and slander in his power, and with

some not in his power, a calendar that I was enjoying in quiet peace and that had been received, on the authority of the supreme Pontiff Gregory, by all who think rightly of the Christian religion; and though I was importunately provoked and long resisted, I had nevertheless to take up arms for the Catholic cause and to descend to a kind of writing previously hateful and unknown to me.) But something had to be granted to my years and to my temperament. There is this further reason too: to be willing to review and enumerate every single one of the errors bound up in that whole paralogistic little book of the man's would have been the work of no one man and of no one lifetime. For he has picked out nearly every one of his propositions with paralogisms — and thick, heavy ones at that — as one sets rings with gems.

But you, my Scaliger, unlearn your trifling at last; strip off that insane rashness of yours. Learn that there are some men whom you cannot deceive, who see clean through you and your work, and who have long known how to tell the false from the true. Acknowledge in how many matters, and in how foul a fashion, you slip; and, grown wiser now that your years are sinking toward their close, lay down the name of mathematician, a burden unequal to your strength. Get used at last to respecting other men, and to not setting yourself so far above everyone that you mock and despise them as though they stood beneath you. And have this last word from me. A man redeemed, as the poet says, by no virtue from his vices we can nevertheless love; we can refrain from hating you for being wicked, though that would not be very hard for us. But a man who barks at good and honoured men, who provokes the peaceable; a liar and a false mathematician, unclean and impious — him neither men will endure, nor God, against whom you are storing up wrath for yourself, vast wrath.

AD LECTOREM.

It has been our great care, kind Reader, that this edition should come out as correct as possible; and so we judged it better to warn you, even in a place not its own, of two errata which we noticed too late in the Geometria practica, than to neglect them altogether. The one is at page 187, line 60, where for* maius recta CD read maius semisse rectæ CD*. The other is at page 221, where for the cube of the root 138 (2628072.) read 2628027.**

FINIS.

**Christoph Clavius of Bamberg, of the Society of Jesus, on the *Threefold
Calendar* of Georg Germann. To Georg Germann of Wartenberg in Prussia.**

Scarcely had I taken delivery, this year 1609, of my reply to Scaliger's abuse and
slanders against the Gregorian calendar, printed at Mainz, when — behold —
there was brought to me from Germany your own new reform of the calendar,
Germann, whose title runs as follows.

Computus Ecclesiasticus **S I V E CALENDARIVM TRIPLEX.**

Gregorianum, Antiquum, & Nouum, cum nouo cyclo Lunari, &
refutatione quorundam insignium errorum Christophori Clauij
Bambergensis è Societate I E S V clarissimi nostri temporis Mathematici.

A V T H O R E

GEORGIO GERMANNO VVARTENBERGENSI BORVSSO.

[*Ecclesiastical Computus, or the Threefold Calendar* — Gregorian, Old, and
New — with a new lunar cycle, and a refutation of certain signal errors

of Christoph Clavius of Bamberg, of the Society of Jesus, the most distinguished mathematician of our time. By Georg Germann of Wartenberg in Prussia.]

In order to disparage me and my Calendar in complimentary language, Georg Germann, you hit on a new device — a doubtful artifice, to my mind. On the very title-page of your book, as though in the entrance hall, you address me far too indulgently as "the most distinguished mathematician of our time," while on the other side you advertise my signal errors. How well those two things fit together is for you to judge; to me they certainly look like a contradiction, since a man who could go so badly wrong in so commonplace a matter did not deserve to be counted a distinguished mathematician. But you reckoned, I suppose, that poison lies more safely hidden in sweet honey — and, as people do with children to make them swallow a bitter medicine, you coated the rim of the cup, so to speak, with the sweet nectar of a praise I never sought and long ago refused. You ought to have realized that deceiving an old man would prove as hard as unravelling your stratagems was easy; you had not put them together well.

Still, if you acted honestly and, as the phrase goes, in the good old way, I commend your candour — but I find the judgement wanting, and let that be said without offence. It would have been wiser and more agreeable if you had said nothing about praises of me which I do not claim for myself, and had proceeded instead by reasons and solid arguments, as you had implied on the book's very title-page that you would do. Where you have made that good is not at all clear. Perhaps the things you were turning over in your mind, and thought you could prove, looked easier at the outset; but the pen proved less obedient to your will than you expected, and refused to set down what the mind had not properly worked out. Even so, let the credit — however slight — of having *wanted* to do it be yours; and if the result did not answer the wish, put that down to the condition of human intelligence, which cannot hammer out just anything at its own pleasure.

One thing at least you should have weighed. Many men's talents have already been crushed, worn out by attacking the Calendar and racked to no purpose, and that has robbed everyone of any hope of victory; so doubtful and so heavy a task ought not to be attempted unless one's strength is matched to the difficulty of the thing. And — to confess frankly what is the fact — I have often asked myself what the reason can be why not a few mathematicians of our age, and not obscure ones, have poured all their industry and effort into this, when they might otherwise put their labour to use in so broad and open a field as this vast

discipline, and instead attack, besiege and try to demolish the Gregorian Calendar as though it were a hostile and dangerous citadel. As I turned this over, the following came into my mind: men of this kind resemble the man who wanted to win a notoriety made famous by the burning of Diana's temple and ennobled by sacrilege. Out of the very attack on the Calendar they are unjustly struggling to beg an inglorious glory, and to court a praise that merits none.

Good God! Now, an old man broken in years, I am dragged from one labour into another — not to fortify the Gregorian Calendar, but to

[Global p. 849 — printed page 3]

overturn, cunningly and maliciously, the engines that slander levels against it — engines struck off the press for that very purpose, while every day still others are freshly contrived, so that I myself, worn out at last by the same trifles and by matter full of tedium, may leave every man free to babble whatever he pleases: the aim being that the victory which cannot be had by reasons and by the justice of the case should be won through my silence and an improvident holding of my tongue. And they would in fact have obtained that from me easily enough, had I judged that what these men bring forward deserved any notice. But I saw that the dignity of so weighty a business would be diminished if I kept quiet without due thought, and refused to answer their frivolous sophisms and false inferences even in a couple of words, as the phrase goes. So I have never been willing to fail in my duty, nor did I think I ought to allow a freer field to be opened to their licence.

One thing at least I would not deny: of all who have so far broken in upon the Calendar, no one has written more expertly, or better, than you, Georg. That is why I came to have the highest hope that you would prove one of the keenest defenders of our Calendar, if you approached the weighing of my reasons candidly and sincerely — as you will. For it makes a great difference in what spirit a man writes, or reads another's work through. A turbid and muddy spring can neither receive an image nor return one; but let that same spring be clear and unclouded, and it will faithfully give back whatever you set before it.

As a friend, then, I give you the warning I always give: do not think more of yourself than is usual, and do not measure your opinions by the Lesbian rule, as they say, but by the unshakeable standard of mathematics. Apply that standard, and you will see more clearly than daylight that no errors whatever — let alone signal ones — have slipped from us in the Calendar. Things that necessity, not ignorance, brings with it are not to be called errors, nor are things which no

subtlety of intelligence could avoid. So, my good man, remember to be sparing in throwing such charges at men. Once words have slipped out they cannot be called back, and silence has very often helped even towards winning glory — the very glory you are too eager for, and lose the more shamefully by hounding other men's writings.

Nor should undertakings beyond one's strength and talent be attempted. A man who aims at posterity by publishing books should do what unfledged nestlings do, which have not yet tried the sky: they keep from flying and stay within the nest, conscious of their own weakness, until a stronger wing can carry their slight body through the air unharmed. Little by little and gradually — as the saying goes, imperceptibly — he ought first to entrust to the unkind and malicious light only such things as, even if they bring him back no abundant praise, will at any rate leave him with no mark of envy or stain of ignorance.

I believe you will not take it hard to be warned so kindly by an old man who for so many years has driven his chariot in this uncertain dust — since, as you yourself say, truth, still tiny and of an ill-favoured birth, may indeed give rise to hatred at first, but soon, grown stronger and sturdier by its native power, begets goodwill and love. And in truth, however much a sick man shrinks at first from the bitterness of the draught, once he has drunk it he soon loves it and is glad, so long as he hopes to carry off from that unlovely root an altogether delightful fruit.

But if you will listen to me, you will cultivate that talent of yours with a sterner discipline and a far stricter judgement. Shun the light for a time, and avoid the ambition of publishing, until whatever work you strike off — kept back even to the ninth year — can go safely through men's hands. That way you will have nothing to regret; and if you persevere you will reap the fruit both of your labours, which you would then not have spent at all badly, and of your talent. For, as I said not long ago, it is not talent I find lacking in your writings, but truth in the reasonings and judgement in the opinions — since you have written against me, without due thought, things you have neither proved nor will ever be able to prove, and have promised things that appear nowhere.

As for your saying at the end that you went down to so difficult a task on my advice, that you add out of your own head. Indeed, had you consulted me, you would [?] have come forward on the stage at the wrong moment, before you had long tuned up with yourself and the Muses, and had long and silently filed down a work that was to be laid before so many and such various human judgements. But now — I shall not deny it — I do come forward as your adviser, and the advice is a wholesome one: that you sing back what you have sung badly, and

show yourself teachable towards what I am about to say. Do not be ashamed to have learned something, even though you went wrong; for, as the man says, an athlete who has never been bruised cannot bring great spirit to the contest [Seneca, *De Providentia* 4]. The man who has shed his own blood, whose teeth have cracked under the fist; the man who, tripped, carried his opponent down with his whole body, and who, thrown down, did not throw away his courage; who as often as he fell rose up more skilled — that is the man who goes down to the fight with high hope.

I have added this last point so that you may understand that I am applying medicine and not poison, and bringing a cure and not a sword. Take in good part, then, and God love you for it, the things I say; for all ill intent is absent, and there will be no sting in my discourse that does not prick pleasantly, and goad you in kindness rather than in insult.

And to begin here: this Calendar of yours, Germann, is above all things faithless and inconstant — "wind and clouds," as the man says, "and no rain following" [Proverbs 25:14]. It promises much at the outset, and then performs nothing; and so that you may not complain that this is merely said by us in words and not shown in fact, here is how I prove it.

1. **PRIMO** — First, I do not see the new lunar cycle you boast of. Where, I ask, does it lie hidden in this whole Calendar? Into what recesses, pray, so deeply buried, has it withdrawn? Is it because you set up thirty golden numbers, some simple and some equated? But that is not to found a new lunar cycle; it is to throw the nineteen-year cycle [*cyclum decēnouennalem*] of golden numbers into remarkable confusion, and to muddle it with certain numbers inserted among them. For throughout all antiquity, even before the coming of Christ our Lord, the lunar cycle has always contained nineteen years and no more, as I have shown abundantly both in the *Apologia* against Maestlin and in the *Explicatio* of the Calendar. But of this ill-ordered constitution of the golden numbers, and of their number, I shall speak a little later. For it is not to be admitted in the Church that thirty golden numbers be introduced: fictitious and unheard-of as they are, they drag many errors after them, as will be plain in its own place.
2. **DEINDE** — Next, I do not acknowledge those signal errors of mine which you boast of having refuted; and I shall show this in its own place. But let us first wash away everything you said thoughtlessly against the Gregorian Calendar in your dedicatory Epistle. You assert, first of all, that astronomers complain bitterly that the Gregorian Calendar is neither

correct nor preserves the ancient rites of the Orthodox Church — because, that is, in it neither the apparent nor the mean equinox, nor even that fictitious one which the reformers of the Calendar devised, stays fixed on 21 March. But who, I ask, are these astronomers? Men like yourself, certainly, who think they know more than everyone else.

3. **ADDIS** — You add that these same astronomers complain that the epacts of the Calendar have been fitted to the celestial reckoning in such a way that not seldom the moon which on their showing is *xiiij* is, by the first reckoning, *xiiij*. From which it follows that we often celebrate the holy Pasch in the last month of the Hebrews, and often too on the moon's *xiiij* day.
4. **DENIQUE** — Lastly, you say that those astronomers take it ill that the reformers of the Calendar [set up] a certain new and troublesome cycle of epacts, one that leaps from year to year through discontinuous intervals of numbers,

[Global p. 850 — printed page 4]

which the Church has never used before, whereas the ancient golden number — provided the equation is applied to it — could do the same as the epacts, and by an easier method at that.

5. **HÆ** — These are the very grave complaints which those astronomers bring against the Gregorian Calendar out of your own mouth; and the following will show you that they carry no weight whatever. The first is pure slander. The Gregorian Calendar is entirely correct and preserves all the ancient rites of the Catholic Church, as I have demonstrated at length both in the *Apologia* against Maestlin and in the *Explicatio* of the Gregorian Calendar. As for what you add — that the equinox which the reformers of the Calendar devised, neither apparent nor mean nor fictitious, does not stay fixed on 21 March — you appear not to have read chapter 5 of the *Explicatio* of the Calendar, or cap. 5. lib. 1. of the *Apologia* against Maestlin. There I teach at length that the reformers were speaking neither of the true nor of the mean astronomical equinox, nor of any fictitious one, but of the equinox of the Alphonsine year, which is midway between the longest and the shortest year, and in accordance with which the four-hundred-year equation of the equinox was established — since, as all astronomers teach, it runs ahead by one day in 134 years and by three days in 402. Nor were they much troubled about the true equinox, which

advances unevenly, now retreating from 21 March towards the end of the month, now approaching that day again towards the beginning of the month; your own calculation in chapter 7 makes that perfectly plain. And the Church is certainly not bound to the irregular motion of the equinox, for that would stir up endless disagreement among the faithful. Please read the chapter 5 I mentioned above, and you will easily see that in your Calendar you throw the true equinox in our faces, to the point of nausea, for nothing.

6. **AD** — To the second complaint I have replied in many places in the *Explicatio* of the Calendar [printed *Celendarij*]. Namely: because of the imperfection of the cycle — whatever cycle it may be — it does sometimes happen (though very rarely indeed in the Gregorian Calendar) that Easter is celebrated in the Hebrews' last month, or even on the moon's *xiiij*. That happens in your Calendar too; and what is more absurd, in it you very often celebrate Easter in the second month or in the last, and indeed outside the limits which the Fathers prescribed for us.
7. **TERTIA** — The third complaint fits your Calendar better than ours. Your equated golden numbers leap about with no order at all, more freely than you would wish, and are held by no fixed laws, as I shall set out more clearly in its own place. The cycle of epacts, by contrast, is not new, and it is not true that the Church has never used it before. Have not country people, sailors, and the untaught crowd always tracked the moon's age by epacts? Is not the finding of the epact and its use taught in all the Church's books, in the breviaries and missals? What could be devised that is better suited to exploring the mean new and full moons than the cycle of epacts? For the epacts are the number of days that remain over in December after the year's last lunation, as I explained in chapter 9 of the *Explicatio* of the Calendar. Nor do they leap from year to year without order, as you jeer: they always advance by 11, except when the golden number is 19 — then 12 is added to the epact to form the following year's epact, as I said in chapter 10 of the *Explicatio* of the Calendar.
8. **IN** — Later, in the same dedicatory Epistle, you sing a triumph over me on the ground that in the *Apologia* against Maestlin I said what all but contradicts itself: on page 296 I boast splendidly that all errors have been avoided in the Gregorian Calendar, and then on page 322 I assert that in no calendar can all errors be avoided. But listen, my good man. In the earlier passage I do not mean that absolutely every error has been avoided — that

cannot be done, since some cannot be avoided and for that very reason are not to be called errors without qualification — but that of these same errors far fewer, and smaller ones, are found in our Calendar than in the old one. That, in fact, is how you will find I put it on page 299:

[Margin: » guillemets set against the four lines of the quotation below]

As for the third error — that Easter should not follow moon xxj, that is, should not fall in the fourth week of the lunar month — if it is to be called an error at all (since it can be avoided in no cycle), we frankly admit that, by Canon. 2. of the new Calendar, on account of the necessary postponement it does sometimes happen that Easter falls at the beginning of the fourth week, that is, on moon xxiij, or on the moon's later quadrate aspect.

What objection, then, do you have at this point? None whatever, since in that very place I explained plainly that there must necessarily be some errors which cannot be avoided because of the imperfection of the cycle. Wait a little, until in what follows you see how many errors you yourself run into unawares on account of your equated golden number and your equation of the true equinox.

9. **AD** — Finally, in the same Epistle you give the reason why you wrote this Calendar of yours: because, that is, I urged Maestlin to venture something of the kind, and so you boast of having brought successfully to completion what he himself could not do. But here, Germann, I have a thing or two to enquire of you rather more closely. First: if you are a Catholic, as you profess to be — though one might have one's suspicions about that, since you submitted your Calendar to the judgement and censure of David Origanus [David Origanus], a heretic, when you know perfectly well that heretics will approve any writing whatever published against the Roman Church — what possessed you, after the Bull of Gregory XIII, which commands everyone to use the new Gregorian Calendar, to dare to force your new one upon us? Especially since Clement VIII in his Bull forbids all other Calendars that may be set up by your side hereafter. My own exhortation, by which I invited Maestlin to do the same, cannot defend you: since he is a heretic, I knew well that he sets little store by the authority of the Catholic Church, and would therefore dare to contrive another Calendar at his own discretion, even against the Pope's command, because he does not fear the Pope's threats or penalties. No one ought to persuade himself of that where a Catholic is concerned.

Next, you have not delivered what you promised, or what I urged upon Maestlin. Your Calendar does not employ the civil year and the cycles the Church uses; it sets before us instead the true motion of the equinox, and a cycle of the golden number remarkably disturbed and confused, as I shall say in its own place. Nor does it prescribe easy and perpetual rules suited to the ordinary person's grasp. Lastly, if you had something that displeased you in the Gregorian Calendar, why did you not put it forward before the Calendar was published, at the time when Stephen, King of Poland [Stephen Báthory], had the *Compendium* of the Calendar — sent by Gregory XIII to the Princes — examined by his own mathematicians, and approved it? At that point everyone was still free to set out his own opinion. But now this diligence of yours in patching together a new Calendar comes far too late. For even if it were correct in every particular, as you falsely proclaim, it would still not have to be accepted, since the Gregorian Calendar has already been received everywhere by the Catholic Church, and appro[ved]...

[Global p. 851 — printed page 5]

approved — especially since the Gregorian Calendar is better fitted to the common and popular understanding than yours is. And let this stand as my answer to the objections you bring against the Gregorian Calendar in your dedicatory Epistle.

10. **IAM** — Now, so far as your Calendar itself is concerned, I do not deny that many things in it have been discovered and thought out with ingenuity and acuteness; but not all of them belong to the plan of an ecclesiastical Calendar, which ought to be popular and suited to the ordinary person's grasp — indeed most of them run against it. First: who could tolerate with an even mind the insertion of those 11. numbers between pairs of golden numbers that are not adjacent? Since they are neither golden numbers nor epacts, on what authority, or on what precedent, are they thrust in there? The device is downright new and unheard-of, and contrived without any necessity, since without it the new moons are found far more easily by the epacts, as I said above at Num. 7 and taught in the *Explicatio* of the Calendar, and as I shall set out more plainly when we come to your equation of the golden numbers. For the present, take it thus: your equated golden numbers are altogether like a chimera, since they have been put together at random, and were certainly not rightly devised by you. Add that some of them make a single lunation of 31. days, indeed sometimes of 32. days. What could be called more monstrous or more absurd than that? But of this below.

11. **QVIS** — Who, again, would not be angry with you for rejecting, in your chapter 4, the equation of the equinox which advances over four hundred years and is framed for the mean year, and for embracing instead the equation drawn according to the true motion, which is highly uneven and irregular? Did we not expressly teach, in the *Compendium* of the Calendar sent to the Christian Princes in the year 1577., how that ought to be done if it were expedient? What, I ask you, came into your mind at that time? Is it not folly to want to tie the Church to the true motions and to force the faithful to compute the true equinox? Who will settle the disagreement that will necessarily arise among them, when one man contends that these tables are to be followed and another that those are? The Prutenic Tables [*tabulæ Prutenicæ*] certainly throw the true equinox on one day, the Alphonsine Tables [*tabulæ Alphonsinæ*] on another, and the Tychonic calculation [*calculus Tychonicus*] on another. For example, in the year of the Lord 43103. — a year so far distant that you chose it with the greatest care, in order to trump up a charge against our Calendar — the spring equinox by the Prutenic Tables will fall about 8. days after 21 March; by the Alphonsine, only about 4. days after; whereas the Tychonic calculation shows it about 8. days before 21 March. Which of these, then, is the Catholic Church to follow? The same can be seen in other years. Indeed I have computed the equinox for a great many years, both from the Prutenic and from the Alphonsine tables: for the year 9103., for instance, the Prutenic Tables give the equinox on 27. March, whereas the Alphonsine draw it back to the 24.

Change your opinion, I beg you, if you have any sense, and accept with us the stable and uniform equation of 400. years, which I discussed at length in the *Explicatio* of the Calendar, cap. 5. 6. & 7. — and especially because, as you yourself testify at your chapter 10, the Church disregards the true conjunctions of the luminaries and uses the mean ones. What is more, François Viète [François Viète], a most learned man, and Joseph Scaliger, who attacked the Gregorian Calendar most fiercely, did not dare to censure this equation of the equinox of ours advancing over 400. years; they accepted it of their own accord as probable. And if it should sometimes happen that Easter is celebrated before the true equinox, that is not absurd, as I explained in the *Explicatio* of the Calendar, cap. 5. Num. 12. In the same chapter, at Num. 14., I taught how the equinox is to be restored to the twenty-first day of March, should it happen to withdraw too far from that day with no hope of returning to it; and I repeated this again at cap. 7. Num. 5.

On this showing all your objections and outcries collapse — the ones with which you reproach the Gregorian Calendar for not always keeping Easter after the equinox. Acknowledge your own fault too: you did not carry out the advice I gave Maestlin, since you do not propose rules that are easy and popular, as would be right, and that have always been in use in the Church. As for what you call my slips over the equinoxes in 22. years, which I computed in the *Explicatio* of the Calendar, cap. 7., and which you noted in cap. 7. of your own Calendar — anyone will easily see that they are of no importance, if he carefully compares my equinoxes with yours. He will find only a small difference between them, since yours are reckoned after midnight, whereas mine are referred to a time about noon, or midnight, or at any rate about sunset, without account being taken of hours. For instance, in the year 3156. I put the equinox on 20. March about sunset, which you put on the 20. at hour 21. after midnight: what difference, I ask, is there between the two? Practically none. So too in the year 1653. I set the equinox on the 20. after midnight, which you place on the 21. at hour 0. after midnight. Again, in the year 15804. the equinox was found by me on the 23. about midnight, which you put on the 23. at hour 22. after midnight — that is, only two hours before the midnight which we reckon after the noon of the 23. And so with the rest. And so you are looking for a knot in a bulrush, as the saying goes, and seem to want nothing but to slander.

Besides, I was not the only one to calculate those equinoxes: other practised men calculated them along with me, so that there can be no doubt about them. And no one will deny that in the year 20005. the equinox has not yet withdrawn from the 21., since it falls on the 20. after midnight — which your calculation places on the 21. at hour 5. after midnight, that is, after the midnight which follows the 20. — although in some lesser years, and especially in the year 9103. which you adduce, it is found some days beyond the 21. But this does not obstruct the equation of the Gregorian Calendar, since in the following years it returns of its own accord to the 21. again. What deserves blame in this business is the inconstancy and uncertainty of the tables, which forced me to assert that before the year 20005. the spring equinox could never fall beyond 23. March, seeing that at that point it still sticks about the 21. And who would have believed that in some lesser years it would slip beyond the 23. and the 24. and further still, and then approach the 21. again, unless calculation showed it? Anyone could have been led by a conjecture probable enough to suppose that it could not withdraw so far from the 21. before the year 20005. That this happened to me too, through want of foresight, I frankly admit — and the reason is that I had not computed the equinoxes of all the preceding years.

12. **QVOD** — Next you charge me with having said that the mean equinox precedes or follows by just as much time as is enough for the Sun, on its true motion, to run through the arc of the equation of the precession of the equinoxes. See that it is not you who are deceived. For I have on my side Erasmus Reinhold [Erasmus Reinhold] and Giuseppe Moletti [Giuseppe Moletti], along with other learned astronomers. The arguments by which you attack that position carry no weight whatever, and neither does your solution of my objection — which I leave to the kind Reader's judgement. For otherwise the true and the mean equinox would occur at one and the same moment whenever the prosthaphæresis of the equinoxes [*prosthaphæresis æquinoc[t]iorum*] is nil, which is contrary to all astronomers. On much the same footing you are wrong to censure me for having written that the Sun's equation never [amounts to] two

[Global p. 852 — printed page 6]

degrees. Look at the Prutenic Tables somewhat more attentively, I beg you; and if you ever catch the equation of the orb [*æquatio orbis*] amounting to two degrees, I shall gladly yield the point. But you will never find this — even though the equation of the orb, corrected by the proportional part, may sometimes exceed two degrees. That makes nothing against us, since we were speaking of the Sun's equation as it is found in the table; just as the greatest equation of the precession of the equinoxes is likewise set down in those same tables as Grad. 1. Min. 10. Sec. 22. Ter. 30., whatever may be the case about the correction of it.

13. **DENIQUE** — Lastly, as to your thinking that I go wrong when I teach that the new moons run ahead of their seats in the Calendar by one day once 312½ years are completed, and not when 304. years have elapsed: it is you yourself, and splendidly, who go wrong, not I — as I proved at length only recently in the *Responsio* to the abuse and slanders of Joseph Scaliger against the Gregorian Calendar, printed at Mainz, from page 13. through to page 22. For if the lunar month comprises 29. days 12. hours 44. minutes 3. seconds 10. thirds 48. fourths, as the Prutenic Tables will have it, then 235. lunar months will make up 6939. days 16. hours 32. minutes 27. seconds 18. thirds 0. fourths. Since therefore 19. solar years consist of 6939. days 18. hours, the 235. lunar months will fall short of the 19. solar years by 1. hour 27. minutes 32. seconds 42. thirds. And by that interval of time the Moon anticipates her seats in 19. years.

At this point, too, I do not know what came into your mind, that you should say that in other Julian years — those which do not arise by an increment of 76. years

— the anticipation of the new moons cannot be noted, even though the same golden number is running; whereas I have in fact noted the anticipation here within 19. years. Hence, when the calculation is properly carried through, in 312½ years the Moon will run ahead of her seats by 23. hours 59. minutes 53. seconds 5. thirds, which fall short of a whole day by only 0. hours 0. minutes 6. seconds 55. thirds [printed Tert.].

POSITA — Assume the same magnitude of the lunar month, 29. days 12. hours 44. minutes 3. seconds 10. thirds 48. fourths, according to the same Prutenic Tables, and work the same calculation through: you will find that in 304. years the Moon anticipates her seats by only 23. hours 20. minutes 43. seconds 12. thirds, which fall short of a whole day — that is, of 24. hours — by 0. hours 39. minutes 16. seconds 48. thirds; and for these too to be anticipated, a further 8. years and more are required. Do you not see, Germann, that the Moon anticipates one day more truly in 312½ years than in 304.? Read, I beg you, the reply of mine mentioned above. There you will also learn the reason why Hipparchus [Hipparchus], whom the crowd of computists follows, asserted that the anticipation of one day takes place in 304. years. You will come to know, further, that the new moons cannot anticipate one day in 304. years unless you suppose them to anticipate 1½ hours within a single nineteen-year period [enneadecateride] — which we said above is false.

ATQVE — And with this I believe I have answered those signal errors which you have fastened upon me: I have shown that there are none. As for the 35. Paschal full moons you list in your chapter 8 running somewhat ahead of the true equinox, that is not to be reckoned an error, since the Church does not observe the true equinox: it is enough that those full moons follow 21 March, the day assigned to the equinox. And that the Paschal full moons run ahead of the moons xiiij which you enumerate in chapter 9, more than is fair, comes from the imperfection of the cycle — a defect which the Dominical letter usually compensates for, as I said in the *Explicatio* of the Calendar.

14. **SED** — But let us now examine the doctrine in that new Calendar of yours, so that everyone may understand that it is not free of every blemish, as you proclaim. To begin with, I ask you what that device is, before chapter 7, in the investigation of the day of the equinox — the marking of the hour-numbers with a little stroke. Does this not give printers occasion for countless errors, since they can easily omit some stroke, or add one where it is not needed? The device really looks childish to me. You ought to have handed down a rule by which one could tell to which numbers the stroke is

to be attached and to which not, so that anyone might correct the mistakes, should any happen to have been made by the printer; and that you did not do. Weigh the tables of our Calendar carefully, and you will always find the principle on which they are constructed. Add that those strokes teach contradictory things, so much so that by them the same equinox is found, in some years, to fall on two different days, if your own precept is observed. To bring forward one example out of countless: in the year 1900. the equinox is marked in your Calendar on the 20. at hour 22. of March. But if we take the year 1800. with 100. in the side column, so as to make 1900., the same equinox will come out on the 19. at hour 22. — because, since the stroke is marked at hour 22., the day one unit less must be taken, as you direct. Do you see how badly that table and your own precept agree with each other? Why did you not notice so glaring a contradiction? I should be ashamed if anything of the sort were found in my rules.

15. **EODEM** — Your rule in chapter 15 for finding the equated golden number labours under much the same fault. Since you attach a point to certain of the equation numbers — so that the equated golden number is then taken as xiiij for 14 — who does not see that this is exposed to a thousand dangers, seeing that the point can easily be left out, or added where there is no need? Why did you not teach to which numbers the point of equation is to be attached and to which not, so that a diligent Reader could mark the mistakes which may perhaps have crept in here through the printer's negligence? For such carelessness you can certainly have no excuse.

But tell us, Germann, why that equated golden number of yours pleases you so greatly. It certainly does not satisfy me, since it is neither a golden number nor an epact, but a number inserted among the Calendar's golden numbers by chance and not by art — even though you generate it by adding another number to the golden number. Why, on the same principle, cannot the epacts of the Gregorian Calendar be called equated golden numbers? For just as your equated numbers are made up out of the ordinary golden numbers with certain numbers added, so too the epacts are put together out of those same ordinary golden numbers with certain other numbers added, as I taught in the ecclesiastical Computus. And indeed the epacts are put together in that way far more easily than your equated golden numbers, since you have not been able to prescribe any fixed rule for what number of equation ought to be taken in this or that hundredth year [printed *velillo*]. And this, perhaps, was the reason why you did not go on beyond the year 4900.

Again, the epacts advance in the Calendar in their natural series, whereas your equated golden numbers leap very disorderedly through the days of the months. And among its other absurdities, your equated golden number *xiiij* badly upsets the harmony of the new moons in March. For in the years in which you teach that the golden number *xiiij* assigned to 8. March is to be taken, the lunation beginning on 5. February, which ends on 7. March, contains 31. days — and in leap years 32. days; whereas the lunation whose beginning is on 8. March and whose end is 4. April takes in only 28. days. All of this is repugnant to the nature of the months, since no [month can contain...]

must contain more than 30. days, nor fewer than 29. — apart from certain lunations that begin in February and end in March, which necessarily consist of 31. days in leap years because of the intercalary day. But never 32., as happens in your Calendar. You see, then, how badly things go with your equated golden numbers, since they give birth to so great an absurdity and to such monstrosities.

But if I guess rightly, I see that you assigned that golden number *xiiij*. to the eighth day of March for this reason alone: so that not all the Easters of the equated golden number 14. should fall in April, but that some of them should be celebrated in March. Yet in this very matter you very often exhibit the Paschal full moons, contrary to the Decrees of the Fathers, in the last month — that is, before the 21. of March that is assigned to the equinox — as is clear in the following table.

Table (printed p. 7). Column-group headings as printed: the first group *Anni Domini.* | *Aur. numeri.* | *Epactæ.* | *Plenil.Pasch.Cal. Gregoriani.* (subdivided *D. H. M.* | *Mēf.*); the second group *Aureus numer. æquat. Germā.* | *Plenil.Pasch.Cal. Germani.* (subdivided *D. H. M.* | *Mēf.*).

VIDES — Do you not see that in all these years the Paschal full moons of the Gregorian Calendar belong to the first month, since they follow the 21. of March

assigned to the equinox, whereas in your Calendar they belong to the last month, since they come before that same 21. of March? You were wrong, then, to push the number *xiiij.*, marked with a different character, down by one day in March in place of the equated golden number 14. — since, by your own equation of the true equinox, all the full moons of the equated golden number 14. fall in April. And it is your equated golden number *xiiij.* that throws you into these errors.

SED — But look also at the following table, in which you commit further errors on account of that same equation of the true equinox of yours: for you exhibit the Paschal full moon either in the last month — that is, not after the ecclesiastical equinox, or after the 21. of March, as is proper — or else certainly in April, a whole month later, that is, than in the Gregorian Calendar.

Table (printed p. 8). Column-group headings as printed: *Anni Domini.* | *Aur. numeri.* | *Epactæ.* | *Plenil.Pasch.Cal. Gregoriani.* (subdivided *D. H. M.* | *Mēf.*); then *Aureus numer. æquat. Germā.* | *Plenil.Pasch.Cal. Germani.* (subdivided *D. H. M.* | *Menf.*).

IN — In all these years, two excepted, your Paschal full moons not only fall in April though in the Gregorian Calendar they occur in March; four of them actually run out beyond the limit that the Fathers and the Councils prescribed for us, that is, past the 19. of April. And indeed in the year 4403., where your Dominical letter is D., you propose that Easter be celebrated on the 19. of April — before the mean full moon.

SED — But to come back to your equated golden numbers: let us look more deeply into their table in chapter cap.15. of your book [lib. tui], and weigh whether you constructed it by art and not rather by accident. To me, certainly, it does not appear to have been put together to the standard and rule of the lunations; on the contrary, it is wholly opposed to that rule.

Table (printed p. 8, lower). Two panels side by side, each headed *Dies mensis Martij.* | *Aur. num. æquati in Martio.*

For since the new moons, on your own account, run one day ahead in 304. years, the Moon had to be equated every three-hundredth year — which you have by no means done. You equated it only in these years: 1800. 3100. 3400. 3800. 4700. 5000. 5300. — and of these, no one following exceeds the one immediately before it by 300. years. On the contrary, the year 3100. exceeds the year 1800. by 1300. years; the year 3800. exceeds the year 3400. by 400. years; and the year 4700.

goes beyond the year 3800. by 900. years. Indeed, what is still more astonishing, you have not even kept a consistent reckoning of the centesimal leap-[years]...

-[years]: and both of these failings are unworthy of a mathematician. But that the matter really stands so you will grasp plainly from the following table, once I have first taught you on what principle the Moon is to be equated every three-hundredth year, the centesimal leap years not being neglected — as I taught at greater length in the exposition of the Calendar.

1. **QVANDO** — When, therefore, the intercalary day is omitted in some centesimal year and the Moon does not need an equation, the new moons fall one day later.

2. **QVANDO** — But when in some centesimal year the intercalary day is not omitted, while the Moon does need an equation, the new moons rise by one day.

Table (printed p. 9). Headings as printed: Num. addendi fecundum Germannū. [numbers to be added according to Germann] | Vbi Germānus Lunam æquat. [where Germann equates the Moon] | Centefimi anni. [centesimal years] | Vbi fieri debeat æquatio Lunæ. [where the equation of the Moon ought to be made] | Numeri addendi fecundum nos. [numbers to be added according to us].

3. **QVANDO** — When, finally, both the intercalary day is omitted in some centesimal year and the Moon needs an equation; or else neither is the intercalary day omitted nor does the Moon need an equation — then the new moons neither rise nor fall, but occur on the same days as before.

HÆC — If these precepts are observed, it will be easy to construct the table of numbers that have to be added to the golden numbers so that the equated golden numbers may be produced. From the preceding table it appears plainly that you have not always kept the three precepts given above. Moreover, we have set the sign * against those centesimal years in which the Moon is equated; and against the centesimal years that are leap years — those, that is, in which the intercalary day is not omitted — you have the letter B written in. We have also prefixed to this table the month of March, with your equated golden numbers.

VERVM — But I shall teach you a little more carefully by what method the numbers are to be extracted for the finding of the equated golden numbers. Since the year 1800. has 11., we shall put 0. for the year 1900., by the first precept; for since in that year the intercalary day is omitted and the Moon does not need an equation, the new moons will fall back. And therefore, the golden number being 1. in the year 1805., the equated golden number was 12.; and in the year 1900. it will be 1., one day below the num-[ber]

-ber 12. But since in the year 2000. the intercalary day is not omitted and the Moon does not need an equation, we shall keep 0., by the third precept. Likewise, since in the year 2100. both the intercalary day is omitted and the Moon has to be equated, we shall again keep 0., by the same third precept — so that, the golden number being 1., the equated golden number is also 1. You, however, have the number 19. to be added to golden number 1., and the equated golden number 20., which lies below 1., and so you force the new moons to descend.

Again: the year 3200. has the number 13., and in the following centesimal year 3300. the intercalary day is not omitted while the Moon does need an equation. The new moons will therefore rise by one day, as the second precept requires, and accordingly the number to be taken is 24., to be added to golden number 1. You, by contrast, force those same new moons to descend, against the reckoning of the new moons, because you keep 13. as the number to be added, so as to make the equated golden number xiiij. So either the new moons do not run ahead by one day in 304. years — which you will not concede, since it contradicts Hipparchus and every computist — or else you have certainly gone wrong in recording the numbers that must be added to the ordinary golden numbers if the equated golden numbers are to be produced. From all this it will not be difficult to understand by what method the numbers we add have been assembled.

VT — To let you see that the new moons are shown more correctly if you had traced out the equated golden numbers as we have just explained, weigh the 3. examples that follow. In the year 2109., with golden number 1., you make the

equated golden number 20., where we set 1. But calculation puts the new moon in March on day 28. at hour 23., which you throw back to day 31.; we, more correctly, to day 30.

ITEM — Likewise, in the year 5244., with golden number 1., your equated golden number is 8., placed beside day 13. of March; ours is 19., set beside day 12. of March. Calculation gives the new moon on day 11. at hour 3. of March, and the new moon of our equated golden number comes closer to it than yours does.

RVRSVS — Again, in the year 3648., with golden number 1., you set the equated golden number at xiiij., beside day 8. of March; we, by contrast, have the equated golden number 25., beside day 6. of March. Since calculation offers the new moon in March on day 5. at hour 6., you can see plainly that day 6. comes nearer to this new moon than day 8. does. And in fact the full moon of this lunation falls on day 20. at hour 1. of March, before the ecclesiastical equinox. Your Easter, then, which you celebrate in March, belongs to the last month. See, therefore, how badly matters go with your equated golden number xiiij. The same test can be made in the other centesimal years in which our numbers — the ones by which the equated golden numbers are produced — differ from yours. For the new moons of our equated golden numbers always come closer to the new moons found by calculation than yours do.

SATIS ne — Have you now seen clearly enough, my dear Germann, what that calendar of yours amounts to — the one you boast of so loudly, on whose breath you swell so — even if you were to propose no rules adapted to the ordinary reader's grasp, but rather to thrust upon us the true equinox (and whether that serves any purpose at all, no sane man can fail to see)? Do you see, I say, how far short it falls of what you could, with puffed-out cheeks, as the saying goes, proclaim complete in every particular? And so, since you have by no means built a calendar for common use — as was to be wished, and as I took care to urge upon Maestlin — one course alone remains: either receive the Gregorian calendar with your fullest approval, or turn your mind and your labour, from the ground up, to devising a new one. That is what I, for my part, put to Maestlin.

HIC RHODVS, HIC SALTVS. [Here is Rhodes, here is where you jump.]

FINIS.

ADMONITIO THEODOSII RVBEI PRIVERNATIS S.
THEOLOGIÆ, ET V. I. D. Pro CHRISTOPHORO
CLAVIO BAMBERGENSI SOCIETATIS IESV
ADVERSVS FRANCISCI VIETÆ
EXPOSTVLATIONEM.

A Warning by Theodosius Rubeus [Teodosio Rossi] of Priverno, Doctor of Sacred Theology and of Both Laws, on behalf of Christoph Clavius of Bamberg, of the Society of Jesus, against the Remonstrance of François Viète.

Set as a full divisional title page in display capitals, line for line as printed:

ADMONITIO
THEODOSII
RVBEI PRIVERNA-
TIS S. THEOLO-
GIÆ, ET V. I. D.
Pro
CHRISTOPHORO CLAVIO BAMBER-
GENSI SOCIETATIS IESV
ADVERSVS FRANCISCI VIETÆ
EXPOSTVLATIONEM.

(V. I. D. = *Vtriusque Iuris Doctor*, "Doctor of Both Laws"; the Pro line and the two lines naming Clavius are set in italic.)

CLEMENTI VIII. PONT. MAX. THEODOSIVS RVBEVS
PRIVERNAS. F.

To Clement VIII, Supreme Pontiff — Theodosius Rubeus of Priverno. [The closing F. is an abbreviation left unexpanded in the print — probably a dedicatory formula (*felicitem*, "wishes happiness"); [?] as to its expansion.]

EDIDIT — François Viète has published a calendar of his own and stamped it with the title of the *Gregorian Calendar* — far too boldly, to put it no more harshly, since the true Gregorian calendar was already in existence and had been received into use by the Catholic princes. Nor was he content with that. He wrote against the reform of that same calendar, which had gone out to the public only after the greatest care had been taken over it and the most learned men had given it their study; and on top of that he issued a remonstrance against

Christoph Clavius, my teacher in mathematics, who had not provoked him by so much as a word — hoping, perhaps, to frighten Clavius off the legitimate defence of the Gregorian reform. I could not, then, command myself to leave so unjust a remonstrance unanswered, since I could see that Clavius, with the moderation of temper that is his, preferred to let the matter pass in silence rather than pay back abuse with abuse. And so, since this case has to be argued before you alone, Most Blessed Father — for the cognizance of it is yours — I decided to publish this *Admonitio* of mine under your most august name, so that every handle for provocation may be taken from Viète, and so that your authority may at last set an end to this controversy.

ADMONITIO THEODOSII RVBEI PRIVERNATIS S. THEOLOGIÆ, ET I. V. D. Pro CHRISTOPHORO CLAVIO BAMBERGENSI ADVERSVS FRANCISCI VIETÆ EXPOSTVLATIONEM.

ADMONITION of Theodosius Rubeus of Priverno, Doctor of Sacred Theology and of Both Laws, on behalf of Christoph Clavius of Bamberg, against the remonstrance of François Viète.

AS SOON AS YOUR REMONSTRANCE AGAINST Christoph Clavius, my teacher, reached us — François Viète — I read it right through, and read it again, with the keenest attention, as coming from a man of the greatest learning. I could not bring myself to believe that such a man would credit mere false rumours so far as to attack a man of the highest character and the greatest modesty, when Clavius had neither provoked nor challenged you, and when the defence he wrote of the Gregorian reform of the year — against the criticism, or, to use your own word, the accusation, that you published long ago — had not yet appeared. Had you chosen to wait for it before making your complaint, you would certainly have seen how respectfully you are mentioned throughout, and with what restraint Clavius sets out his defence, without a trace of bitterness or abuse. That might perhaps have drawn you back from so venomous a remonstrance; but you preferred to strike first, supposing perhaps that Clavius, dazzled as it were by the flash of your eloquence, would give up his case for lost. If that is the guess you made about him, you will never be acknowledged a good prophet by those who hold that a good guesser makes a good prophet.

I therefore took it hard that you should have entered this contest at such cost to your own reputation, and I could not restrain myself from warning you, in a few words, that it was not permissible to leap from a scholarly discussion to a remonstrance so injurious and so full of abuse. For I do not think that saying of Hesiod's — [Greek: κεραμεὺς κεραμεῖ (kerameus keramei, "potter [envies] potter" — *Works and Days* 25)] — is fit for men brought up in the humane letters, among whom a shared devotion to study usually does, and ought to, produce affection without disparagement. Moreover, since what is at issue (as you yourself assert) is a public cause, one that concerns the mysteries of our Religion, the concord of the Christian commonwealth, and the divine authority of the Supreme Pontiff, then just as the accusation touches everyone, so the defence is everyone's business — and mine on more grounds than one. For you appear to have made improper use of the power and authority of the Supreme Pontiff, among whose household I am enrolled. You have likewise made a mockery of the deliberations of other orthodox princes, and above all of the August Emperor Rudolph II, to whose kindness and generosity I acknowledge myself deeply indebted, since my whole family has been enriched with enormous benefactions and privileges. And finally you have shown contempt for the night-work and the long vigils of those other most expert men whom Gregory chose to undertake this task — above all those of

Christoph Clavius, under whose instruction I served my apprenticeship.

Let me now go on to set out my reasons for thinking that this piece of writing has damaged your reputation. There are a good many of them, and I have decided to take them in order. Since you bring forward against Clavius both an accusation and a remonstrance — the first of which requires a crime, the second an injury — I shall begin with the accusation, and my first question to you is this: on what criminal charge do you mean to arraign Clavius? Unless I am mistaken, you will say, as you profess, that you mean to prosecute him under the head of corrupting the Calendar and of contempt of Religion, and of plagiarism besides. I am ashamed to see so learned a man handle the subject so childishly. For that accusation of yours is a reproof rather than an accusation. Grant that men who go wrong in matters of learning may be corrected, put right and warned of their error; even so, mistakes — apart from those that touch Religion — are not usually charged as crimes, but put down to lack of skill. And so, since here it is a question

Nec de vi, neque de cæde, nec veneno.

"Not of violence, nor of murder, nor of poison."

— nor indeed of any capital crime at all, but of the correction of the Calendar and the restoration of the year — I cannot help wondering that a man of such learning should have wished to impose on us by trading on the double meaning of the word "accusation," and to misuse the authority of the law and of the canon that deny accused men the licence of bringing charges before they have cleared themselves of the crime that presses on them. For this neither is, nor can be, a true judicial accusation: no crime is at issue; no formal indictment [inscriptio] has preceded it (and if you are wise you will take my advice and abstain from one, so as not to run the risk of the counter-penalty, especially in a case involving an outrage against Religion); and finally it is not brought before any judge sitting judicially to take cognizance of the grounds of accusation. But neither should so great a jurist as yourself have been unaware that the prohibition in question is not to be admitted without exception — namely, unless the accusation has its case entangled with the defendant's defence, or unless the accuser is being prosecuted by the defendant on a graver charge. Both of these fit the present controversy, if — on your own authority — it can have the force of a true accusation. For the defence that Clavius is preparing, and has already carried through to the finish [ad vmbilicum], cannot be prised apart from your accusation; and, what is the heart of the matter, he can prove that you have offended against the *lex Cornelia de falsis* [l. Corneliā de falsis], since you have not only corrupted a Calendar that rests on the authority of the best of Pontiffs, but have also stamped it with the false title of the *Gregorian Calendar*.

But since you are so far ignorant of what Clavius will reply to your accusation, and what line of defence he will take, I cannot help wondering to see you prophesying about matters you know nothing of — unless it was your own conscience that drove you into these speculations, because you are afraid you cannot maintain your own position; and that, I suppose, is why you wanted to frighten Clavius off the undertaking with this little declamation of yours. But he for his part holds fast to the helm [clauo hæret], and will not desert his post until he has brought the ship safe into harbour. Meanwhile, though, when I see so great a man insisting on these quibbles, the suspicion comes into my mind that you meant to play with us rather than to make fools of us. For I do not suppose you think us so witless that you could hope to deceive us with so transparent a sophism.

As for the charge you bring about the corrupting of the Calendar, I am wise enough to leave that whole business to Clavius to handle. Since this controversy has to be settled by mathematical demonstrations, I should be a fool to want to insert it here among your scholastic declamations, against Aristotle's own rule.

And on that discussion depends the complaint about contempt of religion, which touches not only Clavius but the honour of the Supreme Pontiffs — an honour you, as a Catholic, ought to have had at heart. As for the charge of plagiarism, I have absolutely nothing to say about it. Clavius has not sold a free man, nor concealed another man's runaway slave, nor abducted or corrupted one, nor lent his services to someone who was corrupting one; he has not rifled your desk, nor published your opinion about the Calendar as his own — on the contrary, he has sharply refuted it, as will be plain from the book now finished, which will appear in public any day now. This dreamed-up plagiarism, then, cannot incur the penalty of the *lex Fabia* [legis Fabiæ]; instead the penalty of a false accuser awaits you, or at least — to deal with you more gently — that of a collusive prosecutor [prævaricator], should anyone choose to proceed against you at law.

Now I hurry on to your remonstrance, which, as I said, requires an injury. If you can prove that Clavius inflicted one on you, I do not refuse to take the beating for him at your discretion. But to make the matter clearer, the origin of this quarrel must be traced back a little further; and in that I shall, so far as it lies with me, explain the whole affair exactly as it really happened.

Gregory XIII, an excellent man and a great lover of the Christian commonwealth, saw that a reform of the Calendar was necessary, so that with the slipping of the years matters should not reach the point where Easter was no longer kept at its lawful time, and where the so-called movable feasts, and those that fall at the fixed seasons of the year, gradually drifted into another part of the year — until at length the summer months would have turned into winter ones. He therefore began to consider the reform of the Calendar. At that time Antonio Lilio [Antonius Lilius] laid before him the paper of his dead brother Luigi [Aloysius Lilius] on a method of correcting the year, which Luigi had been prevented by death from completing. Gregory instructed Clavius, and several other highly expert men, to examine and approve Lilio's reform and then to settle on some definite method of correction — which they did, carefully and with every diligence applied. Yet that most prudent Pontiff was unwilling to decide anything in so great a matter without first communicating it to the orthodox princes of the Christian world: the reform was sent to them, so that they might appoint expert mathematicians to a commission and examine whether it should be accepted or rejected. Having weighed the matter thoroughly, they approved this reform of the Calendar; and so it came about that Gregory ordered by his own decree [diplamate] that the approved reform be observed by all. Only the heretics, out of hatred of the Roman see, refused to obey it — and perhaps some others as well, who still wish to live in schism, like those men who, once grain had been

discovered, preferred to feed on acorns. This reform has been observed from the year 1582 to the present day. But you, after so many years, have surfaced as its fiercest opponent — whether rightly or wrongfully, the outcome of the case will show. And in the meantime, where in the world were you hiding when this reform was being put to the mathematicians of Germany, France, Spain and other nations for examination? At that time the duty of your office demanded that you give your opinion for the common good of the Church, mark the errors, and point out the right way to correct them. But perhaps you will say that you were not summoned to that consultation,

very well. Even so, you could have done what many other distinguished men did, who sent in their contributions for the reform of the Calendar to the Roman commission by letter. But let us allow that you were at leisure at that time, so far as we are concerned, and let us admit you even though you come late, when the thing is finished, and stir up a controversy about it. Let us look at this one point: on what confidence — puffed up with what [Greek: κενοδοξία (kenodoxia, "vainglory," empty self-conceit)] — did you rush in to decide this contest? For without taking counsel with a single person, you abruptly had that "accusation" of yours, as you call it, against Clavius put into print, when it would have been more courteous to disclose your view to him first and ask him to answer your objections. Yet even that could have been borne, had you not on your own private authority published your Calendar under the title of the *Gregorian Calendar*. What do you suppose Gregory would say, if he came back to life and saw your effrontery — to put it no more sharply? "Come now, Viète, what are you about? On what authority do you undertake to attack our Calendar, worked out by the long vigils of the most eminent men, approved by the Christian princes after consulting the most expert mathematicians, and confirmed and published by the perpetual constitution we issued? And why do you falsely ascribe to us something that neither existed in our lifetime nor was ever fortified by the authority of our successors? Away with such reckless daring! Keep your own and do not defile ours — *neque assumas testamentum meum per os tuum* [and do not take my covenant into your mouth — Psalm 49(50):16, Vulg.]." What would you answer to this, Viète? Not so much as a grunt, I think.

This, then, was the beginning of the present controversy, and no one can fail to see that you were the challenger and Clavius the challenged. And how did Clavius respond? Two years ago, on the order of Pope Clement VIII, he was seeing through the press the book on the new method of restoring the Calendar which Gregory had promised; and in the meantime that novel *pseudo-Gregorian* concoction of yours came out, together with a pamphlet in which you attack the

whole method of restoring the true Gregorian calendar and — if you are to be believed — maintain that it must be hissed off the stage altogether. This verdict struck as harsh not only the Supreme Pontiff, a man who loves truth and quiet above all things, but everyone who has now used the Gregorian Calendar for a full twenty years — the more so because you set out to overturn it with all the force of your intellect, in contempt of the decree of excommunication passed against those who use any other Calendar. And so, on the occasion thus arising, Clavius began to plan a *Defence* of the Calendar approved by the whole assembly of orthodox Christian princes and received into use; and it will shortly be on view in print — even if it makes your eyes smart. But after all, what injury was done to you by any of this? "A great deal," you say: in the letters he writes to a number of people, Clavius indicates that he has thoroughly refuted my pamphlet in his book on the new restoration of the Calendar, which he will publish some day, if God so please. So this is that appalling injury, this that insult worthy of your remonstrance, which you magnify and all but turn into tragedy — as if Clavius were not free to write in defence of the Pontifical Calendar, when you have claimed the freedom to attack it with all the force of your intellect. If your own findings please you, and you fight for them as for altar and hearth, why should anyone grudge it if Clavius takes the field to defend ours, and uses in yours the same right that you use in ours?

Non solos tangit Atridas iste dolor.

"That grief does not touch the sons of Atreus alone."

It is not right to endure your insults and leave our cause undefended, especially when in these times the Roman Church has quite enough rivals and enemies to bear. If you think you are wronged because we did not at once embrace your new formula of restoration, consider that our own was not published at once either, but only after long investigation, transmission to the princes, and the approval of the mathematicians of the better part of Europe. And are you indignant that yours is not accepted by us [Greek: ἀβασανίστως (abasanistōs, "without being put to the test," untested)]? *This* is the injustice, Viète, and the true [Greek: ἀλαζονεία (alazoneia, "imposture," boastful pretension)] — not the one you rashly charge against us. Were we bound to believe you at once, as though you were a new Pythagoras, simply because "he himself has said it"? Reason is not on your side. We must not lightly depart from what long use has established; but you seem far too devoted to the doctrines of the son of Mnesarchus, since you are busy imposing on us not a five-year silence but a perpetual one, as though you were exercising a dictatorship. That is why you breathe a kind of palingenesis, when you keep pressing on us your resurrected *Apollonius Gallus* and *Sosigenes*; indeed

they hand down that he was also a [Greek: μάντις] (mant[is], "seer" — accusative of μάντις; four letters legible, the compressed terminal cluster supplied in brackets)] and Divine — and in that respect you come very close to him, since everyone admits not only that you are learned in the science of numbers to the point of a miracle, but also that you pronounce so boldly about matters of which no knowledge is possible, as if you had them before your eyes, thoroughly explored. Do you dare to play the prophet even about Clavius's learning in theology, of which no monuments have yet appeared? And still you boast that you mean, today or tomorrow, to break down his efforts — how that can be managed I do not see, since those efforts have not yet reached you. What is more, you dream up prophecies that Clavius's defence will be published as false and plagiarized, on a re-dated day [repetita die]. You are in too much of a hurry, Viète; you give your case away by the excessive heat of your haste and your indignation. Be patient, and let Clavius's defence come out in public; and if you find anything wrongly written, or falsely demonstrated, or immoderately said, then refute it, arraign it, correct it — and in the end celebrate your triumph as well. But wait a while, in case truth herself forces you to withdraw this whole remonstrance of yours; otherwise you will hear applied to you that well-worn gibe of your own countrymen, that you are like the eels of Melun, which squeal before they are skinned. But if in the end you win the case on better arguments, then you will be for me not only an Apollonius Gallus or a Sosigenes, but even — if you prefer — the Delian Apollo.

And so, seeing that in this whole tragedy of yours you have so far found no injury done to you — unless you measure injury by our not having assented to your discoveries before their truth had been examined — you nevertheless try to convince us that the Protestants will embrace your true reckoning of the year, while admitting that they will acknowledge it as coming from you and not from the Supreme Pontiff. I could wish that this had not come from you: you who, to prop up your own decrees, seem to set such store by the approval of heretics, once the consent of the orthodox has been disregarded — those men, I say, who out of hatred of the Roman Church, when they saw that they were without a head, chose rather to court the Primate of the Greek schismatics than to acknowledge the true Vicar of CHRIST, however fruitless their attempt turned out to be.

Still, I am aware that I may perhaps be pressing my attack on your remonstrance too sharply. Yet I judge that this was necessary, since in you Clavius has for his opponent a jurist, a theologian, a mathematician, an orator, and finally a poet — an all-round athlete [pentathlum]. This contest therefore calls for no small

diligence, industry and learning if it is to withstand the onset of so great a man. But we put our trust in the goodness and the truth of our case, which is not to be handled as a piece of oratory and admits no poetic allurements. For indeed —

Ornari res ipsa negat contenta doceri.

"The subject itself refuses to be dressed up: it is content to teach."

So as soon as Clavius's defence appears, then set about this business, and bid the skirmishings of the schools a long farewell — without forgetting, in the meantime, that moderation and modesty of which you will find a shining example in Clavius's writings. And if I could seem to you a man of any credit (for I am wonderfully well disposed towards your learning, your standing and your seriousness), I would give you advice even unasked — but in your ear, so that no ill-natured person should take it amiss. [Greek: τὸς ἄλλος ἐνά[?]ιζ[?] ἀπὸ δ' Ἑκτορος / i[?]χε[?] χ[?]ρᾶς — a Homeric tag, apparently "kill the rest, but keep your hands off Hector." The first two words are set with the 8 (ov) ligature sort and the last with this fount's ρ rho sort, both kept here as printed; a further vowel stands after χε before the word-space, and it too is left unread. The flagged clusters are withheld rather than completed from the received text.]

RESPONSIO LAVRENTII CASTELLANI PATRITII ROMANI AD EXPOSTVLATIONEM FRANCISCI VIETÆ ADVERSVS CHRISTOPHORVM CLAVIVM.

REPLY of Lorenzo Castellani, patrician of Rome, to the remonstrance of François Viète against Christoph Clavius.

RESPONSIO LAVRENTII CASTELLANI PATRITII ROMANI Ad
Expostulationem Francisci Vietæ aduersus Christophorum
Clauium.

Reply of Lorenzo Castellani, patrician of Rome, to the remonstrance of François Viète against Christoph Clavius.

PRÆFATIO AD LECTOREM.

PREFACE TO THE READER.

FRANÇOIS VIÈTE, with real effrontery, wanted to foist a calendar of his own on the whole world in place of the Gregorian one, and published it with the Gregorian decree [diplomate Gregoriano] attached, without having sought any man's authority for doing so. But when he learned that Christoph Clavius — a man distinguished alike for learning and for piety — meant in his *Explanation of the Gregorian Calendar* to make public the absurd consequences that follow from Viète's contrivances, he brought out a thoroughly disgraceful remonstrance against him: either to frighten Clavius off what he had undertaken, or because he hoped that by shaking a solid and firm argument he could prop up his own fictions. To me, at any rate, he seems to be doing nothing else than trying to destroy the authority of the Gregorian Calendar root and branch. That is why, in the first place, he ascribes to Clavius alone a work on which the most eminent men, called in from nearly the whole world, laboured for almost a full decade — a work approved by pontifical authority and by now received by every people. High praise indeed, if Clavius stood in need of it. And then, in order to overturn the Calendar, he sets about undermining Clavius's standing. So when I read this remonstrance I lost patience, and I could not help answering its heads of complaint briefly — not only because the respect I owe to my teacher Christoph Clavius demanded it of me, but plainly because I saw that the matter touches Christian conduct and the public peace. For who could bear to see a man of the deepest piety, who has deserved so well of the common good, disparaged so bitterly, and with the deliberate design that the lowering of his authority should turn to the damage of Religion and of the public interest alike? If Viète had anything in the Lilian Calendar [Calendario Liliano] that he could not approve, he ought to have brought it forward at the time when it was sent by Gregory xij. to the Christian princes, and at the same time to Henry iij., King of France, so that they might order it to be examined and weighed by their own mathematicians and should accept it unless they had something better to offer. Why does he turn up only now, when twenty years' use has spread it so far and wide and it has struck such deep roots? And if he has at last learned something now that he cannot know by himself alone, why does he not act properly, as good men should, and lay it before those whom it concerns, to weigh and approve? Instead he suddenly stamps the name of the truly Gregorian Calendar on his own inventions, and prefixes the Gregorian decree to them. But Clavius shows perfectly plainly how many absurdities follow from that pseudo-calendar of his. As I said, I shall answer the remonstrance, and shall insert the whole of it as I go. For I am sure that it will be made plain to everyone — not so much by my reply as by the remonstrance itself — that in this business Viète is led by no zeal for a

good cause. And so that his words may be distinguished from my reply, I shall set the wording of the remonstrance in larger type. He begins, then, as follows.

I long ago accused Christoph Clavius.

Does Viète really mean that Christoph Clavius was accused by him? For if he actually did accuse him, he ought first to say before whom he laid the accusation, and when; then whether the accusation was admitted; and besides, why the princes should tolerate a man who is himself a defendant acting against divine and human law. But if there was no lawful accusation — indeed, if there was none at all — what need was there to cite, lower down, both the Canon and the Rubric? Let Viète, who professes to have reconciled the motions of the heavenly spheres to perfection, explain on what principle these few words of his hang together; and let him, if he pleases, hammer out a new Dialectic here, just as he hammered out a new Calendar there.

On the corrupted Roman Calendar.

It is certainly a most serious crime to corrupt a thing which the Supreme Pontiffs, the councils [Consiliis, so printed], and the whole Catholic Church have always worked so hard to keep uncorrupted — and rightly worked: for if the Calendar is faulty, the order and the due timing of things human and divine alike are thrown into confusion. But whether a crime of this kind — the corrupting of the Roman Calendar — falls on Clavius or on Viète, the *Explanation of the Calendar* itself demonstrates. Notice, though, how he attributes the making of the Gregorian Calendar to Clavius. For although under the single name of Clavius he is accusing and condemning all the learned men who sweated over the making of it, and all the princes and peoples who received it — and he is perfectly aware of that himself — he still reckons it safer and surer that they should all be wounded alike by him if he aims his blow at one man.

For as divine and august as the Gregorian decree on the restoration of the year is, so profane and ill-starred is the Clavian execution of the Gregorian decree — and its defence.

So on this account, when Clavius had corrupted the Calendar, Gregory xiiij., Supreme Pontiff, framed his divine and august decree to set before the universal Church, for its embrace, that very Calendar which Clavius had corrupted! Did Clavius then dare what Viète dared? Did he prefix a pontifical decree, without the Pontiff's knowledge, to a Calendar he had himself corrupted? And was Clavius more successful in a wicked act than Viète in a good one? — who, in the Curia [in Curia totius, so printed; the word *totius* is left without the noun it should govern

[?]], before the eyes of so many distinguished astronomers who had been summoned from every quarter, and before the eyes of Gregory himself, when he set the divine and august decree at the head of a corrupted Calendar, contrived to escape the notice of the whole world, of a City packed with inquisitive and sharp-eyed observers, and of the Pontiff himself, most cautious and most clear-sighted of men — whereas now to achieve

he could not, set so far off, with everyone else busy about other matters, in a Calendar he had himself corrected — so Franciscus Vieta [François Viète] says. Was Gregory, then, framing that decree for an uncertain future, approving in advance a Calendar that would be born at some later date? Was he handing Viète a page signed in blank, so that after so many Pontiffs — with Clement alive and administering God's Church in the holiest and most faithful way, and correcting a great many things back to the ancient standard of piety, and himself wholly unaware [*plano* so printed] — some Gregory-Viète might correct the Calendar in France? What a mathematician the man is, who either does not see what all this amounts to, or supposes there will be any sane man alive who does not see it!

Gregory had used Aloysius Lilius [Luigi Lilio] as his Sosigenes; and since Clavius could not understand the working papers [*aduersaria*] of that man, whom fate had snatched away, he wretchedly corrupted them, and chose to fall into the crime of contempt of Religion — ready to overturn everything at whatever risk — rather than to be seen as ignorant of the subject.

What, I ask, are we to call defamatory pamphlets [*famosi libelli*], if *this* passes for a Remonstrance? But our good man is always stuck at the same point: the more easily to overturn the authority of the Gregorian Calendar, he fathers its whole composition on Clavius. And though he himself pretends not to know which men contributed their labour to that work, others are not therefore ignorant of it. For it is perfectly well known — still within the memory of the survivors, and celebrated in the records of letters — that a great many outstanding mathematicians took part in the correction of the Calendar; and above all the rest there took part Antonius Lilius [Antonio Lilio], superbly skilled in mathematics, Aloysius's full brother, who from the very beginning had helped his brother in drafting that little book, and was no less privy to Aloysius's mind in the matter than Aloysius himself. And so, since he and a great many others were present at the consultations held on the correction of the year, they were able to explain anything in Aloysius's papers that Clavius had failed to understand; nor would they in any way have allowed everything to be overturned by one man for the

covering-up of his own ignorance — unless Viète takes them for downright irreligious men, or for blockheads. And yet it is easy to see which of the two is overturning everything: Clavius, who keeps the Church's ancient practice and expounds only what was decreed in an assembly of the most learned men [*doct[i]ffimorum*, the *i* broken in the print] and what Gregory ratified by pontifical authority — or Viète, who brings in an unheard-of beginning for the year, and, importing other novelties as well, at whatever risk seeks a warrant for his own rashness from the Gregorian decree.

It is no business of mine to pronounce on his competence or incompetence in matters mathematical and theological. I shall pronounce — and not wrongly — if I have to. But whatever kind of mathematician he may be, he has introduced a false lunar period into the equation of the epacts [*æquatio Epactarum*].

Many of Clavius's works are in print, and they show what his learning is like. Let Viète pronounce on that as much as he pleases, provided he does it in a manner worthy of himself, and not wrongly. For while he threatens that one day, if he has to, he will pronounce — and not wrongly — meanwhile, when it is in no way either necessary or fair, he pronounces wrongly. That lunar period is not false, and Clavius did not introduce it: he took it over from Ptolemy, Alfonso [Alfonso X], Copernicus, and others — something an excellent mathematician ought not to have been unaware of. But in his usual manner and practice Viète supposes that what is good can be spoiled more easily by himself, once he has diverted it onto Clavius, than at its own sources.

He is bound sometimes to place conjunctions [*synodi*, new moons] at the full moons, and full moons [*panseleni*] at the conjunctions. And if that is in any way to err, then, in the proverb's phrase, it is τὸ παράπαν τῆς ὁδοῦ [Greek: *to parapan tēs hodou*, "clean off the road" — the *ov* is set out in full here, not as the ligature sort 8] — since the middle of the full moon is set diametrically opposite the middle of the conjunctions, 8 ψευδονύμως [Greek: the first token is a single ligature sort (8 = *ov*) carrying a breathing, i.e. *οὐ*; the second is printed ψευδονύμως, with the page's *o* where the received form has *ω* (ψευδονύμως) — "not falsely so named"].

Long before Viète's book came out, Clavius saw perfectly well that this drawback arises in the Lilian equation of the epacts. It does not occur on account of the lunar period, as Viète falsely charges, since that period is the one belonging to the ancient astronomers — and the very one Viète himself employs. Moreover, that drawback will only come about after a very long stretch of time; and at the same

time Clavius prescribed the method by which it is to be met, and corrected Lilius's equation. But Viète runs into exactly the same thing, and does not notice that he himself is straying τὸ παράπαν τῆς ὁδοῦ, nor does he offer any remedy at all. Indeed, though he knows his proverbs, he is not afraid to take offence at other men's warts when he has swellings of his own — or, to keep the saying from being turned against himself: ἄλλων ἱατρὸς αὐτὸς ἔλκεσι βρύων [Greek: *allōn iatros autos helkesi bryōn*, "a physician of others, himself teeming with sores"].

And whatever kind of theologian he may be, he has adopted a profane beginning of the year for the solemn feasts, and from this has followed an absurd ordering of the epacts, and an unfair and monstrous division of the months, with the Paschal new moon [*Neomenia Paschalis*] taking its law from other quarters — ἄνω ποταμῶν ἱερῶν [Greek: *anō potamōn hierōn*, "the sacred rivers [run] upstream"] — whereas true Theology, received from the word of God and from the blessed Fathers, and not also Hebrew and superstitious as the Adiphorists hold (on that very champion's own testimony), teaches that Nisan is the first of the months in dignity, and that from it the year's solemnities are to be renewed; and that the worshippers of the pagan religion themselves caught the scent of this very thing in the performance of their own sacred rites, not without a great mystery of our true religion, which it has been a sacrilege to despise.

The beginning of the year which the Church now uses neither ought to be called profane, nor is it. For it is the one she has always used since the Council of Nicaea; and from it the Epacts have been rightly ordered in the Calendar; nor did Gregory xij. approve any division that was either unfair or monstrous. Nor did that body of most learned men, who collaborated successfully on the restoration of the year with joint effort and diligence, disregard the beginning of the first paschal month from 8 March, since they knew perfectly well that this had been observed by the Nicene Fathers, whose lead they were following. But they chose not to begin the ordering of the Cycle from that point, because no necessity required it. Even the Nicene Fathers themselves disregarded this, since to 8 March they assigned not golden number 1. but 16. — especially as the Cycle can begin from any Epact whatever, and therefore also from the xxij. assigned to 8 March in the Gregorian Calendar [*Calendario* so printed]. What is it, after so many ages, to summon from some other quarter the course of the years drawn from a single source — what is it but, to the insult of antiquity, to drive ἄνω τοὺς ποταμοὺς [Greek: *anō tous potamous*, "the rivers upstream"], or (what is likewise not permitted) to divert a river's channel?

Therefore I have set against the false Clavian lunar period the true one — the one that is truly Lilian and Gregorian.

That period, as I have said, is neither false nor Clavius's; Lilius too adopted it, and Gregory confirmed it. Indeed, not even Franciscus

Vieta acknowledges any other lunar period — so that it is truly astonishing that this Corrector should claim to have set against the Clavian Lunar Period (that is, against the very one he himself also uses) a true one, truly Lilian and Gregorian. But in fact he has not set another period against a lunar period; he has only set a false Calendar, and a genuinely Vietan one, against the Gregorian. And in that business he is not merely an excellent mathematician but more than divine. For a man who neither knew Lilius nor was ever known to Gregory has all the same brought out into the light a "Lilian and Gregorian" Calendar, with a new beginning of the year that neither of the two ever dreamed of — so that each of them might truly say ὥς πολλὰ μου κατεψεύδετο [Greek: *hōs polla mou katepseudeto*, "what a mass of lies he told about me"; the *ov* of μου is set out in full, not as the ligature sort ϑ, and the page sets the acute over the ε of κατεψεύδετο, not over the υ].

And, a profane beginning of the year having been adopted, [I restored] the beginning laid down beforehand by the Nicene Fathers out of God's law.

About the beginning of the year I have said enough already: Viète ought neither to call it profane nor to think it so. If he insists on naming and judging it that way, then it is the holy Catholic Church that names and judges it — the Church that has always used this beginning and marks it off from profane things by her own holy usage. Here too that saying from Scripture has its place: what God has cleansed, do not call common. Nor does he bring in the beginning laid down beforehand by the Nicene Fathers out of God's law: what he brings in is new and unheard-of in the Church, something he has lately fabricated out of the rule of his own Computus, ἐκτὸς λεωφόρου βαδίζον [Greek: *ektos leōphorou badizon*, "walking off the highway"; the *ov* of λεωφόρου set as the ligature sort ϑ; the participle is printed with the final -ον, where the sense wants βαδίζων — transcribed as set].

From this there followed a consistent ordering of the Epacts, and a correct and even division of the months, with the paschal New Moon [*Neomenia*] beginning the cycle, and the year's remaining New Moons taking their law from it, as was fitting, in accordance with the divine decrees of the Fathers.

But the book of the *Explicatio Calendarii* shows how discordant an ordering of the Epacts arises out of Viète's new beginning of the year. And if he is as certain of his own correct ordering of the Epacts as he makes out, why does he fear a refutation from Clavius? A man who sees plainly that he has demonstrated something actually welcomes the arguments of those who think and argue against him. Let him therefore boast less, and less tear down other men's reputations with abuse: nothing is stronger than the truth, and therefore nothing safer — she will come forward of herself and defend herself.

Having brought out a pamphlet on the subject and presented it, on royal authority, to the Supreme Pontiff, under the title of a *Report on the truly Gregorian Calendar*, addressed to the Doctors of the Church — to whose judgement and censure I submitted both myself and my writing.

There is much here that Viète, I imagine, would wish undone and unsaid, if deeds and words could be recalled. For what was the part of a prudent and dutiful man, if he had something about the Calendar that he thought ought to be brought forward publicly — and especially at a time when all Catholics were at rest in the Calendar as already restored, and held it to be truly Gregorian, as it is? Ought he not to have disclosed his plans to the Pontiff before branding them with any title at all? While the Pontiff was ordering these matters to be looked into and examined carefully and at length, as is fitting in so great a matter so soon after the correction, so that no suspicion of levity could attach to pontifical decrees — ought he not to have waited for the Pontiff's consent before he printed? Grant that he went wrong here; what next? He says the pamphlet was presented to the Pontiff. Suppose it was: ought he not, until the Pontiff answered, to have held back all the other copies in the meantime? If anything new was to be set in motion, the Calendar the Church now uses would have to be abrogated, and Viète's approved and promulgated, so that there should be no disturbance. And yet Viète — not merely before his pamphlet reached the Pontiff's hands, but before any rumour whatever of his plans could reach the Pontiff's ears — strikes off a new Calendar, entitles it *A truly Gregorian Calendar*, prints it, publishes it, and arms it with Gregory's decree. Does a man who acts like this look as if he were submitting himself to the judgement and censure of the Doctors of the Church? Very conveniently, too, he calls a "writing" what he had already printed — so that even if he wanted to suppress it, he could not. Is this not to make sport of the Pontiff and throw everything into confusion? So that two calendars, widely discrepant and contrary to each other, circulate in the Church, and each of them with a pontifical decree? Which of them will the faithful follow — the Gregorian, or (as he calls his) the "truly Gregorian"? And what is "truly Gregorian"? Is the

Calendar that Gregory set before the Church, that the Church has used ever since and uses today, then falsely called Gregorian? On that showing Gregory was an utter fool; the Pontiffs who followed him were blind; those hand-picked mathematicians were frauds and cheats; and all mortals except Viète are σκαιοὶ[?] ἄσσοφοι[?] [Greek: the two words read as *skaioi* ... *assophoi*, "dull-witted and unlearned"; the termination of the first word and the doubled σ of the second do not resolve on the scan [?]]. Finally, I put this question to Viète: since he cites laws and canons, he will not be ignorant of the penalty laid down against those who forge pontifical letters — so what difference is there between the crime of a man who slips in a false decree, and that of a man who abuses [*abutatur* so printed] a genuine one for his own purposes, without the Pontiff's knowledge and against his will?

But it was not fair that a defendant should be condemned with his case unheard [*indicta causa*].

Once a book has been sent out into public circulation, if it is condemned, it is never condemned with the case unheard. For the book itself pleads the case both for its author and (what this man would not like) against him: it is at once his advocate and his accuser, and a witness on both sides.

And so a copy of my pamphlet was put into Clavius's hands two years ago.

Yes — printed in good type, with the title *A truly Gregorian Calendar*, and with the Gregorian decree, at the sight of which he shuddered. Though the copy was put into his hands not two years ago, as Viète says, but a few months before.

What, then, were Clavius's duties, you fair-minded judges?

Pronounce, whoever you are that are fair Judges: what were the duties of Clavius, who by the command of Clement 8. was writing an exposition of the true and truly Gregorian Calendar — in a cause that is (as Viète knows perfectly well) public, one that touches the mysteries of our religion, the concord of the Christian commonwealth, and the divine authority of the Supreme Pontiff? If any calendars turned up from elsewhere, wearing a respectable face while opposing the Gregorian one by Gregory's own authority, was it not his duty to strip the mask from them, to convict their errors and bring them into the light? To defend pontifical authority? To let neither Gregory, now dead, nor Clement, most happily alive, nor the whole assembly of the faithful be imposed upon? And, finally, to strive as far as in him lay that the public peace and the ancient rites of the Church should in no way be torn up? These were the duties of an outstanding

mathematician and man — that is, they were Clavius's duties. And in fact he performed rather more of them than Viète finds welcome; but Viète ought to set the common good before his own grievance, and to be angry with no one but himself, who let himself be carried away too thoughtlessly — and even to thank Clavius, who took pains that his offence should do as little harm as possible.

Was it his part to acknowledge and confess his own error unprompted, especially in a public cause, in which the Mysteries of our Religion are at stake —

is at stake, and the concord of the Christian commonwealth, and the divine authority of the supreme Pontiff? That, surely, seemed very much to be hoped for from a theologian of the Society of Jesus — ὡς ἱερῶ τὴν τέχνην καὶ τὰ ἦθη [Greek: *hōs hierō tēn technēn kai ta ēthē*, "as one consecrated in his art and in his character"; καί set as the ligature sort κ, and ἱερῶ printed without the iota subscript].

What error, pray, was Clavius to acknowledge as his own? He has published a great deal; if he has aimed wide anywhere, he will be grateful to a surer intelligence. Who has ever seen a *Calendar of Clavius*? What does exist is his *Apologia for the Gregorian Calendar against Mestlinus the heretic* [Michael Mästlin], and his *Castigation of Joseph Scaliger's Castigation*. Where in these he has put forward views of his own, if he has taught anything less than rightly, let Viète teach him — and Clavius will acknowledge his error unprompted. But let him stop harrying the Gregorian Calendar as though it were Clavius's, and let him remember religion, the public concord, and pontifical authority. In fact, though (as I have said more than once), a man greedy for whatever he wants understands perfectly well that Viète's Calendar cannot be thrust in unless the Gregorian is thrust out. He does not dare to fight Gregory in the open; but he does seem to hope that the Pontiff can be wounded through Clavius's side.

But however the matter turns out, we are hardly brought to condemning what is our own and approving what is another's. We are all swept away by φιλαυτία [Greek: *philautia*, self-love], however much sanctity we may feign; and by whatever art we can, we do violence to the truth so as not to seem beaten in any way. Even in wise men the desire for glory is the last thing stripped off: τὴν κενοδοξίαν ὡς τελευταῖον χιτῶνα ἢ ψυχὴ πέφυκεν ἀποτίθεσθαι [Greek: *tēn kenodoxian hōs teleutaion chitōna hē psychē pephyken apotithesthai*, "vainglory is the last garment the soul is by nature to lay aside"; τὴν set as a contraction ligature].

It is just as well that he does not exclude himself from the number of men. Let the Remonstrant, then, consider which is the likelier to be led by self-love. Is it the man who, in whatever he does about the Calendar, does nothing of his own accord, nothing on his own, nothing rashly, but by order of the Supreme Pontiffs, in a council of the wisest men, with the utmost prudence and caution — to say nothing of the man himself, plainly *ἱερῶ τὴν τέχνην* κατὰ ἤθην, whose knowledge of the subject has been on view for very many years in so great a City, and whose moderation and piety are no less? Or is it the man who pushes himself in, at no one's order or urging whose business it was — who, having devised certain things alone and by himself, first put them into print by arts not so honourable, then also published them headlong, and finally, when he was afraid they might be refuted, vomited up this new species of defamatory Remonstrance?

But that it was Clavius's business, given the charge under which he stands, to resort to recrimination — that, in truth, no one will rightly say. For the law says so, and the Canon says so: the licence of bringing charges must be denied to the accused before they have cleared themselves of the charge that presses on them, according to the rulings of the old authorities on Law. Nor could that Doctor grant himself licence to pass sentence in his own case. For the Rubric forbids it: *Let no one judge in his own cause, or pronounce the law for himself.*

A man who has the Canons and the rubrics so conveniently at his fingertips can only be reckoned extremely learned in both laws — but I have no wish to make a fool of myself over trifles.

And yet, with no regard whatever for divine and human Law, Clavius resorts to slander, so as to injure my name and reputation with the Supreme Pontiff.

As the rule of divine and human Law required — with no abusive Remonstrance and no slander — Clavius supposed that he was entitled to defend by a public reply the Gregorian Calendar which Viète had thought it right to attack in a public work; and that suit had to be decided not by rubrics and Canons but by astronomical calculation. Nor is Clavius the man to want anything taken away from anyone's name and reputation; nor is the Pontiff the man to lend his ears to detractors. At this point Franciscus Vieta fails to consider that, if Christophorus Clavius was ever accused by him, it is now Clement viij. who is being accused — the Pontiff who, though he alone ought to preside over this judgement, is supposed to be letting Clavius use recrimination in contempt of divine and human Law, and grant himself licence to pass sentence in his own case.

Moreover, in a good many letters, written to a good many people, he lets it be known that he has thoroughly refuted my pamphlet in a book on the new restoration of the Calendar, to be published one day, if it please God.

Clavius denies that he has written any letter to anyone on the subject, except one to Doctor Adrianus Romanus [Adriaan van Roomen], who had asked him what he thought of Viète's Calendar. Nor would it have been a crime to write that he had done what in fact he did do, and with the highest credit, in that book which — whether or not it pleases Viète — it will at last please God to have brought out into the light.

What insult is this, Clavius? What insolent and empty boasting? Is it that, because you have made an attempt (as by your own right you may) to refute my pamphlet, you have therefore refuted it? Let that attempt of yours come out, and, God willing, I shall break it tomorrow — today, in fact.

Mind your language, Francis. You are not saying this in a corner: you are offering it to everyone's ears and eyes. What do you think men will make of you — men who know Clavius (and who does not know him?) — when they see you flinging insult at a man of the greatest moderation, and a priest, with so much insolence, vanity and boastfulness (I turn your own words back on you)? That attempt of his will come out; break it yourself this very moment, if you have it in you; and if you cannot do it today or tomorrow, break it the day after, or on another day and another, in another year, another century. You will have God on your side, if what you want is something good.

That is not the order of judicial proceedings and process. I have demonstrated that you are a false mathematician — if indeed you are a mathematician at all — and a false theologian. And so, when the plan is to prosecute you as a defendant, your case must be pleaded according to the form of the Constitutions, not bawled out from the wagon [*ex plauastro*]. And if you deny that you are convicted [*contuinci* so printed] by my τεκμηρίοις [Greek: *tekmēriois*, "proofs"; the sort after μη is the fount's bowl-with-descender ρ, which reads as an ε unmagnified — established by comparison with τεκμήρια on the same tile], then the fallacies of my demonstrations must be exposed and pointed out before the Judges who have been agreed upon, before you are acquitted by their verdict. Before acquittal, your ἀντικατη[?]ορίας, κ ἀλαζονείας [Greek: *antikatē[?]orias kai alazoneias*, "counter-accusation and boasting" — both

genitive singular, set with the fount's curled -ας ligature (which reads as -αι unless magnified) and confirmed by the Latin *tuæ*; the tightly-kerned sort after μη, very probably γ, does not resolve [?]] count for nothing.

Which of the two is the false theologian and mathematician, Viète or Clavius, the book of the *Explicatio Calendarii* will demonstrate rather more openly, more lucidly, and more humanely than Viète does here. From it, too, it will be plain how absurd Viète's τεκμήρια [Greek: *tekmēria*, "proofs"; the same bowl-with-descender ρ] are, and how solid Clavius's arguments are on every point, by which they are refuted. And as for which of the two speaks "from the wagon" — or rather, ὅλας ἀμάξας βλασφημιῶν κατασκεδαί[ση?] [Greek: *holas hamaxas blasphēmiōn kataskedaí[sh?]* [Greek: *holas hamaxas blasphēmiōn kataskeda...*, "pouring down whole wagon-loads of abuse"; the page prints no terminal ν — the two glyphs after κατασκεδαί read as ση (possibly ση) and are given with a query] — this generous Remonstrance speaks for itself. About judges and the pleading of the case I add not a word: sentence will be passed by a competent Judge. For the rest, let the whole race of men be judge as well.

And what new anxiety is this that holds you about a book on the new restoration of the Calendar, when that book has already been published by me — a book which holds its place and its force, as was only right, from the very day of the decree?

Viète's Calendar was published barely two years ago; the decree is already twenty years old. So from the day of the decree, Viète's work — that is, eighteen years before it existed — has held its force. Who would deny that a thing had a place before it existed, when after it began to exist it has none? It belongs to that class of things for which the best is not to be born, and the next best to be abolished as quickly as possible.

The edition you are planning is untimely, and from now on to be spurned as false and plagiarized. Its falsity even a repeated day will convict. As for the plagiarism — my book, my *Report on the truly Gregorian Calendar*, I mean, with its theolo-

—gical, political and astronomical [supports], and fortified [*muniti*] on every side. Δὶς καὶ τρεῖς τὰ καλὰ [Greek: *dis kai tris ta kala*, "twice and thrice the good things" — the proverb for what bears repeating; this first setting prints τρεῖς, the fount's ε-for-ρ substitution (its ρ carries a long descender), and is transcribed as set — the italic re-quotations below set τρεῖς correctly]. But since it is your intention and your design to snatch away another man's right, it is not for you, Clavius, αὐθις ἀ[??]ζήλω

εἰρημένα μυθολογεῦν [Greek: "to make a tale once more of things already said quite plainly" — Homer, *Odyssey* XII, where the received text reads αὖτις ἀριζήλως; the θ of αὖθις is clearly inked in the fount's curly θ sort, and the two glyphs after the initial ἀ do not resolve on the scan [?]].

Here is a man with a modest opinion of himself — a man who may fairly be allowed to point out φιλαυτίαν [Greek: *philautian*, "self-love"] and ἀλαζονείαν [Greek: *alazoneian*, "boastfulness"] in somebody else! He has been caught in manifest astronomical errors; he overturns rites that have flourished in the Church from the most ancient times down to this day; he acts openly against the peace of the commonwealth — and then he says, Δις κ τρις τὰ καλὰ. The effect is that anyone who wanted to fling these very words back at the man who has overturned matters theological, political and astronomical would have his material ready to hand, with only a K put into the place that Λ wrongly occupies. And on the charge of plagiarism, what does he say? Does he seriously suspect that Clavius has filched those brilliant doctrines of his? — those doctrines, Δις κ, τρις κακά [Greek: *dis kai tris kaka*, "twice and thrice the bad things" — the proverb turned by the single letter just described]. Very well then: Clavius will publish them — not his own, perhaps, but at least good. Yet what sane man would entertain such a suspicion of plagiarism, when it has for so long been perfectly well known to everyone that Clavius was at work on the *Explicatio* of Gregory's Calendar; and when a great many know that it was finished before Viète appeared, and would have been published even then, had Viète himself not given cause for something to seem worth adding in its commendation? Learned men, indeed, will decide the point — men who know Clavius's *Apologia*, published long ago, and who will easily notice what Viète has carried over from it into his own Calendar: which of the two is guilty of the plagiarism, Clavius or his accuser. Take the equation of the Sun in the four-hundredth year, and the equation of the Moon in the three-hundredth year, with the caution to be applied in twenty-five centuries; and finally the perpetual Cycle of Epacts, which our Clavius was the first to compress into a summary and a short compendium out of Lilius's expanded table, in the Calendar that Pope Gregory issued, and which he repeated in his defence against Maestlin and at last in the *Explicatio* of the Calendar. Perhaps someone would say — truly, and without any suspicion of malice — that Viète drew all this off from the Clavian spring to water his own little garden. Clavius published every one of these things before Viète, and even a date looked up again will prove it. Clavius had neither the intention nor the design of forestalling anybody's right: by a right granted him at the Pontiff's command [*iussu Poncificis* so printed, for *Pontificis*] he undertook the *Explicatio* of the

Calendar and carried it through. And even if Viète had committed no fault at all, he still ought not to persuade himself that the spring of genius has been drained dry by him. Much was left over for Aristotle after Plato, and for many others after Aristotle; and in mathematics too the excellence of outstanding men is no less abundant.

As for the Pontiff's hatred, which you strive by evil art to stir up against me — take care that you do not find it embittered against yourself instead. Οἱ αὐτῷ κακὰ τεύχει ἄνῆρ, ἄλλῳ κακὰ τεύχων, Ἡ δὲ κακὴ βδλή τῷ βδλεύσαντι κακίση [Greek: "a man contrives evil for himself in contriving evil for another, and the evil counsel is worst for the counsellor" — Hesiod, *Works and Days*; the ligature sorts ϑ (= ου) and ς (= στ) are kept as sorts, and the opening Oi is left as printed where the received text has οἱ].

He is afraid that some man's evil art may make him hateful to the Pontiff undeservedly — when he himself has done [?] the very things for which he deserves to be hated. For in a case that touches Religion and the public good, a case in which he professes that the supreme authority of the Supreme Pontiff is at issue, he has dared so much that he seems to have set out deliberately to try the Pontiff's Clemency and to provoke against himself a hatred entirely justified — and even now he does not stop embittering it, while he scatters Remonstrances of this kind about. Listen, fair-minded judges, and consider where the words he adds are meant to lead.

For what if the Protestants embrace the true reckoning of the year, which I have faithfully reported out of Gregory's own mind, and acknowledge it as coming from themselves and not from the Supreme Pontiff?

He asks what will happen if the Protestants accept the reckoning of the year that he has reported. That is easy to say: those will accept it who in plain fact do not accept the sacrosanct Gospel of Christ. But Viète — ποῖον σε ἔπος φύγεν ἕρκος ὀδόντων, ὅρσεις μετ' ἀκίνητα διὰ φρενῶν φράσαι [Greek: "what a word has escaped the barrier of your teeth..." — the Homeric formula, transcribed as the page sets it; the page carries no accent on the second omicron of ποῖον]. How is it fitting, in a business of this kind, to make any mention of such people at all? Is it Clavius you are threatening, or the Pontiff? Grant that you have discovered something good: did you discover it in order to arm the enemy? A change made from what is good is not always praiseworthy, even when it is a change for the better. And so what you had worked out should have been offered by you to the

supreme Prelate of things sacred, for him to bring out — if he saw fit, in the manner and at the time he saw fit — and not flung out suddenly among the common people in a way calculated to feed the impious dissensions of the heretics. What, in the end, are these words of yours driving at now? Is it not to point the firebrands, who are pressing for a chance to set everything ablaze, to the opportunity you have handed them? But there is this much comfort: that torch of yours has more smoke in it than light. You, of course, have faithfully reported the reckoning of the year out of Gregory's mind — you who set up your own Calendar in flat opposition to the Gregorian one! Then let the Protestants acknowledge Viète's restoration as their own, as much as they please. For no one can acknowledge as coming from the Pontiff a thing that is false and hostile to the rites of the Church. And what of you in that case — for I take you to be a devout man? Would you not rather have had no talent at all than have had the talent by which you soldier for the most worthless deserters against the Church of God?

To whom is it that you so obstinately ascribe your own reckoning, false and moreover absurd and monstrous? And so let him shun its authority — nay rather, let him one day convict you as a false Procurator and defender.

He presses his purpose steadily — not to say obstinately. Under Clavius's name he goes on abusing the Gregorian Calendar; the most learned men who made it; those who presided over the making; the Pontiffs who approved it and set it before the Church; and the Princes, Commonwealths and Peoples, all of them, who received it. The danger is real indeed: that once Viète's Calendar has been received from the Protestants, the Pontiff will learn the true rites of the Church from them, and will at last, one day, convict Clavius as a false Procurator and defender — that is, when Peter's successor accepts a Calendar from Protestants, and Christ's Vicar learns from heretics how to correct the erring Church. Immortal God! It can never have come into Viète's mind to say such a thing — however much he does say it.

Julius Caesar corrected the year, and he too was Supreme Pontiff. But when the priests carried out the Julian ordering of the year badly, Augustus Caesar removed the error — and he too was Supreme Pontiff. On that account no less glory was assigned to him than to his predecessor Julius. Great is the glory of Gregory the Great in the restoration of the year. But no less will be the glory of Clement the Great, when he has rejected you — an ill-occupied reckoner — together with your false periods and your hypotheses that conflict with the divine law in fixing

the beginning of the year, and has decreed by an Apostolic Brief the lawful execution of the Gregorian diploma. And this even though, to keep that from happening, you smear the Pontiff's face for the present moment, drawing darkness over matters that were clear, κ βαδίζων, ὡς ὄνος, εἰς ἄχυρα τραγημάτων [Greek: "and walking, like an ass, to the chaff from the sweetmeats" — the proverb of the ass that leaves dainties for straw]. But you alone as a law to yourself — to come back to your slanders — no one will tolerate.

There is no call for you to mock the Roman Pontiffs with your inept learning. What, I ask, becomes of the great glory of Gregory the Great in the restoration of the year, if he promulgated a corrupt Calendar on pontifical authority? And how is the glory of Clement the Great no less, if for the present moment he lets his own face be smeared by Clavius, and lets darkness be drawn over matters that were clear in a case of religion and of the public good, and lets the Church remain in error until it has Protestants for its teachers? Each of the two Pontiffs, truly Great, has a glory of his own — solid and unalloyed, from many other quarters and from this one as well: Gregory's, that he restored the Calendar; Clement's, that he does not allow you to destroy it. As for that utterly unjust insult, this is my whole answer, and a friendly warning with it. Viète, you are not on the right road: it is plain that you are worked up, plain that you are intemperate, over-fierce, contemptuous. You are a learned man, of course; you know how famous the saying is, that speech is εἶδωλον τῆ βίῃ [Greek: *eidōlon tou biou*, "the image of a man's life"; the ῆ (= ου) ligature sort kept as printed]. What need was there to shove a jeer in at this point? Or, if I cared for my wit on the bitter side, would not the Aristophanic bird conveniently furnish me an omen against you — you who guarantee that the ailing year will soon be better off through your good offices? But I would rather that you, now that the heat has boiled off, were at long last rebuked by your own self.

Unless you take the warning and come to your senses, you are bound to clear yourself of the charges you stand accused of, and meanwhile to obey the Civil Constitutions.

There is no one of sound judgement who thinks Clavius guilty of any charge whatever. On the contrary, everyone acknowledges owing him a great deal, because he expounds the Gregorian Calendar and, prudently and piously, dissolves the charges brought against it, whether impiously or rashly. There is no Civil Constitution and no Canon that he has not obeyed; he has never laid a hand on any pontifical diploma; he has never published a book on matters touching

Religion without pontifical authority. In short, he has never so much as contemplated any of the things that Viète, having done them, then ἐκτραγωδίζει [Greek: *ektragōdizeî*, "turns into high tragedy"] — while he also threatens the very people he ought least of all to threaten.

But I beseech you, Venerable Fathers and Prelates of the Society of Jesus: use your own authority over your own colleague and hold an inquiry into him; and, when the case has been heard — ἢ χαμόθεν, ἢ πρὸ βήματος [Greek: "either from the ground or from the tribunal"] — set yourselves squarely against his obstinacy and his spite. Do not let him alone, with his false and unhappy Apologetics, so ill-deserving of the Apostolic See, be the reason — to the insult and reproach of your College — why the Calendar is not received back by all the nations that used to use the Roman one, restored as it has been under the most fortunate sponsorship of Gregory xiiij. Let him be κενόδοξος ἐν ταῖς ἀδιαφόραις [Greek: *kenodoxos*, "vainglorious," in matters indifferent], by all means; but let him be ὀρθόδοξος ἐν ταῖς ἱεραῖς καὶ ὁσίαις [Greek: *orthodoxos*, "orthodox," in things sacred and holy].

For this admonition and adjuration I quite believe that the Fathers and Prelates of the Society of Jesus, excellent men as they are, are grateful to their monitor. To me, however, who read the thing for what it is, this looks like no adjuration but an insult. What is it Viète is saying? What need was there of this adjuration? Did you suppose that prudent and religious men would trust your whisperings more than their own eyes? You have never, I imagine, so much as seen Clavius. But he has a great many colleagues, with whom he has lived for very many years; they are diligent, watchful men, and they have charge of his life and conduct. Not one of them has ever marked him with a single one of the charges you shout about. They have known him not only as ὀρθόδοξον ἐν ταῖς ἱεραῖς καὶ ὁσίαις, but have also admired him as a man ἐν ταῖς ἀδιαφόροις διαφέροντα ἀφιλόδοξον [Greek: "outstanding in matters indifferent, and no lover of glory" — the play on διαφόρ-/ἀδιαφόρ- is the printer's, kept as set]. So you have seen more than all of them? And what is less capable of being kept hidden than κενοδοξία, ἀλαζονεία [Greek: vainglory, boastfulness], obstinacy, spite? Or let this Remonstrance of yours simply be read. And yet Clavius, so he tells us, once deceived Gregory; now he smears Clement's face; he persists in spite and obstinacy — and nobody ever noticed things so open and public: not his intimates, not his colleagues, not the Prelates, no good man at all. Nobody except you, sited far away across the Alps — and not even you, until after Clavius began to refute your Calendar. Whoever, then, you can convince that these things were rightly said and rightly seen by

you, is a man to whom you may commend your Calendar as well. But whether Clavius has deserved well or ill of the Apostolic See by his Apologetics — who on earth does not know? And whom do those Apologetics distress, except heretics — and Viète?

How much disturbance a disagreement over the reckoning of the year stirs up, and how much trouble in the exchange of goods at the more frequented fairs and at every considerable trading centre! And besides that, it nurses dissension of minds on the disputed heads that bear on Religion.

You tell the truth — but who introduced this disagreement, and who keeps it alive, if not the heretics, so as to set themselves against Catholic rites and the Roman Pontiff as far as they can? What astonishes me about you, Viète, is that you judged yourself the fit man to be, as the saying goes, like a fingernail on this ulcer, and to tear open again the wounds that were slowly closing over.

Let every disguise be stripped away; let pride and spite yield to the force of naked truth. For the equation and ordering of the Epacts, false and profane and moreover absurd and monstrous, let there be substituted one that is just, pious, and free of all absurdities and monstrosities — one that is, in short, as the words of the diploma and an honest interpretation of them establish, truly Lilian and Gregorian.

Let it be exactly so: let pride and spite yield to truth; let the passion for innovation yield to pontifical authority; and let everything that insinuates itself by stealth, without the Pontiffs' knowledge, and insidiously angles for authority out of false titles, yield to the Calendar that Gregory promulgated with his own diploma, while he was alive and watching. Let the reckoning of the year be the Lilian one, which Lilius proposed; let it be the Vietan one, which Viète proposed; and let lawful authority suppress as soon as may be the reckoning contrary to that one [*& hanc nempe nempe illi* so printed — *nempe* set twice across the line-break; recte: *& hanc nempe illi*] which is true, convenient, and perfectly congruent with the Canons, the Fathers, and the Gregorian diploma.

No astronomer will show himself anywhere in the world, and no one who swears by the words of those expert in the art, who will fail to admire the admirable Gegorian [so printed, for *Gregorianam*] restoration of the year; and if any such man happens to have strayed from the Holy Roman Church, he will not fail to press at once to work his way back into it, ἀμφασίη κραδίην ἀμφιχυθείς μεγάλη [Greek: "his heart wrapped about

in a great speechlessness"]. This is the very thing that all devout men have in their prayers, Venerable Fathers and Prelates.

This is the very thing that all genuinely devout men have in their prayers, and we hope it will come about in great measure, once the solidity of the Gregorian Calendar has shown itself the more clearly out of Viète's fruitless attempts, and it has been made plain to everyone how many errors that new invention of his teems with — as everyone will see plainly from the book of the *Explicatio Calendarii*.

Whoever shall have obstructed so great a good of the Christian commonwealth, by aid, by counsel, or by malicious guile — let them be accursed and incapable of bearing witness, and let them be barred as outcasts from the blessed assembly of the devout.

About the word "outcasts" I have my own suspicions. But I shall pursue nothing except your own curse. Those who shall have resisted pontifical orders; who shall have put anything under pontifical diplomas other than what the Pontiffs willed; who in any way at all, out of a passion for innovation, shall have dared to tamper with what stands in good order [*moliri ri* so printed — *ri* set twice across the line-break; recte: *moliri*]; who, in short, by aid, by counsel, or by malicious guile shall have obstructed the good of the Christian commonwealth — let them be anathema.
